Note: Hide Unused Tables isn't available for blank worksheets.

Build Data Views from Scratch

This section describes the various features at your disposal and tasks related to building visualisations in Tableau.

Every view that you build in Tableau should start with a question. What do you want to know? Every time you drag a field into the view or onto a shelf, you are asking a question about the data. The question will vary depending on where you drag various fields, the types of fields, and the order in which you drag fields into the view.

For every question you ask about your data, the marks in your viz update to represent the answer visually – with shapes, text, size, colour, headers, axes, hierarchies or table structures.

For information on building and viewing visualisations on the web, see [Use Tableau on the Web on page 3182](#).

Looking for a data set to work with? Download one from the [Tableau Public sample data page](#), or check out our tips to [find good data sets](#).

Start Building a Visualisation by Dragging Fields to the View

The basic structure for every view is made of dimension and measure fields placed on the Rows and Columns shelves, and on different properties in the Marks card.

You build visualisations by adding fields from the Data pane to the view. As you build a visualisation, you can add as many fields as necessary to different areas of the view, and then move those fields around as you explore your data.

Different ways to start building a view

When you build a view, you add fields from the **Data** pane. You can do this in different ways. For example:

- Drag fields from the **Data** pane and drop them onto the cards and shelves that are part of every Tableau worksheet.
- Double-click one or more fields in the **Data** pane.
- Select one or more fields in the **Data** pane and then choose a chart type from **Show Me**, which identifies the chart types that are appropriate for the fields you selected. For details, see [Use Show Me to Start a View on page 1237](#).
- Drop a field on the **Drop field here** grid, to start creating a view from a tabular perspective.

As you start exploring data in Tableau, you will find there are many ways to build a view. Tableau is extremely flexible, and also very forgiving. As you build a view, if you ever take a path that isn't answering your question, you can always undo to a previous point in your exploration.

- To undo or redo, click undo  or redo  on the toolbar.

You can undo all the way back to the last time you opened the workbook. You can undo or redo an unlimited number of times.

Dragging basics

When you begin creating a new data view on a blank worksheet, you can drag a field from the **Data** pane and drop it directly into the view, rather than to a shelf.

In Tableau Desktop, while dragging fields, you can hover over the different areas in the view to see how the field will be incorporated into the structure of the view. For example, dimensions typically add a row and column headers to the view, while measures add continuous axes. Below are some examples of how fields can be added to the view:

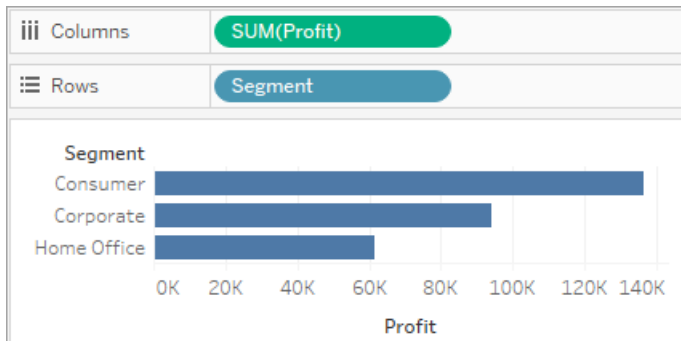

- Dimensions add headers and have a blue drop area
- Measures add axes and have a green drop area
- Show Me automatically adds the field according to best practices

For a more advanced discussion of dimensions and measures, see [Dimensions and Measures, Blue and Green](#) on page 146.

When you drop a field on one of the active areas in the view, the field is added to the view and also to one of the shelves or cards. For example, in the view below, the **Segment** dimension was

added to the **Rows** shelf and the **Profit** measure was added to the **Columns** shelf – and automatically aggregated so that the values in the data are summed.

You can, of course, also drag fields directly to the shelves instead of to the active areas in the view. You can also drag fields from one shelf to another shelf. To remove a field from a shelf, drag it off the worksheet or select **Remove** from the field's menu (available when you right-click (control-click on Mac) a field in the view). In Tableau Desktop, you can also quickly remove multiple fields from a shelf by right-clicking (control-click on Mac) the shelf and selecting **Clear Shelf**.

Add headers

You can add headers to a view by dragging a discrete (blue) dimension and dropping it to either side of an existing header, or to the left of an axis. For example, in the view below, you can add the **Region** dimension by dragging it and dropping it in various places.

As you hover over the view, a dotted black line indicates active areas where you can add headers.

Add axes

You can add axes by dragging a continuous (green) measure and dropping it on an active area in the view. If an axis already exists in the view you can replace the existing axis, blend the new measure with the existing axis, or add a secondary axis.

Replace the existing axis

Drag the new measure to the top left portion of the axis in the view. A small square drop zone appears and a single axis icon displays to indicate that a single axis will be left when you drop the measure. In this case you are replacing one measure (**Sales**) with another (**Profit**).

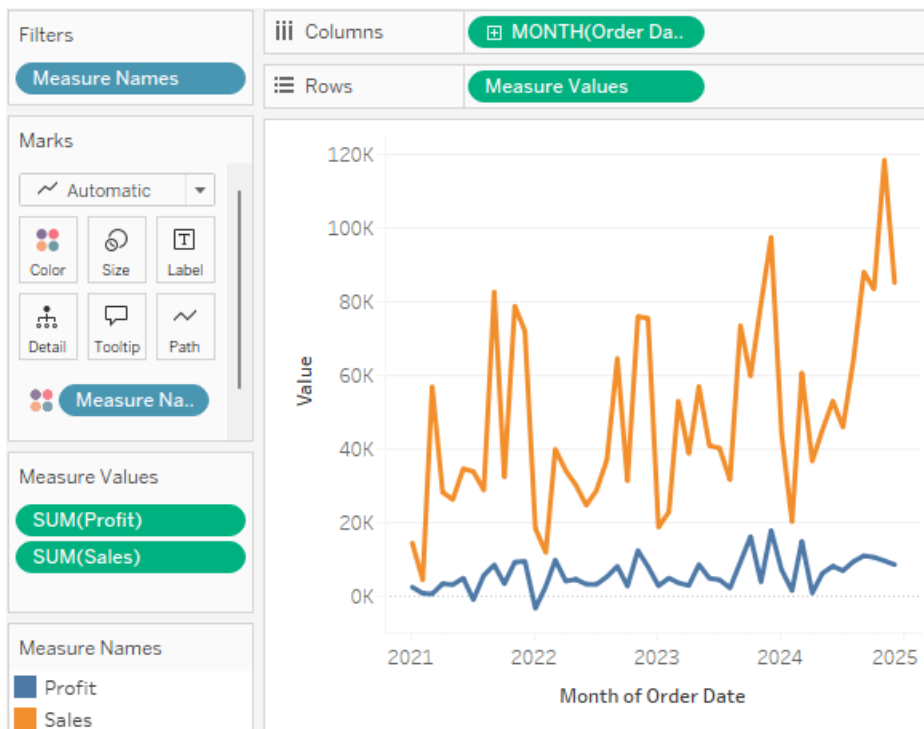

Blend the measures on single axis

You can show multiple measures on a single axis by dragging the new measure directly on top of the existing axis. Blending measures uses the Measure Names and Measure Values fields. For more information, see [Measure Values and Measure Names on page 1220](#).

In the image below you are adding a second measure (**Profit**) to the existing measure (**Sales**) on the axis.

The result is a view with both measures plotted along a single axis. In this case, Sales is shown in orange and Profit is shown in blue.

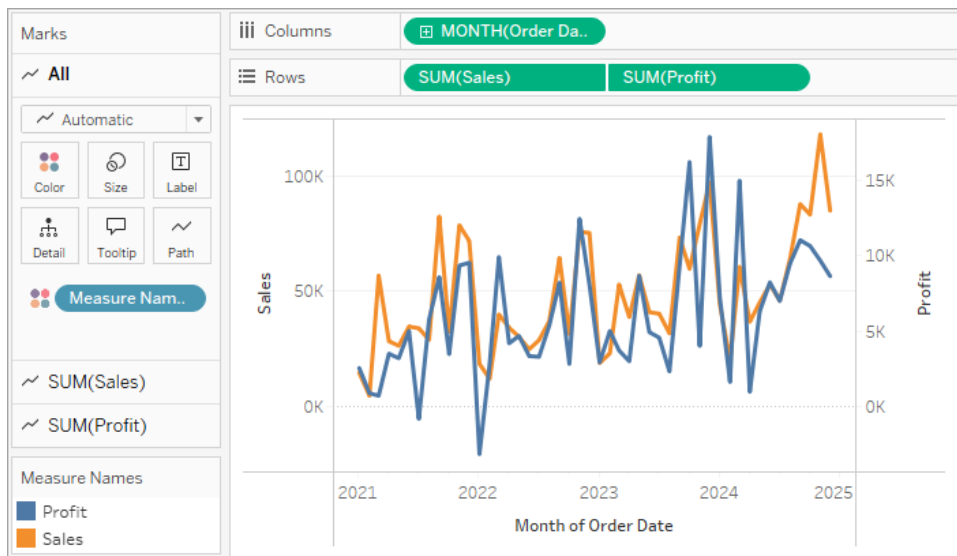

Add a dual axis

Drag the field to the right side of the view to add the measure as a dual axis. Dual Axes are useful when you want to compare two fields that have different scales. In this case, blending the

two axes would distort the view. Instead you can add a dual axis.

The result is a dual axis view where the Profit axis corresponds to the blue line and the Sales axis corresponds to the orange line.

Use dual axes

- You can add up to four axes to the view: two on the Columns shelf and two on the Rows shelf.

- To turn a measure into a dual axis, right-click (control-click on Mac) a field on the **Rows** or **Columns** shelf and select **Dual Axis**.
- To synchronise dual axes (keeping both vertical axes but syncing their scales), right-click on the right-hand axis (in this case, Profit) and select **Synchronise Axis**.
- To change the order of how the marks are stacked, right-click on either axis and select either **Move marks to front** or **Move marks to back**.

Rearrange rows and columns

You can rearrange the rows and columns in the view by changing the order of the fields in the Rows and Columns shelves, or by dragging the selection border for headers or an axis.

Sheet 1

| Ship Mode | Segment | Category | | |
|----------------|-------------|-----------|-----------------|------------|
| | | Furniture | Office Supplies | Technology |
| First Class | Consumer | 599 | 1,664 | 530 |
| | Home Office | 229 | 621 | 217 |
| | Corporate | 415 | 1,113 | 336 |
| Same Day | Consumer | 251 | 664 | 216 |
| | Home Office | 75 | 246 | 72 |
| | Corporate | 127 | 237 | 87 |
| Second Class | Consumer | 876 | 2,367 | 697 |
| | Home Office | 334 | 694 | 259 |
| | Corporate | 415 | 1,486 | 418 |
| Standard Class | Consumer | 2,544 | 7,282 | 2,154 |
| | Home Office | 822 | 2,626 | 717 |
| | Corporate | 1,682 | 4,268 | 1,314 |

Automatically add fields to the view with double-click

Tableau supports an additional method for automatically generating views of data called Automatic Double-Click. To use this method, double-click fields in the Data pane you are interested in. Tableau automatically adds each field to the view. That is, each double-click results in an additional field added to a shelf in an intelligent way. Like **Show Me**, this function leverages Tableau's ability to make an intelligent 'best guess' of how the data should be displayed. Double-clicking sometimes creates a view that you can use without further modification. More often, it can provide a starting point, which you can then modify to get the ideal result.

1. Double-clicking the **Profit** measure in the **Data** pane automatically adds that field to the view in an intelligent way.

2. Double-clicking the **Category** dimension in the **Data** pane automatically adds that field to the view based on the fact that Profit is already on the Rows shelf.

3. Double-clicking the **Order Date** dimension in the **Data** pane automatically adds that field to the **Columns** shelf based on the placement of other fields in the view. As you double-

click fields they are successively added to the view. The order in which you click fields determines the type of view created.

The following table describes some of the rules used in creating automatic views by double-clicking fields in the **Data** pane.

| | |
|-----------------|--|
| Text Table | Adding a dimension first produces a text table (or cross-tab). All subsequent clicks on fields result in refinement of the text table. |
| Bars | Adding a measure first and then a dimension produces a bar view. All subsequent clicks result in refinement of the bar view, unless a date dimension is added, at which time the view is changed to a line. |
| Line | Adding a measure and then a date dimension produces a line view. All subsequent clicks result in refinement of the line view. |
| Continuous Line | Adding a continuous dimension and then a measure produces a continuous line view. Subsequent dimensions result in refinement of the continuous line view. Subsequent measures add quantitative axes to the view. |
| Scatter | Adding a measure and then another measure produces a scatter view. Subsequent dimensions result in refinement to the scatter view. Subsequent measures will create a scatter matrix. |
| Maps | Adding a geographic field produces a map view with latitude and longitude as |

axes and the geographic field on the Level of Detail shelf. Subsequent dimensions add rows to the view while subsequent measures further refine the map by adding size and colour encoding.

Build Common Chart Types in Data Views on page 1481

Add Axes for Multiple Measures in Views

There are several different ways to compare multiple measures in a single view. You can:

- Create individual axes for each measure.
- Blend two measures to share an axis.
- Add dual axes where there are two independent axes layered in the same pane.

In any of these cases you can customise the marks for each axis to use multiple mark types and add different levels of detail. Views that have customised marks are called combination or combo charts.

Note: For details on how to edit axes, see [Edit Axes on page 2948](#).

Add individual axes for measures

To add individual axes for each measure, drag measures to the **Rows** and **Columns** shelves.

- Adding a continuous field on the Rows shelf adds an additional axis to the rows of the table.
- Adding a continuous field on the Columns shelf adds an additional axis to the columns of the table.

The example below shows quarterly sales and profit. The Sales and Profit axes are individual rows in the table and have independent scales.

The Order Date field on the Columns shelf is a discrete date dimension. Because it is discrete, it creates headers rather than an axis. For details on how to edit axes, see [Edit Axes on page 2948](#).

Blend axes for multiple measures into a single axis

Measures can share a single axis so that all the marks are shown in a single pane.

To blend multiple measures, drag one measure or axis and drop it onto an existing axis.

Instead of adding rows and columns to the view, when you blend measures there is a single row or column and all of the values for each measure is shown along one continuous axis. For example, the view below shows quarterly sales and profit on a shared axis.

Note: If you drag a measure on to the canvas and only see a single ruler indicator instead of the double ruler indicator shown below, Tableau creates dual axes instead of a blended axis. For more information about how to create dual axes, see [Compare two measures using dual axes on the next page](#).

Blending measures uses the **Measure Names** and **Measure Values** fields, which are generated fields that contain all of the measure names in your data source and all of the measure values. The shared axis is created using the **Measure Values** field. The **Measure Names** field is added to **Colour** on the Marks card so that a line is drawn for each measure. Finally, the **Measure Names** field is filtered to only include the measures you want to blend.

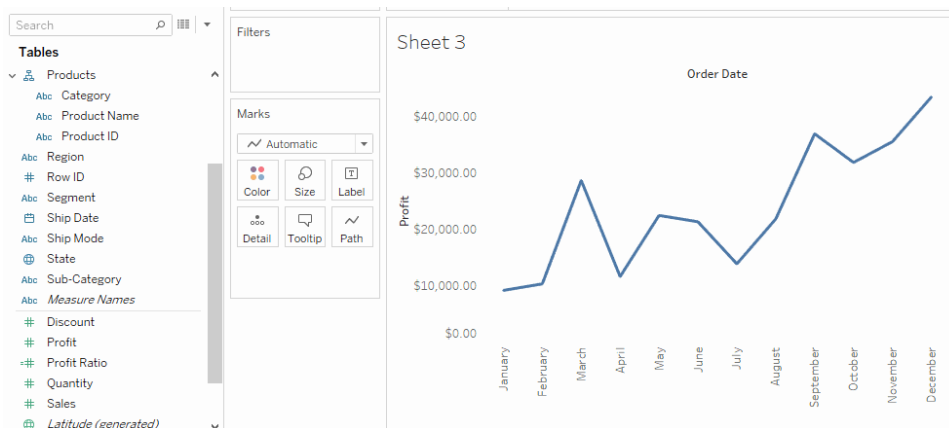

Note: Blending axes is most appropriate when comparing measures that have a similar scale and units. If the scales of the two measures are drastically different, the trends may be distorted.

Compare two measures using dual axes

You can compare multiple measures using dual axes, which are two independent axes that are layered on top of each other. Dual axes are useful for analysing two measures with different scales.

To add a measure as a dual axis, drag the field to the right side of the view and drop it when you see a black dashed line appear.

You can also right-click (control-click on Mac) the measure on the Columns or Rows shelf and select **Dual Axis**.

The result is a dual axis view where the Profit axis corresponds to the blue line and the Sales axis corresponds to the orange line.

You can add up to four layered axes: two on the Columns shelf and two on the Rows shelf.

Synchronise axes to use the same scale

To align the two axes in a dual axes chart to use the same scale, right-click (control-click on Mac) the secondary axis, and select **Synchronise Axis**. This aligns the scale of the secondary axis to the scale of the primary axis.

In this example, the Sales axis is the secondary axis and the Profit axis is the primary axis.

Note: To synchronise axes, the data types for both measures must be the same. If the data types for your measures are different, see the section below.

You can synchronise dual axes for numeric data types that don't match. For example, you

can synchronise an axis that uses an integer data type and an axis that uses decimal data type.

If you would like to change which axis is the primary, and which axis is the secondary, select the field on the Columns or Rows shelf that is the secondary, and drag it in front of the primary field on the shelf until you see an orange triangle appear.

In this example, you can select the **SUM(Sales)** field on the **Rows** shelf, and drag it in front of the **SUM(Profit)** field. The Sales axis is now the primary and the Profit axis is the secondary.

Synchronise axes with measures of different data types

The **Synchronise Axis** option ensures that you make a scaled and correct comparison in a dual axes chart. However, sometimes this option may not be available (greyed out). This is because the data type of one of the axes is different from the other.

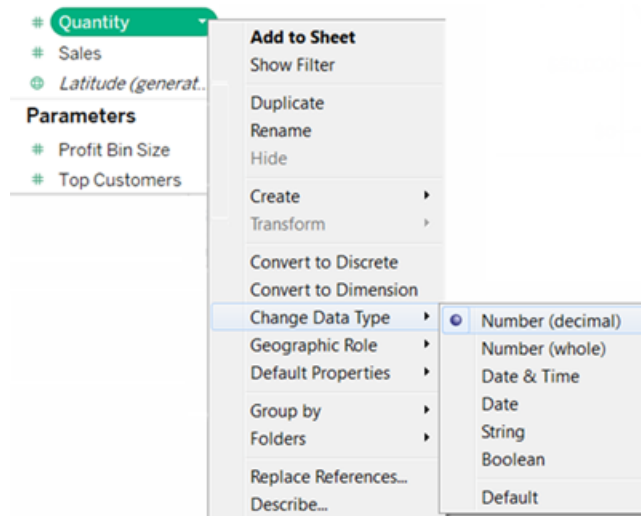

Note: In a chart with dual axes, starting with version 2018.1, you can synchronise dual axes for numeric data types that don't match. For example, you can synchronise an axis that uses an integer data type and an axis that uses decimal data type.

To resolve this issue, you must change the data type of one of the axes. Follow the example below to change the data type for an axis.

1. Click the new Worksheet  icon to open a new worksheet.
2. Drag **Order Date** to Columns, then click the drop-down arrow on the field on the shelf and select **Month** from the context menu.
3. Drag **Sales** to Rows, then drag **Quantity** to the right side of the view and drop it when you see a black dashed line appear to create a dual axis.

If you right-click on the **Quantity** Axis, you can see that the **Synchronise Axis** option is greyed out

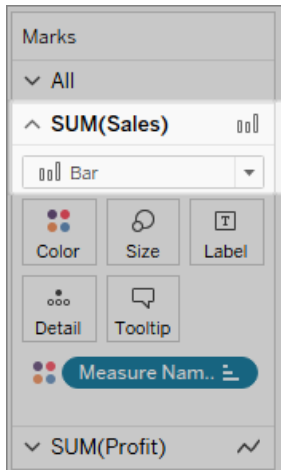

4. In the Data pane, click on the drop-down arrow on the **Quantity** field, and select **Change Data Type > Number (decimal)** in the context menu. This changes the data type for this field.

5. Replace the **Quantity** measure on the view.
6. Right-click the secondary axis, and then select **Synchronise Axis**.

Customise the marks for a measure

1. Select the Marks card for the measure that you want to customise. There is a Marks card for each measure on the Rows and Columns shelves.

2. Select a new mark type for the measure.

Any changes to the mark type, shape, size, colour, detail and other mark properties will be applied to the selected measure.

For example, in the view below the **Sales** Marks card is active. The Mark Type has been changed to **Bar** and when **Product Type** is placed on **Colour** on the **Sales** Marks card, the encoding and level of detail is only applied to the Sales marks. The Budget Sales mark is not broken down by Product Type.

Tips

- Select a field in the Marks card to modify only its properties.
- Select the **All** Marks card to modify properties for all measures at once.
- To change the order of a field's marks in the view, right-click its axis, and then select **Move marks to front**.

Create a combo chart (assign different mark types to measures)

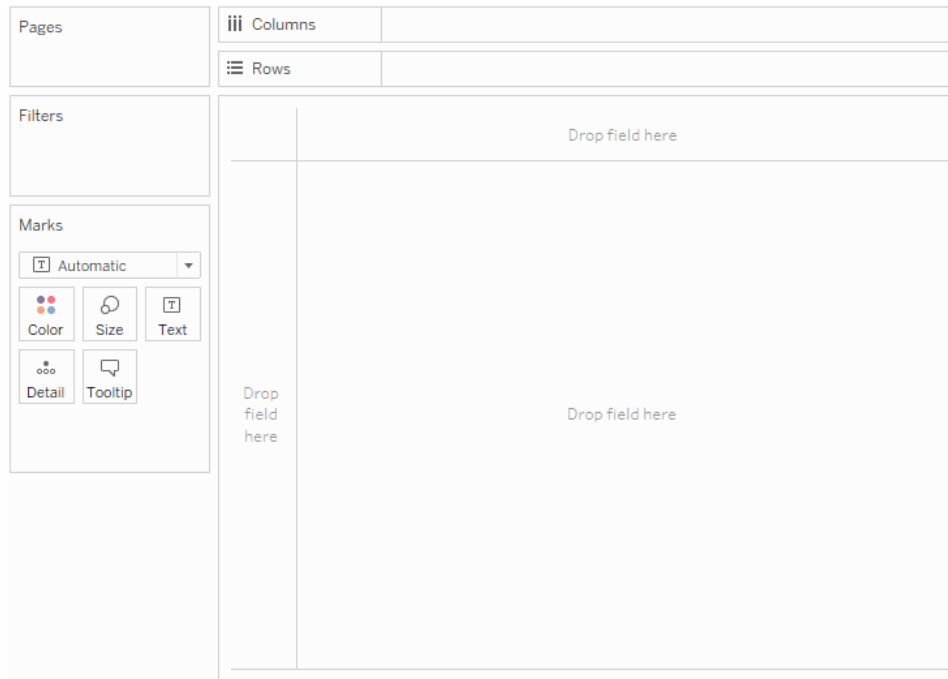

When working with multiple measures in a view, you can customise the mark type for each distinct measure. Because each measure can have customised marks, you can customise the level of detail, size, shape, and colour encoding for each measure, too.

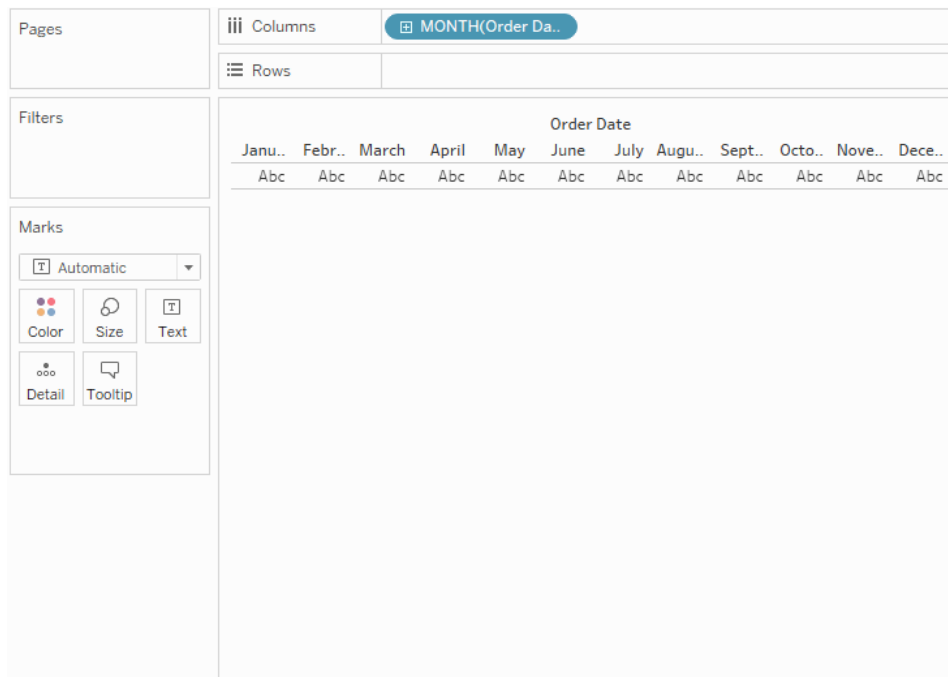

For example, you could create a view that uses two measures in dual axes. One measure shows Profit with a line mark, and the other measure shows Sales with bar marks. You could also choose to display the measures as individual axes or blended axes.

To create a combo chart like this example

1. Connect to the Sample - Superstore data source.
2. Drag the Order Date measure to the Columns shelf, and then click Order Date change Year to Month.

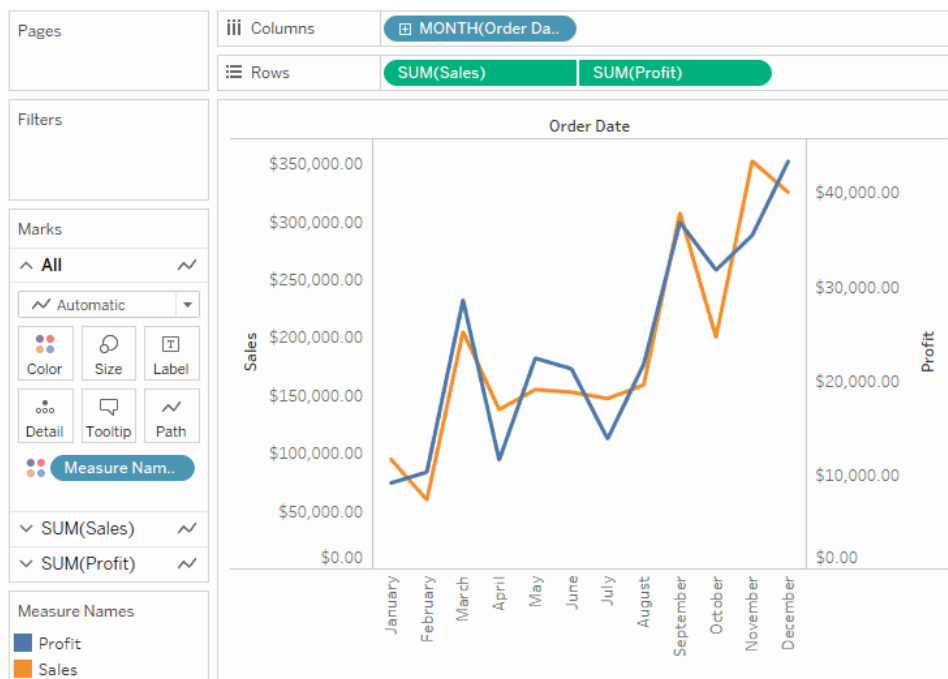

3. Drag the Sales measure to the Rows shelf.

4. Drag the Profit measure to the right side of the view and drop it when you see a black dashed line appear.

5. Click the Sales card. Change the Sales mark type to **Bar**.

Optional: To adjust the colours used for the Sales and Profit marks:

1. Click the **All** card, click **Colour**, and then click **Edit Colours**.
2. Click the Profit data item, and then click a different colour in the palette. Click the Sales data item, and then click a different colour in the palette.
3. Click **Apply**, and then click **OK**.

Measure Values and Measure Names

The Data pane always contains a number of fields that do not come from your original data, two of which are **Measure Values** and **Measure Names**. Tableau automatically creates these fields so that you can build certain types of views that involve multiple measures.

- The **Measure Values** field contains all the measures in your data, collected into a single field with continuous values. Drag individual measure fields out of the Measure Values card to remove them from the view.
- The **Measure Names** field contains the names of all measures in your data, collected into a single field with discrete values.

How you can use Measure Names and Measure Values

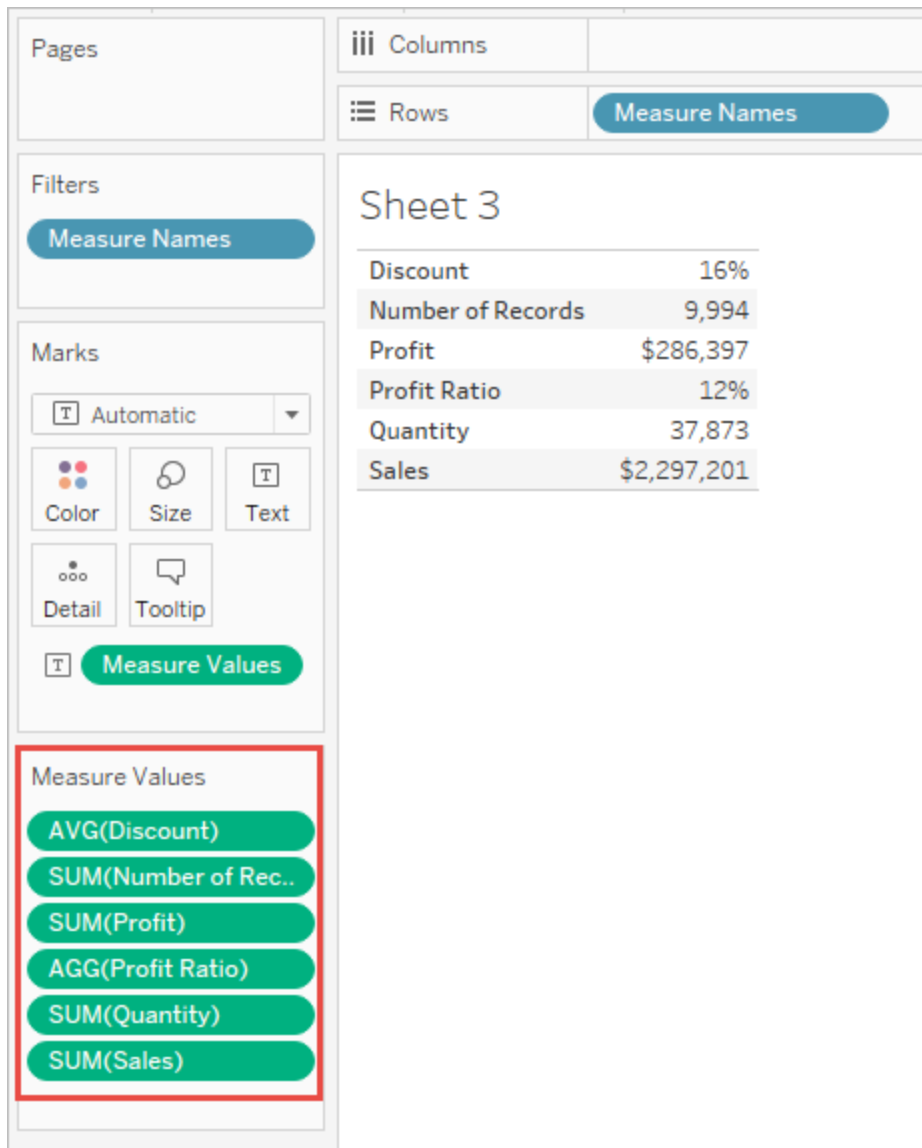

Tableau automatically creates these fields so that you can build certain types of views that involve multiple measures.

Measure Values and **Measure Names** are in most respects like other fields in Tableau:

- You can display a filter for **Measure Names**.
- You can format **Measure Values** – the formatting is then inherited as the default formatting for all measures.
- You can drop **Measure Values** and **Measure Names** on shelves.
- You can assign aliases to the values for **Measure Names**.
- You can change the manual sort order for the values for **Measure Names**.

The Measure Values card

When **Measure Values** is in the view, Tableau creates a **Measure Values** card, outlined in red, below, that lists the measures in the data source with their default aggregations.

You can remove individual measures from the view by dragging them out of the **Measure Values** card.

About Measure Names

When you want to show multiple measures in a view, you can use the **Measure Values** and the **Measure Names** fields. When you add **Measure Names** to a view, all of the measure names appear as row or column headers in the view. The headers include each measure name. This feature becomes useful when you are working with a text table that shows multiple measures. For example, suppose you have a text table containing the aggregated profit of each product category by region.

The interface shows a text table with the following dimensions and measure:

- Columns:** Category
- Rows:** Region
- Measures:** SUM(Profit)

The resulting table is:

| Region | Category | | |
|---------|-----------|-----------------|------------|
| | Furniture | Office Supplies | Technology |
| Central | -\$2,871 | \$8,880 | \$33,697 |
| East | \$3,046 | \$41,015 | \$47,462 |
| South | \$6,771 | \$19,986 | \$19,992 |
| West | \$11,505 | \$52,610 | \$44,304 |

Now suppose you want to show both the **Profit** and the **Sales** for each category and region. When you add **Sales** to the text table (by dragging it and dropping it in the view), the measures are combined and the **Measure Values** field is added to Text. The **Measure Names** field is automatically added to the **Rows** shelf.

The interface shows a text table with the following dimensions and measures:

- Columns:** Category
- Rows:** Region, Measure Names
- Measures:** SUM(Profit), SUM(Sales)

The resulting table is:

| Region | | Category | | |
|---------|--------|-----------|-----------------|------------|
| | | Furniture | Office Supplies | Technology |
| Central | Profit | -\$2,871 | \$8,880 | \$33,697 |
| | Sales | \$163,797 | \$167,026 | \$170,416 |
| East | Profit | \$3,046 | \$41,015 | \$47,462 |
| | Sales | \$208,291 | \$205,516 | \$264,974 |
| South | Profit | \$6,771 | \$19,986 | \$19,992 |
| | Sales | \$117,299 | \$125,651 | \$148,772 |
| West | Profit | \$11,505 | \$52,610 | \$44,304 |
| | Sales | \$252,613 | \$220,853 | \$251,992 |

Notice how the header names removed the aggregation label by default. You may want to include the aggregations or call it "Total Profit" and "Total Sales." To change the measure names, right-click (control-click on Mac) the Measure Names field on the Rows shelf and select **Edit Aliases**. Make the changes and click **OK**.

| Region | | Category | | |
|---------|--------------|-----------|-----------------|------------|
| | | Furniture | Office Supplies | Technology |
| Central | Total Profit | -\$2,871 | \$8,880 | \$33,697 |
| | Total Sales | \$163,797 | \$167,026 | \$170,416 |
| East | Total Profit | \$3,046 | \$41,015 | \$47,462 |
| | Total Sales | \$208,291 | \$205,516 | \$264,974 |
| South | Total Profit | \$6,771 | \$19,986 | \$19,992 |
| | Total Sales | \$117,299 | \$125,651 | \$148,772 |
| West | Total Profit | \$11,505 | \$52,610 | \$44,304 |
| | Total Sales | \$252,613 | \$220,853 | \$251,992 |

Create a visualisation using Measures Names and Measure Values

You can use **Measure Values** and **Measure Names** to display the values for all measures in your data source, using their default aggregations, simultaneously. The view below was created with the Sample - Superstore data source. It shows the values of all measures in the Data pane, using their default aggregations.

To create this view

Create a new worksheet using the Superstore example workbook.

Drag **Measure Values** to Rows

Click Text Table in Show Me.

Text Table from Show Me.

Of course, this view is not well suited for any more than a quick survey of your data because you can't generate a great deal of insight by comparing numbers that aren't measuring the same thing—**Profit** and **Sales** are both in dollars, but **Discount** and **Profit Ratio** are percentages.

When Measure Names and Measure Values automatically get added to the view

Tableau will automatically add **Measure Names** and **Measure Values** fields to the view in response to certain actions on your part.

Blending Axes

You can show multiple measures on the same continuous axis by blending axes. For details, see [Blend axes for multiple measures into a single axis on page 1210](#). When you use this

technique, Tableau automatically adds Measure Names and Measure Values to the view, allowing you add additional measures to the blended axis.

Using Show Me When Multiple Measures Are in the View

When there are multiple measures in the view, Tableau will automatically add **Measure Names** and **Measure Values** – or just **Measure Names** – when you choose certain visualisation types from Show Me.

- When you choose side-by-side bars when there are multiple measures in the view, Tableau adds both **Measure Values** and **Measure Names**. For example, your original view might use lines to show **Sales** and **Profit** over time:

- If you choose side-by-side lines from Show Me, the view updates to include **Measure Names** and **Measure Values**:

- When you choose side-by-side circles from Show Me when there are multiple measures in the view, Tableau adds **Measure Values** and **Measure Names**:

- When you choose dual lines from Show Me when there are multiple measures in the view, Tableau adds **Measure Names** but not **Measure Values**:

This is similar to blending axes, except that Tableau uses separate value ranges (one on the left of the view and one on the right) to make the lines align as closely as possible. With blended axes, Tableau uses a single value range and the lines may or may not align well.

How Measure Names and Measure Values work with Legends Per Measure

When **Measure Values** and **Measure Names** are in the view, you can colour code data for each individual measure. For details, see [Measure values and colour legends on page 91](#).

Handling Null and Other Special Values

Some data requires special handling in Tableau. Specifically:

- null values
- unrecognised or ambiguous geographic locations
- negative or zero values when working with a logarithmic scale
- negative or zero values when working with treemaps

Special values indicator

When your data contains any of these special values, Tableau cannot plot them in the view. Instead, it displays an indicator in the lower right corner of the view. Click the indicator to see options for how to handle these values.

If you don't know how to handle the values, you can choose to leave the special values indicator. Generally, you should continue to show the indicator so that you know there is data that is not being shown in the view. However, you can choose to hide it as well. Hiding doesn't alter the data, it simply hides the indicator.

Show and hide the indicator

To hide the indicator, right-click on it (control-click on a Mac) and select **Hide Indicator**. Alternatively, open the Analysis menu and select **Special Values > Hide**.

If you've hidden the special values indicator and want to bring it back, open the Analysis menu and select **Special Values > Show**.

Null numbers and dates, and negative values on log axes

A null value is a field that is blank, and it signifies missing or unknown values.

When you drag a measure or continuous date to the view, the values are shown along a continuous axis. If the field contains null values, or if there are zeros or negative values on a logarithmic axis, Tableau cannot plot them. When these values exist, Tableau displays an indicator in the lower right corner of the view that says unknown values exist. Click the indicator and choose from the following options:

- **Filter Data** – exclude the null values from the view using a filter. When you filter data, the null values are also excluded from any calculations used in the view.

- **Show Data at Default Position** – show the data at a default location on the axis. The null values will still be included in calculations. The default position depends on the data type. The table below defines the defaults.

| Type of Data | Default Position |
|-------------------------------|------------------|
| Numbers | 0 |
| Dates | 12/31/1899 |
| Negative Values on a Log Axis | 1 |
| Unknown Geographic Location | (0,0) |

Remove null values

- To filter null dimensions or discrete measures, drag the pill to the Filter shelf and deselect **Null**. The null value will appear in the list with discrete values, where you can then remove it.
- When a measure contains null values, they are usually plotted in a view as zero. To see other options, including how to suppress these null values altogether, see [Format null values on page 2999](#).

Note: See [Logical Functions on page 2090](#) for functions, such as ISNULL() and IFNULL(), which you can use to handle null values with a calculated field.

Unknown geographic locations

When working with maps and geographic fields, unknown or ambiguous locations are identified by the indicator in the lower right corner of the view. Click the indicator and choose from the following options:

- **Edit Locations** – correct the locations by mapping your data to known locations.
- **Filter Data** – exclude the unknown locations from the view using a filter. The locations will not be included in calculations.
- **Show Data at Default Position** – show the values at the default position of (0, 0) on the map.

Zero and negative values in treemaps

When working with treemaps, any null or zero values display in the indicator in the lower right corner of the view. Click the indicator and choose from the following options:

- **Filter Data** – exclude the unknown locations from the view using a filter. The locations will not be included in calculations.
- **Use Absolute Values** – use the absolute value to determine the size of the corresponding area in the view. For example, both values of 5 and -5 are shown as the same size.

Show or Hide Missing Values or Empty Rows and Columns

When you're working with dates or numeric bins, Tableau only shows the values that are represented in your data. If your data does not contain the complete range of values, the missing values will not be shown.

Consider the following data set. It contains a column for **Month** and a column for **Size**. There are rows for January through to May and September through to December, with no data recorded for June, July or August. If you create a line chart in Tableau, the missing months will not be shown. You can optionally show the missing months to make it clear that there was no data recorded during that time.

| Month | Size |
|-----------|------|
| January | 7 |
| February | 6 |
| March | 3 |
| April | 9 |
| May | 7 |
| September | 5 |
| October | 5 |
| November | 8 |
| December | 7 |

Show missing values from a known range

Tableau can infer the missing months of June, July and August from this example data set because there's a clearly defined possible domain, such as for dates or numeric bins. If your data contains Monday, Tuesday, Wednesday, Saturday and Sunday, Tableau can fill in the missing values as Thursday and Friday. However, if your data set was a list of colours, such as Teal, Green, Blue and Yellow, Tableau can't infer the missing values because there's no definitive way to know what the rest of the values should be.

If you don't see the option for **Show Missing Values**, your data doesn't meet the requirement where Tableau can determine the missing values.

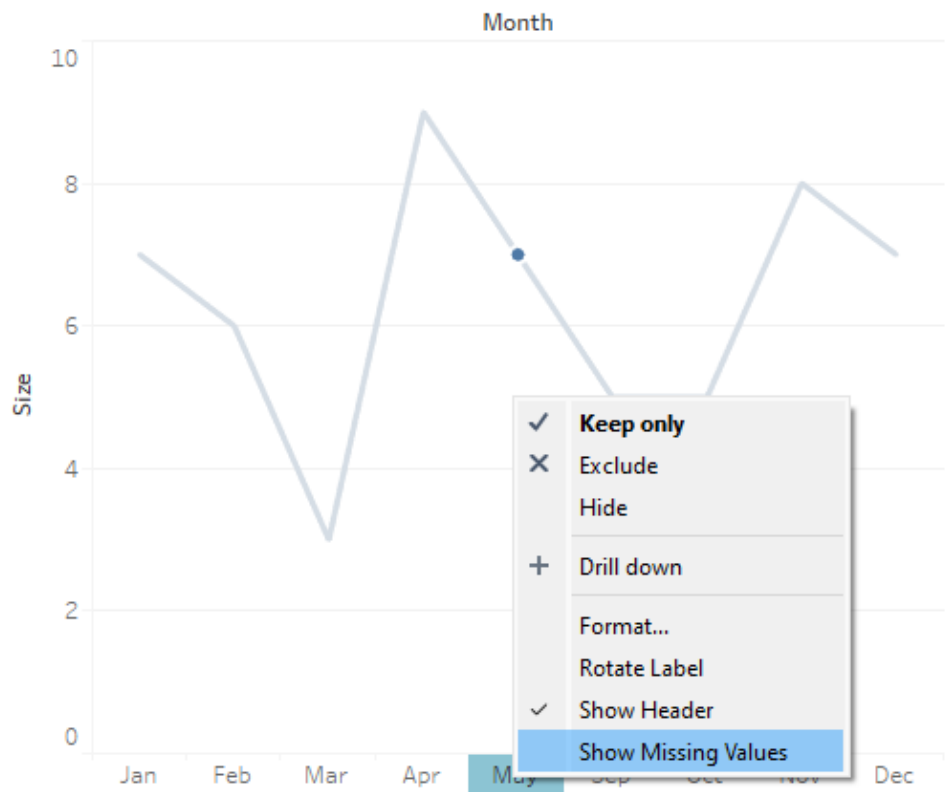

Toggle missing values

By default, missing header values in a date range or numeric bins are not shown. The x-axis in this example goes from May to September.

You can display the missing header values to indicate incomplete data.

- Right-click (Control-click on Mac) the date or bin headers and select **Show Missing Values**.

The x-axis in this example updates to include headers for June, July and August.

To go back to the default behaviour, you can turn Show Missing Values back off.

- Right-click (Control-click on Mac) the date or bin headers and untick **Show Missing Values**.

Null vs Missing

There's a difference between missing header values and null data. In the example of the missing months, June, July and August are missing from the data set as entire rows. March is present as a row in the data, but the value for the Size column for March is empty. This is a null value.

| Month | Size |
|-----------|------|
| January | 7 |
| February | 6 |
| March | |
| April | 9 |
| May | 7 |
| September | 5 |
| October | 5 |
| November | 8 |
| December | 7 |

In a viz, there is a null indicator only for nulls, not for gaps due to missing header values.

Null indicator

You can replace null values with a calculated field using the `ZN()` function. `ZN` replaces nulls (but not missing header values) with zeros. Size for March is null, so `ZN(Size)` would put a zero for March. However, there are no rows at all for June, July or August. `ZN` would not create rows or add zeros for those months as they are missing rather than null.

Null and ZN versus missing data

See [Number Functions](#) on page 2039 for details about the ZN function, or [Format null values](#) on page 2999 for more information about how to handle nulls.

Note: You can also perform calculations on missing values that are shown in the view. To do this, open the **Analysis** menu at the top, and then select **Infer Properties from Missing Values**. For an example of this, see [Predictive Modelling with Generated Marks](#) on page 2607.

Show and Hide Empty Rows and Columns

Available in Tableau Desktop only.

When you are working with fields that are not dates or numeric bins, Tableau hides empty rows and columns by default.

For example, imagine you're looking at student clubs and the students who are in those clubs. If there's a student who isn't in a club, that student's name won't appear in a dimension-only viz of student and club. You can show empty rows by selecting **Analysis > Table Layout > Show Empty Rows**.

Empty Rows Hidden (default)

Jay isn't in any clubs, so there's no row for the student Jay. Every row has a placeholder

Empty Rows Shown

Jay isn't in any clubs, but empty rows are shown, so there is a row for Jay with no

mark (Abc).

placeholder mark (Abc).

| Columns | | Columns | |
|-------------|----------|-------------|--------------|
| Rows | Club | Rows | Club Student |
| Club | Student | Club | Student |
| Art | Cardinal | Null | Jay |
| | Finch | Art | Cardinal |
| | Sparrow | | Finch |
| First Aid | Robin | | Sparrow |
| Juggling | Sparrow | First Aid | Robin |
| Photography | Finch | Juggling | Sparrow |
| Travel | Cardinal | Photography | Finch |
| | | Travel | Cardinal |

Similarly, show any empty columns by selecting **Analysis > Table Layout > Show Empty Columns**.

Note: If you are working with multi-fact relationships in data sources with multiple base tables, there may be more complex logic that determines when nulls are seen in empty rows. For more information, see [About Multi-fact Relationship Data Models on page 743](#).

Use Show Me to Start a View

Show Me creates a view based on the fields already used in the view and any fields you’ve selected in the Data pane. Open Show Me by clicking **Show Me** on the toolbar  **Show Me** .

Start a view based on fields that you select

To use Show Me, select the fields you want to analyse in the Data pane, and then select the viz type you want to create in the Show Me pane. Tableau automatically evaluates the selected fields and gives you the option of several types of views that would be appropriate for those fields.

1. In the **Data** pane, select the fields that you want to analyse. Hold the Ctrl key (Command key on a Mac) to make multiple selections.

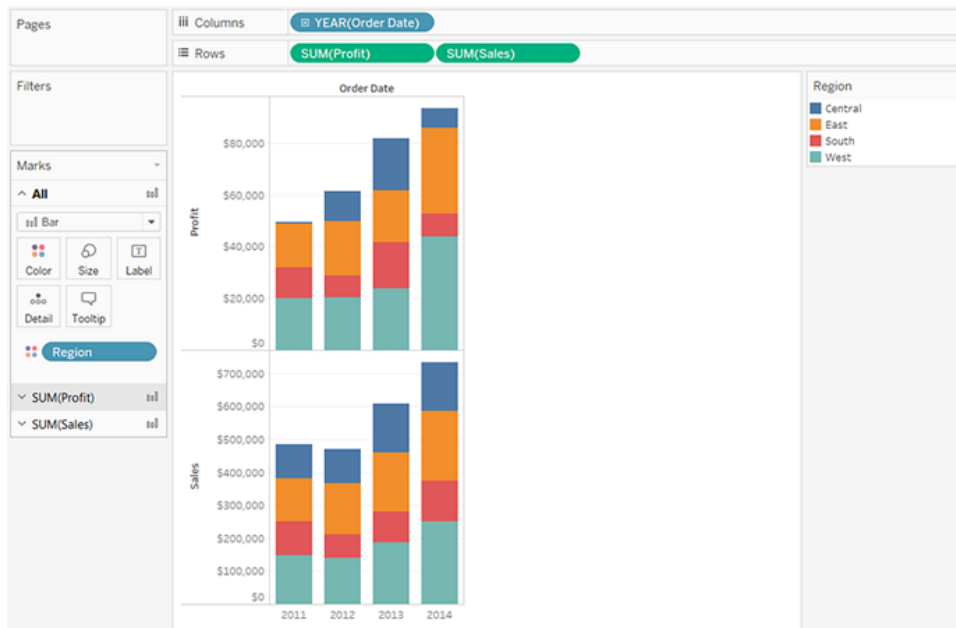

2. Click **Show Me** on the toolbar and then select the type of view you want to create.

As you hover over each viz type, you'll see a description showing the minimum requirements for each viz type. In this example, we've selected stacked bars.

3. Tableau automatically creates a view of the data.

Start a view based on fields from your data source

Starting in version 25.2, Tableau can help build your viz using fields from your data source, even if you have little to no data on your worksheet. Just be sure that your data source is selected in the Data pane.

Select the viz type that you'd like to make and then select **Choose for me**.

Tableau automatically creates a viz using the fields from your data source. You can drag fields onto the viz to further refine the view.

Create a line chart with Show Me

In this example, you use **Show Me** to create a line chart that displays profit as a function of time.

1. In the **Data** pane, select **[Order Date]** and **Profit**. Hold down the Ctrl key (or the command key on a Mac) as you select the fields.
2. Click **Show Me** on the toolbar to display the **Show Me** card, if it isn't already displayed.

3. In the **Show Me** pane, see what type of view Tableau suggests with an orange outline.

Because a date dimension and a measure are selected, Tableau suggests you build a line view. A line is often the optimal way to look at how measure values change over time.

The view below shows the resulting chart. Each point on the line represents the sum of profit for the corresponding year.

You can more easily see the points by clicking the **Show Mark Labels** button on the toolbar.

Create a scatter plot with Show Me

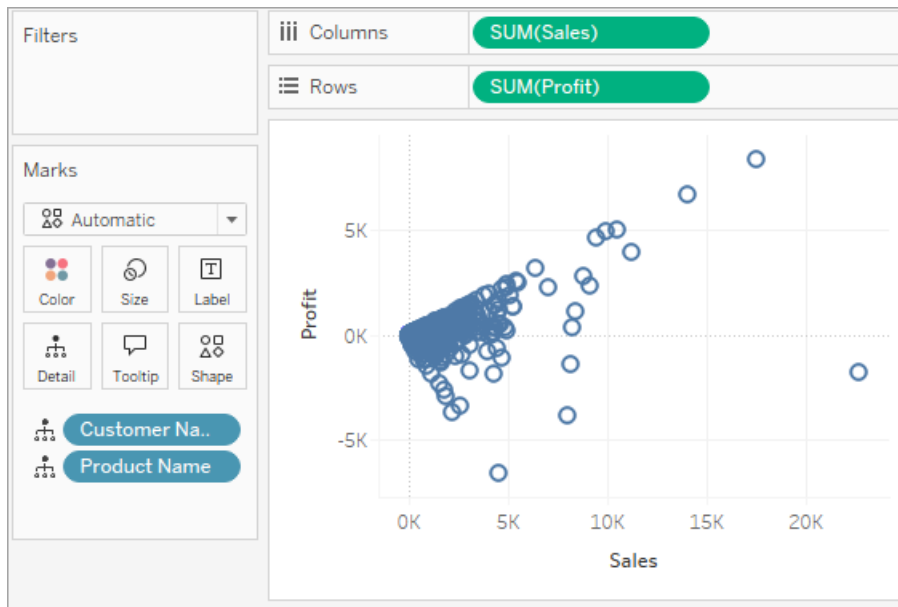

In this example, you use **Show Me** to build a scatter plot to show sales versus profit for each product and customer.

1. In the **Data** pane, select the **Customer Name** and **Product Name** dimension fields and the **Profit** and **Sales** measure fields. To select multiple fields, hold down the Ctrl key (or

- the command key on a Mac) as you click fields.
2. Click **Show Me** on the toolbar.
 3. Select the scatter plot chart type from **Show Me**.

Tableau creates a scatter plot using the fields you selected. You can drag fields onto the viz to further refine the view.

Add Detail

The Marks card is a key element for doing visual analysis in Tableau. When you drag measures and dimensions to the Marks card, you encode your data with colour, size, shape, text and other properties that add context, detail and meaning to the marks in the view.

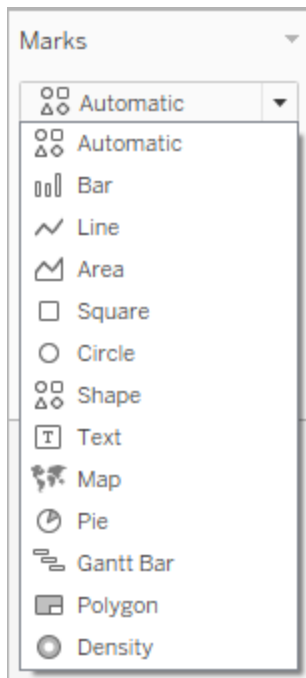

Change the Type of Mark in the View

You can change the type of marks displayed in the view to fit your analysis. For example, you can change the marks from bars to lines. This article describes how to change the type of marks used in the view, and explains the different types of marks available. For related information on marks, see [Control the Appearance of Marks in the View](#) on page 1268 and [Marks card](#) on page 62.

Change the mark type

To change the mark type:

- On the [Marks card](#) on page 62, click the Mark Type drop-down and select an option from the list.

For descriptions of each mark type, see the following sections:

- [Automatic mark](#)
- [Bar mark](#)
- [Line mark](#)
- [Area mark](#)
- [Square mark](#)
- [Circle mark](#)
- [Shape mark](#)
- [Text mark](#)
- [Map mark](#)
- [Pie mark](#)
- [Gantt Bar mark](#)
- [Polygon mark](#)
- [Density mark](#)

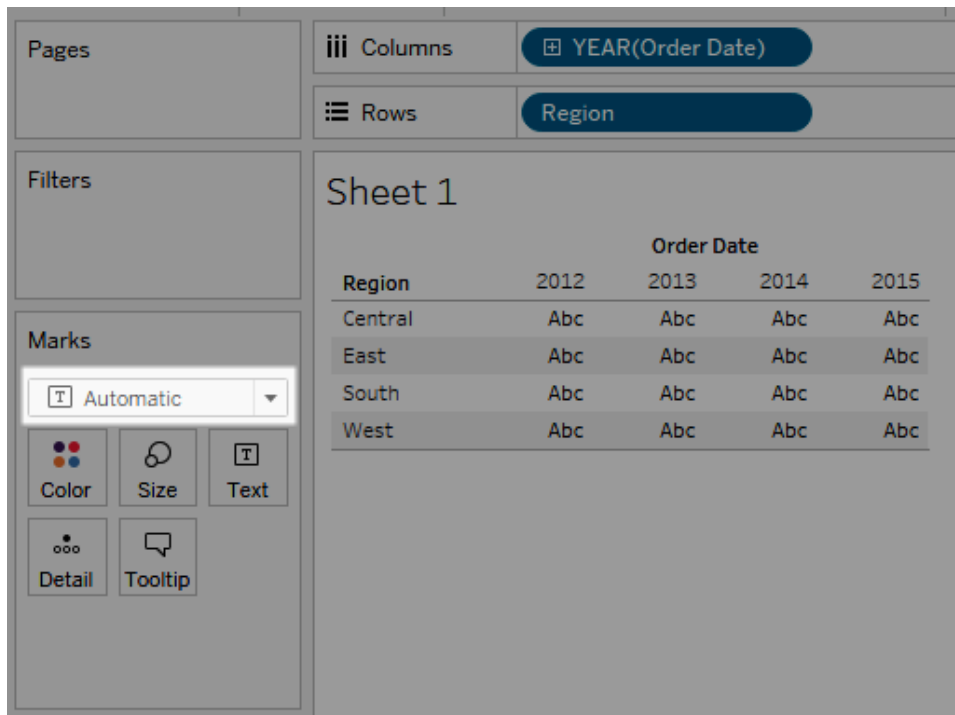

Automatic mark

When the Marks card drop-down menu is set to **Automatic**, Tableau automatically selects the best mark type for your data view. The mark type that is automatically selected is determined by the inner fields on the **Rows** and **Columns** shelves. The icon in the Marks card drop-down

menu indicates which type of mark was automatically selected. The mark types below are automatically selected for the following scenarios.

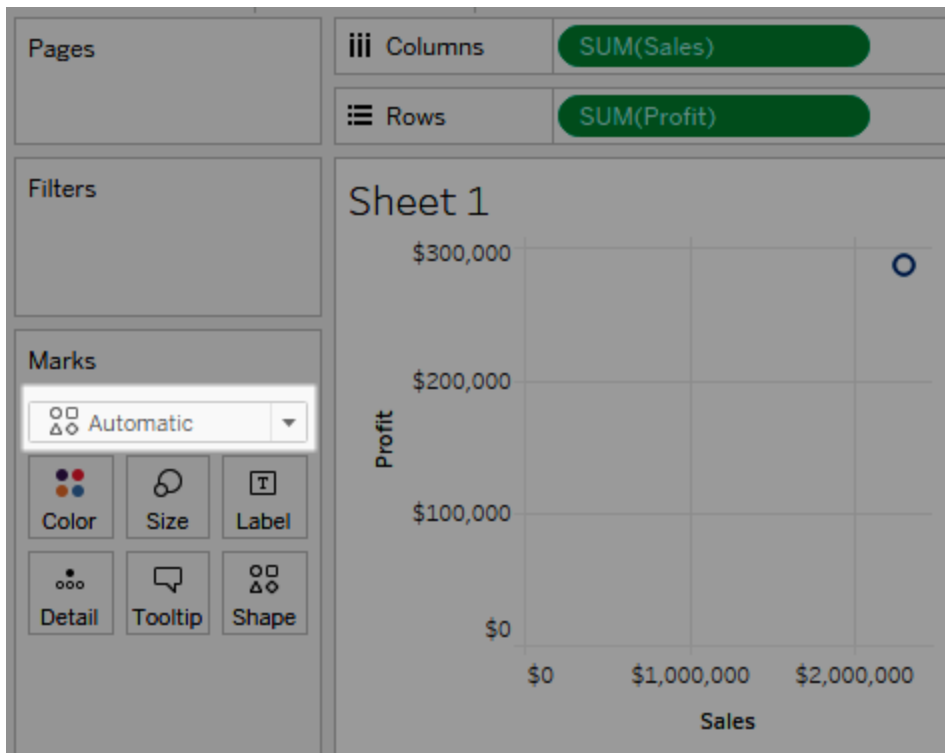

Text

The Text mark type is automatically selected when there are dimensions as inner fields on both the **Rows** and **Columns** shelves.

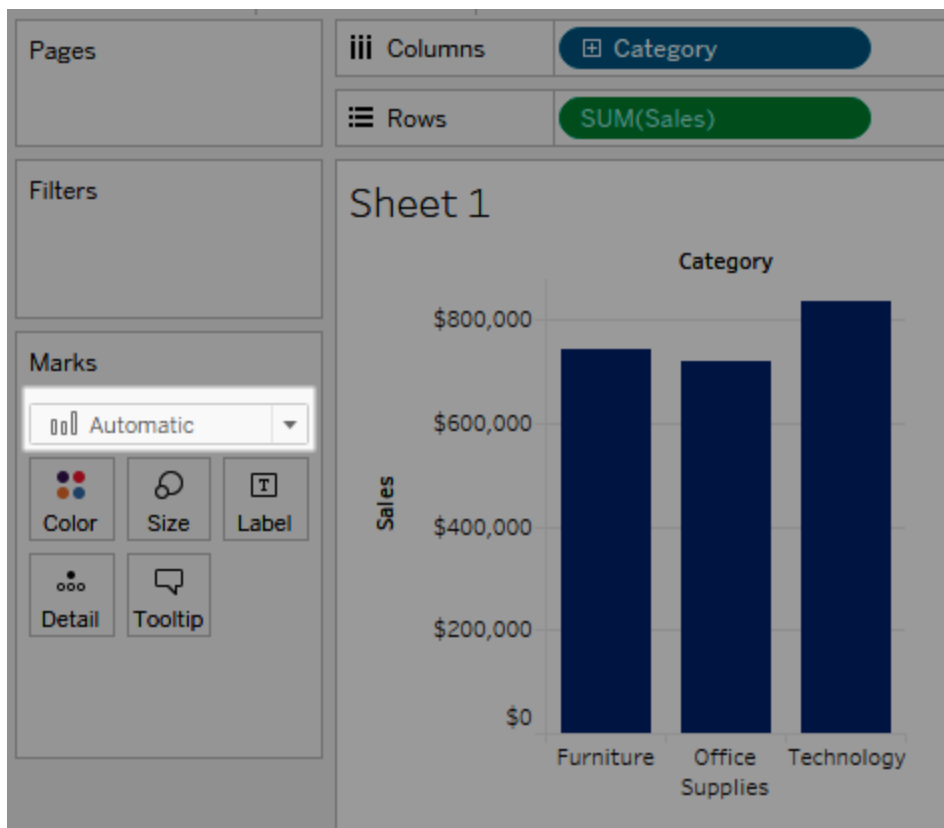

Shape

The Shape mark type is selected when there are measures as inner fields on both the **Rows** and **Columns** shelves.

Bar

The Bar mark type is selected when there is a dimension and a measure as inner fields on **Rows** and **Columns** shelves.

Line

The Line mark type is selected when there is a date field and a measure as the inner fields on the **Rows** and **Columns** shelves.

Note: You can override the default selection and use any mark type that provides insight into your data. However, you should exercise some caution when manually selecting a mark type because the resulting view might hide important information about your data.

Bar mark

The Bar mark type is useful when you want to compare measures across categories, or when you want to break data down into stacked bars. Tableau displays your data using bars when:

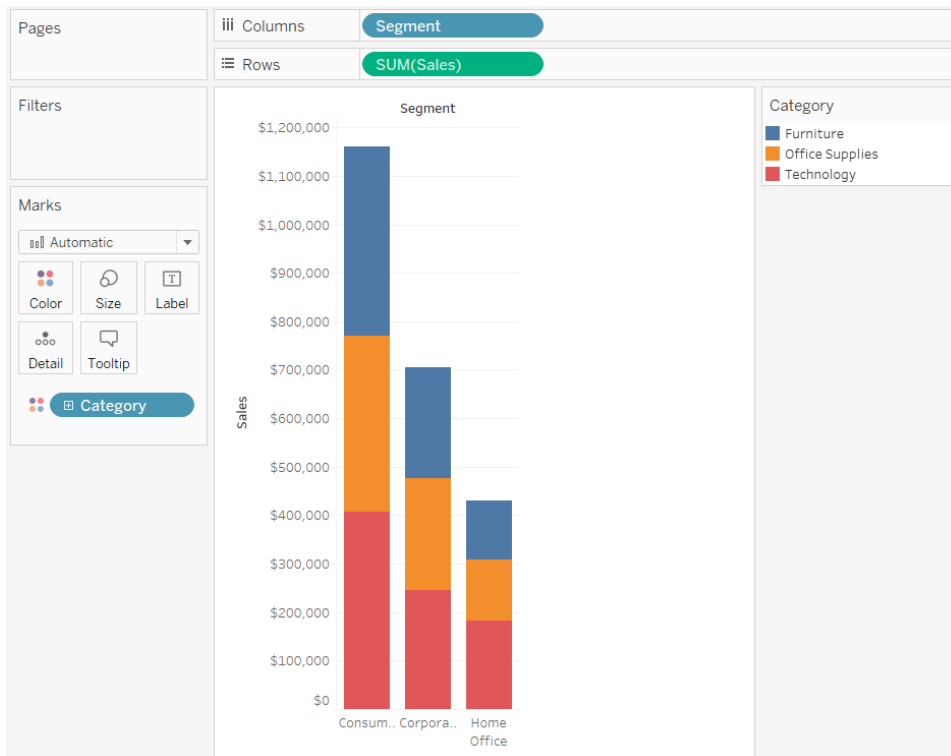

- The Marks card drop-down menu is set to **Automatic**, and you place a dimension and a measure as the inner fields on the **Rows** and **Columns** shelves. If the dimension is a date dimension, the Line mark is used instead.
- You select **Bar** from the Marks card drop-down menu.

Marks are automatically stacked.

Note: For views where the mark type is Bar and there are continuous (green) fields on both **Rows** and **Columns**, Tableau supports additional options and defaults for sizing the

bar marks on the axis where the bars are anchored. See the Continuous axis mark sizing section in [Change the size of marks on page 1270](#) for details.

The data view shown below displays a dimension as the columns of the table, and a measure as the rows of the table. It is also colour-encoded by a dimension (**Category**). Because the Marks card drop-down menu is set to **Automatic**, data is displayed using bars.

To try some hands-on exercises for building bar charts, see [Build a Bar Chart on page 1483](#).

Line mark

The line mark type is useful when you want to see trends in data over time, your data are ordered, or interpolation makes sense. Tableau displays data using lines when:

- The Marks card drop-down menu is set to **Automatic**, and you place one or more measures on either the **Columns** shelf or the **Rows** shelf, and then plot the measures against a date dimension or a continuous dimension.
- You select **Line** from the Marks card drop-down menu.

Note: In views that use the line mark type, you can use the **Path** property in the Marks card to change the type of line mark (linear, step or jump), or to encode data by connecting marks using a particular drawing order. For details, see [Path properties](#) in the [Control the Appearance of Marks in the View](#) on page 1268

The data view shown below displays a date dimension as the columns of the table and a measure as the rows of the table.

As the density of data increases, trends are often easier to see when using lines. This view shows 93 data points.

To try some hands-on exercises for building line charts, see [Building Line Charts on page 1521](#).

Area mark

The Area mark type is useful when you have a view where the marks are stacked and do not overlap. For more information about stacked marks, see [Stack Marks on page 1298](#). In an area chart, the space between each line and the next line is filled with a colour. This type of chart is not the best way to show specific values along the line but it can clearly show the total values so you can get an idea of how a dimension is contributing to an overall trend. Tableau displays your data using areas when:

- The Marks card drop-down menu is set to **Automatic** and one or more measures is plotted against a date dimension or continuous dimension. The **Analysis > Stack Marks** option must also be selected.

The view below shows a date dimension on the **Columns** shelf and a measure on the **Rows** shelf. Each line represents the sales for a product category. The lines have been stacked so that they do not overlap.

Note: You can add labels, edit the colour legend and highlight areas. In addition, you can turn on colour effects, such as mark borders. For more information, see [Control the Appearance of Marks in the View](#) on page 1268.

Square mark

The square mark type is useful when you want to clearly see individual data points. When you select **Square** from the **Marks** card drop-down menu, Tableau displays your data using squares.

The view shown below displays several dimensions on both the rows and columns shelves. By default, the data is displayed using text. However, when you place a measure on **Colour**, Tableau converts the marks to squares and creates a heat map. To try some hands-on exercises for building highlight tables, see [Build a Highlight Table or Heat Map](#) on page 1512.

When you add additional levels of detail by placing a dimension on **Detail**, **Colour**, **Shape**, **Size** or **Label** on the **Marks** card, the squares are displayed side-by-side and wrap to fill the cell. If the window is too small to show all of the squares, an ellipsis indicates that there are more values than you can see.

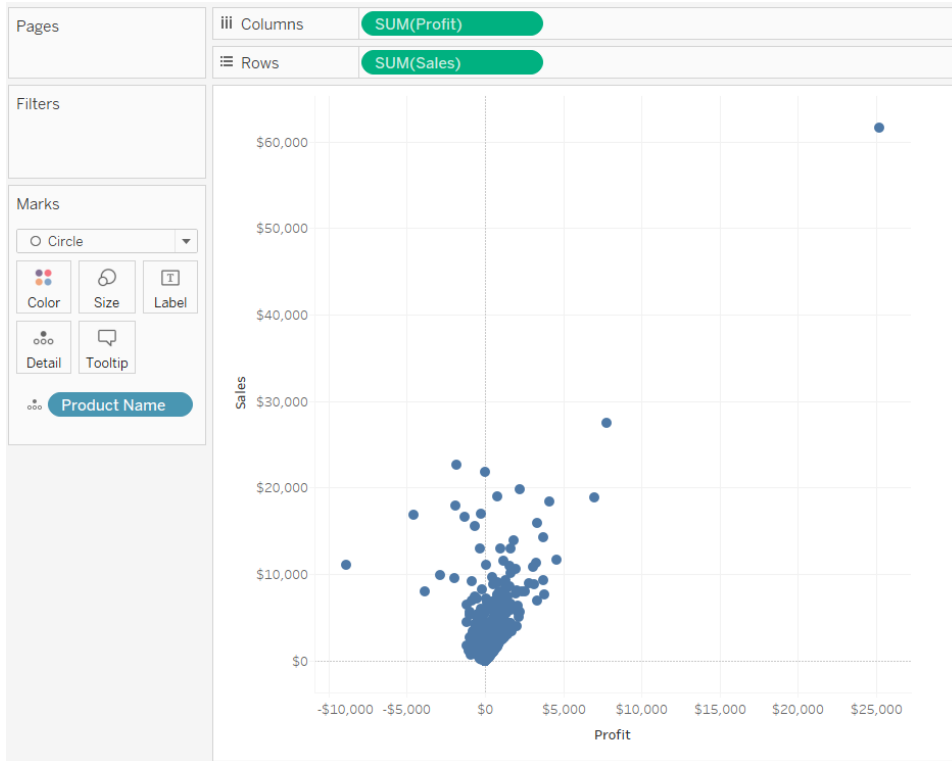

You can also use the square mark to create treemaps. A treemap displays hierarchical data as a set of nested rectangles. To try a hands-on exercise for building a treemap, see [Build a Treemap on page 1542](#).

Circle mark

When you select **Circle** from the Marks card drop-down menu, Tableau displays your data using filled circles.

If the mark type was set to **Automatic**, Tableau would display the data using a shape (that is, an open circle).

Shape mark

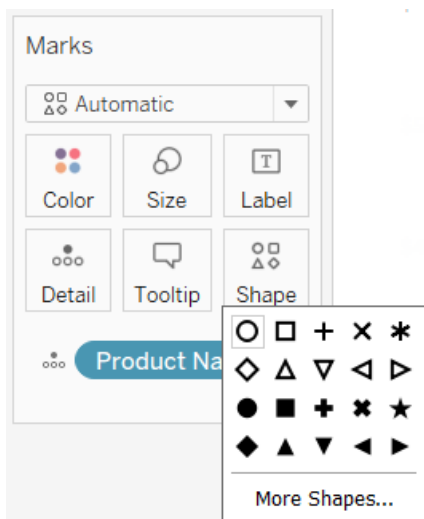

The shape mark type is useful when you want to clearly see individual data points while also viewing categories associated with those points. Tableau displays your data using a shape when:

- The Marks card drop-down menu is set to **Automatic**, and you place one or more measures on both the **Rows** and the **Columns** shelves.
- You select **Shape** from the Marks card drop-down menu.

The view shown below displays the data from two measures. Because the Marks card drop-down menu is set to **Automatic**, the data are displayed using a shape.

By default, the shape used is an open circle. To select a different shape, click **Shape** on the Marks card. Twenty unique shapes are available:

To add more data to the view, you can place a field on **Shape** on the Marks card. Tableau separates the marks according to the values in the field. If the field is a dimension, each member is assigned a unique shape. If the field is a measure, the measure is automatically binned into

distinct buckets and each bucket is assigned a unique shape. The shape legend displays how shapes are distributed.

As shown below, the **Ship Mode** dimension is placed on **Shape** on the Marks card to encode each mark with information about how the order was shipped.

For details on how to build a scatterplot, see [Build a Scatter Plot](#) on page 1533.

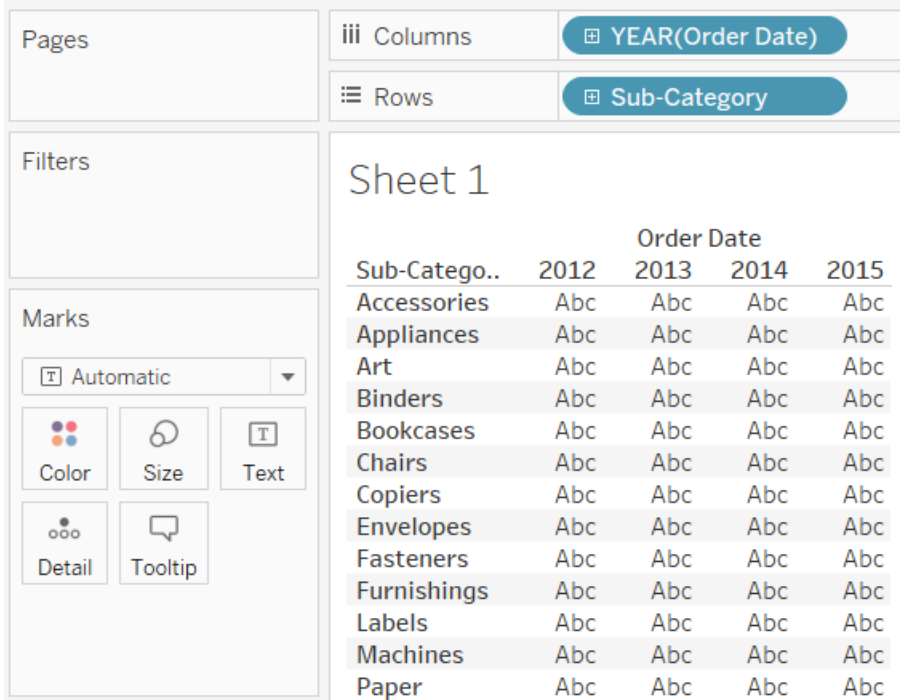

Text mark

The Text mark type is useful when you want to display the numbers associated with one or more dimension members. This type of view is often called a text table, a cross-tab, or a pivot table.

Tableau displays your data using text when:

- The Marks card drop-down menu is set to **Automatic**, and you place one or more dimensions as the inner fields on both the **Rows** and the **Columns** shelves.
- You select **Text** from the Marks card drop-down menu.

Initially, the data is displayed as **Abc**.

To complete the view, you must place a field (typically a measure) on **Text** on the Marks card. In the view below, the **Sales** measure, which is aggregated as a sum, is used to complete the table.

Note: To create a cross-tab of any data view, select **Worksheet > Duplicate as Crosstab**.

When you add additional levels of detail by placing a dimension on **Detail**, **Colour**, **Shape**, **Size** or **Text** on the Marks card, the values are shown side-by-side and wrap to fill the cell. Allowing the text to stack up makes it possible to create word cloud visualisations like the one shown below.

If the application window is too small for all of the text values, some of the displayed text values will be truncated.

Tableau interface showing a text table visualization. The Columns shelf contains YEAR(Order Date) and the Rows shelf contains Sub-Category. The Marks shelf contains Manufacturer (Text) and SUM(Sales) (Size). The table displays sales data by Sub-Category and Year, with ellipses indicating truncated text values.

| Sub-Catego.. | Order Date | | | |
|--------------|--------------|--------------|-------------|--------------|
| | 2012 | 2013 | 2014 | 2015 |
| Accessories | \$552 ... | \$438 ... | \$32 ... | \$522 ... |
| Appliances | \$715 ... | \$294 ... | \$114 ... | \$156 ... |
| Art | \$178 ... | \$98 ... | \$42 ... | \$153 ... |
| Binders | \$6 \$13 ... | \$17 \$6 ... | \$11 ... | \$9 \$64 ... |
| Bookcases | \$2,095 ... | \$7,406 ... | \$5,161 ... | \$3,954 ... |
| Chairs | \$461 ... | ... | \$1,084 ... | \$230 ... |
| Copiers | \$1,200 ... | \$2,700 ... | \$480 ... | \$480 ... |
| Envelopes | \$69 ... | \$51 ... | \$45 ... | \$9 \$64 ... |
| Fasteners | \$26 ... | \$22 ... | \$78 ... | \$68 ... |

If the application window is too small for all of the text values, the cell displays an ellipses to indicate that there are more values than can be displayed. Number values that can't be displayed are indicated with pound signs (#).

For details on how to build a text table, see [Build a Text Table](#) on page 1537.

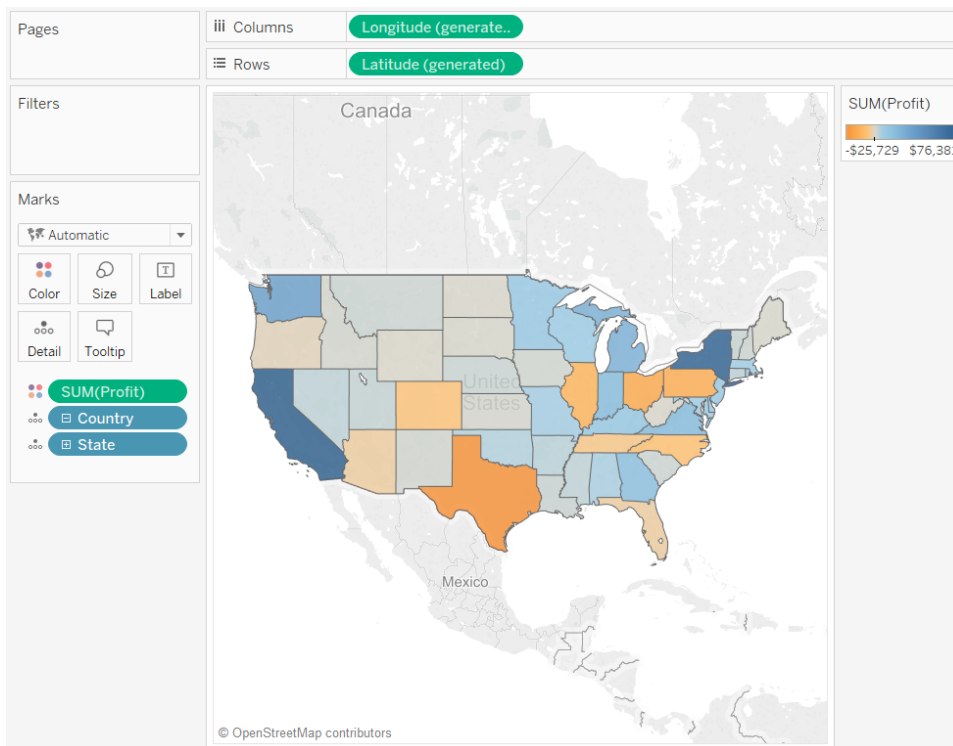

Map mark

The Map mark type uses geocoding to fill a polygon or line with a colour based on data. The primary use of the map mark type is for creating polygon or line maps. The area to be filled is defined by the geographic fields used in the view. Tableau displays data using a filled map when:

- A geographic dimension is on **Detail** on the Marks card, along with **Latitude** and **Longitude** on the **Rows** and **Columns** shelves. A measure or continuous dimension is added to **Colour** on the Marks card.
- You select **Map** from the Marks card drop-down menu.

The data view below shows a map with the **State** geographic dimension on **Detail** on the Marks card. The **Profit** measure is on **Colour** on the Marks card.

The polygon for each state is filled with a colour based on the profit for that state. The profit in Texas is low (in fact, negative) while the profit in California is high.

You can also use the Map mark type when you are plotting two measures against each other. By default, placing measures on both the **Rows** and **Columns** shelves creates a scatter plot. However, adding a geographic dimension allows you to change the mark type to Map. Each

mark becomes the area defined by the geographic field. For example, the view below shows **Sales** versus **Profit** for a selection of states. Rather than showing a round mark with a label for each state, the view uses the Map mark type to draw the outline of each state. While this works well for recognisable areas, it is not the best choice for areas that are similar in shape or difficult to recognise.

For more details on building maps, see [Get Started Mapping with Tableau](#) on page 1635 and [Maps and Geographic Data Analysis in Tableau](#) on page 1635.

Pie mark

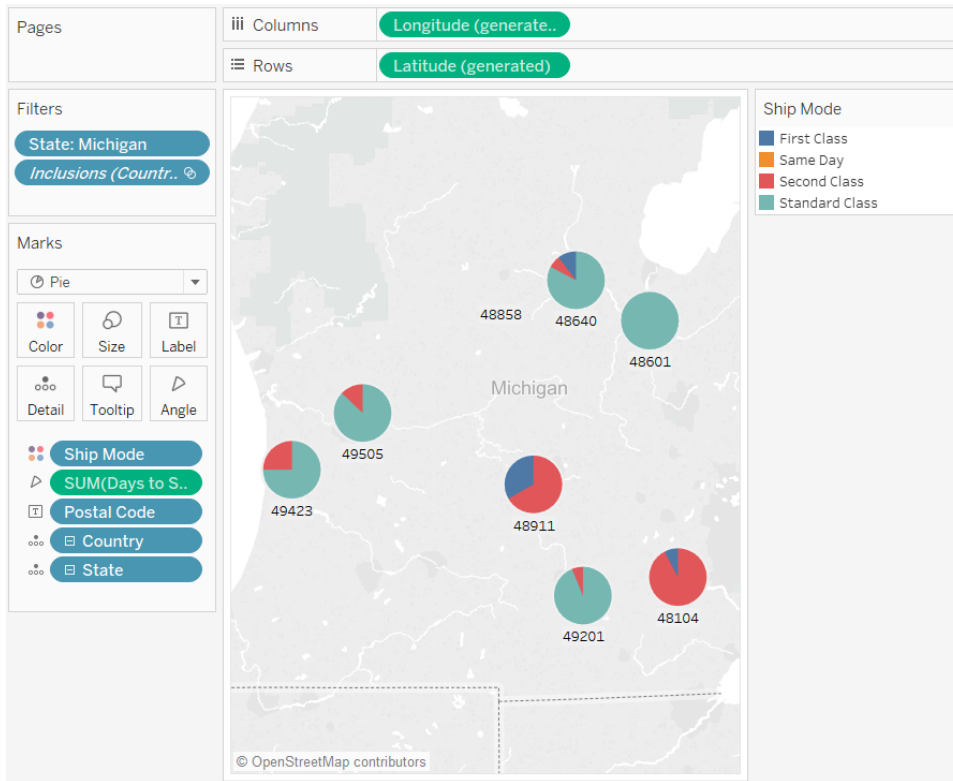

You can use the Pie mark to show proportions. Although generally this type of information can be better shown using stacked bar charts, there are cases where pie marks can be very effective – for example, when trying to convey the percentage allocation of marketing expenses by state where the spending of geographically close states are very relevant.

Tableau will never use the Pie mark as an automatic mark type, but you can select **Pie** from the Marks card drop-down menu.

When you select the Pie mark type, an additional target named Angle is displayed on the Marks card. The Angle target determines the angular measure of the pie wedges. For example, if you place a measure such as **Sales** on **Angle** on the Marks card, the 360 degrees of the pie

corresponds to the total sum of sales, and each wedge is divided by the values of the field on **Colour** on the Marks card.

The view below shows the time it took to ship products by various ship modes. The data overlays a map and shows data by state. We can see that standard class shipping takes the longest in most areas.

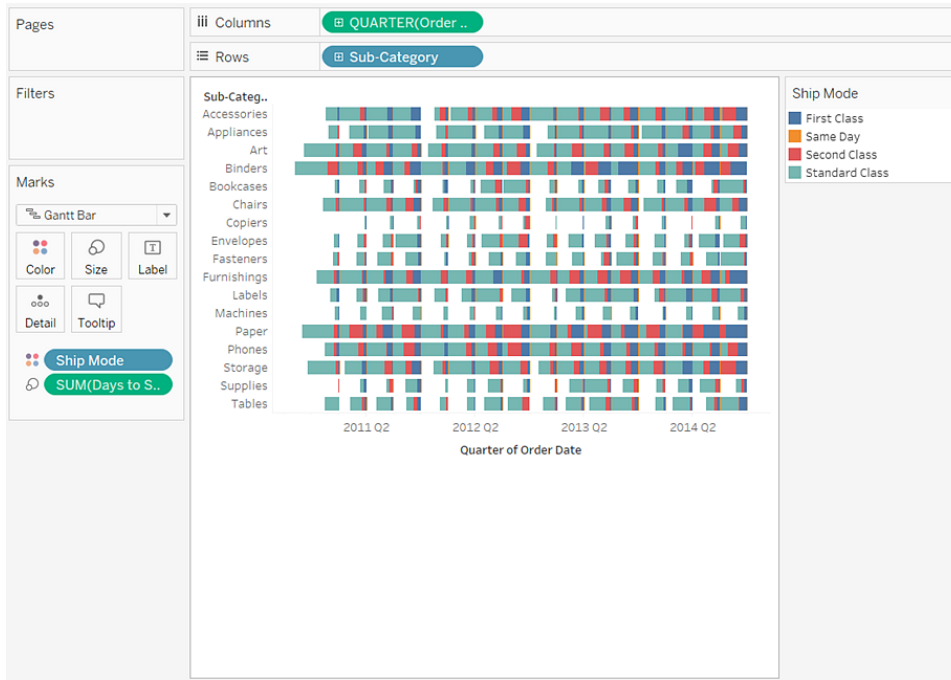

For details on how to build and use pie charts, see [Build a Pie Chart on page 1530](#) and [Get Started Mapping with Tableau on page 1635](#).

Gantt Bar mark

- The Marks card drop-down menu is set to **Automatic** and you place one or more dimensions on either the **Columns** shelf or the **Rows** shelf, and then plot the dimensions against a continuous quantity.
- You select **Gantt Bar** from the Marks card drop-down menu.

The distinguishing characteristic of Gantt Bars is that the length of every mark is proportional to the measure placed on **Size** on the Marks card.

The view below displays a dimension as a function of a continuous date. If the Marks card drop-down menu is set to **Automatic**, the data would be displayed using bars. Selecting **Gantt Bar** and adding additional fields will display a view like the following.

In particular, placing the **Days to Ship** measure on **Size** on the Marks card causes every bar in the view to be drawn with a length that indicates the delivery time of an order. Additionally, placing the **Ship Mode** dimension on **Colour** on the Marks card causes each bar to be coloured according to the ship mode.

For details on how to build Gantt Bar chart, see [Build a Gantt Chart on page 1507](#).

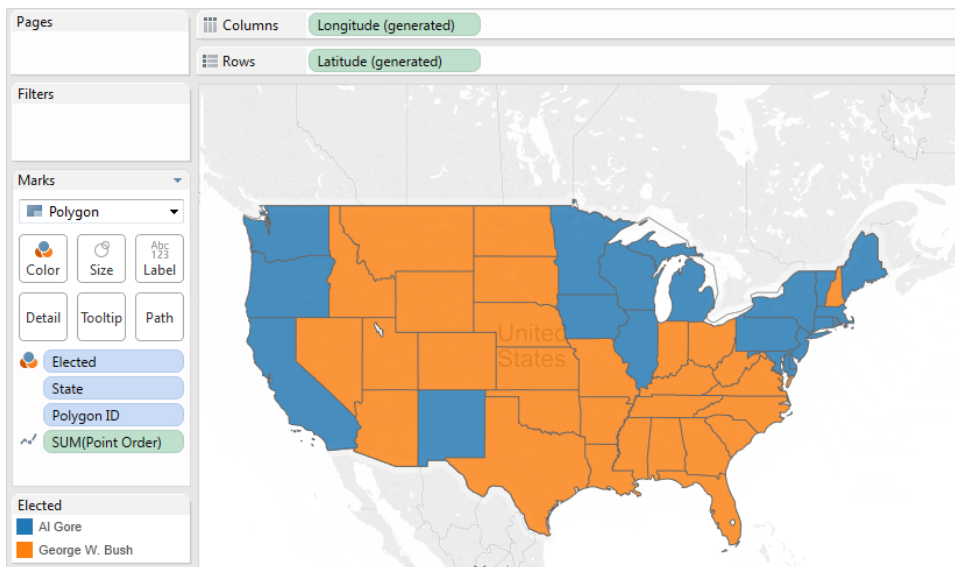

Polygon mark

Polygons are points connected by lines enclosing an area. The polygon mark type is useful when you want to connect points to create data areas. Tableau displays data using polygons when you select Polygon from the **Marks** menu.

The polygon mark is not commonly used and often requires a specially constructed data source.

The view shown below comes from a specially constructed data source that holds geographic and election data. It displays the 48 contiguous US states as a function of latitude and longitude and colour-encodes each state by the 2000 presidential election results.

If **Marks** is set to Automatic, the data will be displayed using a shape. Manually selecting Polygon and adding additional fields to the view causes a different view to be created.

Every state is considered to be a polygon in the data source. The **PolygonID** field on the **Detail** target is distinct for each US state. You can remove states from the view by filtering this field.

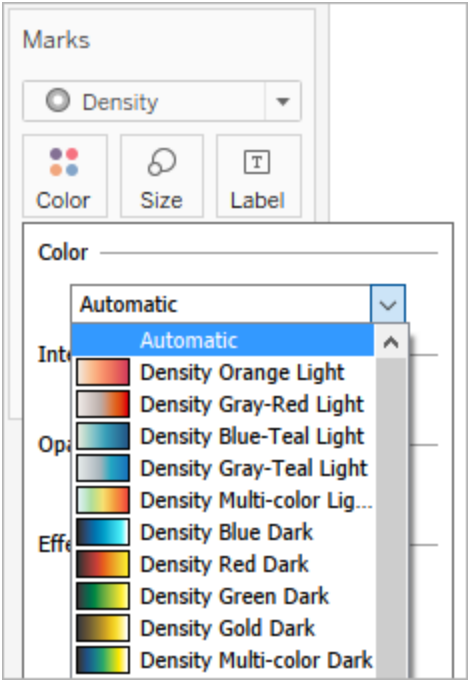

Additionally, you can specify the drawing order of the lines that constitute each polygon by placing a field on the **Path** target. In this example, the **PointOrder** measure is used to draw each state.

Density mark (Heatmap)

You can use the density mark to visualise patterns or trends in dense data with many overlapping marks. Although generally this type of information can be shown using a circle mark, there are cases where density marks can be very effective – for example, when there are many data points in an area, and you need to understand where those marks are most concentrated. The density mark can be used effectively with maps or charts that use point-based marks (scatterplots, unit histograms, box plots over individual marks or point maps).

Tableau does this by grouping overlaying marks, and colour-coding them based on the number of marks in the group.

Density marks work by using colour to show the relative intensity of data in a given area of the chart. You can adjust the colours of the density mark by selecting Colour from the Marks card. Choose from ten density colour palettes, or any of the existing colour palettes.

In the Colour menu, use the Intensity slider to increase or decrease the vividness of the density marks. For example, increasing intensity, or vividness, lowers the "max heat" spots in your data, so that more appear.

Low Intensity (50%)

High Intensity (80%)

The view shown below comes from a data source that contains many geographic points for one month of taxi pick-ups in Manhattan. It displays the location and frequency of taxi pick-ups, with lighter colours being most frequent.

You can select **Density** from the Marks card drop-down menu.

For details on how to build a density map or a density chart, see [Create Heatmaps that Show Trends or Density in Tableau](#) on page 1790 and [Build with Density Marks \(Heatmap\)](#) on page 1501.

Control the Appearance of Marks in the View

Control colour, size, shape, detail, text and tooltips for marks in the view using the Marks card. Drag fields to buttons on the Marks card to encode the mark data. Click the buttons on the Marks card to open Mark properties. For related information on marks, see [Change the Type of Mark in the View](#) on page 1245 and [Marks card](#) on page 62.

Note: The order of dimension fields on the Marks card is hierarchical from top to bottom, and affects sorting in the view. Tableau first considers the topmost dimension field when ordering marks in the view, and then considers the dimensions beneath it on the Marks card.

Assign colours to marks

To assign a colour to marks in the view, do one of the following:

- On the Marks card, click **Colour**, and then select a colour from the menu.

This updates all marks in the view to the colour you choose. All marks have a default colour, even when there are no fields on **Colour** on the **Marks** card. For most marks, blue is the default colour; for text, black is the default colour.

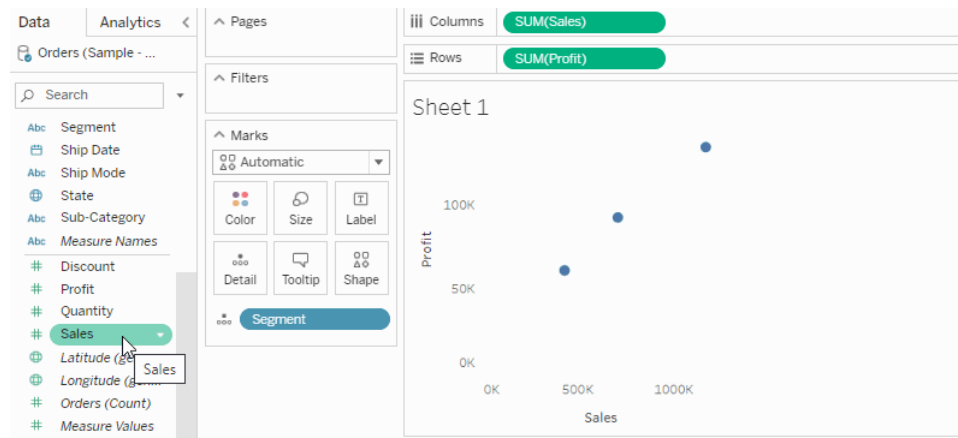

- From the **Data** pane, drag a field to **Colour** on the Marks card.

Tableau applies different colours to marks based on the field's values and members. For example, if you drop a discrete field (a blue field), such as Category, on Colour, the marks in the view are broken out by category, and each category is assigned a colour.

If you drop a continuous field, such as SUM(sales), on Colour, each mark in the view is

coloured based on its sales value.

Edit colours

To change the colour palette or customise how colour is applied to your marks:

- On the Marks card, click **Colour** > **Edit Colours**.

For more information, see [Colour Palettes and Effects](#) on page 1300.

Change the size of marks

To change the size of marks in the view, do one of the following:

- On the Marks card, click **Size**, and then move the slider to the left or right.

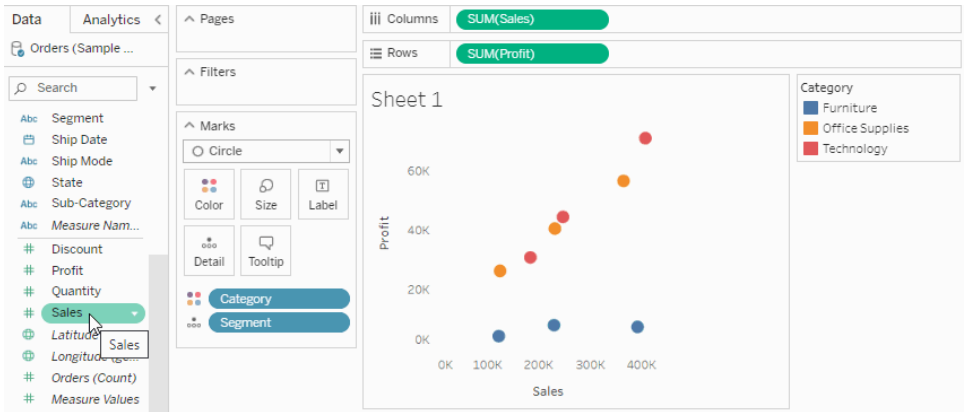

The Size slider affects different marks in different ways, as described in the following table.

| Mark Type | Description |
|-----------------------------|---|
| Circle, Square, Shape, Text | Makes the mark bigger or smaller. |
| Bar, Gantt Bar | Makes bars wider or narrower. |
| Line | Makes lines thicker or thinner. |
| Polygon | You cannot change the size of a polygon. |
| Pie | Makes the overall size of the pie bigger and smaller. |

The size of your data view is not modified when you change marks using the **Size** slider. However, if you change the view size, the mark size might change to accommodate the new formatting. For example, if you make the table bigger, the marks might become bigger as well.

- From the **Data** pane, drag a field to **Size** on the Marks card.

When you place a discrete field on **Size** on the **Marks** card, Tableau separates the marks according to the members in the dimension, and assigns a unique size to each member. Because size has an inherent order (small to big), categorical sizes work best for ordered data like years or quarters.

Size-encoding data with a discrete field separates the marks in the same way as the **Detail** property does, and then provides additional information (a size) for each mark. When you add categorical size encoding to a view, Tableau displays a legend showing the sizes assigned to each member in the field on the **Size** target. You can modify how these sizes are distributed using the Edit Sizes dialog box.

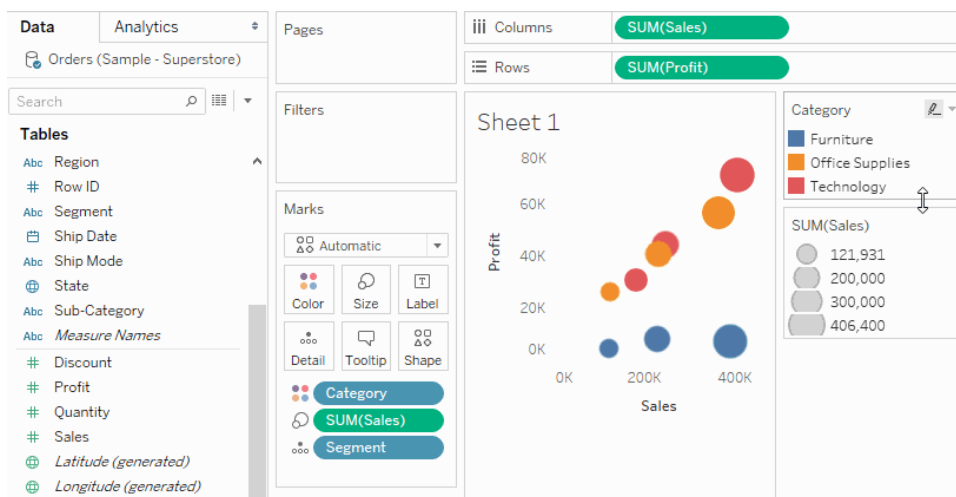

When you place a continuous field on **Size** on the **Marks** card, Tableau draws each mark with a different size using a continuous range. The smallest value is assigned the smallest sized mark and the largest value is represented by the largest mark.

When you add quantitative size encoding to the view, Tableau displays a legend showing the range of values over which sizes are assigned. You can modify how these sizes are distributed using the Edit Sizes dialog box.

Edit marks sizes

To edit the size of marks, or change how size is being applied to marks in the view:

1. On the Size legend card (which appears when you add a field to Size on the Marks card), click the drop-down arrow in the right-hand corner and select **Edit Sizes**.

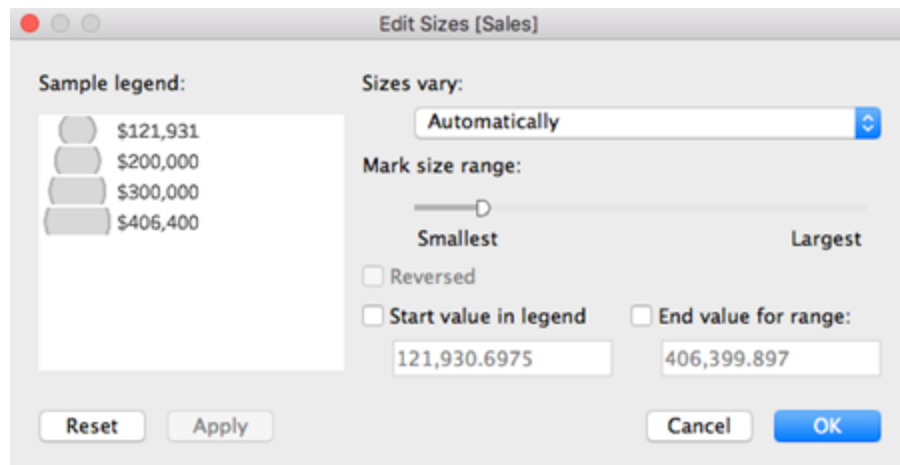

2. In the Edit Sizes dialog box that appears, make your changes and then click **OK**.

The options available depend on whether the field being applied to Size is a continuous or discrete field.

For continuous fields, you can do the following:

- For **Sizes vary**, click the drop-down box and select one of the following:
 - **Automatically** - Selects the mapping that best fits your data. If the data is numeric and does not cross zero (all positive or all negative), the From zero mapping is used. Otherwise, the By range mapping is used.
 - **By range** - Uses the minimum and maximum values in the data to determine the distribution of sizes. For example, if a field has values from 14 to 25, the sizes are distributed across this range.

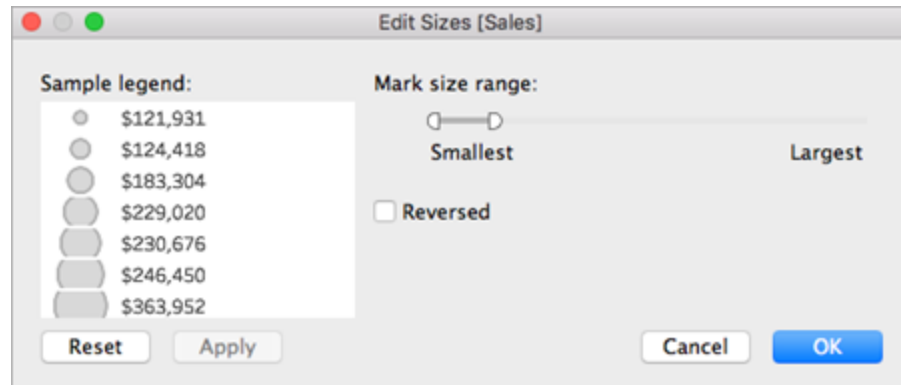

- **From zero** - Sizes are interpolated from zero, assigning the maximum mark size to the absolute value of the data value that is farthest from zero.
- Use the range slider to adjust the distribution of sizes. When the From zero mapping is selected from the Sizes vary drop-down menu, the lower slider is disabled because it is always set to zero.
- Select **Reversed** to assign the largest mark to the smallest value and the smallest mark to the largest value. This option is not available if you are mapping sizes from zero because the smallest mark is always assigned to zero.
- To modify the distribution of sizes, select the **Start value in legend** and **End value for range** check boxes and type beginning and end values for the range.

For discrete fields, you can do the following:

- Use the range slider to adjust the distribution of sizes.
- Select **Reversed** to assign the largest mark to the smallest value and the

smallest mark to the largest value.

Continuous axis mark sizing

For views where the mark type is **Bar** and there are continuous (green) fields on both **Rows** and **Columns**, Tableau supports additional options and defaults for sizing the bar marks on the axis where the bars are anchored.

- The bar marks in histograms are continuous by default (with no spaces between the marks), and are sized to match the size of the bins. See [Build a Histogram on page 1516](#) for an example.
- When there is a field on **Size**, you can determine the width of the bar marks on the axis where the bars are anchored by using the field on **Size**. To do this, click the **Size** card and select **Fixed**.

- When there is no field on **Size**, you can specify the width of the bar marks on the axis where the bars are anchored in axis units. To do this, click the **Size** card, choose **Fixed**, and then type a number in the **Width in axis units** field.

- When there is a continuous date field on the axis where the bars are anchored, the width of the marks is set to match the level of the date field. For example, if the level of the continuous date field is MONTH, the bars are exactly one month wide – that is, slightly wider for 31-day months than for 30-day months. You can configure the width of the bars by clicking the **Size** card, choosing **Fixed**, and then typing a number in the **Width in days** field, but the resulting bar widths don't take into account the varying lengths of time units such as months and years.

Add labels or text for marks

To add mark labels or text to the visualisation:

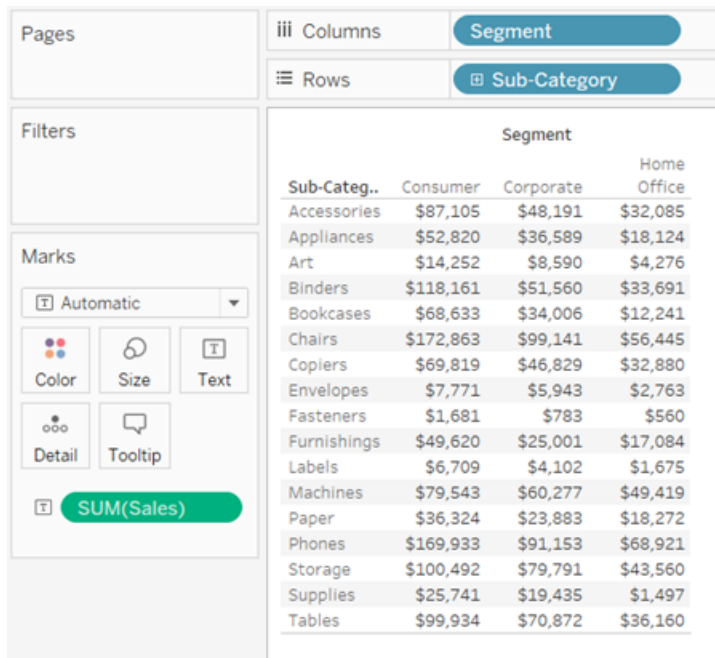

- From the **Data** pane, drag a field to **Label** or **Text** on the Marks card.

When working with a text table, the Label shelf is replaced with Text, which allows you to view the numbers associated with a data view. The effect of text-encoding your data view depends on whether you use a dimension or a measure.

- **Dimension** – When you place a dimension on **Label** or **Text** on the Marks card, Tableau separates the marks according to the members in the dimension. The text labels are driven by the dimension member names.

- **Measure** – When you place a measure on **Label** or **Text** on the Marks card, the text labels are driven by the measure values. The measure can be either aggregated or disaggregated. However, dis-aggregating the measure is generally not useful because it often results in overlapping text.

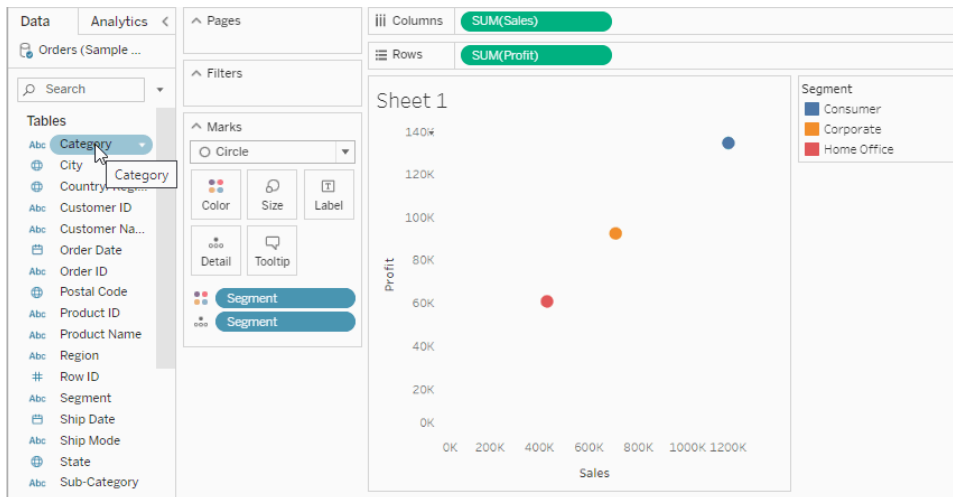

Text is the default mark type for a text table, which is also referred to as a cross-tab or a PivotTable.

Separate marks in the view by dimension members

To separate marks in the view (or add more granularity):

- From the **Data** pane, drag a dimension to **Detail** on the Marks card.

When you drop a dimension on **Detail** on the Marks card, the marks in a data view are separated according to the members of that dimension. Unlike dropping a dimension on the **Rows** or **Columns** shelf, dropping it on **Detail** on the Marks card is a way to show more data without changing the table structure.

Add tooltips to marks

Tooltips are details that appear when you hover over one or more marks in the view. Tooltips are also convenient for quickly filtering or removing a selection, or viewing underlying data. You can edit a tooltip to include both static and dynamic text. You can also modify which fields are included in a tooltip and whether you want to be able to use those fields to select marks in the view.

For details on showing a visualisation from a worksheet in a tooltip (Viz in Tooltip), [Create Views in Tooltips \(Viz in Tooltip\)](#) on page 1378.

Add a tooltip

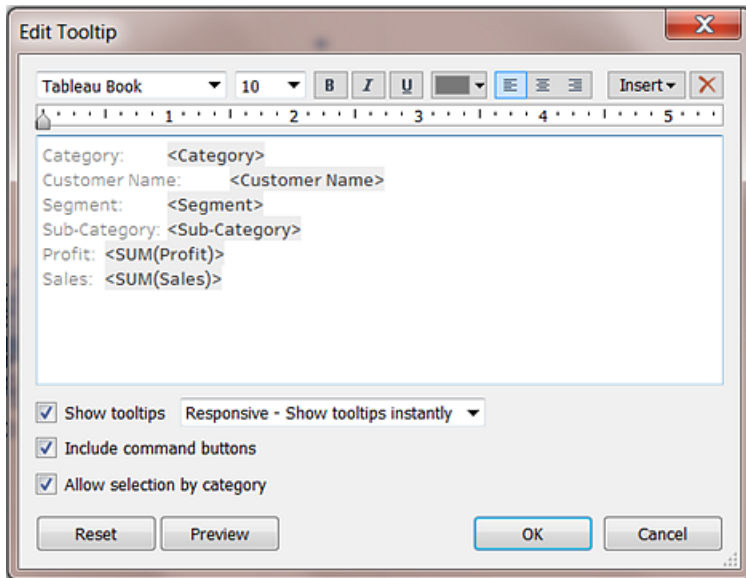

1. Drag a field to **Tooltip** on the **Marks** card.
2. Click **Tooltip** on the **Marks** card to open the Edit Tooltip dialog box, where you can add text, rearrange the tooltip contents and insert more fields.

Note: Dimensions are added to the tooltip using the ATTR aggregation, which means the tooltip may sometimes display as an asterisk. The asterisk indicates that there are multiple dimension members that apply to the mark you are pointing at. For example, a mark may represent the aggregated sales for all regions. Adding the Region field to the tooltip results in an asterisk because the mark represents more than one region. To avoid showing an asterisk, add the dimension to Detail on the Marks card or use it elsewhere in the view to ensure the marks are at the same level of detail.

Tooltip options

After you open the Edit Tooltip dialog box, there are several options that you can choose from to format the tooltips in your view and configure their behaviour. You can choose from the options below.

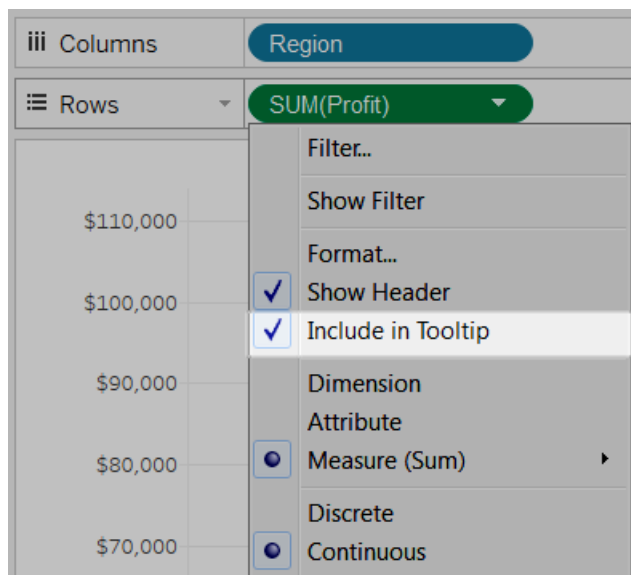

- **Format tooltips:** Tooltips are specified on a per-sheet basis and can be formatted using the tools on the top of the Edit Tooltip dialog box.
- **Adding dynamic text:** Use the **Insert** menu at the top of the dialog box to add dynamic text such as field values, sheet properties and more. The **All Fields** command on the **Insert** menu adds all field names and values that are used in the view to the tooltip for any mark in the view.
- **Show tooltips:** Tooltips are shown by default. If you prefer to hide automatic tooltips, clear the **Show Tooltips** check box.
- **Configure tooltip behaviour:** Configure how tooltips behave by selecting one of the following options in the drop-down list next to the **Show Tooltips** check box:
 - **Responsive - Show tooltips instantly:** Select this option to show tooltips instantly as you move the cursor over the marks in the view. This is the default for all views.

With this option, tooltips appear without command buttons. You must first click a mark in the view to see the command buttons.
 - **On Hover - Show tooltips on hover:** Select this option to show tooltips only after you rest the cursor on a mark. However, with this option, command buttons appear on the tooltip without any further action from you (unless you specify otherwise in the Edit Tooltips dialog box).

- **Show commands:** Select the **Include command buttons** check box to add **Keep Only**, **Exclude**, **Group Members**, **Create Set** and **View Data** buttons at the top of the tooltip. These buttons show both in Tableau Desktop and when the view is published to the web or viewed on a mobile device.

For more information about grouping members, see [Correct Data Errors or Combine Dimension Members by Grouping Your Data on page 1099](#). For more information about creating sets, see [Create Sets on page 1101](#).

- **Select marks in a view from the tooltip.** Select the **Allow selection by category** check box to be able to select marks in a view that have the same value by clicking on a discrete field in a tooltip. If this check box is selected, you can use this feature to select marks in a view in Tableau Desktop, when the view is published to the web or viewed on a mobile device.
- **Add or remove fields:** To add and remove fields when using the automatic tooltip, right-click (control-click on Mac) the field on one of the shelves in the view and select **Include in Tooltip**.

Note: The **Include in Tooltip** option is only available if you have not customised the tooltip. If you have customised the tooltip, you can return to the automatic tooltip by clicking **Tooltip** on the Marks card and then clicking **Reset** in the Edit Tooltip dialog box.

Change the shape of marks

To change the shapes of marks:

- From the **Data** pane, drag a field to **Shape** on the Marks card.

When you place a dimension on **Shape** on the **Marks** card, Tableau separates the marks according to the members in the dimension, and assigns a unique shape to each member. Tableau also displays a shape legend, which shows each member name and its associated shape. When you place a measure on **Shape** on the **Marks** card, the measure is converted to a discrete measure.

Shape-encoding data separates the marks in the same way as the Detail property does, and then provides additional information (a shape) for each mark. Shape is the default mark type when measures are the inner most fields for both the **Rows** shelf and the **Columns** shelf.

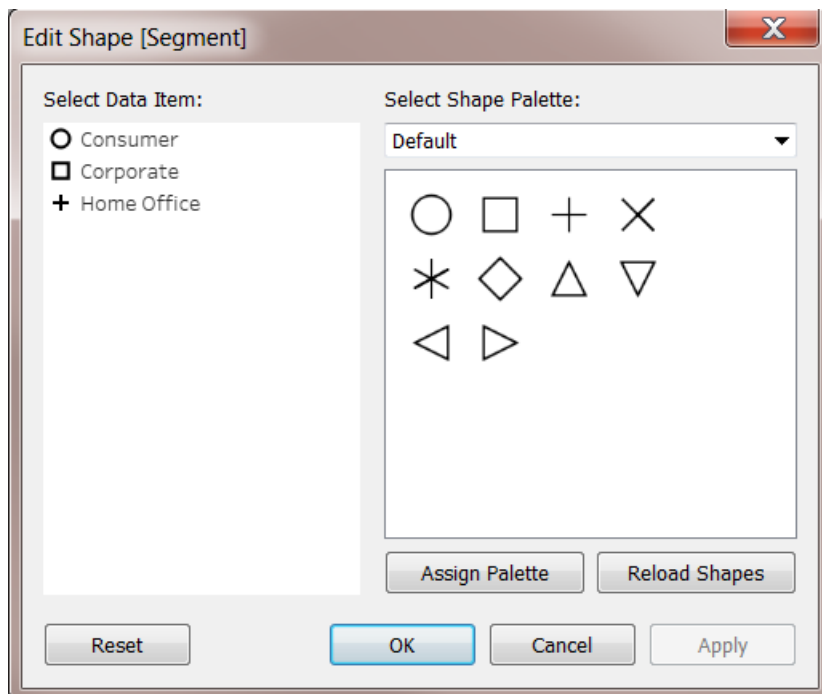

In the view below, the marks are separated into different shapes according to the members of the **Customer Segment** dimension. Each shape reflects the customer segment's contribution to profit and sales.

Edit shapes

By default, ten unique shapes are used to encode dimensions. If you have more than 10 members, the shapes repeat. In addition to the default palette, you can choose from a variety of shape palettes, including filled shapes, arrows and even weather symbols.

1. Click **Shape** on the **Marks** card, or select **Edit Shape** on the legend's card menu.
2. In the Edit Shape dialog box, select a member on the left and then select the new shape in the palette on the right. You can also click **Assign Palette** to quickly assign the shapes to the members of the field.

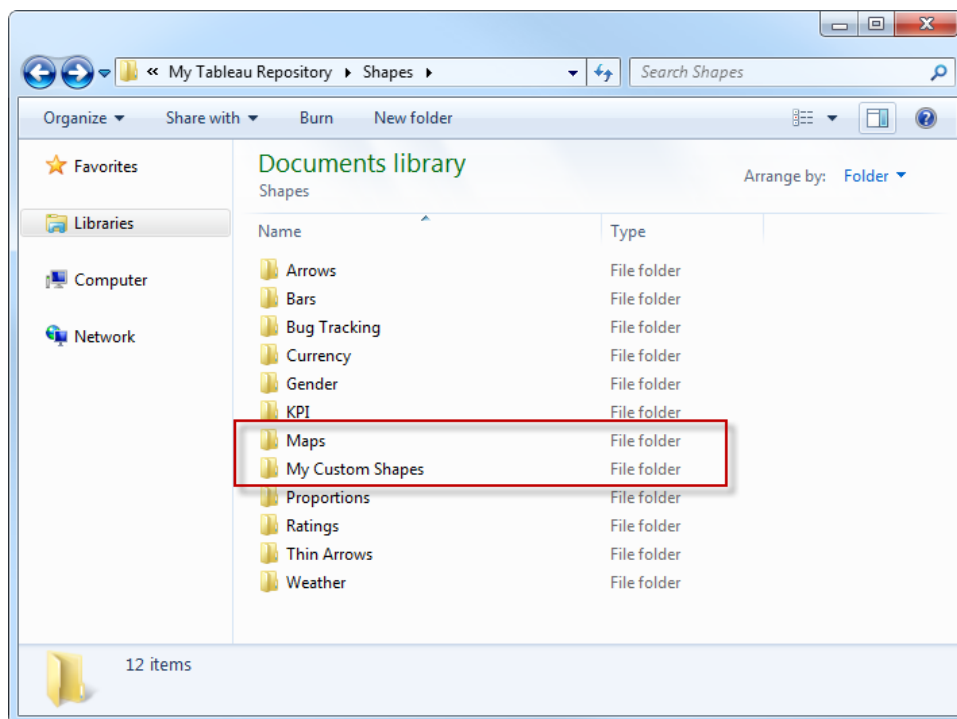

Select a different shape palette using the drop-down menu in the upper right.

Note: Shape encodings are shared across multiple worksheets that use the same data source. For example, if you define Furniture products to be represented by a square, they will automatically be squares in all other views in the workbook. To set the default shape encodings for a field, right-click (control-click on Mac) the field in the **Data** pane and select **Default Properties > Shape**.

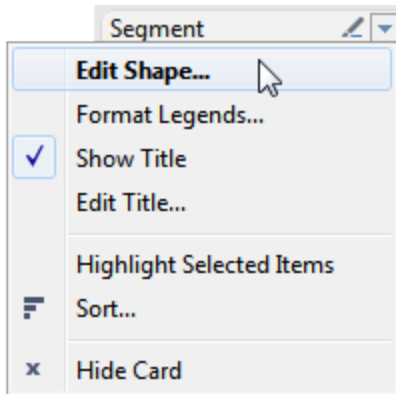

Use Custom shapes

You can add custom shapes to a workbook by copying shape image files to the Shapes folder in your Tableau Repository, which is located in your Documents folder. When you use custom shapes, they are saved with the workbook. That way the workbook can be shared with others.

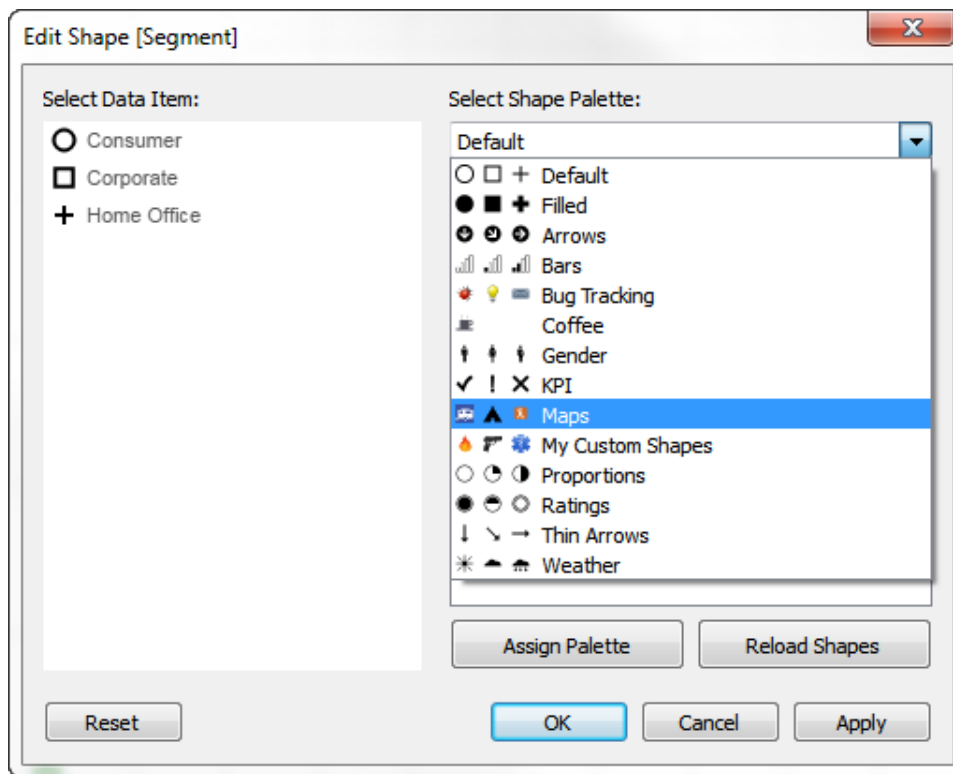

1. Create your shape image files. Each shape should be saved as its own file and can be in any of several image formats including bitmap (.bmp), portable network graphic (.png), .jpg, and graphics interchange format (.gif).
2. Copy the shape files to a new folder in the My Tableau Repository\Shapes folder in your Documents folder. The name of the folder will be used as the name of the palette in Tableau. In the example below, two new palettes are created: Maps and My Custom Shapes.

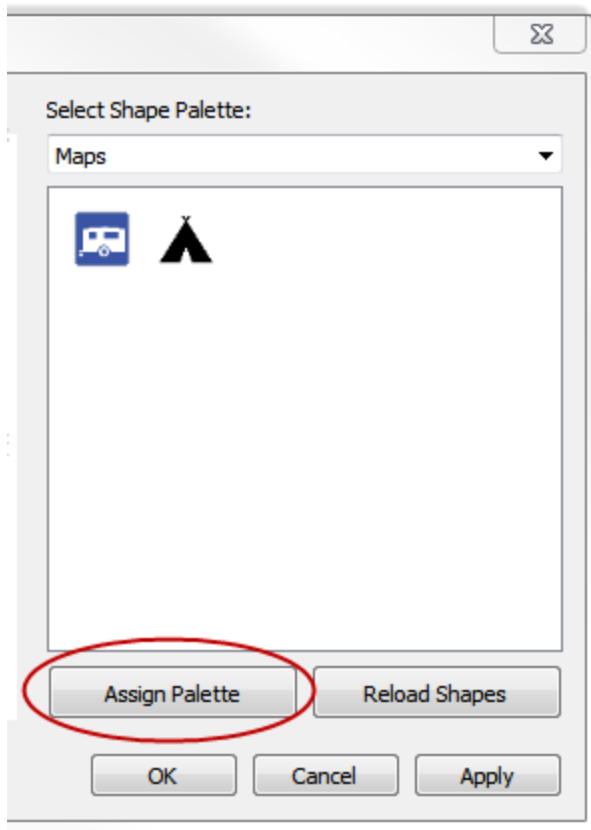

3. In Tableau, click the drop-down arrow on the shape legend, and select **Edit Shape**.

4. Select the new custom palette in the drop-down list. If you modified the shapes while Tableau was running, you may need to click **Reload Shapes**.

5. You can either assign members shapes one at a time, or click **Assign Palette** to automatically assign the shapes to the members.

Note: You can return to the default palette by clicking the **Reset** button. If you open a workbook that uses custom shapes that you don't have, the workbook will show the custom shapes because the shapes are saved as part of the workbook. However, you can click **Reload Shapes** in the Edit Shapes dialog box to use the ones in your repository instead.

Below are some examples of views that use both the default and custom shape palettes.

Tips for creating custom shapes

When you create custom shapes there are a few things that you can do to improve how your shapes look and function in the view. If you are creating your own shapes, we recommend following general guidelines for making icons or clip art.

- **Suggested size** - Unless you plan on using Size to make the shapes really large, you should try to make your original shape size close to 32 pixels by 32 pixels. However, the original size depends on the range of sizes you want available in Tableau. You can resize the shapes in Tableau by clicking Size on the **Marks** card, or by using the cell size options on the **Format** menu.
- **Adding colour encoding** - If you plan to also use Colour to encode shapes, you should use a transparent background. Otherwise, the entire square of the image will be coloured rather than just the symbol. GIF and PNG file formats both support transparency. GIF files support transparency for a single colour that is 100% transparent, while PNG files support alpha channels with a range of transparency levels available on every pixel in the image. When Tableau colour encodes a symbol, the amount of transparency for each pixel won't be modified, so you can maintain smooth edges

Note: Avoid including too much transparency around an image. Make the size of the custom shape as close to the size of the image as possible. Extra transparent pixels around the edges of the image can negatively effect the hover or click behaviour near the image, especially when custom shapes overlap each other. When the actual shape area is bigger than what is visible, it can make hovering and clicking the shape more difficult and less predictable for users.

- **File formats** - Tableau doesn't support symbols that are in the Enhanced Meta File format (.emf). The shape image files can be in one of the following formats: .png, .gif, .jpg, .bmp and .tiff.

Draw paths between marks

The Path property is available when the **Line** or **Polygon** mark type is selected in the **Marks** card drop-down menu. For more information about how to change the type of mark displayed in your viz, see [Change the Type of Mark in the View on page 1245](#).

You can use the Path property in the Marks card to change the **type of line mark (linear, step or jump)**, or to encode data by connecting marks **using a particular drawing order**. You can path-encode your data using either a dimension or a measure.

- **Dimension** – When you place a dimension on **Path** on the Marks card, Tableau connects the marks according to the members in the dimension. If the dimension is a date, the drawing order is driven by the date order. If the dimension includes words such as customer names or product types, the drawing order is driven by the order of the members in the data source. You can change the order that data points are connected by changing the sort order of the members. For more information, see [Sort Data in a Visualisation on page 1352](#).
- **Measure** – When you place a measure on **Path** on the **Marks** card, Tableau connects the marks according to the values of the measure. The measure can be aggregated or disaggregated.

Change the line type (linear, step, jump)

When the mark type is set to be a line (Automatic or Line), you can click the **Path** property in the Marks card to change the line type.

Use these line types for numeric data that remains constant for periods of time, with noticeable changes or deltas – such as account balances, inventory levels or interest rates. Step lines work

well for emphasising the magnitude of change. Jump lines help to emphasise the duration of change between data points.

1. Click **Path** in the Marks card.
2. Select **Linear**, **Step**, or **Jump** to change the line type.

Change the line pattern (solid, dashed, dotted)

Starting in Tableau 23.2, when the mark type is set to be a line (Automatic or Line), you can click the **Path** property in the Marks card to change the line pattern.

Use different line patterns to help differentiate secondary measures. For example, when you want to highlight actual values vs baseline metrics. Line Patterns are helpful when indicating that specific lines are thresholds (such as goals and limits) and other measures are less certain (such as a forecast or modelled data). Line patterns soften the visual weight of a line and can help certain trends from being the primary focus when comparing multiple trends against one another.

1. Click **Path** in the Marks card.
2. Select **Solid line**, **Dashed line**, or **Dotted line** to change the line pattern.

Note: Dashed and dotted line patterns aren't compatible with continuous size encoding. If you have a mark set to change size or thickness based on a quantitative value, you must use a solid line pattern.

Create a path-encoded view

To create a useful path-encoded view, your data table should contain at least one measure. You can't create a path that connects only categorical data (dimensions).

The view below was created using storm data from the Atlantic basin in 2010. The view uses line marks with the path determined by the date of the storm. This lets you see the path of the storm. By placing the continuous date on **Path** on the **Marks** card, this tells Tableau to draw the lines in chronological order. For more information, see [Create Maps that Show a Path Over Time in Tableau](#) on page 1782 and [Create Maps that Show Paths Between Origins and Destinations in Tableau](#) on page 1796.

Show, Hide and Format Mark Labels

You can add labels to the marks in your viz. Labels can display the data already represented in that mark, or additional fields can be added to the Label shelf on the Marks card.

Labels aren't quite the same thing as annotations (which are more like comments than labels). For more information on annotations, see [Add Annotations](#) on page 1369.

Turn labels on or off

To show mark labels in a viz, do one of the following:

- Select the Mark Label button in the tool bar 
- On the Marks card, select **Label**, and then select **Show mark labels**.
- Drag a field to the Label shelf on the Marks card.

Note: If the Mark type is Text (including Automatic text), the label shelf may say **Text** instead of **Label**.

To turn off labels, select the Mark Label button again or clear the Show mark labels option.

Use a specific field as a label

If you didn't specify what field to use as the label, Tableau will use a default field. To set a specific field as the label, drag the desired field to the **Label** shelf on the Marks card.

Change what labels appear

By default, all marks are labelled unless the labels would overlap. Overlap can often be illegible if there are too many marks nearby, but you can turn it on if you choose.

On the Marks card, click **Label**. Check the option **Allow labels to overlap other marks**.

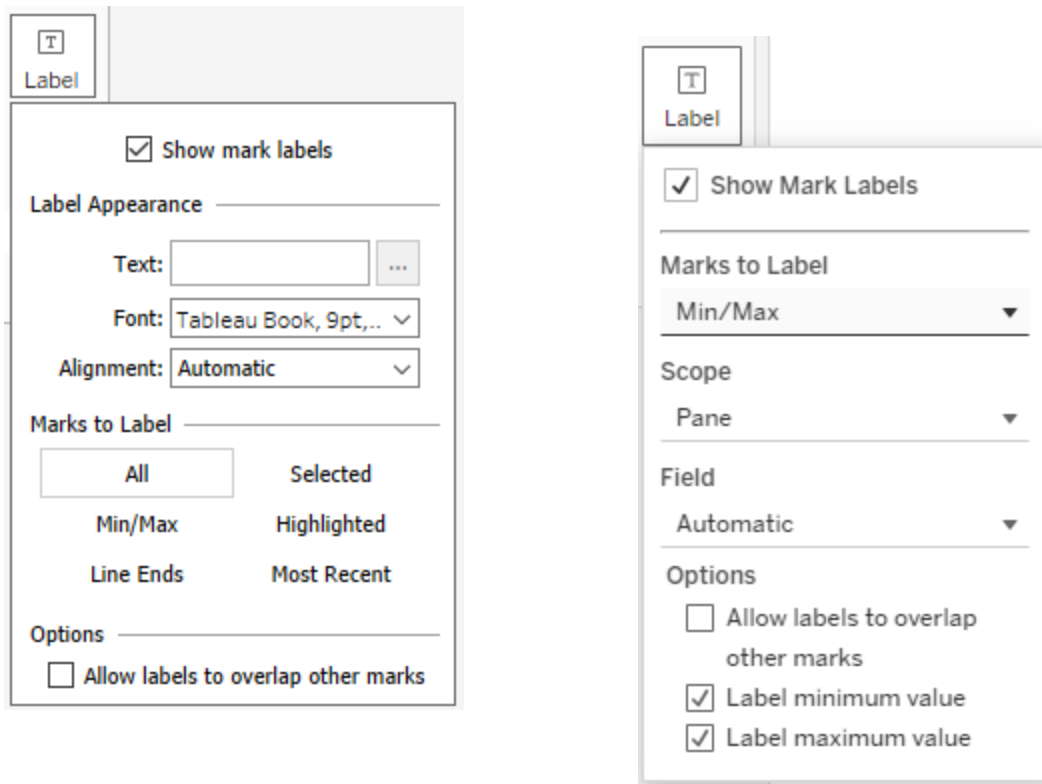

Configure Marks to Label

The **Marks to Label** section offers more nuanced settings for what labels appear.

Not all options are available at all times. Some, like Line Ends, only appear when the structure of the viz supports it. The appearance of the dialog differs depending on if you're using Tableau Desktop or web editing in the browser.

Label options in Tableau Desktop: All

Label option in Web Editing: Min/Max

On the Marks card, click **Label**. Select an option:

- **All**. Label all marks in the viz. (This is the default)
- **Min/Max**. Label only the minimum and maximum values for a field in the viz. Additional options appear with this setting:
 - Scope: you can label the min/max for the entire table, per pane, per cell or per line/pie.
 - Field: set which field's min/max is used.
 - Options: you can choose to label only the min or max or both.
- **Line Ends**. Label the ends of all lines. Use the Additional options if you want to label only the start or end.
- **Selected**. Labels appear when you select one or more marks in the viz.
- **Highlighted**. Label only the highlighted marks in the view. Highlighting can occur in several ways:
 - Selecting a member in a legend
 - Selecting a mark or marks in the viz (this is the same behaviour as the Selected option)

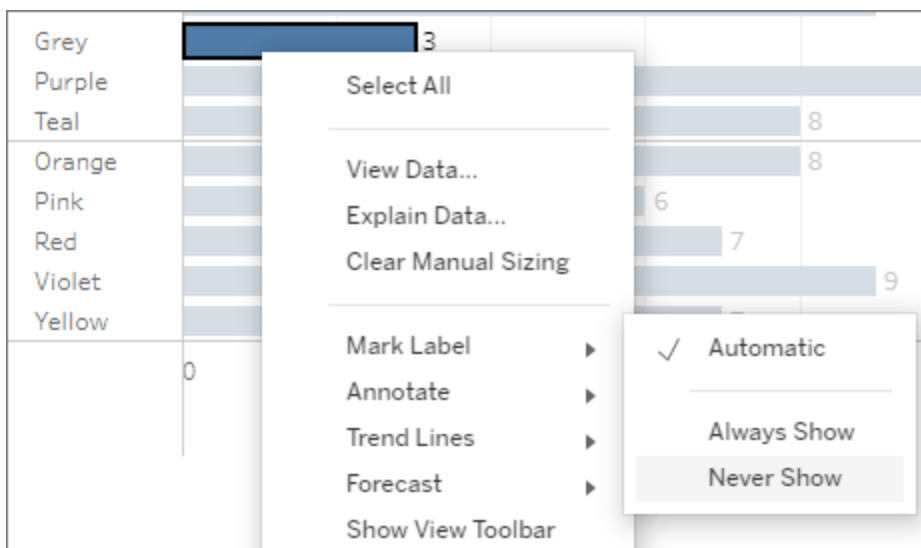

- Using the Highlighter. For more information about how to use the Highlighter, see [Highlight Data Points in Context on page 1405](#).
- **Most Recent.** Label the most recent marks in the view. When there's a date field in the view, you can label all marks that correspond to the most recent date or time in the view. Like Min/Max, this setting has a scope option.

Show and hide individual mark labels

You might want to show labels for only individual marks, or hide specific overlapping mark labels.

In the viz, right click the mark you want to show or hide a mark label for, select **Mark Label**, and then select one of the following options:

- **Automatic:** select this option to turn the label on and off depending on the view and the settings in the Label drop-down menu.
- **Always Show:** select this option to show the mark label.
- **Never Show:** select this option to hide the mark label.

Format mark labels

There are several formatting options to help you adjust the appearance of the labels. You can customise the text, adjust the font properties and set an alignment. These options only available in Tableau Desktop.

Edit the label text

Note: A field must be on the Label shelf before you can edit the label text.

1. On the Marks card, click **Label**.
2. In the dialog box that opens, under **Label Appearance**, click the more options button [...] next to **Text**.
3. Edit the text.
 - You can edit aspects of the font and alignment in this text editor, but for more complete options, use the Label dialog itself (see the next sections).
 - You can use the Insert button in the editor to add more fields to the label, but only fields that were added to the Label shelf are available in that drop down.
4. Select **OK**.

Edit the label font

1. On the Marks card, click **Label**.
2. In the dialog box that opens, under **Label Appearance**, click the **Font** drop-down. Here you can:
 - Select a font type, size, and emphasis.
 - Select a colour for the labels:
 - To select a specific colour, click a colour from the options.
 - To match labels to the colour of their marks, click **Match Mark Colour**.
 - Adjust the opacity of the labels by moving the slider at the bottom of the menu.

Edit the label alignment

1. On the Marks card, click **Label**.
2. In the dialog box that opens, under **Label Appearance**, click the **Alignment** drop-down. Here you can:
 - Align the label horizontally (left, centre, right).
 - Change the direction of the text.
 - Align the label vertically (bottom, middle, top).
 - Set the Wrap to automatic, on or off.

Move mark labels manually

Once a label is present, you can drag it to a new position. For example, in a stacked bar chart, the mark labels are automatically placed in the centre of each bar. However, you may want to stagger the labels so that the longer ones don't overlap.

Select the mark label and, without releasing the mouse button, drag the label to its desired location.

Move Marks

In a dual-axis view that contains many marks, some marks can become hidden behind others, making it difficult to see details in your view. Tableau provides a **Move Marks** option to move selected marks forward or backward, depending on the axis that you select.

To move marks forward or backward, right-click on one of your axes and select one of the following options:

- **Move Marks to Front**
- **Move marks to Back**

Example - Move marks forward

In this example, suppose you have a view that uses the **Circle** mark type on a dual axis and shows department **Sales** and **Profit** for each **Category**.

The shape of each mark represents **Sales** and **Profit**, while **Category** is encoded as **Colour**. The right axis represents the **Sales** mark, while the left represents the **Profit** mark.

Because the profit marks are in front, it is difficult to see the **Sales** marks in the **Office Supplies** category.

To move the **Sales** marks in front of the **Profit** marks, do the following:

1. Right-click on the **Sales** axis.
2. Select **Move marks to front** from the context menu.

By moving the **Sales** mark to the front, you can now see that rubber bands are below \$100,000 in sales, whereas they were nearly invisible before.

Stack Marks

Stacking marks is relevant when your data view includes numeric axes. That is, at least one measure has been placed on the **Rows** or **Columns** shelves. When marks are stacked, they are drawn cumulatively along an axis. When marks are not stacked, they are drawn independently along an axis. That is, they are overlapping.

Stacking marks is particularly useful for bar charts which is why Tableau automatically stacks bars. You might find that stacking marks is useful for other marks such as lines as well.

You can control whether marks are stacked or overlapping in any given view by selecting the **Analysis > Stack Marks** menu item.

You can either allow Tableau to automatically select whether the marks are stacked or you can specify **On** or **Off**. The default setting is **Automatic**. When you are in automatic mode, the Stack Marks menu shows whether stacked marks is on or off.

Selecting **On** or **Off** on the **Stack Marks** menu, switches into manual mode. Your selection remains throughout any changes you make to the view.

The following examples illustrate stacking marks.

Example: Stacking Bars

Consider the stacked bars view shown below. It was created by placing a dimension on the **Columns** shelf, placing a measure on the **Rows** shelf, and colour-encoding the data by a dimension (that is, dropping a dimension on **Colour** on the Marks card).

Example: Stacking Lines

Consider the data view shown below. It was created by placing a date dimension on the **Columns** shelf, placing a measure on the **Rows** shelf, and colour-encoding the data by a dimension (that is, dropping a dimension on **Colour** on the Marks card). Because the mark type is Line, the marks are not automatically stacked. Instead, they are drawn independently from the horizontal axis.

Colour Palettes and Effects

All marks have a default colour, even when there are no fields on **Colour** on the **Marks** card. For most marks, blue is the default colour; for text, black is the default colour. Also see [Assign colours to marks on page 1269](#) and [Example – Multiple Fields on Colour on page 1310](#).

Categorical Palettes

When you drop a field with discrete values (typically a dimension) on **Colour** on the **Marks** card, Tableau uses a categorical palette and assigns a colour to each value of the field. Categorical palettes contain distinct colours that are appropriate for fields with values that have no inherent order, such as departments or shipping methods.

To change colours for values of a field, click in the upper-right corner of the colour legend. In Tableau Desktop, select **Edit Colours** from the context menu. In Tableau Server or Tableau Cloud, the Edit Colours dialog opens automatically.

Tableau Desktop version

Web version

Change the colour for a value

1. Click on an item on the left, under **Select Data Item**.
2. Click a new colour in the palette on the right. In Tableau Desktop you can hover over a swatch to identify the colour.
3. Repeat for as many values that you want to change.
4. In Tableau Desktop, click **OK** to exit the Edit Colours dialog box. In Tableau Server or Tableau Cloud, simply close the dialog box.

Select a different palette

The **Select Colour Palette** drop-down list in the Edit Colours dialog box provides colour palettes that you can use for discrete fields. The list contains both categorical and ordinal palettes.

At the top of the list are categorical palettes, such as *Tableau 10*. As noted above, categorical palettes are appropriate for discrete fields with no inherent order.

At the bottom of the list are ordinal palettes such as *Orange*. Ordinal palettes contain a range of related colours and are appropriate for fields that have an associated order, such as dates or numbers.

After you select a palette, click **Assign Palette** to automatically assign the new palette colours to the members in the field.

To return to the Automatic palette and the default colour assignments, click **Reset** in the Edit Colours dialog box.

Quantitative Palettes

When you drop a field with continuous values on the **Marks** card (typically a measure), Tableau displays a quantitative legend with a continuous range of colours.

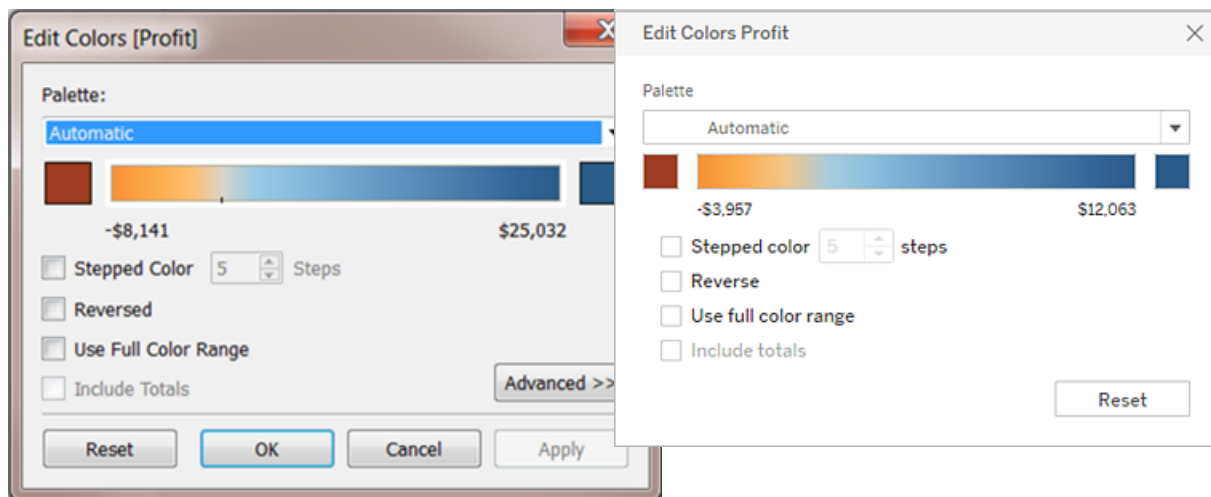

You can change the colours used in the range, the distribution of colour and other properties. To edit colours, click in the upper right of the colour legend. In Tableau Desktop, select **Edit Colours** from the context menu. In Tableau Server or Tableau Cloud, the Edit Colours dialog opens automatically.

When there are both negative and positive values for the field, the default range of values will use two colour ranges and the Edit Colours dialog box for the field has a square colour box on either end of the range. This is known as a diverging palette.

Tableau Desktop version

Web version

Edit Colours dialog box for a diverging palette

When all values are either positive or negative, the default range of values will use a single colour range and the Edit Colours dialog box for the field has a square colour box only at the right end of the range. This is known as a sequential palette.

Tableau Desktop version

Web version

Edit Colours dialog box for a sequential palette

You can specify whether Tableau uses a diverging or a sequential palette for a continuous field on **Colour**, and also configure the range of colours for the field's values.

The **Palette** drop-down list provides a range of colour palettes from which you can choose. There are two types of quantitative palettes available for continuous fields:

- All palettes with *Diverging* in the name are diverging quantitative palettes – for example, *Orange-Blue Diverging*. You can choose a diverging palette for any continuous field – it isn't necessary for the range of values to contain both positive and negative numbers.

To change the colours for a diverging palette, click one of the square colour boxes at either end of the palette spectrum. Depending on whether you are authoring in Tableau Desktop or on the web, do one of the following:

- In Tableau Desktop, in the colour configuration dialog box (which is part of your computer's operating system), select a colour from the colour picker or enter custom values.
- In Tableau Server or Tableau Cloud, enter a custom Hex value in the **Custom Colour** field. If the value isn't valid, no changes are made.
- All other palettes are sequential quantitative palettes. To change the colours for a sequential palette, click on the square colour box at the right-hand end of the palette spectrum to either open the colour configuration dialog box (Tableau Desktop) or to enter a custom Hex value in the **Custom Colour** field (Tableau Server or Tableau Cloud).

Options for quantitative palettes

The following options are available in the Edit Colours dialog box for a continuous field.

Note: Options differ where noted for Tableau Server and Tableau Cloud.

Stepped Colour

Select **Stepped Colour** to group values into uniform bins, where each bin is associated with a colour. Use the spin control to specify how many steps (bins) to create. For example, for a range of values from 0 to 100 you could specify five steps to sort values into five bins (0-20, 20-40, etc.).

Tableau Desktop version

Web version

If a diverging colour palette is selected, the point where the palette transitions between colours is shown on the colour ramp with a small black tick mark. When the number of steps is odd, the mark is placed in the middle of the transitional step. When the number of steps is even, the mark is placed at the boundary between the steps where the colour changes.

Reversed

Select **Reversed** to invert the order of colours in the range. For example, if you want lower values to have a darker intensity in a sequential palette, reverse the palette. For a diverging

palette, reversing the colour palette means swapping the two colours in the palette, in addition to inverting the shades within each colour range.

Use Full Colour Range

With a diverging (two-colour) palette, you can select to **Use Full Colour Range**. Tableau assigns both the starting number and the ending number a full intensity for both colour ranges. So if the range is from -10 to 100, the colour representing negative numbers will be adjusted to change in shade much more quickly than the colour representing positive numbers. If you don't select **Use Full Colour Range**, Tableau assigns the colour intensity as if the range of values was from -100 to 100, so that the change in shade is the same on both sides of zero. This means there will be much less change on the negative side, where actual values only range from -10 to 0, than on the positive side, where values range from 0 to 100.

The image on the left below shows a red-green diverging colour palette for values from -858 to 72,986. Without using the full colour range, -858 (associated with the small box at the lower right of the chart) shows as grey, because -858 is only about 1% as far to the negative side as 72,986 is to the positive side. When the full colour range is used, as in the image on the right, -858 shows as a dark red, equal in intensity to the maximum positive value.

Include totals

Select **Include Totals** to include totals, sub-totals and grand totals in the colour encoding. This option only applies when total values are included in the view.

Limit the colour range

In Tableau Desktop, when you click **Advanced** in the Edit Colours dialog box, you can choose to specify the start, end and centre values for the range by selecting the check box and typing a new value into the field and the colour ramp is adjusted accordingly.

The **Start** value is the lower limit in the range, the **End** value is the upper limit, and the **Centre** value is where the neutral colour is located on a diverging colour palette.

Note: This option is not currently available in Tableau Server or Tableau Cloud.

Reset the colour range

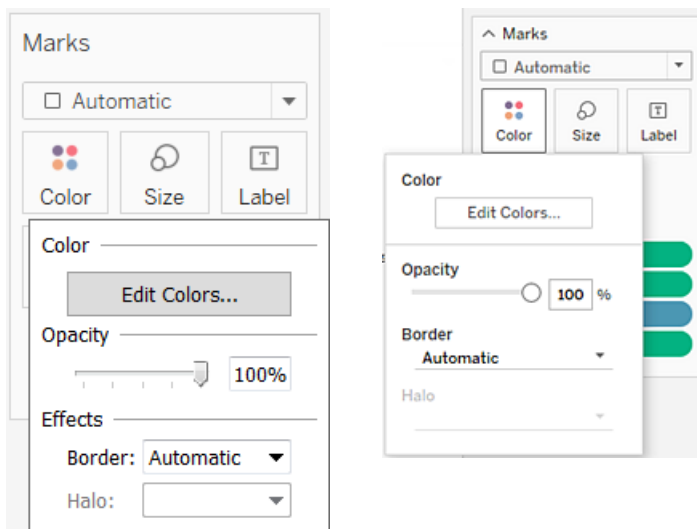

To return to the Automatic palette and the default colour assignments, click **Reset** in the Edit Colours dialog box.

Note: If you are in web authoring mode and click **Reset**, the colour palette will return to the default settings. Any options that were set in the **Advanced** option will also be reset. To undo this action, you can click **Undo** in the top menu. If your changes have already been saved, you must change the Advanced options in Tableau Desktop and republish the view.

Configure Colour Effects

Click the **Colour** drop down on the **Marks** card to configure additional **Colour** settings not related to the actual colours shown.

Tableau Desktop version Web version

Opacity

Modify the opacity of marks by moving the slider.

Adjusting opacity is especially useful in dense scatter plots or when you are looking at data overlaying a map or background image. As you slide the slider toward the left, marks become more transparent.

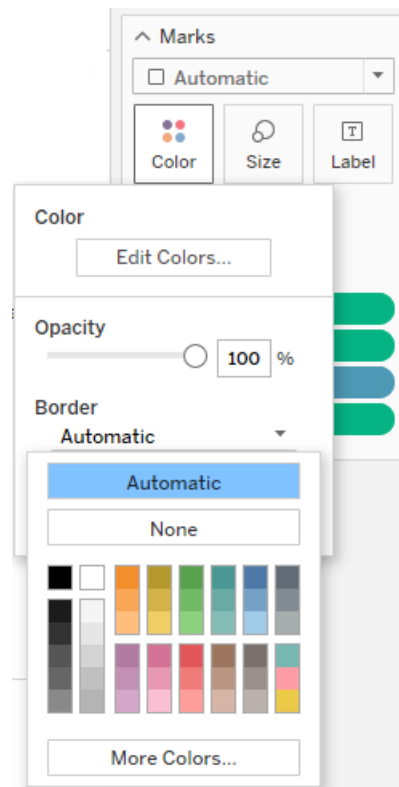

Mark borders

By default, Tableau displays all marks without a border. You can turn on mark borders for all mark types except text, line and shape. On the **Colour** drop-down control, select a mark border colour.

Tableau Desktop version

Web version

Borders can be useful for visually separating closely spaced marks. For example, the views below show a scatterplot with mark borders turned on (left) and turned off (right). When borders are turned on, marks are easier to distinguish in areas where they are tightly clustered.

Note: You can also use the opacity setting to show the density of marks.

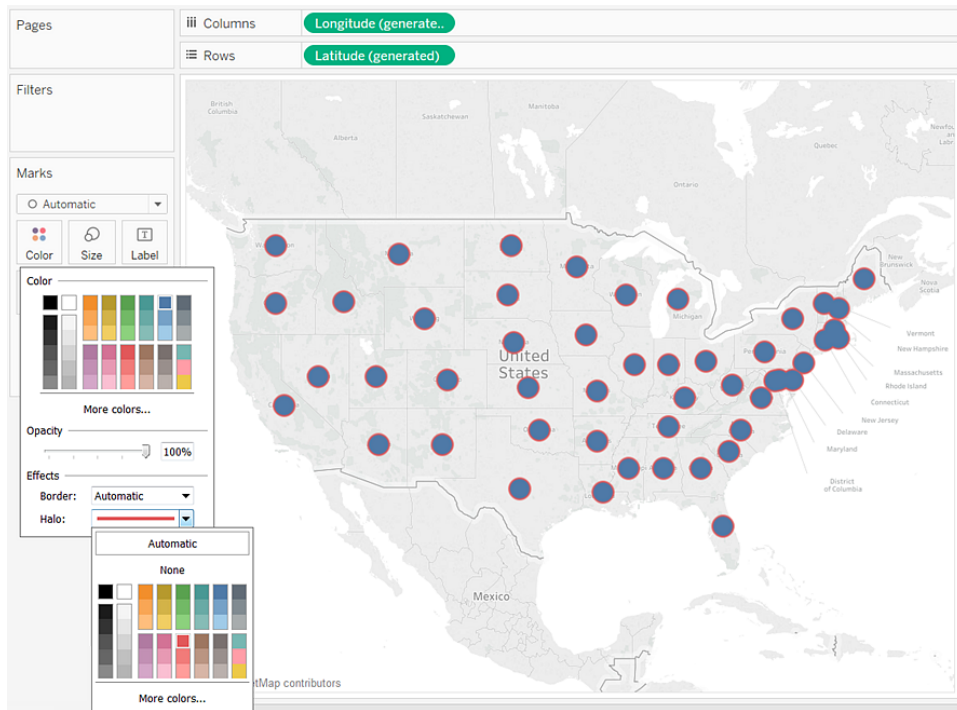

When you are viewing a large number of colour-encoded small marks, it is usually better to leave mark borders off. Otherwise borders can dominate the view, making it difficult to see the colour encoding.

For example, the views below show bars that are segmented by a large number of colour-encoded dimension members. With mark borders turned on (right), some of the narrower marks are difficult to identify by colour. With borders turned off (left), the marks are easy to distinguish.

Mark halos

To make marks more visible against a background image or map, surround each mark with a solid contrasting colour called a halo. Mark halos are available when you have a background image or a background map. On the **Colour** drop-down control, select a mark halo colour.

Markers

In Tableau Desktop, when you are using the Line mark type, you can add a marker effect to show or hide points along the line. You can show selected points, all points or no points. On the **Colour** drop-down control, select a marker in the **Effects** section.

Note: This option is not currently available in Tableau Server or Tableau Cloud.

Example - Multiple Fields on Colour

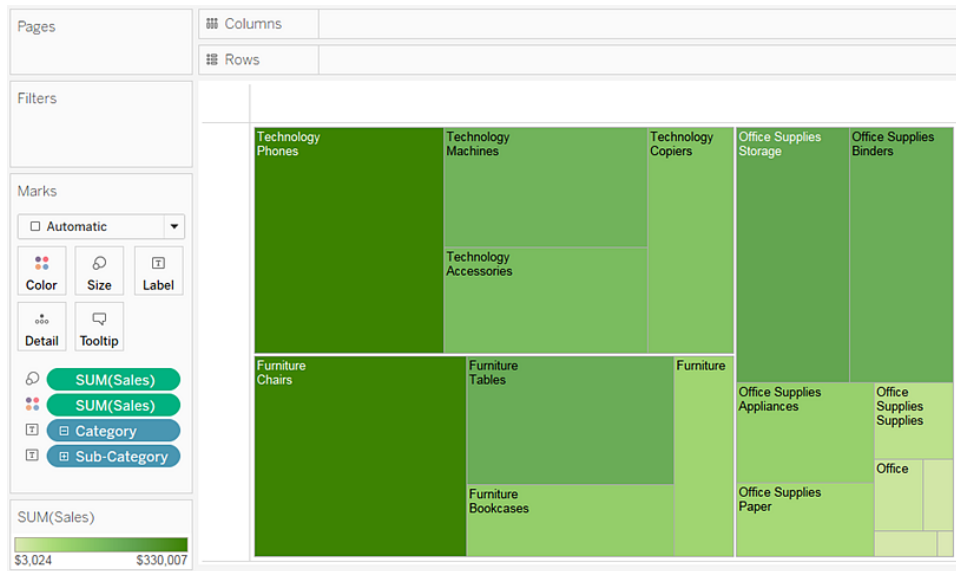

If you drop one field on Colour and then drop a different field on Colour, the second field replaces the first field. However, depending on the chart type, for example treemaps and bullet graphs, you can put multiple fields on colour. You can use one field to set the hue, and the other to show gradations within that hue.

Follow these steps, using the Sample - Superstore data source, to build a treemap with two fields on Colour.

1. Drag **Category** and **Sub-Category** to **Columns**.
2. Drag **Sales** to **Size** on the **Marks** card.
3. Click **Show Me** in the toolbar, then select the Treemap chart type.

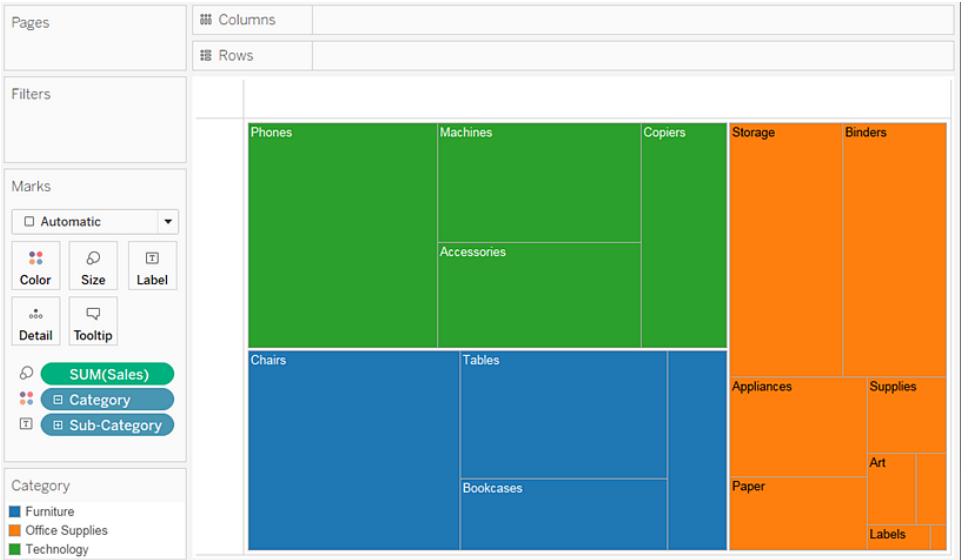

Tableau moves all fields to the **Marks** card, putting **SUM(Sales)** on both **Size** and **Colour**, and **Category** and **Sub-Category** on **Label**:

- Click the label icon to the left of **Category** on the **Marks** card and select **Colour**:

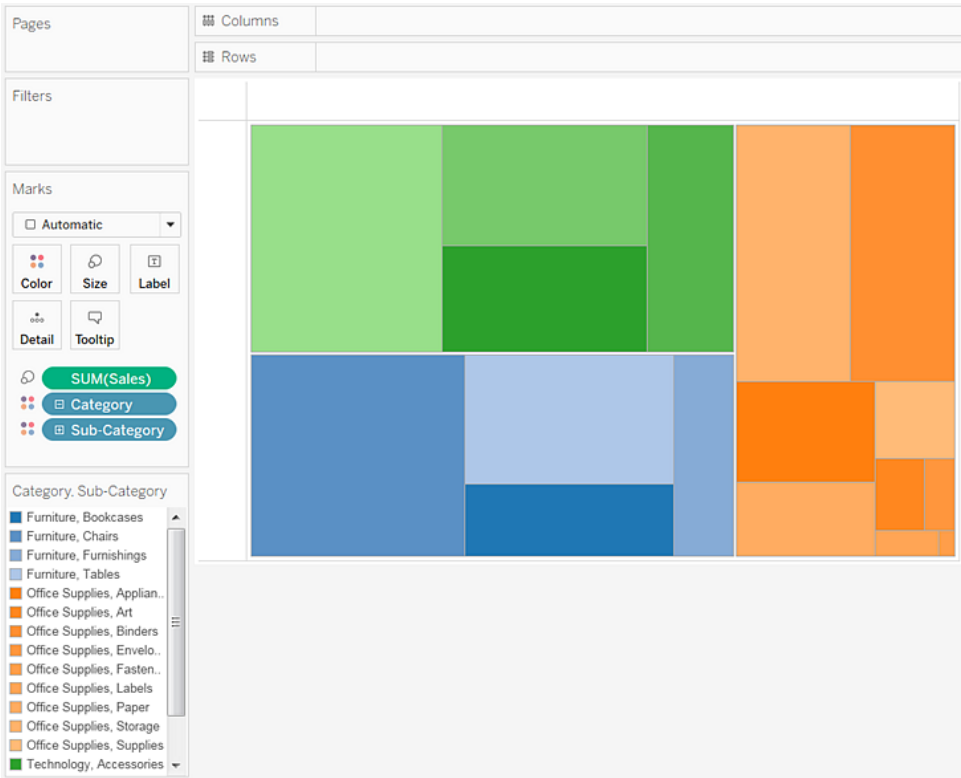

Category replaces **SUM(Sales)** on **Colour**. The marks are still sized by the sum of **Sales**, but now they are coloured by **Category**:

5. Click the label icon to the left of **Sub-Category** on the Marks card and select **Colour**.

Tableau uses distinct, categorical colours for the first field, **Category**, and a range of sequential shades to distinguish values for the second field, **Sub-Category**:

The size of the individual rectangles is still determined by **Sales**, per **Category** and **Sub-Category**.

The two fields on **Colour** (**Category** and **Sub-Category**) are related within a hierarchy, so if you swap their positions on the **Marks** card, moving **Sub-Category** to be above **Category**, the effect is the same as if you had removed **Category** from the view altogether. The treemap changes to show a uniquely coloured rectangle for each **Sub-Category**:

When the two fields on Colour are not related within a hierarchy, you can switch the order of the fields on the Marks card so that the field that was used for categorical colours was used for sequential shades, and vice versa.

If you aren't satisfied with the colours that Tableau used, you can change them. To open the Edit Colours dialog, do one of the following:

- In Tableau Desktop, double-click the colour legend.
- In Tableau Server or Tableau Cloud, click on the drop-down arrow in the top, right-hand corner of the legend.

6. Make the view more readable by adding **Category**, **Sub-Category**, and **Sales** to **Label**. Users can hover to see tooltips for any rectangle that is too small to show text by default.

Filter and Sort Data in the View

This section describes the various ways you can filter and sort data in Tableau visualisations. Read the following articles for information on how to filter data from your visualisations and across multiple worksheets and data sources, sort data in the visualisation, create nested sorts and more.

Filter Data from Your Views

Filtering is an essential part of analysing data. This article describes the many ways you can filter data from your view. It also describes how you can display interactive filters in the view, and format filters in the view.

Filtering Order of Operations

Before you begin filtering data in Tableau, it's important to understand the order in which Tableau executes filters in your workbook.

Tableau performs actions on your view in a very specific order; this is called the Order of Operations. Filters are executed in the following order:

1. Extract filters
2. Data source filters
3. Context filters
4. Filters on dimensions (whether on the Filters shelf or in filter cards in the view)
5. Filters on measures (whether on the Filters shelf or in filter cards in the view)

To learn more, see [Tableau's Order of Operations on page 161](#).

Note: When you drag a discrete dimension to the Filters shelf, the **Filter** dialog box offers four tabs for filtering: General, Wildcard, Condition and Top. The settings on each of these tabs are additive starting with the General tab; what you set on each tab will affect the filter results on each tab to the right. For details on the Filter dialog box, see [Drag dimensions, measures and date fields to the Filters shelf on page 1318](#) and [Filter categorical data \(dimensions\) on page 1319](#).

Select to keep or exclude data points in your view

You can filter individual data points (marks), or a selection of data points from your view. For example, if you have a scatter plot with outliers, you can exclude them from the view so you can better focus on the rest of the data.

To filter marks from the view, select a single mark (data point) or click and drag in the view to select several marks. On the tooltip that appears, you can:

- Select **Keep Only** to keep only the selected marks in the view.

- Select **Exclude** to remove the selected marks from the view.

Note: These filtering options are not available if a Wildcard Match filter is already specified for the same field. See [Drag dimensions, measures and date fields to the Filters shelf on the next page](#) to learn more about Wildcard Match filters.

Select headers to filter data

You can also select headers to filter them from your view.

To filter entire rows or columns of data from your view, select the header in the view. On the tooltip that appears, select to **Exclude** or **Keep Only** the selected data.

When you select a table header that is part of a hierarchy, all of the next level headers are also selected. For example, the view shown below consists of two unrelated dimensions placed on the **Columns** shelf, and two levels of the same hierarchy placed on the Rows shelf.

The selected row headers include the Furniture member of the **Category** dimension, and the Binders and Labels members of the **Sub-category** dimension. When Furniture is selected, all members from the next (inner) level in the hierarchy are automatically selected. In this case, that means the Bookcases, Chairs, Furnishings and Tables members.

| Columns | | Region / State | | | | | | | | | |
|-----------------|--------------|----------------|----------|---------|--------|----------|----------|----------|----------|--------|----------|
| Rows | | Central | | | | | | | | | |
| | | North | | | | | | | | | |
| | | Dakota | | | | | | | | | |
| Category | Sub-Catego.. | Illinois | Indiana | Iowa | Kansas | Michigan | Minnes.. | Missouri | Nebras.. | Dakota | Oklaho.. |
| Furniture | Bookcases | \$4,283 | | | | \$810 | | \$213 | | | \$342 |
| | Chairs | \$14,563 | \$6,463 | \$1,408 | | \$13,878 | \$6,079 | \$61 | \$564 | | \$3,963 |
| | Furnishings | \$2,878 | \$1,514 | \$49 | \$111 | \$1,916 | \$232 | \$941 | \$1,381 | | \$1,445 |
| | Tables | \$6,551 | \$3,519 | \$1,185 | | \$5,717 | \$1,300 | \$1,722 | | | \$2,534 |
| Office Supplies | Appliances | \$975 | \$4,160 | | \$82 | \$4,324 | \$2,844 | \$3,670 | \$501 | | \$1,491 |
| | Art | \$930 | \$389 | \$147 | \$163 | \$1,005 | \$103 | \$240 | \$19 | \$182 | \$59 |
| | Binders | \$4,539 | \$4,012 | \$248 | \$612 | \$22,822 | \$12,470 | \$1,876 | \$128 | \$26 | \$445 |
| | Envelopes | \$384 | \$890 | \$13 | | \$310 | \$31 | \$71 | | | \$407 |
| | Fasteners | \$141 | \$8 | \$46 | \$24 | \$110 | \$43 | | \$58 | \$7 | |
| | Labels | \$225 | \$276 | | \$19 | \$881 | \$161 | \$15 | \$14 | | \$64 |
| | Paper | \$3,456 | \$1,880 | \$316 | \$303 | \$2,011 | \$320 | \$302 | \$333 | | \$197 |
| | Storage | \$9,080 | \$4,120 | \$13 | \$394 | \$6,187 | \$3,398 | \$1,792 | \$1,165 | \$705 | \$2,345 |
| | Supplies | \$178 | | | \$358 | \$74 | \$37 | \$4,217 | \$17 | | \$22 |
| Technology | Accessories | \$5,536 | \$2,279 | | \$92 | \$4,933 | \$1,520 | \$1,022 | \$240 | | \$1,817 |
| | Copiers | \$5,920 | \$18,500 | | | \$1,150 | \$550 | \$5,500 | | | |
| | Machines | \$3,756 | \$84 | | | \$3,411 | | | | | |
| | Phones | \$16,772 | \$5,460 | \$1,154 | \$757 | \$6,731 | \$775 | \$565 | \$3,046 | | \$4,551 |

Drag dimensions, measures and date fields to the Filters shelf

Another way to create a filter is to drag a field directly from the Data pane to the Filters shelf.

When you add a field to the Filters shelf, the Filter dialog box opens so you can define the filter. The Filter dialog box differs depending on whether you are filtering categorical data (dimensions), quantitative data (measures) or date fields.

Filter categorical data (dimensions)

Dimensions contain discrete categorical data, so filtering this type of field generally involves selecting the values to include or exclude.

When you drag a dimension from the Data pane to the Filters shelf in Tableau Desktop, the following Filter dialog box appears:

- **General:** Use the General tab to select the values you want to include or exclude.
- **Wildcard:** Use the Wildcard tab to define a pattern to filter on. For example, when filtering on email addresses you might want to only include emails from a specific domain. You can define a wildcard filter that ends with '@gmail.com' to only include Google email addresses.
- **Condition:** Use the Condition tab in the Filter dialog box to define rules to filter by. For example, in a view showing the average Unit Price for a collection of products, you may want to only show the Products that have an average unit price that is greater than or equal to £25. You can use the built-in controls to write a condition or you can write a custom formula.
- **Top:** Use the Top tab in the Filter dialog box to define a formula that computes the data that will be included in the view. For example, in a view that shows the average Time to Ship for a collection of products, you can decide to only show the top 15 (or bottom) products by Sales. Rather than having to define a specific range for Sales (e.g. greater

than \$100,000), you can define a limit (top 15) that is relative to the other members in the field (products).

Important Note: Each tab adds additional definitions to your filter. For example, you can select to exclude values under the General tab, and also add limits under the Top tab. Selections and configurations from both tabs are applied to your filter.

At any time, you can see the definitions of your filter under Summary on the General tab.

Filter quantitative data (measures)

Measures contain quantitative data, so filtering this type of field generally involves selecting a range of values that you want to include.

When you drag a measure from the Data pane to the Filters shelf in Tableau Desktop, the following dialog box appears:

Select how you want to aggregate the field, and then click **Next**.

In the subsequent dialog box, you're given the option to create four types of quantitative filters:

Range of Values: Select the Range of Values option to specify the minimum and maximum values of the range to include in the view. The values you specify are included in the range.

At Least: Select the At Least option to include all values that are greater than or equal to a specified minimum value. This type of filter is useful when the data changes often, therefore specifying an upper limit may not be possible.

At Most: Select the At Most option to include all values that are less than or equal to a specified maximum value. This type of filter is useful when the data changes often, therefore specifying a lower limit may not be possible.

Special: Select the Special option to filter on Null values. Include only Null values, Non-null values or All Values.

Note: If you have a large data source, filtering measures can lead to a significant degradation in performance. It is sometimes much more efficient to filter by creating a set containing the measure and then apply a filter to the set. For more information about creating sets, see [Create Sets on page 1101](#).

Filter dates

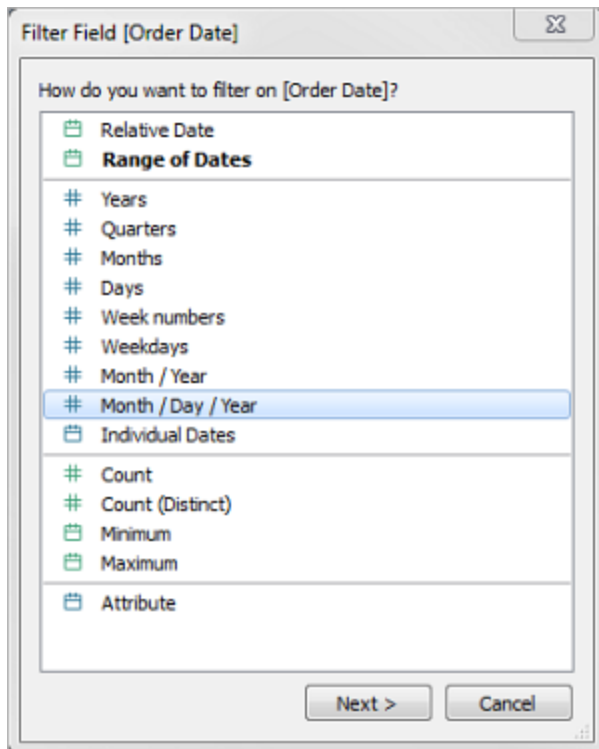

When you drag a date field from the Data pane to the Filters shelf in Tableau Desktop, the following Filter Field dialog box appears:

You can select whether you want to filter on a relative date; filter between a range of dates; or select discrete dates or individual dates to filter from the view.

- **Filter relative dates:** Click Relative dates to define a range of dates that updates, based on the date and time you open the view. For example, you may want to see Year to Date sales, all records from the past 30 days, or bugs closed last week. Relative date filters can also be relative to a specific anchor date rather than today.
- **Filter a range of dates:** Select Range of dates to define a fixed range of dates to filter. For example, you may want to see all orders placed between 1 March 2009 and 12 June 2009.
- **Filter discrete dates:** Select a discrete date value in the dialog box if you want to include entire date levels. For example, if you select Quarters, you can choose to filter specific quarters (e.g. Q1, Q2, Q3, Q4) from your view, regardless of the year.

Latest date preset: If you want to ensure that only the most recent date in a data source is selected in the filter when the workbook is shared or opened, select a discrete date such as Month/Day/Year or Individual Dates and then, on the General tab, select **Filter to latest date value when workbook is opened**.

Notes: When you filter to the latest date value, this setting applies only to data source filters in a workbook.

In the order of operations, the latest date filter is global to the workbook, while context filters apply per worksheet. The latest date is determined just after the workbook opens for first use, after data source filters, but before context filters. At that point the date is set, and the latest date preset is used as a dimension filter.

If you are using additional filters in views (including relative date filters and context filters), the latest date value setting may result in an empty view with no data when those additional filters do not select data from the latest date in the database.

On Tableau Server and Tableau Cloud, presets are applied when the view first loads in the browser but not when the browser or data is refreshed.

- **Filter individual dates:** Select Individual dates to filter specific dates from your view.
- **Additional date filter options:** When you select Relative dates or Range of dates, the Filter dialog box opens. In that dialog box, you can define a Starting date or Ending date. You can also select Special to include null dates, non-null dates or all dates.

Filter table calculations

To create a table calculation filter, create a calculated field, and then place that field on the Filters shelf.

Filters based on table calculations do not filter out underlying data in the data set, because table calculation filters are applied last in the order of operations. This means Tableau evaluates any table calculations in the view first, and then applies table calculation filters on the results in the current view.

Apply table calculation filter to totals

When you show totals in a view and you want a table calculation filter to apply to the totals, you can select **Apply to totals** in the drop-down menu for that filter (on the Filters shelf). This option lets you decide when a table calculation filter should be applied to totals.

The screenshot shows the Tableau Desktop interface. The Columns shelf contains 'MONTH(Order Date)' and the Rows shelf contains 'Category'. The Filters shelf contains 'Order Date' with a dropdown menu set to 'Latest Values Filter: True'. A context menu is open over the filter, showing options: 'Edit Filter...', 'Show Filter', 'Clear Filter', 'Measure', 'Compute Using', 'Edit Table Calculation...', 'Apply to Totals' (highlighted by the mouse), and 'Remove'. The view displays a table with columns for 'Month of Order Date' (October 2012, November 2012, December 2012) and rows for 'Category' (Furniture, Office Supplies, Technology, Grand Total). The Grand Total row shows values: \$351,247, \$256,020, and \$354,709.

| Category | October 2012 | November 2012 | December 2012 |
|-----------------|--------------|---------------|---------------|
| Furniture | | | \$143,101 |
| Office Supplies | | | \$83,246 |
| Technology | | | \$128,363 |
| Grand Total | \$351,247 | \$256,020 | \$354,709 |

The screenshot shows the same Tableau Desktop interface as above, but the 'Apply to Totals' option in the context menu is now checked with a blue checkmark. The view displays a table with columns for 'Month of ..' (December 2012) and rows for 'Category' (Furniture, Office Supplies, Technology, Grand Total). The Grand Total row shows values: \$143,101, \$83,246, and \$354,709.

| Category | December 2012 |
|-----------------|---------------|
| Furniture | \$143,101 |
| Office Supplies | \$83,246 |
| Technology | \$128,363 |
| Grand Total | \$354,709 |

This options is available when you show totals in the view, and you add a table calculation filter to the view. Select **Apply to totals** to apply the table calculation filter to all of the results in the table, including the totals.

Display interactive filters in the view

When an interactive filter is shown, you can quickly include or exclude data in the view.

Note: In web authoring, interactive filters are automatically added to the view when you drag a field to the Filters shelf.

To show a filter in the view:

1. In the view, click the field drop-down menu and select **Show Filter**.

The field is automatically added to the Filters shelf (if it is not already being filtered), and a filter card appears in the view. Interact with the card to filter your data.

Note: In Tableau Desktop, you can add an interactive filter to the view for a field that is not currently used in the view. To do so, In the Data pane, click the field drop-down menu, and then select **Show Filter**.

Set options for filter card interaction and appearance

After you show a filter, there are many different options that let you control how the filter works and appears. You can access these options by clicking the drop-down menu in the upper right corner of the filter card in the view.

Some options are available for all types of filters, and others depend on whether you're filtering a categorical field (dimension) or a quantitative field (measure).

You can customise how filters appear in the view, in dashboards or when published to Tableau Server or Tableau Cloud.

Here are some of the general filter card options:

- **Edit Filter** - This option opens the main Filter dialog box so you can further refine the filter by adding conditions and limits.
- **Remove Filter** - Removes the filter from the Filters shelf and removes the filter card from the view.
- **Apply to worksheets** - Allows you to specify whether the filter should apply to only the current worksheet or be shared across multiple worksheets. For more information, see [Apply Filters to Multiple Worksheets on page 1349](#).
- **Format Filters** (Tableau Desktop only) - Customise the font and colours of all your filter cards in the view.
- **Only relevant values** - Specifies which values to show in the filter. When you select this option other filters are considered and only values that pass these filters are shown. For example, a filter on State will only show the Eastern states when a filter on Region is set.

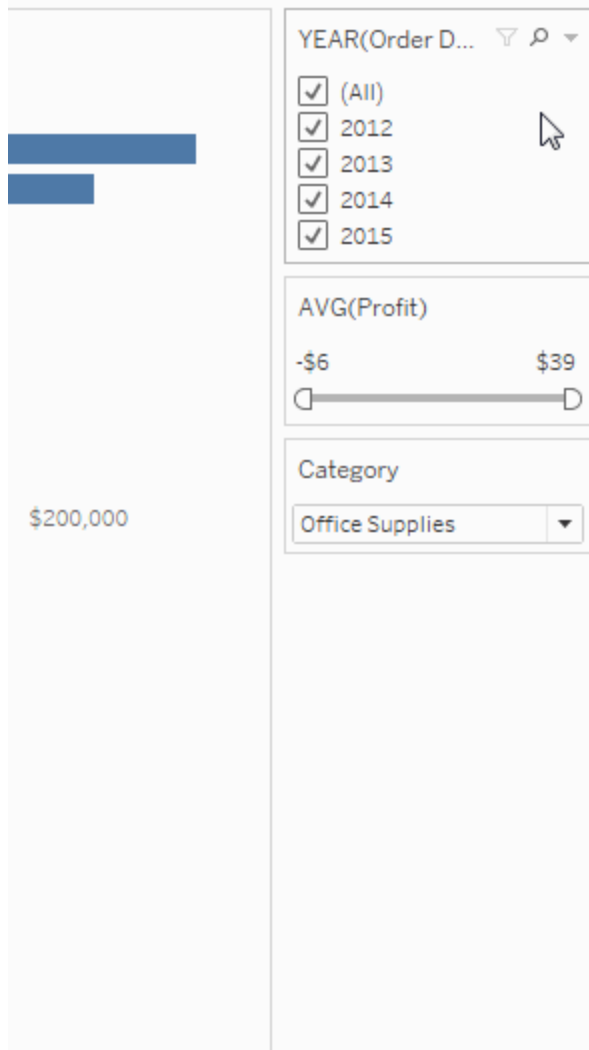

You can use the toggle at the top of the filter card to switch between this option and the All Values in Database option.

- **All values in hierarchy** - Specifies which values to show in the filter. When you create a filter from a hierarchical field, this option is selected by default. Filter values are displayed based on relevance of the parent/child relationships in the hierarchy.
- **All values in database** - Specifies which values to show in the filter. When you select this option all values in the database are shown regardless of the other filters on the view.
- **All values in context** (Tableau Desktop only) - When one of the filters in the view is a context filter, select this option on a different filter to only display values that pass through the context filter. For more information, see [Use Context Filters on page 1344](#).
- **Include values** - When this option is selected, the selections in the filter card are included in the view.
- **Exclude values** - When this option is selected, the selections in the filter card are excluded from the view.
- **Hide Card** (Tableau Desktop only) - Hides the filter card but does not remove the filter from the Filters shelf.

Filter card modes

You can control the appearance and interaction of your filter card in the view by selecting a filter card mode.

To select a filter card mode, in the view, click the drop-down menu on the filter card and then select a mode from the list.

The types of filter card modes you see in the list of options depend on whether your filter is on a dimension or a measure. Below you can find brief descriptions of the types of filter card modes available for dimensions and measures.

For dimensions, you can choose from the following filter modes:

- **Single Value (List)**: Displays the values of the filter as a list of radio buttons where only a single value can be selected at a time.
- **Single Value (Dropdown)**: Displays the values of the filter in a drop-down list where only a single value can be selected at a time.
- **Single Value (Slider)**: Displays the values of the filter along the range of a slider. Only a single value can be selected at a time. This option is useful for dimensions that have an

implicit order such as dates.

- **Multiple Values (List):** Displays the values in the filter as a list of check boxes where multiple values can be selected.
- **Multiple Values(Dropdown):** Displays the values of the filter in a drop-down list where multiple values can be selected.
- **Multiple Values (Custom List):** Displays a text box where you can type a few characters and search for the value. Alternatively, you can type or paste a list of values into the text box to create a custom list of values to include.
- **Wildcard Match:** Displays a text box where you can type a few characters. All values that match those characters are automatically selected. You can use the asterisk character as a wildcard character. For example, you can type 'tab*' to select all values that begin with the letters 'tab'. Pattern Match is not case sensitive. If you are using a multidimensional data source, this option is only available when filtering single level hierarchies and attributes.

For measures, you can choose from the following filter modes:

- **Range of Values/Dates:** shows the filtered values as a pair of sliders that you can adjust to include or exclude more values. Click on the upper and lower limit readouts to enter the values manually.

The darker area inside the slider range is called the data bar. It indicates the range in which data points actually lie in the view. Use this indicator to determine a filter that makes sense for the data in your data source. For example, you may filter the Sales field to only include values between £200,000 and £500,000 but your view only contains values between £250,000 and £320,000. The range of data you can see in the view is indicated by the data bar while the sliders show you the range of the filter.

- **Note:** Data bars only show in filters where the filtered field is also used in the view (e.g., on Columns, Rows or on the Marks card, and so on) and are at the same aggregation level as the field on the Filters shelf. For example, a filter on SUM (Sales) will only display data bars if the SUM(Sales) field is used in the view. It won't show if AVG(Sales) is used in the view. Even though in both scenarios, the filtered field, Sales is used in the view; in the latter case the aggregation is different than the

aggregation of the filter.

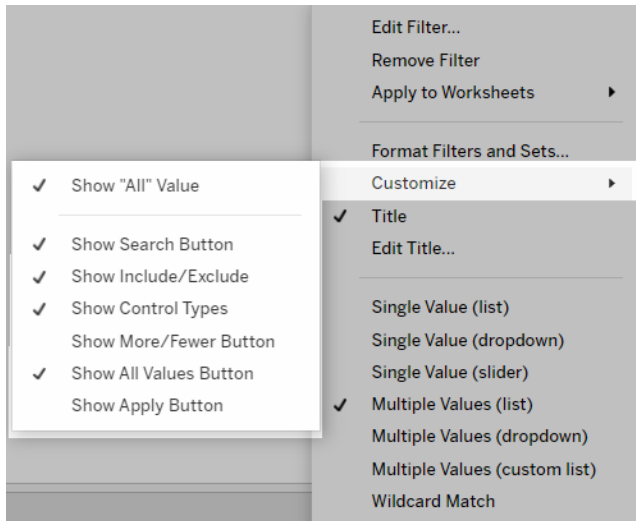

- **At Least/Starting Date:** shows a single slider with a fixed minimum value. Use this option to create a filter using an open ended range.
- **At Most/Ending Date:** shows a slider with a fixed maximum value. Use this option to create a filter using an open ended range.
- **Relative to Now:** this option shows a control where you can define a dynamic date range that updates based on when you open the view. The option is only available for filters on continuous date fields.
- **Browse periods:** shows common date ranges such as past day, week, month, three months, one year and five years. This option is only available for filters on continuous date fields.

Note: When you expose a filter for Measure Values or Measure Names as a single value list, selecting All will automatically convert the filter to a multiple values list. For information on Measure Values and Measure Names, see [Measure Values and Measure Names on page 1220](#).

Customise filter cards

In addition to the general filter options and the filter modes, you control how your filter appears in the worksheet, on dashboards or when published to the web even further in Tableau Desktop.

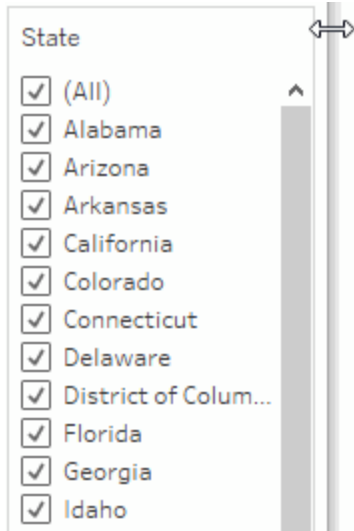

To customise filters, click the filter card drop-down menu and select **Customise**.

You can select from the following options:

- **Show 'All' Value** - toggles whether to show the 'All' option that displays by default in multiple values and single value lists.
- **Show Search Button** - toggles whether to show the search button at the top of the filter.
- **Show Include/Exclude** - toggles whether to show the Include Values and Exclude Values commands on the filter card menu. When shown, users can switch the filter between include and exclude modes.
- **Show Control Types** - Toggles whether to let users change the type of quick filter shown. For example, when shown, a user can change a multiple values list to a compact list.
- **Show More/Fewer button** - toggles whether to show the More/Fewer button  at the top of the filter.
- **Show All Values button** - toggles whether to display the Show All Values button  on the filter card.

Whenever data is excluded in the filter, the small red 'x' appears on the Show All Values button. When all values are showing, the red 'x' disappears.

- **Show Apply Button** - toggles whether to show the Apply button at the bottom of the filter. When shown, changes to the filter are only applied after you click the button. Pending changes are indicated with a green colour. This option is only available in multiple values lists and dropdowns. This options is available in web authoring.
- **Show Readouts** - controls whether the minimum and maximum values are displayed as text above a range of values. The readouts can be used to manually type a new value instead of using the sliders.
- **Show Slider** - controls whether the slider displays. When this option is cleared, the filter only displays the readouts.
- **Show Null Controls** - shows a drop-down list that lets you control how the filter handles null values. You can select from values in a range; values in a range and null values; null values only, non-null values or all values.

Note: Not all of the above options are available for views published to Tableau Server or Tableau Cloud.

Filter Data Across Multiple Data Sources

While working with multiple data sources in a workbook, you might want to compare the data between them using a field they have in common. To do so, you can apply a filter across multiple primary data sources.

For example, the following dashboard shows the order quantity, average sales and average profit for customers. It has three views. Each of the views uses a different data source as its primary data source, and those data sources all have a field in common: Customer Name. There is also a filter card in the view for Customer Name.

This is an interesting dashboard with a lot of great information, but you might want to update all of the views in the dashboard at the same time by the customer you're analysing. For example, maybe you want to see the average sales, profit and number of orders you've received from one of your customers, Aaron Riggs.

To do so, you can filter all three data sources on the Customer Name field.

Follow the steps below to learn how to filter data across multiple data sources.

Before you start, you might want to know the following:

Starting with version 10.0, you can filter data across multiple primary data sources. You cannot filter data across secondary data sources. Filtering data across a worksheet's secondary data source is not currently supported in Tableau Desktop.

If you want to filter data across secondary data sources, consider the following alternatives:

- Join tables that are in the same data source, instead of blending them. For more information, see [Join Your Data on page 796](#).
- Create a cross-database join if your tables are in different data sources. For more information, see [Join Your Data on page 796](#).
- Make the primary data source the secondary data source, and the secondary data source the primary. **Note:** This might not always be feasible given the level of detail you want in the final view.

Note: To ensure the data strings with mixed capitalisation are treated as case-insensitive in the filter, create a calculated field using the UPPER() string function, and then create the filter relationship using that calculated field.

For more FAQs about cross data-source filters, see the [Cross data-source filtering FAQs](#) forum post in the Tableau Community.

Step 1 Define relationships between your data sources

Before you can create relationships between data sources, you must ensure that there is a common field between the data sources you're mapping. The fields do not need to be named the same in each data source, but they should have some data in common.

After you've identified the common fields, you must create relationships between them, or *map the fields* to one another.

If the fields happen to have the same name, Tableau might recognise them as related automatically. You can modify an existing relationship that was created automatically by Tableau, or create a new relationship between two fields in different data sources, by following the procedure below.

To define a relationship between your two data sources:

1. Select **Data > Edit Relationships**.
2. In the Edit Relationships dialog box, do the following:
 - Select a data source for **Primary data source**, and select a data source for **Secondary data source**.
 - Select **Custom**.
 - To define a relationship between fields that have different names, click **Add**.
To edit an existing relationship, select the fields on the right, and then click **Edit**.
3. In the Add/Edit Field Mapping dialog box, do the following, and then click **OK**:
 - Under **Primary data source field**, select a field.
 - Under **Secondary data source field**, select a field with similar data to the field you selected for the primary data source.

For more information about editing relationships, see [Blend Your Data on page 821](#).

Note: After you define your relationships, you do not need to enable blends (that is, you do not have to click the link icon in the **Data** pane) to filter across your data sources.

For more information about the difference between primary and secondary data sources, see [Blend Your Data on page 821](#).

Step 2 Add a filter to the view

After you have defined relationships between your data sources, go to one of your worksheets and drag a dimension to the **Filters** shelf. Then select to include or exclude data from the view. For more information about filtering your data, see [Filter Data from Your Views on page 1315](#).

Optional Step: Display a filter card in the view. Right-click the field on the **Filters** shelf and select **Show filter**. A filter card for that field appears in the view.

For more information about filter cards (previously known as quick filters), see [Display interactive filters in the view on page 1326](#).

Step 3 Apply the filter to your worksheets

After you set up your filter, you can apply that filter to all the worksheets in your workbook that use related data sources, or you can apply it to selected worksheets.

- To apply the filter to all worksheets that use related data sources, right-click the field on the **Filters** shelf and select **Apply to worksheets > All using related data sources**.

The Customer Name field is added to the **Filters** shelf on every worksheet that uses a related data source. An icon is added next to the field on the **Filters** shelf, indicating that the filter is being applied to multiple data sources.

If you hover over the field on the Filters shelf in any worksheet, you can find details about the type of filter, the source field for the filter, and the other sheets the filter applies to.

- To apply the filter to selected worksheets, right-click the field on the **Filters** shelf and select **Apply to worksheets > Selected worksheets**.

The Customer Name field is added to the **Filters** shelf on the worksheets you selected. An icon is added next to the field on the **Filters** shelf to indicate that the filter is being applied to select worksheets.

Now, on the dashboard, when you filter the view down to Aaron Riggs, all three views update and you can see that Aaron made orders in 2010, 2011 and 2013, and spent an average of 3,700 USD. The average profit for these orders was approximately 1,000 USD.

Source fields and target fields

When you apply a filter to multiple data sources, you create a source field and one or more target fields. Both source fields and target fields appear on the **Filter** shelf in their respective worksheets.

The source field is the field you're filtering with.

The target field on any given worksheet is a field from another data source that is related to the source field. This is the field that is actually being filtered on that worksheet.

The source field determines the data that is included or excluded from the target fields. For example, let's say you have three worksheets that use three separate data sources (A, B and C) as their primary data source. Each of the data sources has a field in common (Fruit), and the data is as follows:

| Fruit from data source A | Fruit from data source B | Fruit from data source C |
|--------------------------|--------------------------|--------------------------|
| Apples | Apples | Apples |
| Oranges | Grapefruit | Grapefruit |

| | | |
|---------|---------|----------|
| Bananas | Oranges | Oranges |
| | Pears | Tomatoes |
| | | Bananas |

If the Fruit field from data source A is the source field for the cross data source filter, then the data that appears for the target fields is as follows:

| Fruit from data source A - Source field | Fruit from data source B - Target field | Fruit from data source C - Target field |
|--|--|--|
| Apples | Apples | Apples |
| Oranges | Oranges | Oranges |
| Bananas | | Bananas |

Any data that does not match the data in the source field is excluded from the target fields, and will not appear in your worksheets or in your filter cards.

On the Filters shelf, source fields are indicated with either a  icon when the source field applies to all worksheets with a related data source, or a  icon when it applies to select worksheets. Target fields are indicated with a  icon on the field on the Filters shelf. They are also indicated with a  or  icon next to the field on the Filters shelf.

Create Relative Date Filters

Relative date filters dynamically update to show a time period relative to when you open the view, such as the current week, the year to date or the past 10 days. Relative date filters make it easy to create views that always show the most recent data.

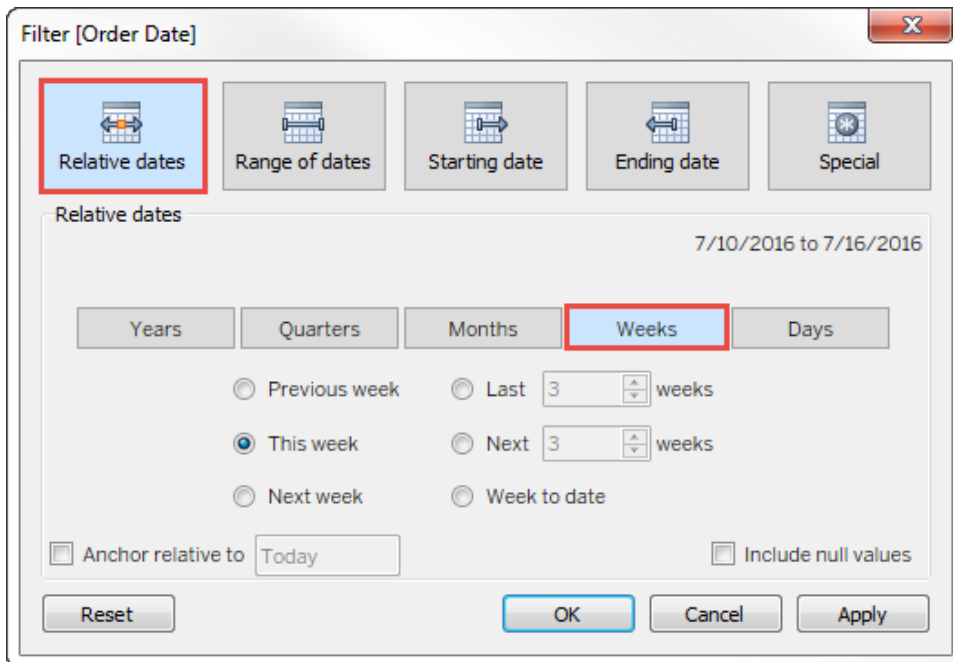

Step 1: Drag a date field to the filter shelf

Drag a date field from the **Data** pane to the Filters shelf. In the Filter Field dialog box, select **Relative Date** and then select **Next**.

Step 2: Select a time unit

In the Filter dialog box, select **Relative dates** and then select the unit of time for the filter. For example, to show only the last three weeks, select **Weeks**.

Step 3: Define the date period

Use the options in the lower part of the Filter dialog box to specify which date period to include in the view. For example, to show the last three weeks, select **Last** and then enter the number **3**.

The specific range of time that you have selected is displayed in the upper right of the Filter dialog box.

Note: "Last" date periods include the complete current unit of time, even if some dates haven't occurred yet. For example, if you select the last month and the current date is 7th January, Tableau will display dates for 1st January to 31st January.

Step 4: Watch the view update

The view will now update to always show the relative date range you've chosen.

Once created, you can show relative date filters in the view as cards. See [Display interactive filters in the view](#) on page 1326. To confirm the specific date range, users can select the menu on the filter card:

Use Context Filters

By default, all filters that you set in Tableau are computed independently. That is, each filter accesses all rows in your data source without regard to other filters. However, you can set one or more categorical filters as context filters for the view. You can think of a context filter as an independent filter. Any other filters that you set are defined as dependent filters because they process only the data that passes through the context filter.

You may create a context filter to:

- Force a filter to be carried out first.
- Create a dependent numerical or top N filter. You can set a context filter to include only the data of interest and then set a numerical or a top N filter.

For example, suppose you're in charge of breakfast products for a large grocery chain. Your task is to find the top 10 breakfast products by profitability for all stores. If the data source is very large, you can set a context filter to include only breakfast products. Then you can create a top 10 filter by profit as a dependent filter, which would process only the data that passes through the context filter.

Create Context Filters

To create a context filter, select **Add to Context** from the context menu of an existing categorical filter. The context is computed once to generate the view. All other filters are then computed relative to the context. Context filters:

- Appear at the top of the Filters shelf.
- Are identified by a grey colour on the Filters shelf.
- Cannot be rearranged on the shelf.

As shown below, the **Ship Mode** dimension is set to be the context for a view. The **Region** filter is computed using only the data that passes through **Ship Mode**.

You can modify a context filter by:

- Removing the field from the Filters shelf – If other context filters remain on the shelf, a new context is computed.
- Editing the filter – A new context is computed each time you edit a context filter.
- Selecting **Remove from Context** – The filter remains on the shelf as a standard filter. If other context filters remain on the shelf, a new context is computed.

Speed up Context Filters

To improve performance of context filters, especially on large data sources, follow these general rules.

- Using a single context filter that significantly reduces the size of the data set is much better than applying many context filters.
- Complete all of your data modelling before creating a context. Changes in the data model, such as converting dimensions to measures, require recomputing the context.
- Set the necessary filters for the context and create the context before adding fields to other shelves. Doing this work first makes the queries that are run when you drop fields on other shelves much faster.
- If you want to set a context filter on a date you can use a continuous date. However, using date bins like YEAR(date) or context filters on discrete dates are very effective.

Note: Context filters can adversely affect any query performance improvements when you use the **Assume Referential Integrity** option in the Data menu of the data source. For more information, see [Assuming Referential Integrity for Joins on page 812](#).

Example: Create Context Filters

This example walks you through how to create a context filter. First you'll filter a view to show the top 10 products by sales. Then you'll create a context filter on product category so you can see the top 10 furniture products.

1. Use the **Sample - Superstore** data source to create the initial view shown below. The view shows the sales for all sub-categories, sorted with the highest sale at the top.

- Now create a Top 10 filter to just show the top selling products. You can create this filter by dragging the **Sub-Category** field to the Filters shelf. In the Filter dialog box, switch to the **Top** tab and define a filter that is Top 10 by Sum of Sales. See [Filter Data from Your Views](#) on page 1315 to learn more about defining a Top N filter.

- When you click **OK**, you'll see that the view is filtered to show the top 10 product sub-categories in terms of sales.

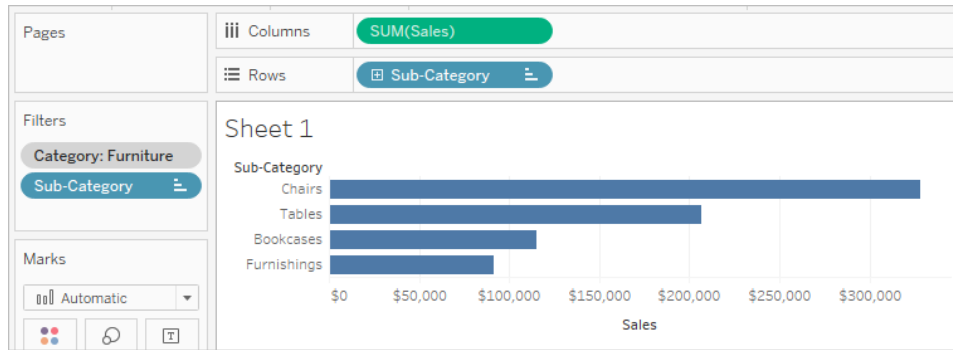

- Now, let's add another filter to show only furniture products. Drag the **Category** field to the Filters shelf and select only **Furniture**. When finished, click **OK**.

The view is filtered but instead of 10 products, it now shows 3. This is because by default all filters are evaluated separately and the view shows the intersection of the results. So this view shows that three of the top 10 overall products are furniture products.

- To find out what the top 10 furniture products are we need to make the Category filter a context filter. Right-click the field on the Filters shelf and select **Add to Context**.
- The filter is marked as a context filter and the view updates to show the top four furniture products. Why not 10? Because only four of the sub-categories contain furniture. But we now know that the Top 10 filter is being evaluated on the results of that context.

Apply Filters to Multiple Worksheets

When you add a filter to a worksheet, by default it applies to the current worksheet. Sometimes, however, you might want to apply the filter to other worksheets in the workbook.

You can select specific worksheets to apply the filter to or apply it globally to all worksheets that use the same data source or related data sources. For example, you might have a filter that only includes a specific region or product of interest. Rather than adding this filter every time you create a new worksheet, you can simply create the filter once and then apply it to multiple worksheets.

For examples of global filters, see [The Global Filters Tab](#) on [Ryan Sleeper's](#) website, and [Dashboard Design: Adding Interactivity](#) on the [Interworks blog](#).

Apply filters to all worksheets that use a related primary data source

This option applies the filter to all worksheets that use related data sources as their primary data source.

Note: To apply a filter to worksheets that use a related primary data source in web authoring, relationships between the data sources must be set up in Tableau Desktop, and then published to the web.

For more information, see [Filter Data Across Multiple Data Sources](#) on page 1335.

To apply a filter to all worksheets using a related primary data source:

- On the Filters shelf, right-click the field and select **Apply to Worksheets > All Using Related Data Sources**.

Filters that use this option are global across the workbook.

Filters that apply to all related data sources are marked with an icon. The filter is automatically created on any existing worksheets, and on any new worksheets you create that use a related data source.

Any changes you make to the filter will affect all of those worksheets.

Apply filters to all worksheets that use the current primary data source

This option applies the filter to all worksheets that use the primary data source of the current worksheet as their primary data source.

To apply a filter to all worksheets using the current primary data source:

- On the Filters shelf, right-click the field and select **Apply to Worksheets > All Using This Data Source**.

Filters that use this option are global across the workbook.

Filters that apply to all worksheets are marked with a data source icon . The filter is automatically created on any new worksheets you create after you drag a field to the view.

Any changes you make to the filter will affect all of those worksheets.

Note: If you are blending multiple data sources in a view, **All Using This Data Source** adds the filter to all sheets that use the same primary data source in the current sheet. The sheets that the filter gets applied to is not based on the filter field's data source.

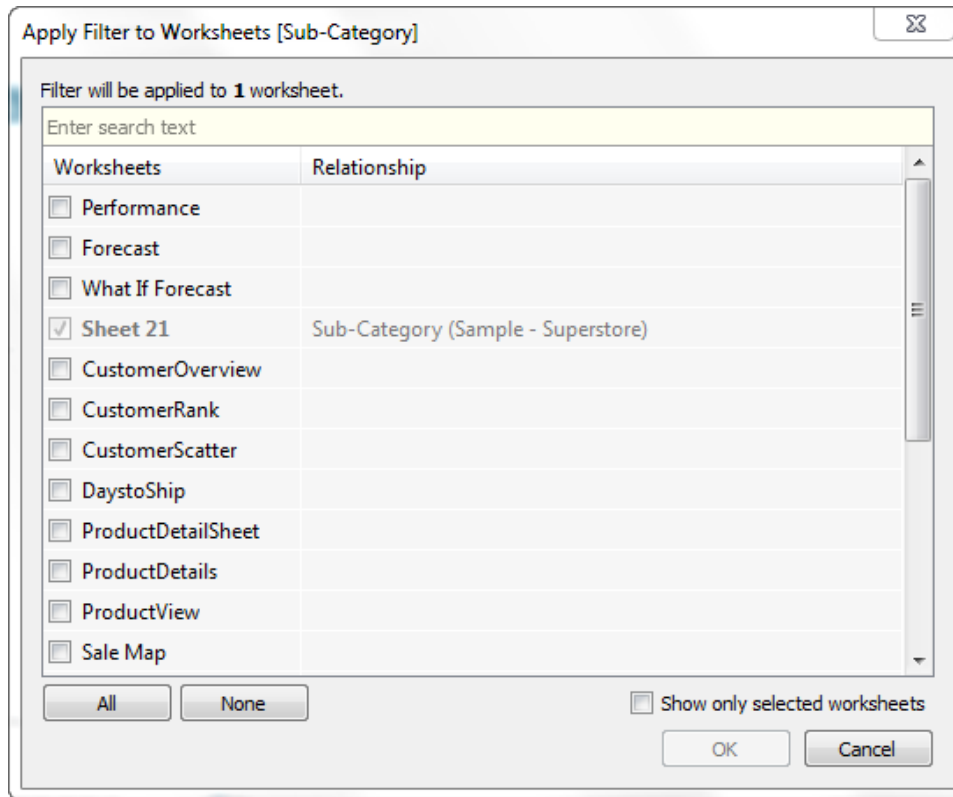

Apply filters to select worksheets

This option opens a dialog box where you can select from a list of worksheets that use the same data source or related data sources.

To apply a filter to select worksheets:

- On the Filters shelf, right-click the field and select **Apply to Worksheets > Selected Worksheets**.
- In the Apply Filter to Worksheets dialog box, select the worksheets that you want to apply the filter. If any of the sheets already contain a filter on the same field, the dialog box will provide details about the filter.

If you select the sheet, the current filter will override any existing filter selections.

Filters that apply to a selection of worksheets are marked with the worksheet icon . Any changes you make to the filter affect all of the selected worksheets.

Apply filters to the current worksheet only

This option only applies to the current worksheet. This option is selected by default when you create new filters. Filters that are local to the current worksheet are shown without any additional icons.

To apply a filter to the current worksheet only:

- On the Filters shelf, right-click the field and select **Apply to Worksheets > Only This Worksheet**.

If you apply a filter to all worksheets or selected worksheets and then change the setting to apply the filter to just the current worksheet, the filters are not removed from all other worksheets.

Rather, the filters are disconnected and they are all made local to their respective worksheets. You can go to each worksheet and remove the filter or modify selections.

Filter all worksheets on a dashboard

This option applies the filter to all worksheets in the dashboard that use the same data source or related data sources as their primary data source.

To filter all worksheets on a dashboard:

- In a dashboard, click the drop-down menu on a filter card and select **Apply to Worksheets > Selected worksheets**.
- In the Apply Filter to Worksheets dialog box, click **All on dashboard**, and then click **OK**.

Note: In previous versions of Tableau Desktop, the **All Using This Data Source** option was called Make Global and the **Only This Worksheet** option was Make Local.

Sort Data in a Visualisation

There are many ways to sort data in Tableau. When viewing a visualisation, data can be sorted using single click options from an axis, header or field label. In the authoring environment, additional sorting options include sorting manually in headers and legends, using the toolbar sort icons or sorting from the sort menu.

Tip: Download the [workbook](#) used in these examples to explore on your own (requires Tableau Desktop).

Quickly sort from an axis, header or field label

There are multiple ways to sort a visualisation with single click sort buttons.

In all cases, **one** click sorts descending, **two** clicks sorts ascending and **three** clicks clear the sort.

Sort icons displayed on an axis (Metric A), header (Light Green) or field label (Hue)

The sort updates if the underlying data changes.

Sort from an axis

1. Hover over a numerical axis to bring up the sort icon.
2. Click the icon to sort.

Sort: Colour is sorted within each Hue in decreasing order of Metric A

In this example, the sort is applied to **Colour** (sorting the rows) based on the values for **Metric A**. If there are hierarchical dimensions like above, the sort is applied to the innermost dimension. In this example, **Colour** will sort inside **Hue**. Dark magenta can't sort to the top of the viz because it must stay inside the pane for the Purple hue.

Sort from a header

1. Hover over a header to bring up the sort icon.
2. Click the icon to sort.

Sort: Materials are arranged in decreasing order of Metric B for Green.

In this example, the sort is applied to **Material** (sorting the order of the columns – Paint, Fabric and Paper) based on the values for Green, since that header was used for the sort.

Note: The sort option is also available from the tooltip for a header. The header tooltip sort option is displayed even when the view contains a table calculation (but not in the header sort option). If the view contains a table calculation, this option creates a manual sort based on the data currently in the view.

Sort from a field label

1. Hover over a field label to bring up the sort icon.

The sort icon for a field label is slightly different from a header or axis. The default option is alphabetical sorting, but there's also a menu where you can choose to sort by a field in the view.

2. Click the A-Z icon to sort alphabetically. Or, click the menu to select a field to sort by. The icon switches to the bar icon and you can click to sort.

Sort: Hues are arranged in descending order by Metric B.

In this example, the sort is applied to the outermost dimension (Hue) based on total Metric B. (Metric B is aggregated for all the colours within each hue and Hue is sorted. Therefore, Purple is first, then Green, then Blue.)

Missing sort icons

If the sort icons don't appear, this functionality may have been turned off or it might not be possible to sort the view. Sort icons aren't available on the axes in scatterplots or for table calculations. For example, scatterplots can't be sorted from a numerical axis because the positions of the marks are fully determined by the data.

Sort options while authoring

In an authoring environment, additional options are available.

Sort from the toolbar

1. Select the dimension you wish to sort.
If you don't select a field before sorting, the default behaviour is to sort the deepest dimension.
2. Choose the appropriate sort button (ascending or descending) in the toolbar.

In this example, the sort is applied to **Hue** unless the **Material** field is selected before sorting. The toolbar sort also applies to the leftmost measure, in this case Metric B. To sort by Metric A, it would be necessary to reverse their order on the Columns shelf or use another method of sorting. This example demonstrates the effect of sorting by Material. Hue is removed from the view.

Sort by drag and drop

To manually sort, select a header in a viz or on a legend and drag it to the correct location – a heavy black line indicates where to drop the header.

Note: Sorting on a legend also changes the order of the marks, not simply how the legend is displayed. Whatever is bottommost in the legend becomes the bottommost mark in the viz. This can either mean closest to the axis or header, or actually underneath in the case of scatterplots and other viz types that may have overlapping marks.

Sort specific fields in the viz

Tableau uses the current International Components for Unicode (ICU) library to determine sort order. You can customize sorting by using the Sort menu for specific fields. (The Sort menu is not available for continuous measures.)

1. Right-click (Windows) or control-click (Mac) the field you want to sort, and select **Sort**.
2. Select a **Sort By** option, and configure its behaviour:
 - **Data Source Order** sorts based on how the data is sorted in the data source. Generally for relational data sources, this tends to be natural sort order. Natural sort order is an alphabetic sort where multi-digit numbers are treated as a single character. For example, natural sorting puts 2 before 19 because 2 is less than 19, whereas alphabetic sorting puts 19 before 2 because 1 is less than 2.

If you are using a multidimensional cube data source, data source order is the defined in hierarchical order of the members within a dimension.

- **Alphabetic** sorts the data alphabetically. This sort is case sensitive, sorts [A-Z] before [a-z], and treats digits individually (that is, 19 comes before 2).

To create a non-case sensitive sort, create a calculated field using the UPPER() or LOWER() functions to remove variation in capitalisation. For more information, see [String Functions on page 2053](#).

- **Field** lets you specify the field value used to determine the sort order. The field doesn't need to be used in the visualisation. You can also select an aggregation for the sorting field. The aggregation options available depend on the field type.
- **Manual** lets you select a value and move it to the desired position, either by dragging it in the list or using the arrows to the right.
- **Nested** lets you select the field value used to determine the sort order. The field doesn't need to be used in the visualisation. You can also select an aggregation for the sorting field. The aggregation options available depend on the field type.

Nested sorts

When the values to be sorted occur in multiple panes, there are two ways to sort: nested and non-nested (or comparative). In the image below, all three values for **Hue** occur for all three **Materials**. Nested sorting considers values independently per pane rather than in aggregate across panes.

Nested

A nested sort considers each pane independently and sorts the rows per pane.

Purple is sorted above Green for Fabric and Paper, but below Green for Paint.

Nested sorts look correct within the context of the pane, but don't convey the aggregated information about how the values compare overall.

Sorting from an axis gives a nested sort by default.

Non-nested

A non-nested sort considers the value across panes and has the same order of values per pane.

Purple is above Green for all materials because in aggregate, Purple is higher than Green.

Non-nested sorts may look incorrect in a single pane, but consistently convey how the aggregated values compare overall.

Sorting from a field label gives a non-nested sort by default.

Note: When creating a nested sort, the sort is inherited when you drill down through the dimensions. For example, a nested sort on Hue will apply to Colour.

If a dimension has been placed on the same shelf as a measure, that measure has an axis in the view for each value of the dimension. Using the axis sort icon generates a nested sort specifically for that value.

In this scenario, an additional field is added to the sort menu dialog for the sorted dimension. To stop breaking down the sort by this value, untick the box for Filter By.

Understanding “incorrect” sorts

It’s easy to think a view is sorted incorrectly when in fact the sort logic is not clear. A view with a nested sort when a non-nested sort is expected (or vice versa) can be perceived as incorrect. Sorting when there are multiple panes can also give results that seem unsorted.

For example, this view might seem unsorted when in fact it’s sorted on Hue by Metric A.

Simplifying the view makes the sort more obvious.

Hovering over the sort icons to see the description of the sort or temporarily simplifying the view can help clarify what is going on.

Clear sorts

You can sort data from many areas of a view. Sometimes it can be useful to clear all sorts at once.

To remove the sort on a specific field, right click to open the menu and select **Clear Sort**.

To remove all sorts in the view, open the menu next to the clear sheet icon in the toolbar and select Clear Sorts. Or, from the Worksheet menu, click **Clear > Sorts**.

Remove the ability to sort

As an author, you can disable the sort icons in published content. This can be useful to preserve the current sort as you built it. Navigate to the Worksheet menu and untick the option to **Show Sort Controls**. This will prevent the sort icons from appearing when a consumer of the view hovers over an axis, header or field label.

Hiding field labels, headers or the axis will also remove the sort icons.

Showcase Insights

This section describes the various ways you spotlight data insights. Read the following articles for information on how to show totals, add annotations and embed visualisations in tooltips when you hover over a data point. For text elements such as titles and captions, see [Format Individual Parts of the View on page 2983](#).

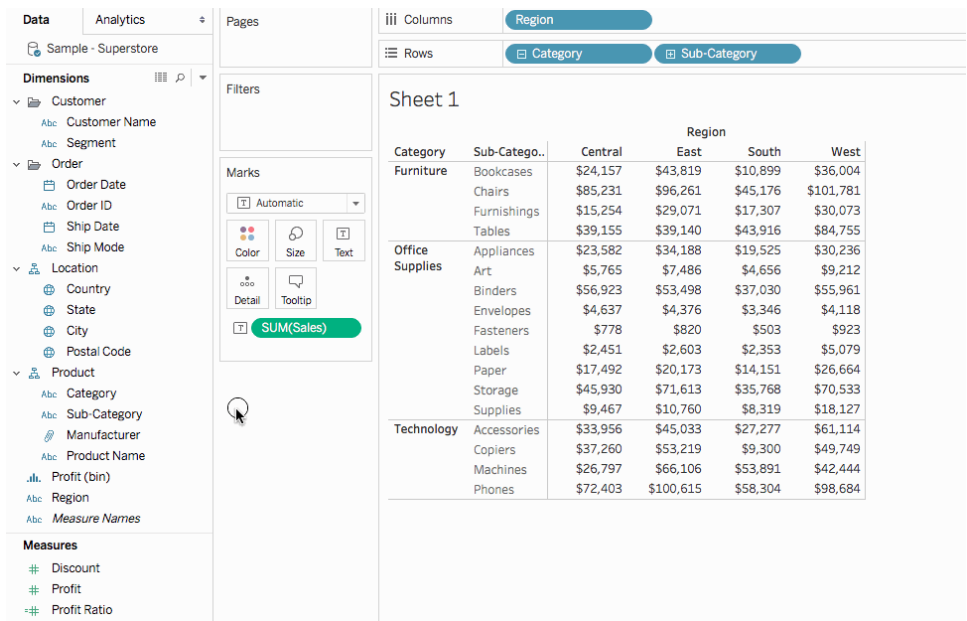

Show Totals in a Visualisation

This article demonstrates how to show grand totals and subtotals in a visualisation, as well as how to customise how those totals are calculated and where they appear in the visualisation.

Show grand totals

To show grand totals in a visualisation:

1. Click the **Analytics** pane.
2. In the **Analytics** pane, under Summarise, drag **Totals** into the Add Totals dialog, and drop it over either the **Row Grand Totals** or **Column Grand Totals** option.

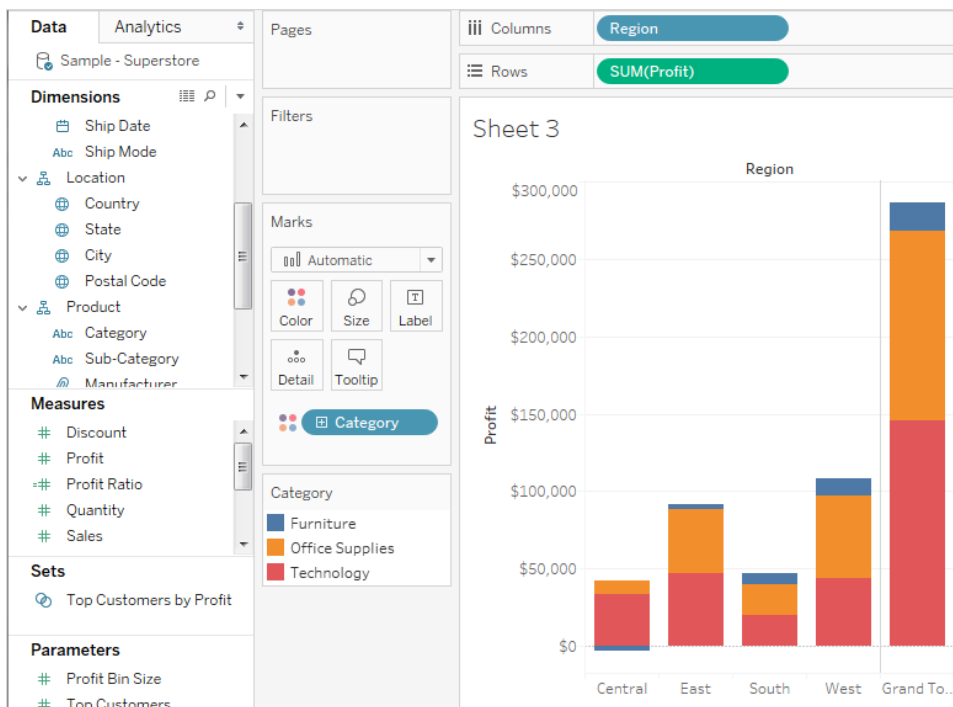

Row grand totals appear automatically on the right-side of the visualisation. Column grand totals appear automatically at the bottom of the visualisation. For information how to move where totals appear, see [Move totals on page 1368](#).

In order to turn on grand totals:

- The view must have at least one header – Headers are displayed whenever you place a dimension on the **Columns** shelf or the **Rows** shelf. If column headers are displayed, you can calculate grand totals for columns. If row headers are displayed, you can calculate grand totals for rows.
- Measures must be aggregated – The aggregation determines the values displayed for the totals. See [Grand totals and aggregations on page 1364](#) for more information.
- Grand totals cannot be applied to continuous dimensions.

You can also display totals for graphical views of data. In the figure below, only column totals are calculated because the table contains only column headers.

Note: By default, totals are computed on the server if you are connected to a Microsoft Analysis Services data source, and locally if you are connected to an Essbase data source, using the aggregation specified in the cube. Refer to [Configure total aggregation on page 1368](#) to learn more.

Options for calculating grand totals

When you first turn on grand totals, the totals are computed using disaggregated data in the underlying data source. Consider the following view:

Sheet 4

| | | Region | | | | |
|----------------|-----------------|---------|-------|-------|-------|-----------|
| Ship Mode | Category | Central | East | South | West | Grand T.. |
| First Class | Furniture | \$329 | \$306 | \$390 | \$348 | \$339 |
| | Office Supplies | \$111 | \$120 | \$120 | \$98 | \$111 |
| | Technology | \$300 | \$524 | \$292 | \$571 | \$463 |
| Same Day | Furniture | \$316 | \$367 | \$225 | \$338 | \$329 |
| | Office Supplies | \$79 | \$103 | \$82 | \$89 | \$89 |
| | Technology | \$320 | \$689 | \$767 | \$620 | \$614 |
| Second Class | Furniture | \$332 | \$347 | \$402 | \$390 | \$366 |
| | Office Supplies | \$127 | \$140 | \$151 | \$142 | \$139 |
| | Technology | \$381 | \$312 | \$604 | \$345 | \$389 |
| Standard Class | Furniture | \$348 | \$356 | \$336 | \$351 | \$349 |
| | Office Supplies | \$119 | \$115 | \$123 | \$116 | \$118 |
| | Technology | \$449 | \$522 | \$500 | \$381 | \$457 |

The average that you see at the right of the first row under Grand Total is \$339. But if you compute the average for the four values you see in the row (\$329, \$306, \$390, \$348), the result comes to \$343.25, not \$339. The discrepancy is due to the fact that Tableau is averaging the data in the underlying data source. In this case there are more than four numbers to average, perhaps many more. The result is derived by averaging all values that have the properties Ship Mode = First Class, Category = Furniture, without regard to region.

To see totals that correspond to the numbers you see in your view requires two averaging operations in Tableau: first, values for the individual marks (or cells) in the view must be derived—for example, by averaging all values that have the properties Ship Mode = First Class, Category = Furniture, and Region = Central. Then the results for each region must be derived, by averaging the results for the individual marks. Fortunately, you do not need to perform two operations. To display a result of this type, from the **Analysis** menu choose **Totals > Total All Using > Average**. Now the average is performed on the values you see, and not on the disaggregated data in the data source:

Sheet 4

| Ship Mode | Category | Region | | | | Grand T.. |
|----------------|-----------------|---------|-------|-------|-------|-----------|
| | | Central | East | South | West | |
| First Class | Furniture | \$329 | \$306 | \$390 | \$348 | \$343 |
| | Office Supplies | \$111 | \$120 | \$120 | \$98 | \$112 |
| | Technology | \$300 | \$524 | \$292 | \$571 | \$422 |
| Same Day | Furniture | \$316 | \$367 | \$225 | \$338 | \$311 |
| | Office Supplies | \$79 | \$103 | \$82 | \$89 | \$88 |
| | Technology | \$320 | \$689 | \$767 | \$620 | \$599 |
| Second Class | Furniture | \$332 | \$347 | \$402 | \$390 | \$367 |
| | Office Supplies | \$127 | \$140 | \$151 | \$142 | \$140 |
| | Technology | \$381 | \$312 | \$604 | \$345 | \$410 |
| Standard Class | Furniture | \$348 | \$356 | \$336 | \$351 | \$348 |
| | Office Supplies | \$119 | \$115 | \$123 | \$116 | \$118 |
| | Technology | \$449 | \$522 | \$500 | \$381 | \$463 |

This kind of total is sometimes referred to as a two-pass total, because the average you see in the grand total column is aggregated twice--once to derive the column or row value, and then again across column or rows to derive the grand total.

Grand totals and aggregations

When you turn on grand totals, the initial values are computed using the current aggregation for the fields in the view. In this case, totals are based on the underlying data rather than the data in the view.

For example, if you are totalling the **SUM(Profit)** for several products, the grand total will be the sum of the sums of profit. For aggregations such as SUM, you can easily verify the grand total because a summation of a group of sums is still a summation. However, be aware that your results may be unexpected when using other aggregations, especially custom aggregations. For details, See [Configure total aggregation on page 1368](#). You can verify any calculation such as an aggregation or a grand total by viewing the underlying disaggregated data.

The following table summarises the standard aggregations and the grand totals that are calculated by default when, from the Analysis menu, **Totals >Total All Using** is set to the default value **Automatic**.

Note: Only Automatic totals are available for table calculations and fields from a secondary data source. Total aggregations cannot be applied to table calculations or fields from a secondary data source.

For more information, see [Showing Grand Totals with Blended Data](#) and [Grand Totals](#)

and Subtotals Do Not Show Expected Numbers With Table Calculations in the Tableau Knowledge Base.

| Aggregation | Calculation Description |
|-----------------------------|---|
| Sum | Shows the sum of the values shown in the row or column. |
| Average | Shows the average of the values shown in the row or column. |
| Median | Shows the median for the values shown in the row or column. |
| Count; Count Distinct | Shows how many values or distinct values are displayed in the rows and columns in the view. |

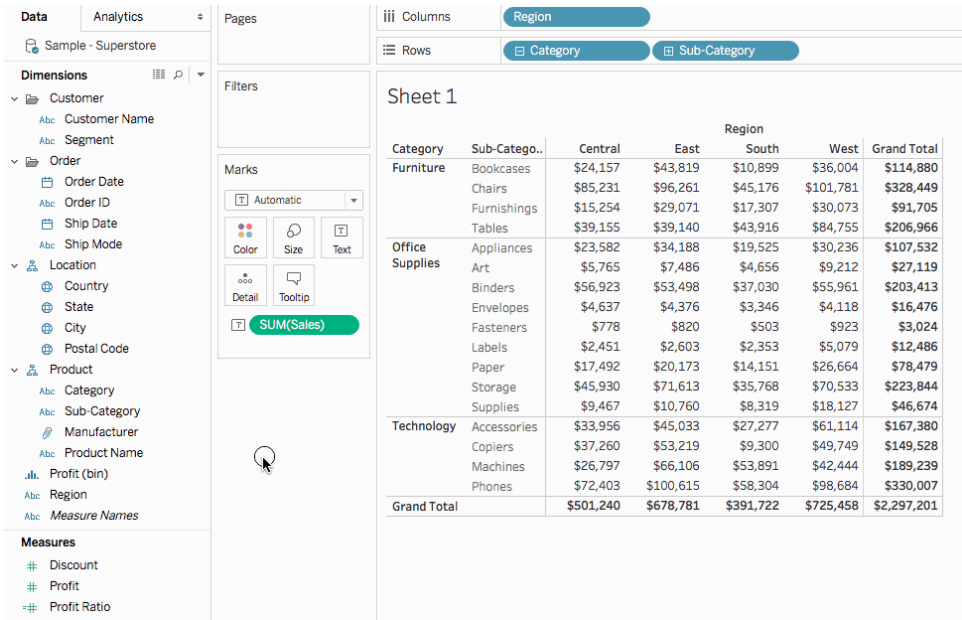

| Aggregation | Calculation Description |
|--------------------|--|
| Minimum | Shows the minimum value shown in the row or column. |
| Maximum | Shows the maximum value shown in the row or column. |
| Percentile | Shows the average percentile for all values shown in the row or column. |
| Standard Deviation | The grand total using standard deviation is the standard deviation of the values shown in the row or column. |
| Variance | The grand total using variance is not the vari- |

| Aggregation | Calculation Description |
|-------------|---|
| | ance of the rows and columns in which they reside but rather of the underlying data behind the row or column. |

Show subtotals

To show subtotals in a visualisation:

1. Click the **Analytics** pane.
2. In the **Analytics** pane, under Summarise, drag **Totals** into the Add Totals dialog, and drop it over **Subtotals**.

Move totals

By default, row grand totals and subtotals appear on the right of the view, and column grand totals and subtotals appear at the bottom of the view.

In Tableau Desktop, you can also select to display totals on the left or top of the view.

To move row totals to the left of the view:

- Select **Analysis > Totals**, and then select **Row Totals to Left**.

To move column totals to the top of the view:

- Select **Analysis > Totals**, and then select **Column Totals to Top**.

Configure total aggregation

When totals are turned on in the visualisation (either grand totals, subtotals, or both), you can specify how totals should be computed. For example, you can choose to calculate totals using a sum, average, minimum, or maximum.

To configure all totals:

- Select **Analysis > Totals > Total All Using**, and then select an aggregation from the list.

To configure totals for a specific field:

- Right-click (Control-click on a Mac) a field in the view, select **Total using**, and then select an aggregation from the list.

When you choose **Automatic**, totals are based on the underlying data, which is disaggregated, and not on the data in the view. See [Options for calculating grand totals on page 1363](#). For details on how Tableau computes totals using the current aggregation, see [Grand totals and aggregations on page 1364](#).

When you choose any of the other values (**Sum**, **Average**, **Minimum**, or **Maximum**), all totals are computed using the selected aggregation. The computations are performed on the aggregated data you see in the view.

An additional value, **Server**, may be available. Server computation is not always available and sometimes the totals will be blank for specific members in the view. When using server computation keep in mind the following information:

- Server computation is only available for ASO cubes.
- Server computation is not available for dynamic hierarchies. This means that if the members in the view are part of a dimension or hierarchy that is tagged as dynamic, they cannot be included in the set of values you are using to compute the totals and will show up as blank in the view.
- If you are computing totals for a calculated field whose formula makes assumptions about other calculated members at different levels in the hierarchy, the totals will display as blank in the view.

[Apply Advanced Analysis to a View \(Analytics Pane\) on page 48](#)

Add Annotations

You can add annotations to a visualisation to call out a specific mark, a specific point, such as a location on a map, or an area, such as a cluster of scatter marks.

Note: In web authoring, you can create and delete annotations by right-clicking the view (in a worksheet or dashboard), and then selecting point or mark annotation. Right-click the annotation again to edit or remove the annotation. Formatting and moving annotations are not currently supported on the web.

To add and format other text elements on a visualization, see [Format Individual Parts of the View on page 2983](#).

Add an annotation

To add an annotation to your viz:

1. In a worksheet, right-click (control-click on Mac) a data point or a spot on the viz where you want to add an annotation and select **Annotate**, and then select the type of annotation you want to add.

There are three types of annotations in Tableau:

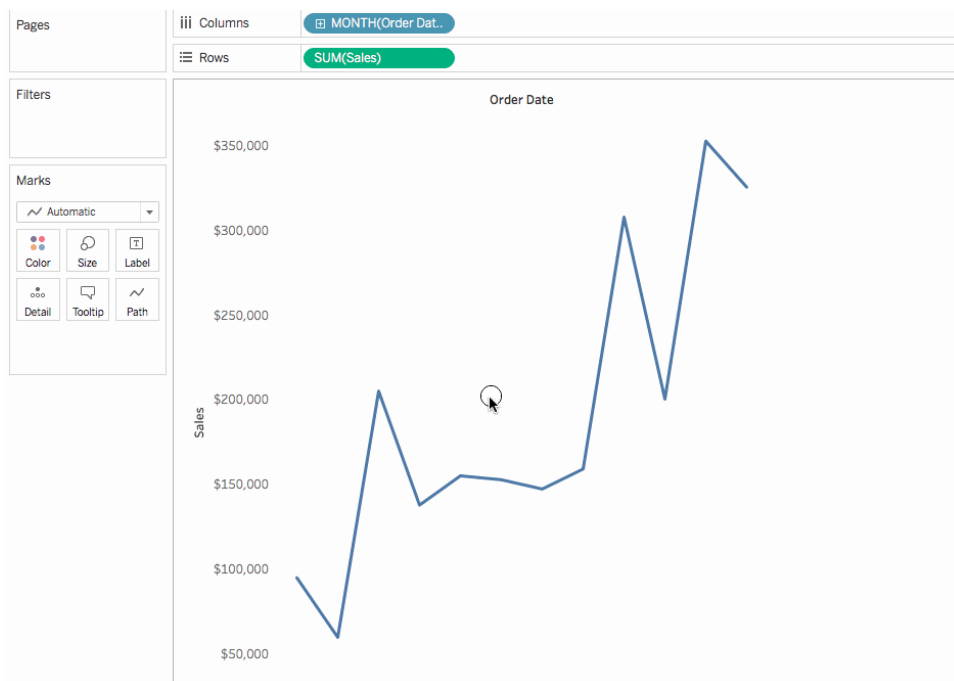

- **Mark** - select this option to add an annotation that is associated with the selected mark. This option is only available if a data point (mark) is selected.
- **Point** - select this option to annotate a specific point in the view.
- **Area** - select this option to annotate an area in the viz, such as a cluster of outliers or a targeted region.

2. In the Edit Annotation dialog box that opens, type the text you want to show in the annotation.

Use the **Insert** menu to insert dynamic variables into the annotation text. For example, the annotation can display data values that update as the underlying data changes. The dynamic variables that are available are dependent on whether you are annotating a mark, point, or area.

3. When finished, click **OK**.

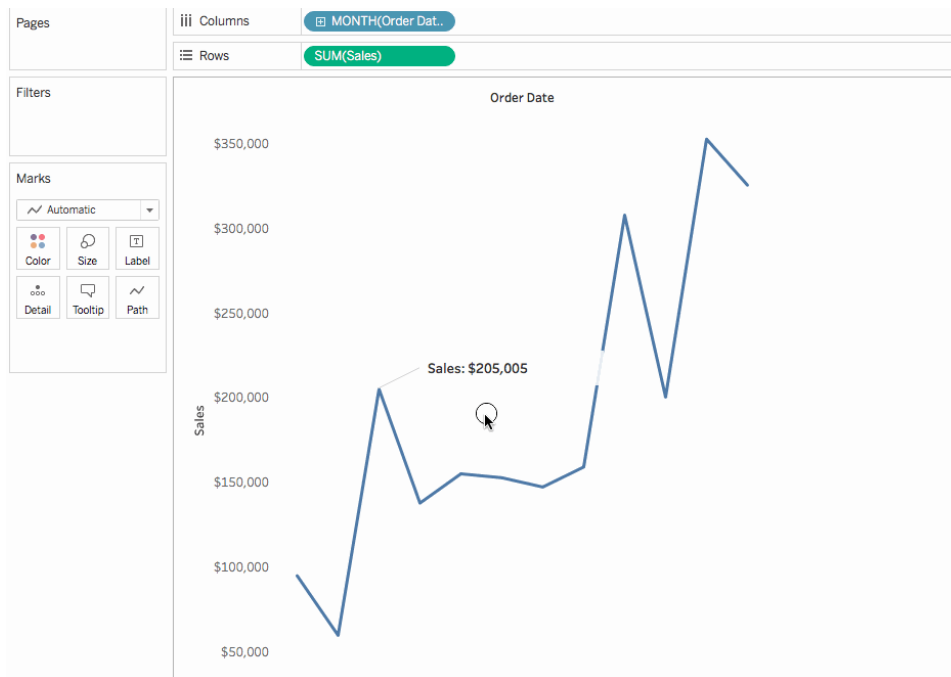

The viz updates with your annotation.

Edit an annotation

To edit an annotation:

1. Right-click (control-click on a Mac) the annotation in the viz and select **Edit**.
2. In the Edit Annotation dialog box that opens, edit the annotation text and then click **OK**.

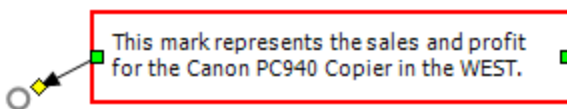

Rearrange an annotation

After you add an annotation, you can move it around, resize it, adjust the line, and move the text. Each type of annotation can be rearranged and modified in different ways. This section discusses how to rearrange, resize, and modify each type of annotation.

Mark annotations

When you select a mark annotation the body and line are selected and several resize handles display. Use these handles to resize the body and line.

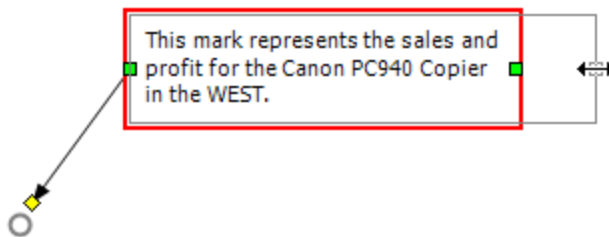

To reposition the body

- Click and drag the body of the selected annotation to a new position.

To resize the body

- Click and drag the body resize handle left and right. The text and height are automatically adjusted to fit the width of the body.

To resize the line

- Click and drag the line resize handle .

Point Annotations

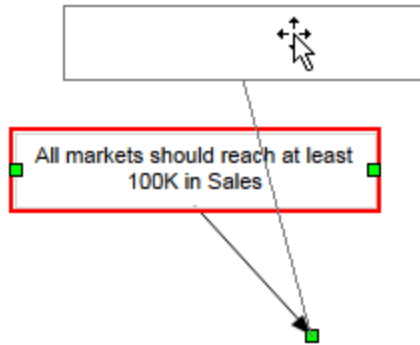

A point annotation marks a specific point in the view, such as a reference line or a value on an axis. Point annotations display as text with a line. When you select a point annotation, several resize handles display. Use these handles to reposition and resize the body and line.

To reposition the body:

- Click and drag the body of the selected annotation to a new position. As you move the body, the line is automatically resized so that it continues to point at the specific point you

selected.

To resize the body:

- Click and drag the side resize handles ■ left and right. The text and height are automatically adjusted to fit the width of the body.

To move the line end point:

- Click and drag the end point of the line ■ so that it points at a new location.

Area Annotations

An area annotation is a way to highlight or call out an area in the view. Area annotations are not associated with any particular mark, in fact, these annotations are commonly used to call out several marks. When you select an area annotation, several resize handles and two text handles display. Use these handles to reposition and resize the box and text.

To reposition the box

- Click and drag the box of the selected annotation to a new position.

To resize the box

- Click and drag one of the box resize handles ■

To reposition the text

- Click and drag the centre text handle ◆ to a new position.

To resize the text width

- Click and drag the right text handle  left and right. The text height is automatically adjusted to fit the width.

Format annotations

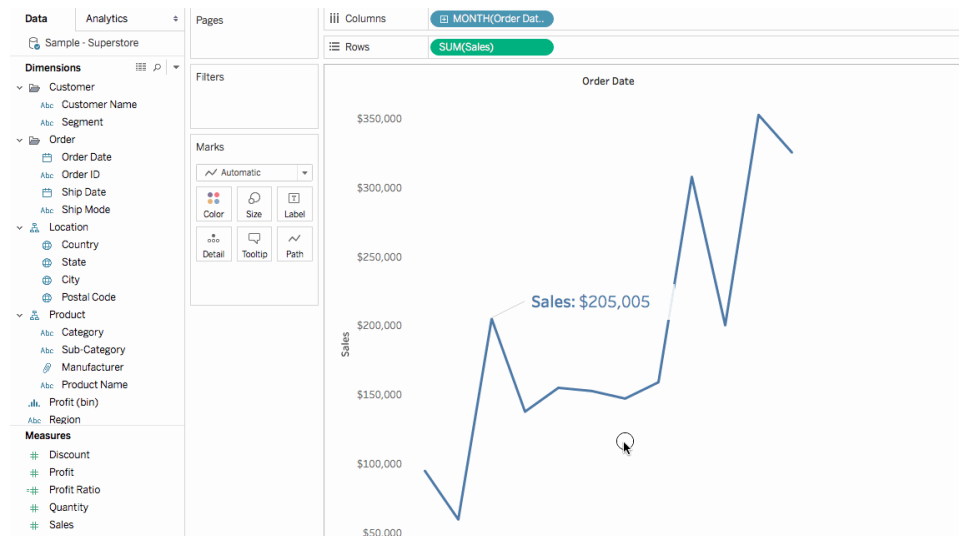

You can modify the text, body, and line of an annotation. For example, you can specify whether the body should be a box, a single edge, or not shown at all. Additionally, you can specify whether the lines on mark and point annotations end with an arrow, dot, or a simple line.

To format annotations:

1. Select one or more annotations, right-click (control-click on Mac) one of the selected annotations, and then select **Format**.

The **Format** pane opens on the left-side of the workspace, over the **Data** pane.

2. In the **Format** pane, use the drop-downs to specify font properties, text alignment, line style, and shading.

Remove an annotation

To remove annotations from the viz:

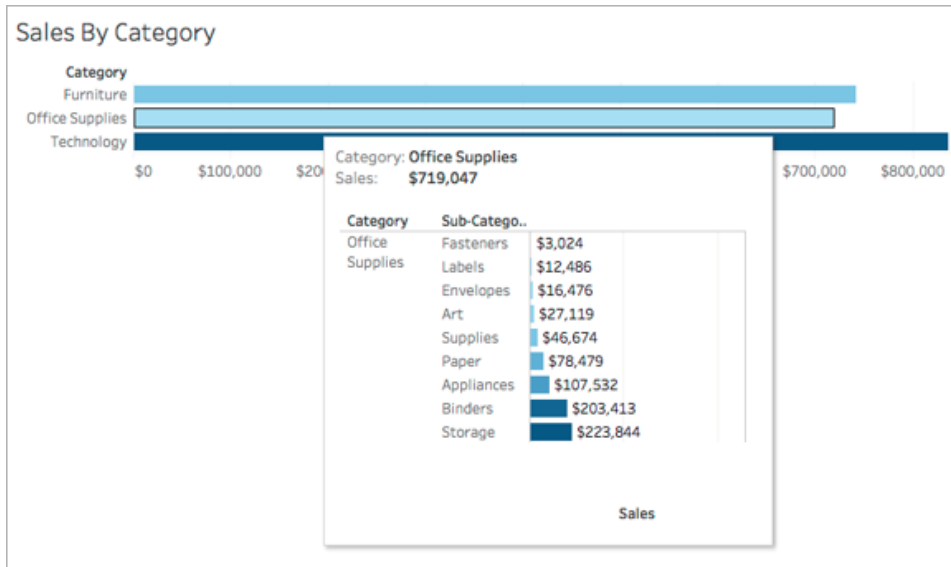

1. Select one or more annotations in the viz.
2. Right-click (control-click on Mac) one of the selected annotations and select **Remove**.

[Show, Hide and Format Mark Labels on page 1291](#)

Create Views in Tooltips (Viz in Tooltip)

As you craft views and look for ways to reveal more details about data to your audience, you can embed visualisations within tooltips – also known as "Viz in Tooltip".

When a user hovers over a mark, the tooltip displays relevant data and details from another visualisation filtered to that mark.

You can show related vizs in tooltips to help your audience engage with the data at a different or deeper level, while keeping them in the current context and maximising the space available for the current view.

Watch a video: For advanced tips, watch [Next Level Viz in Tooltip](#), a 55-minute free video presentation.

For information on how to edit regular tooltips, see [Format tooltips on page 2985](#).

General steps to create a Viz in Tooltip

1. Create a visualisation in the *source* worksheet in Tableau.
2. Create a visualisation in a *target* worksheet view to serve as the Viz in Tooltip. Give the worksheet a name that helps you identify it as a Viz in Tooltip.
3. In the source worksheet, click Tooltip in the Marks card. In the Tooltip Editor, insert a reference to the Viz in Tooltip target worksheet. For details, see [Configure a Viz in Tooltip on the next page](#).
4. **Optional:** Hide the target sheet for the Viz in Tooltip. For details, see [Create Views in Tooltips \(Viz in Tooltip\) on the previous page](#).
5. Test the resulting Viz in Tooltip by hovering over different marks in the source worksheet view. If the Viz in Tooltip is too large for the tooltip window, adjust the height and width of

the target worksheet visualisation. You might also consider simplifying the structure and detail in the target visualisation. For details, see [Change the size of the Viz in Tooltip on page 1384](#).

Notes:

By default, Viz in Tooltip is filtered on *All Fields*. Change the level of detail for Viz in Tooltip by defining a filter on *Selected Fields*. For details, see [Change the filter for the Viz in Tooltip on page 1385](#).

In Tableau version 2023.3 and later, Viz in Tooltip is not available for totals and grand totals.

Notes: By default, Viz in Tooltip is filtered on *All Fields*. Change the level of detail for Viz in Tooltip by defining a filter on *Selected Fields*. For details, see [Change the filter for the Viz in Tooltip on page 1385](#).

In Tableau version 2023.3 and later, Viz in Tooltip is not available for totals and grand totals.

Configure a Viz in Tooltip

You will need a *source* worksheet visualisation and a *target* worksheet visualisation to create a Viz in Tooltip.

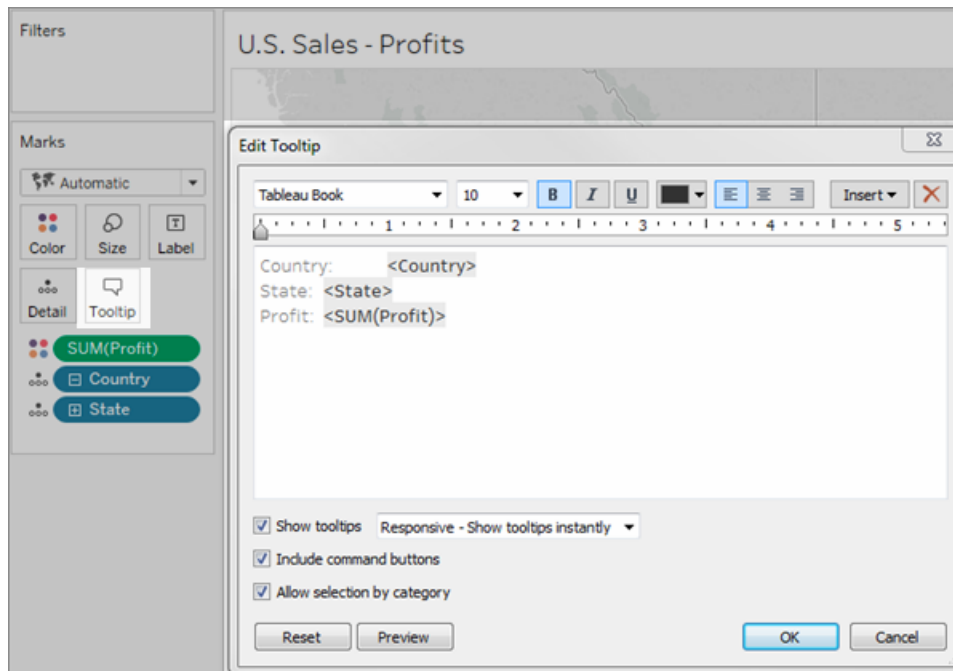

These steps use the example of a source view that is a map showing sales profits by state, and a target sheet with a chart that shows profits by product sub-category.

Create the source and target visualisations in a worksheet

1. In Tableau, figure out the worksheet that you want to use as your source visualisation. Or build a new visualisation on a new worksheet. This will be your source view.
2. Create a new worksheet to serve as the target visualisation.
Keep the number of filters used in the target view to a minimum.
3. Name the target view so that you will be able to identify it in a list of other sheets.

Insert a reference to the target worksheet in the source worksheet tooltip

1. In the source sheet, click the Tooltip button in the Marks card to open the Tooltip Editor.

2. Click the **Insert** menu in the Tooltip Editor. In the **Insert** menu, select **Sheets**, and then select a target sheet.

For example:

The markup for the Viz in Tooltip is automatically added. (In this example, the original markup fields have been removed.)

Example of markup automatically generated for Viz in Tooltip

This is the resulting markup for this example:

```
<Sheet name="Tooltip: Profit by Sub-Category" maxwidth="300"
maxheight="300" filter="<All Fields>">
```

By default, the Viz in Tooltip is filtered on All Fields (filtered on all fields possible, and on the most specific level of detail).

Click **OK**.

3. Go back to the source sheet and test the Viz in Tooltip. Hover over different marks to see the resulting Viz in Tooltip. Make adjustments to the target view as necessary to improve the Viz in Tooltip.

The Viz in Tooltip in this example shows a message that indicates that some of the data in the target view is not being shown. If you see this message, you can adjust the height and width settings in the parameters for the Viz in Tooltip to make the view size larger.

Change the size of the Viz in Tooltip

You can manually change the `maxwidth` and `maxheight` values to resize the Viz in Tooltip. The default size is 300 by 300 pixels. To change the size, manually replace "300" with another value. If you need to set the value greater than 600 pixels, you might want to reconsider whether the target view is a good candidate for Viz in Tooltip.

1. In the source sheet, click the Tooltip button in the Marks card to open the Tooltip Editor.
2. Select the number value for `maxwidth` and `maxheight` and type a different value to replace it. For example:

```
<Sheet name="Tooltip: Profit by Sub-Category" maxwidth="500"
maxheight="500" filter="<All Fields>">
```

3. Click **OK**

Example of a Viz in Tooltip set to 500 pixels width and height. The author also created more space for the header text in the in the target sheet view.

Change the filter for the Viz in Tooltip

By default, Viz in Tooltip is filtered on *All Fields*. This means the view is filtered on all dimensions in the current view (not including fields on the Filters shelf), at the most specific level of detail.

You can change the level of detail for Viz in Tooltip by defining a filter on selected fields, similar to filtering on **Selected Fields** in Filter Actions.

1. In the source sheet, click the Tooltip button in the Marks card to open the Tooltip Editor.
2. Place your cursor within the filter value (`filter="<place cursor here>"`), and then click the **Insert** menu to select an available field. Or, manually replace the `<All Fields>` value with the name of a field in the view. For example:

```
<Sheet name="Tooltip: Profit by Sub-Category" maxwidth="300"
maxheight="500" filter="<State>">
```

You can also filter more than one selected field by separating the field names with a comma. For example:

```
<Sheet name="Tooltip: Profit by Sub-Category" maxwidth="300"  
maxheight="500" filter="<Country>,<State>">
```

To filter on date level, you will need to include the string that specifies the date level with the field name. For example:

```
<Sheet name="Tooltip: Profit by Month" maxwidth="300"  
maxheight="300" filter="<MONTH(Order Date)>">
```

Note: The date filter in the Viz in Tooltip script must match exactly the date level of the field in the view.

Hide or show a Viz in Tooltip worksheet

You can hide and show a worksheet used for Viz in Tooltip with options similar to those for dashboards and stories.

Hide a Viz in Tooltip worksheet

Note: If the source sheet is hidden for a dashboard, you will first need to first unhide that worksheet from its dashboard to access it. For details, see [Manage Sheets in Dashboards and Stories](#) on page 2812.

To hide a Viz in Tooltip worksheet, from the tab for the target worksheet that is the Viz in Tooltip, select **Hide**.

Show a Viz in Tooltip worksheet

To show a Viz in Tooltip worksheet, from the tab for the source worksheet, select **Unhide All Sheets**.

Examples of Viz in Tooltip

When you create a Viz in Tooltip, users can hover over a mark to examine details-on-demand, within the context of the original view. A Viz in Tooltip is a static image of data from another view that is relevant to a mark in the current view. Hovering over or selecting the mark reveals data from another sheet – filtered for that mark – in its tooltip.

Watch a video: To see more examples and related concepts, see [Next Level Viz in Tooltip](#), a 55-minute free video presentation.

Use Viz in Tooltip to show:

- Data at another level of detail

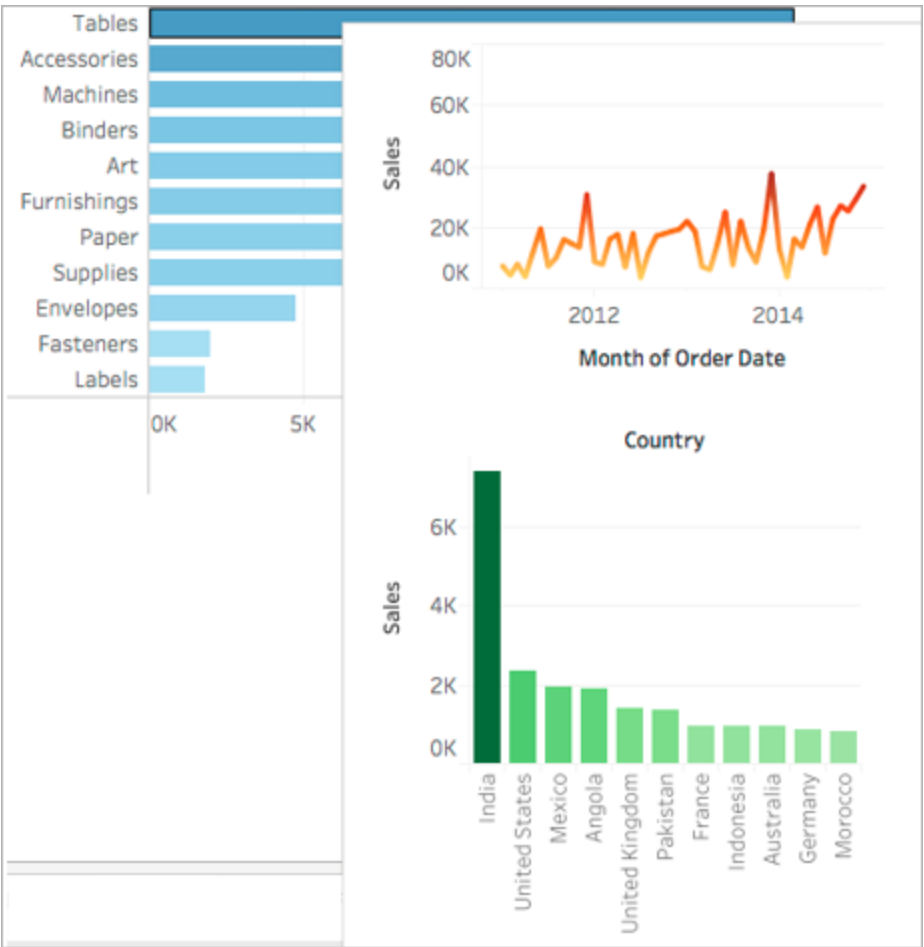

- Different, but relevant data

- How the value of a mark changes over time

- Multiple visualisations in one tooltip

- A legend for the main view

When you show related views in tooltips, you can help your audience engage with the data at a deeper level, while maximising the space available for the current view.

Tips and notes on using and configuring Viz in Tooltip

- You can use worksheets to create a Viz in Tooltip, but you cannot use dashboards or stories to create a Viz in Tooltip.
- A Viz in Tooltip is a static image of a target view, not an interactive sheet. A Viz in Tooltip cannot have its own Viz in Tooltip.
- You will need a *source* worksheet visualisation and a *target* worksheet visualisation to create a Viz in Tooltip. You will need to create a target view to make it available in the Tooltip Editor.
- Use a standard naming scheme for the target sheets you plan to show in tooltips, such as Tooltip: *Name of View*. Using a standard naming scheme will help you keep track of views that you are using in tooltips.
- For the target view, consider the size of the view data and how the view will look in the tooltip. You will be able to specify the size for the Viz in Tooltip when you configure it, but you will need to check to see how it is displaying and possibly make adjustments to the view before you publish it.

Remember that the target view is displayed in the context of the source view. Keeping the target visualisation simple can help with performance and reduce cognitive load.

- If you click Show Me in the source sheet and it changes the view structure, all tooltip edits including Viz in Tooltip references will be reset. You will need to reconfigure the Viz in Tooltip.
- One target sheet can be referenced by one Viz in Tooltip source sheet at a time, because filters are applied directly to the referenced sheet. When a sheet is already being used as a target sheet in a tooltip, it becomes unavailable for selection in the Tooltip Editor.
- By default, Viz in Tooltip is filtered on *All Fields*, which considers all fields in the view (at the most specific level of detail) when identifying matching records. You can change the level of detail for Viz in Tooltip by defining a filter on *Selected Fields*, similar to filtering on **Selected Fields** in Filter Actions. For related details, see [Create Advanced Highlight Actions on page 1410](#).

Filtering on *Selected Fields* does not work across different data sources. If the source and target views are using different data sources, filtering on *All Fields* will automatically

detect the fields in common (if they share the same alias), and filter on them. Filtering on *Selected Fields*, however, will not work.

Actions

Add context and interactivity to your data using actions. Users interact with your visualisations by selecting or hovering over marks, or selecting a link in a tooltip menu, and the actions you set up can respond with navigation and changes in the view.

For example, in a dashboard showing home sales by neighbourhood, you could use actions to display relevant information for a selected neighbourhood. Selecting a neighborhood in one view can trigger an action that highlights the related houses in a map view, filters a list of the houses sold, then opens an external web page showing census data for the neighbourhood. For related information and examples, see [A Rough Guide to Dashboard Actions](#) on the Tableau Public blog.

Types of actions

There are several types of actions, each with a different purpose:

- **Filter.** Use the data from one view to filter data in another.
- **Highlight.** Call attention to marks of interest by dimming all others.
- **Go to URL.** Create hyperlinks to external resources, such as a web page or file.
- **Go to Sheet.** Simplify navigation to other worksheets, dashboards or stories in the same workbook.
- **Change Parameter.** Let users change parameter values by directly interacting with marks on a viz.
- **Change Set Values.** Let users change the values in a set by directly interacting with marks on a viz.

Order of operations

Actions are executed by Tableau in a specific order:

1. Parameter
2. Set
3. Filter
4. Go to sheet
5. Highlight
6. Go to URL

Within each type, actions are performed in alphabetical order. That is, if there are two filter actions, filter action *"A Filter Action"* is performed before *"This is a Filter"*.

Filter Actions

Filter actions send information between worksheets. Typically, a filter action sends information from a selected mark to another sheet showing related information. Behind the scenes, filter actions send data values from the relevant source fields as filters to the target sheet.

For example, in a view showing the sales price of houses, when you select a particular house, a filter action can show all comparable houses in a different view. The source fields for the filter might contain sales price and square footage.

Watch a video to see real-world examples of actions. Filter actions are covered at the 2:20 mark.

Create or edit a filter action

1. Do either of the following:

- On a worksheet, select **Worksheet > Actions**.
- On a dashboard, select **Dashboard > Actions**.

From the drop-down menu of a dashboard sheet, you can also select **Use as Filter**. In the Actions dialog box, "generated" appears in the default names of

actions created this way.

2. In the Actions dialog box, click **Add Action**, and then select **Filter**. Or select an existing action, and choose **Edit**.

3. Specify a name for the action.

Tip: If you plan to launch an action from a tooltip menu, use a descriptive name so users will understand the action's purpose. From the menu to the right of the Name box, you can **insert variables that are drawn from the values of selected fields**.

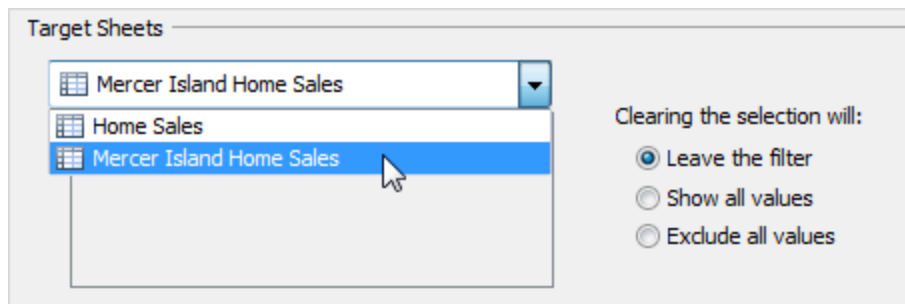

4. Select a source sheet or data source. If you select a data source or dashboard, you can select related sheets you want to launch the action from.

5. Specify how the action runs:

- **Hover** - Runs when you mouse over marks in the view.
- **Select** - Runs when you click marks in the view. If you want to avoid running the action when multiple marks are selected, also select **Single-select only**.
- **Menu** - Runs when you right-click (Windows) or Control-click (macOS) a mark in the view, and then click an option in the tooltip menu.

6. Select a target sheet. When you select a dashboard, you can select one or more sheets within it.

7. Specify what happens when the selection is cleared in the view:

- **Leave the filter** – Continues to show filtered results on the target sheets. (In web-authoring mode, this is labelled **Keep filtered values**.)
- **Show all values** – Changes the filter to include all values.

- **Exclude all values** – Changes the filter to exclude all values. This option is useful when you're building dashboards that only show some sheets if a value in another sheet is selected.
8. Specify the data that you want to show on the target sheets. You can filter on **All Fields** or **Selected Fields**.
 9. If you chose **Selected Fields**, click on a drop-down menu in the **Source Field** column, and select a field. Then select a target data source and field.

Filter

☐ All fields
 ☒ Selected fields

| <input type="checkbox"/> | Source Field | Target Data Source | Target Field |
|--------------------------|----------------|--------------------|--------------|
| <input type="checkbox"/> | Click to add ▼ | | |
| <input type="checkbox"/> | | | |
| <input type="checkbox"/> | | | |

Remove

Note: Filter actions that depend on a **user function**, such as USERNAME(), will not work because **row-level security** restricts access to the data.

Understanding available target fields

In the Add Filter dialog box, the fields available in the Target Field drop-down list are limited to the data type of the Source Field. For example, if you select a text field for the source, only text fields are available as targets.

If you are connected to a relational data source, you can add sheet links across data sources even if the field names don't match. For example, if one data source has a Latitude field while another has a Lat field, you can associate the fields using the drop down lists in the Add Filter dialog box. When using a multidimensional data source, the destination sheet must use the same data source as the source sheet, and the source and target field names must match. (In Tableau, multidimensional data sources are supported only in Windows.)

Highlight Actions

Highlight actions allow you to call attention to marks of interest by colouring specific marks and dimming all others. You can highlight marks in the view using a variety of tools. For example, you can manually select the marks you want to highlight, use the legend to select related marks, use the highlighter to search for marks in context or create an advanced highlight action.

The following table describes the different methods you can use to highlight marks in a view, dashboard or story.

| Highlight method | Benefits | When you might use this |
|---|---|---|
| Select marks on page 1985 | <ul style="list-style-type: none"> Manually select a group of marks to highlight in a view. Your selection is saved with the workbook. | <ul style="list-style-type: none"> When you want to manually highlight a selection of marks and dim all others. Works well with small domains or views with a small amount of data. |
| Legends | <ul style="list-style-type: none"> Supports one-way and two-way highlighting. Highlight on colour, size or shape. You can disable or enable the highlighting action for the workbook or sheets from the toolbar. Your selection is saved with the workbook and can be included in dashboards and stories and when publishing. | <ul style="list-style-type: none"> When you want to focus on select members in a view and dim all others. When you want to highlight using only the legend or the legend and the view. Works well with small domains or views with a small amount of data. |
| Highlighter | <ul style="list-style-type: none"> Search for data points in a view using keywords or select from a drop-down list. Highlight marks while maintaining the context of the other data points. | <ul style="list-style-type: none"> When you want to highlight a mark or group of marks for a discrete field that is included in the view. When you want to do ad hoc comparisons with instant |

| | | |
|-----------------------------------|--|--|
| | <ul style="list-style-type: none"> • Values automatically update when the underlying data is updated. • Highlighters added to worksheets also appear on dashboards and stories. | <ul style="list-style-type: none"> • Works well with large domains and large amounts of data. |
| Actions (Tableau Desktop only) | <ul style="list-style-type: none"> • Highlight data based on criteria that you define. • Specify the source and target sheets to apply the highlight action to. • Specify the fields to use for highlighting. • You can specify different types of actions to run on the same click (for example, filter and highlight). | <ul style="list-style-type: none"> • When you want to build interactive exploration into a dashboard. • When you want to highlight data points in a dashboard using specific fields. |

Legend Highlighting

You can use legend highlighting to focus your users' attention on specific marks in a view. When legend highlighting is on, marks associated with the legend item are highlighted and the other marks are dimmed.

You can enable either one-way  or two-way  highlighting to highlight marks in the view. The icon at the top of the legend indicates which mode you're using.

- One-way highlighting enables you to highlight marks using the values in the legend.
- Two-way highlighting enables you to highlight marks using either the legend or the view. This is the default. When you highlight marks in the view, the matching member in the legend is also highlighted.

You can also turn off highlighting for the workbook or the sheet from the toolbar. This action hides the highlight icon on the legend. For more information about using the toolbar highlighting option, see [Highlight Toolbar Button on page 1408](#).

In this example, the views below show the relationship between order quantity and profit for several products. The view on the left uses the standard functionality for the colour legend,

where all marks are coloured based on their delivery mode. The view on the right uses legend highlighting to call out the products that were delivered via Second Class delivery.

Normal Colour Legend

Colour Legend Highlighting Enabled

You can easily switch between legend highlighting and normal modes using the legend card menu. For colour legends, if you like how a view is highlighted, you can assign the highlight colours to the colour palette. The old colours are replaced with the highlight colours.

Turn on legend highlighting

1. Click the **Highlight** button  at the top of the legend.

If you're using Tableau Desktop you can also turn on legend highlighting by selecting **Highlight Selected Items** on the legend card menu.

This example shows highlighting using the colour legend. Colour legend highlighting is turned on by default.

2. Select an item in the colour legend.

After legend highlighting is turned on, you can quickly focus on specific data in the view by selecting different items in the colour legend. When you turn on legend highlighting, a highlight action is created that you can modify in the Actions dialog box.

Turn off legend highlighting

Click the **Highlight** button  at the top of the legend. This changes highlighting to one-way and you can use the legend to highlight matching marks in the view.

Legend highlighting in Tableau Desktop

If you're using Tableau Desktop you can also turn off legend highlighting by selecting **Highlight Selected Items** on the legend card menu. When you turn legend highlighting off the action is removed from the Actions dialog box.

If you like how the view is highlighted and want to keep a specific member highlighted even when you turn off legend highlight mode, you can assign the highlight colours to the existing colour palette. The original colour legend is discarded and the highlight colours become the new colour palette for the legend.

To assign the highlight colours to the colour palette, select **Assign Highlight Colours to Palette** on the colour legend card menu.

Highlight Data Points in Context

When you have a view with a large amount of data, you might want to explore your data interactively and highlight a specific mark or group of marks while still maintaining the context of where those marks show in your view.

To do this, you can turn on the Highlighter for one or more discrete fields that are included in your view and that affect the level of detail (see [How dimensions affect the level of detail in the view on page 150](#) for more information).

You can use keywords to search for matching data points. The highlighter immediately highlights the marks that match or partially match your keyword search. If you update the underlying data source for your view the data shown in the highlighter is automatically updated too.

In the example below, the Highlighter is turned on for the **College** field. Entering a partial keyword search for **Public** returns two possible matches. In the view, Tableau highlights the group of marks that match the partial search: **Public Affairs** and **Public Health**.

You can turn on highlighters for as many discrete fields in our view as you need. However, you can only highlight using one value set at a time. If you want to include the highlight option on dashboards and stories, turn them on in the worksheet before you add them to the dashboard, or select the worksheet on the dashboard, and then select **Analysis > Highlighters** from the top menu and select from the fields in the list.

Tableau Desktop only: If you want to change the format for the highlighter card after you turn it on, select **Format > Highlighter**.

Highlighters work across worksheets on a dashboard if the same field is included across those worksheets. If the same field is not found, then no match is found for the highlighted value, and the values in those worksheets are dimmed. If you have multiple highlighters showing on a dashboard, only one highlighter can be active at a time. In this situation, the highlight shows for the highlighter that was used last.

Turn on highlighting

1. Right-click on a discrete field that is included in the view and impacts the level of detail in the view. Then select **Show Highlighter** from the context menu.

2. Click in the highlighter dialog box and do one of the following:
 - Enter a keyword to search for matching marks to highlight.
 - Enter a partial key word to search for all relevant matches that contain your search text.
 - Select an item in the drop-down list. You can select one item at a time.
 - Hover over items in the drop-down list to highlight marks in the view for an ad hoc analysis experience.

Click the image above to replay the animation.

3. Repeat steps 1 and 2 to add additional highlighters.

You can also show mark labels on highlighted marks. To turn on mark labels, on the Marks card, click **Label**, tick the **Show mark labels** box and select **Highlighted** in the Marks to Label section.

Highlight Toolbar Button

Another way to add a highlight action is to use the highlight button in the toolbar. Similar to legend highlighting, the toolbar button lets you highlight a collection of related marks in the view and functions the same way that two-way highlighting does. To turn on highlighting, select the fields you want to use for highlighting on the toolbar menu. The drop-down list shows the active fields in the view. Then select a mark in the view to see the related data.

For example, the view below shows **Sales** vs. **Profit** by **Region**. If you turn on highlighting for **Ship Mode**, when a mark is selected, all other marks that were shipped via that mark's ship mode are highlighted. In this example you can quickly see all products from across the United States that were shipped via Second Class.

The toolbar menu also lets you highlight on **All Fields** or **Dates and Times**. **All Fields** considers all fields in the view when identifying matching records; **Dates and Times** considers all date and time fields in the view.

When you use the Highlight toolbar button in Tableau Desktop, an action is created in the Actions dialog box. You can modify the action to create more advanced highlighting behaviour. For more information about editing actions, see [Create Advanced Highlight Actions](#) below.

Finally, you can use the toolbar button to disable highlighting across the entire workbook or for just the active sheet. These options disable highlighting for legends only. They do not turn off the ability to manually highlight marks or use the Highlighter control.

When you turn off highlighting from the toolbar button, the highlight icon is hidden on the legend, and the **Highlight Selected items** menu option is greyed out on the context menu for the legend.

Create Advanced Highlight Actions

You can define more advanced highlight actions using the Actions dialog box. There you can specify source and target sheets and the fields you want to use for highlighting. Follow the steps below to create a highlight action.

1. On a worksheet select **Worksheet > Actions**. From a dashboard, select **Dashboard > Actions**.
2. In the Actions dialog box click the **Add Action** button and then select **Highlight**.

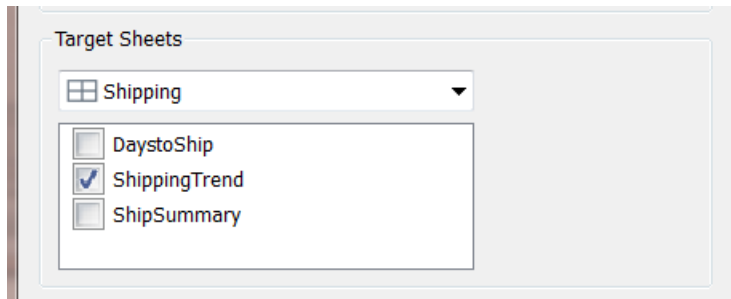

3. Name the action to identify it in the Actions dialog box. Try to make the name descriptive, such as, *Highlight Products Shipped by Delivery Truck*. You can select variables from a drop-down list and use them in the name. Then they are filled in based on the values of the selected field.
4. Use the drop-down list to select the source sheet or data source. If you select a data source or a dashboard sheet, you can further select individual sheets within them.

5. Select how you want to trigger the action. You can select from the following options:
 - **Hover** - Rest the pointer over a mark in the view to run the action. This option works well for highlight and filter actions within a dashboard.
 - **Select** - Click a mark in the view to run the action. This option works well for all types of actions.

- **Menu** - Right-click (control-click on Mac) a selected mark in the view and then select an option on the context menu. This option works well for filter and URL actions.
6. Select a target sheet. If you select a dashboard, you can further select individual sheets within the dashboard.

7. Select the fields you want to use for highlighting. Select from the following options:
- **All Fields** - Marks in the target sheet are highlighted when they match the marks selected in the source sheet. All fields are considered when determining a match.
 - **Dates and Times** - Marks in the target sheet are highlighted when their date and time match those of the marks selected in the source sheet. The source and target worksheets can only have one date field each, however the date fields can have different names.
 - **Selected Fields** - Marks in the target sheet are highlighted based on select fields. For example, highlighting using the Ship Mode field will result in an action that highlights all marks in the target sheet that have the same ship mode as the selected mark in the source sheet.
8. When finished, click **OK** twice to close the dialog boxes and return to the view.

[Highlight Actions on page 1401](#)

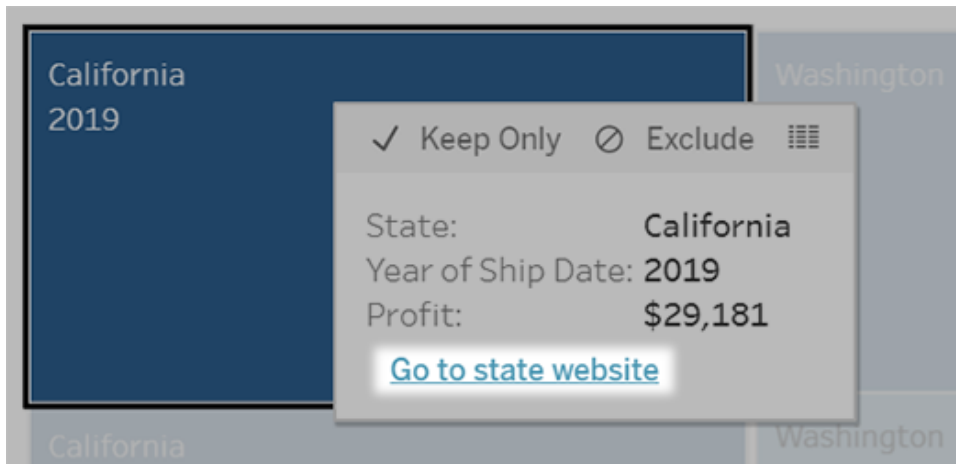

[Highlight Data Points in Context on page 1405](#)

URL Actions

A URL action is a hyperlink that points to a web page, file, or other web-based resource outside of Tableau. You can use URL actions to create an email or link to additional information about

your data. To customise links based on your data, you can automatically enter field values as parameters in URLs.

Tip: URL actions can also open in a web page object in a dashboard. See [Actions and Dashboards](#) to learn more.

A URL action run from a tooltip menu. The link reflects the action name, not the target URL.

Open a web page with a URL action

1. On a worksheet, select **Worksheet > Actions**. From a dashboard, select **Dashboard > Actions**.
2. In the Actions dialog box, click **Add Action** and then select **Go to URL**.
3. In the next dialog box, enter a name for the action. To enter field variables in the name, click the **Insert** menu to the right of the **Name** box.

Note: Give the action a descriptive name, because the link text in the tooltip is the name of the action, not the URL. For example, when linking to more product details, a good name could be "Show More Details".

4. Use the drop-down list to select a source sheet or data source. If you select a data source or dashboard you can select individual sheets within it.

5. Select how users will run the action.

If you

choose this **The action is run when the user...**
option...

- | | |
|---------------|---|
| Hover | Mouses over a mark in the view. This option works best for highlight actions within a dashboard. |
| Select | Clicks a mark in the view. This option works well for all types of actions. |
| Menu | Right-clicks (control-clicks on Mac) a selected mark in the view, then clicks an option in a tooltip (menu). This option works particularly well for URL actions. |

6. For URL Target, specify where the link will open:

- **New Tab if No Web Page Object Exists** – Ensures that the URL opens in a browser on sheets that lack web page objects. This is a good choice when Source Sheets is set to All or a data source.
- **New Browser Tab** – Opens in the default browser.
- **Web Page Object** – (Available only for dashboards with Web Page objects) Opens in the web page object you select.

Note: For New Tab options, the first time the action is run, it opens a new tab. After that, the action will open in the same tab instead of opening additional ones.

7. Enter a URL

- The URL should start with one of the following prefixes: `http`, `https`, `ftp`, `mailto`, `news`, `gopher`, `tsc`, `tsl`, `sms`, or `tel`

Note: If no prefix is entered, `http://` is automatically appended to the beginning and the URL action will work in Tableau Desktop. However, if a URL action with no prefix is published to Tableau Server or Tableau Cloud, it will fail in the browser. Always provide a fully qualified URL for actions if the dashboard will be published.

Note: You can specify an ftp address only if the dashboard doesn't contain a web object. If a web object exists, the ftp address won't load.

- Tableau Desktop also supports local paths like `C:\Example folder-example.txt`, as well as file URL actions.
- To enter field and filter values as dynamic values in the URL, click the **Insert** menu to the right of the URL. Be aware that any referenced fields must be used in the view. For details, see [Using field and filter values in URLs](#) on page 1418.

▼ **Data Values**

[Learn more](#)

☒ Encode data values that URLs do not support

☒ Allow multiple values via URL parameters

Value Delimiter: ,

Delimiter Escape Character: \

Below the URL you enter is a hyperlinked example you can click for testing.

8. (Optional) In the Data Values section, select any of the following options:
- **Encode Data Values that URLs Do Not Support** – Select this option if your data contains values with characters that browsers don't allow in URLs. For example, if one of your data values contains an ampersand, such as "Sales & Finance", the ampersand must be translated into characters that your browser understands.
 - **Allow Multiple Values via URL Parameters** – Select this option if you are linking to a web page that can receive lists of values via parameters in the URL. For example, say you select several products in a view and you want to see each

product's details hosted on a webpage. If the server can load multiple product details based on a list of identifiers (product ID or product name), you could use multi-select to send the list of identifiers as parameters.

When you allow multiple values, you must also define the delimiter escape character, which is the character that separates each item in the list (for example, a comma). You must also define the Delimiter Escape, which is used if the delimiter character is used in a data value.

Create an email with a URL action

1. On a worksheet, select **Worksheet > Actions**. From a dashboard, select **Dashboard > Actions**.
2. In the Actions dialog box, click **Add Action**, and select **Go to URL**.
3. In the Source Sheets drop-down list, select the sheet that contains the field with the email addresses you want to send to.
4. In the URL box, do the following:
 - Type **mailto:**, and click the **Insert** menu at right to select the data field that contains email addresses.
 - Type **?subject=**, and enter text for the Subject line.
 - Type **&body=**, and click the **Insert** menu at right to select the fields of information that you want to include in the body of the email.

In the example below, the "Email" field contains the email addresses, the subject is "City Information", and the body text of the email consists of the city and state data that is associated with the email address.

5. (Optional) Display data from your workbook in the body of your email as a vertical list instead of the default horizontal list. For example, suppose you have a horizontal list of cities, such as Chicago, Paris, Barcelona, which you would rather display vertically, like this:

Chicago
Paris
Barcelona

To make the list vertical, in the Data Values section, do the following:

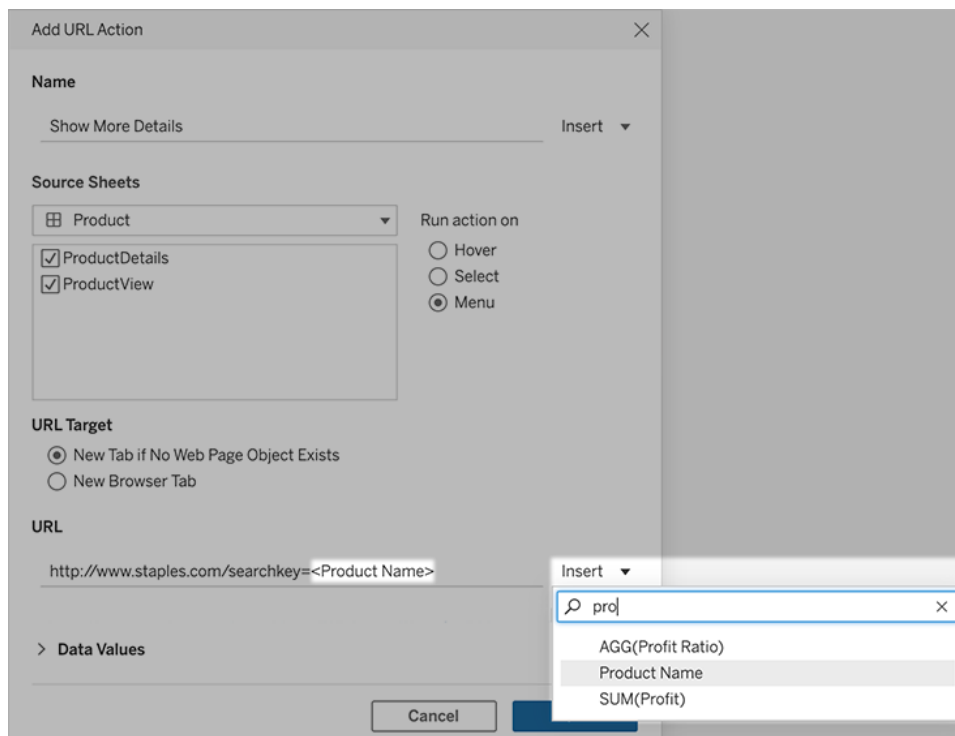

- Deselect **Encode Data Values that URLs Do Not Support**
- Select **Allow Multiple Values via URL Parameters**.
- Type **%0a** in the **Value Delimiter** text box to add line breaks between each item in the list. (These are the URL-encoded characters for a line break.)

Using field and filter values in URLs

When users trigger URL actions from selected marks, Tableau can send field, filter and parameter values as variables in the URL. For example, if a URL action links to a mapping website, you could insert the address field to automatically open the currently selected address on the website.

1. In the Edit URL Action dialog box, begin typing the URL for the link.
2. Place the cursor where you want to insert a field, parameter or filter value.
3. Click the **Insert** menu to the right of the text box and select the field, parameter, or filter you want to insert. The variable appears within angle brackets. You can continue adding as many variables as you need.

Note: Any referenced fields must be used in the view. Otherwise, the link won't display in the viz, even if it functions when you click Test Link.

Including aggregated fields

The list of available fields includes only non-aggregated fields. To use aggregated field values as link parameters, first create a related calculated field, and add that field to the view. (If you don't need the calculated field in the visualisation, drag it to Detail on the Marks card.)

Inserting parameter values

When inserting parameter values, URL actions send the Display As value by default. To instead send the actual value, add the characters `~na` after the parameter name.

For example, say you have a parameter that includes IP addresses, with Actual Value strings such as 10.1.1.195 and Display As strings with more friendly values such as Computer A (10.1.1.195). To send the actual value, you'd revise the parameter in the URL to look like this: `http://<IPAddress~na>/page.htm`.

Parameter Actions

Use parameter actions to let your audience change a parameter value through direct interaction with a viz, such as clicking or selecting a mark. You can use parameter actions with reference lines, calculations, filters and SQL queries, and to customise how you display data in your visualisations.

Parameter actions open up new possibilities for creating summary values and statistics without using calculations. You can configure parameter actions to let users select multiple marks that are automatically aggregated into a single parameter value. For example, a parameter action could show the `AVG(Sales)` or `COUNTD(Orders)` for currently selected marks.

For examples of how parameter actions can be used, see [Examples of parameter actions on page 1425](#).

You can create parameter actions in Tableau Desktop, Tableau Cloud and Tableau Server.

When you define a parameter action, it must include:

- the source sheet or sheets it applies to.
- the user behaviour that runs the action (hover, select or menu).
- the target parameter, the source field and the respective aggregation (if applicable).

The parameter referenced in the action must also be referenced in some part of the visualisation.

You can do this in different ways, such as referencing the parameter in a calculated field or reference line that is used in the viz. You can also build a view that uses a source field that is referred to in the parameter action.

General steps for creating parameter actions

1. Create one or more parameters. For more information, see [Create Parameters on page 1131](#).

2. **Optional:** Depending on the behaviour you want to make available to users for their analysis, you might want to create a calculated field that uses the parameter. For details on creating calculated fields, see [Create a calculated field on page 2010](#).
3. Build a visualisation that will make use of parameter actions.

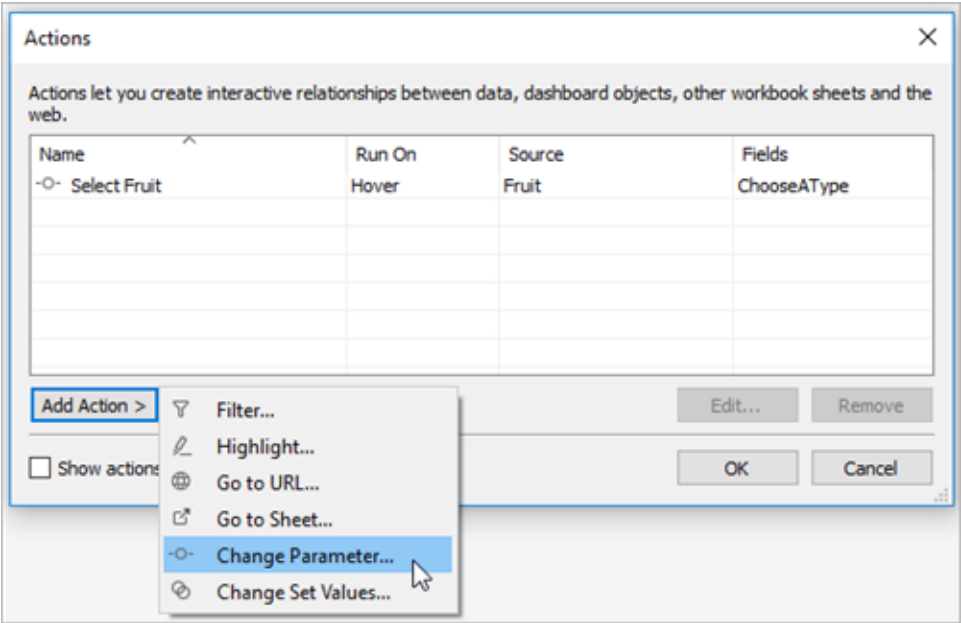

For example, if you created a calculated field that uses the parameter, build the view using that calculated field. Or, drag a field that you plan to tie to the parameter into the view.
4. Create a **parameter action** that uses a parameter. You can create multiple parameter actions for different purposes. The parameter action must refer to the sheet name of the visualisation, the parameter name and the source field that the parameter will be associated with.
5. Test the parameter action and adjust its settings or other related elements in your visualisation as needed to get the behaviour you want your audience to experience.

Note: It is helpful to understand how you can use parameters in Tableau before you start using them in parameter actions. For more information:

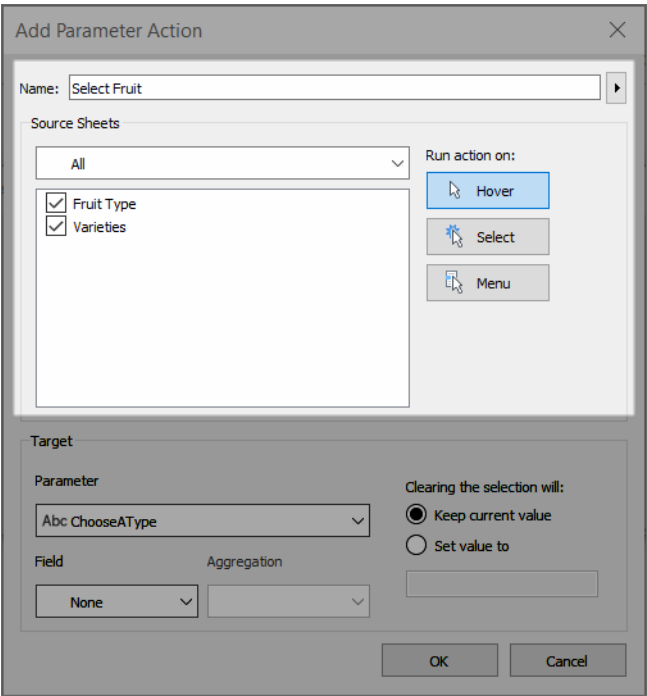

- Read the [Create Parameters on page 1131](#) help topic and related parameter topics.
- See [Use Parameters to Add Multiple Views to Your Viz](#) on the Tableau [blog](#) and multiple practical topics on how to use parameters on the [Data School](#) website, such as [Four Steps to Creating a Parameter](#).
- For an in-depth presentation, watch [Parameters | Oh, the places you'll go!](#) (45 minutes).

Create a parameter action

1. In a worksheet, select **Worksheet >Actions**. In a dashboard, select **Dashboard >Actions**.
2. In the Actions dialog box, click **Add Action** and then select **Change Parameter**.

3. In the **Actions** dialog box, specify a meaningful name for the action.
4. Select a source sheet or data source. The current sheet is selected by default. If you select a data source or dashboard you can select individual sheets within it.

5. Select how users will run the action.

- **Hover** - Runs when a user hovers the mouse cursor over a mark in the view. Also exposes an option for the action in the mark's tooltip.
 - **Select** - Runs when a user clicks a mark or selects multiple marks in the view.
 - **Menu** - Runs when a user right-clicks (macOS: control-clicks) a selected mark in the view, then selects an option on the context menu. Also exposes an option for the action in the mark's tooltip.
6. Under **Target**, specify the target parameter and a source field. All parameters in the workbook are available in the **Parameter** list.

To let your users select multiple marks that get aggregated into a single parameter value, select an aggregation type.

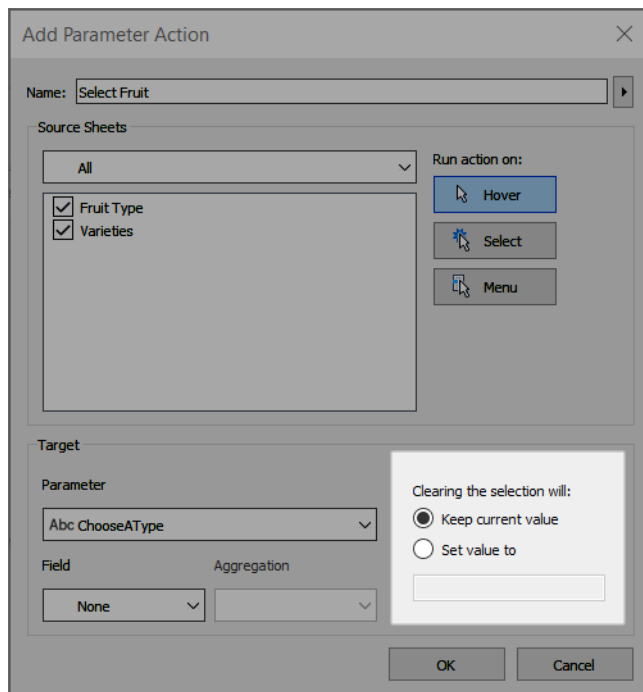

Note: If you want your users to be able to select multiple marks, you will need to select an aggregation. If **Aggregation** is set to **None**, and multiple marks that contain different values for the source field are selected, the parameter action will not run.

The aggregation that you choose for the parameter action can be different than the aggregation used for that field in the view. For example, you could create a view that uses

SUM(Sales), but set the Sales source field referenced in the parameter action to use Average for the aggregation. Note that if you then change the aggregation of the Sales field in the view to AVG(Sales), you will need to update the parameter action to reference the Sales field again.

7. Specify what will happen when the selection is cleared.
 - **Keep current value** - Current parameter value will remain in the view.
 - **Set value to** - Parameter value will revert to the indicated value.

8. Click **OK** to save your changes and return to the view.
9. Test the parameter action by interacting with the visualisation. Tweak some of the settings for the action to adjust the behaviour as needed.

Examples of parameter actions

The following examples demonstrate how you can use parameter actions, but these are just the beginning of what is possible. To follow along, it helps to be familiar with creating and using parameters and calculated fields. For more information, see [Create Parameters on page 1131](#) and [Create a calculated field on page 2010](#).

For additional examples of how you can use parameter actions, see:

- [How and when to use parameter actions](#)
- [Parameter Actions: KPI Navigator](#)
- [Parameter Actions: Year over Year Comparison](#)
- [Parameter Actions: Layered Analysis](#)
- [Parameter Actions: Concatenation](#)
- [3 Creative Ways To Use Tableau Parameter Actions](#) from Tableau Visionary Ryan Sleeper on the [PlayfairData](#) website.
- [Tableau Parameter Actions Sneak Peek](#) from Tableau Visionary Joshua Milligan on the [VizPainter](#) website.

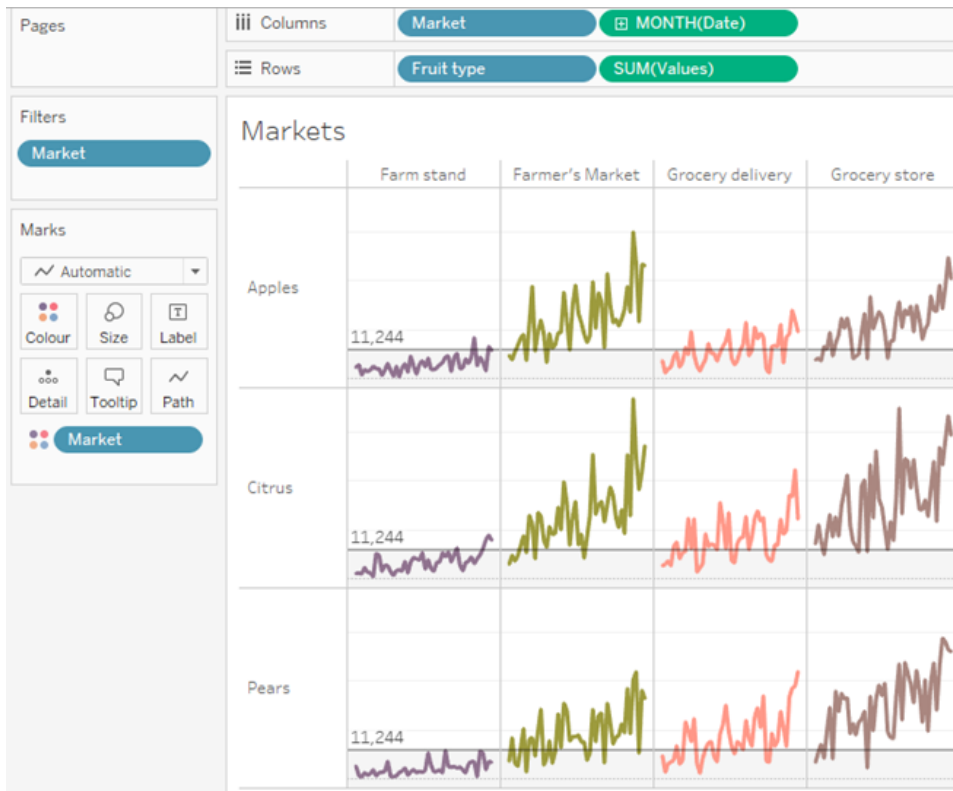

Make reference lines dynamic

This example demonstrates how you could use a parameter action to interactively update a reference line, without using a calculation.

Reference lines provide a convenient way to compare values in a visualisation. You can then use parameter actions to make reference lines dynamic. You can associate the reference line with a parameter, and then use a parameter action to make the parameter interactive. As your users interact with the view, the reference lines automatically update to provide more context to the data.

The following fields are used in this view.

Dynamic reference lines example details

1. Create the parameter. The parameter is named *Threshold*. The data type is set to Float.

Edit Parameter [Threshold]

Name:
Comment >>

3. Create a parameter action. This action references the Threshold parameter and the Values field. The action runs on Hover.

Edit Parameter Action

Name:

Source Sheets

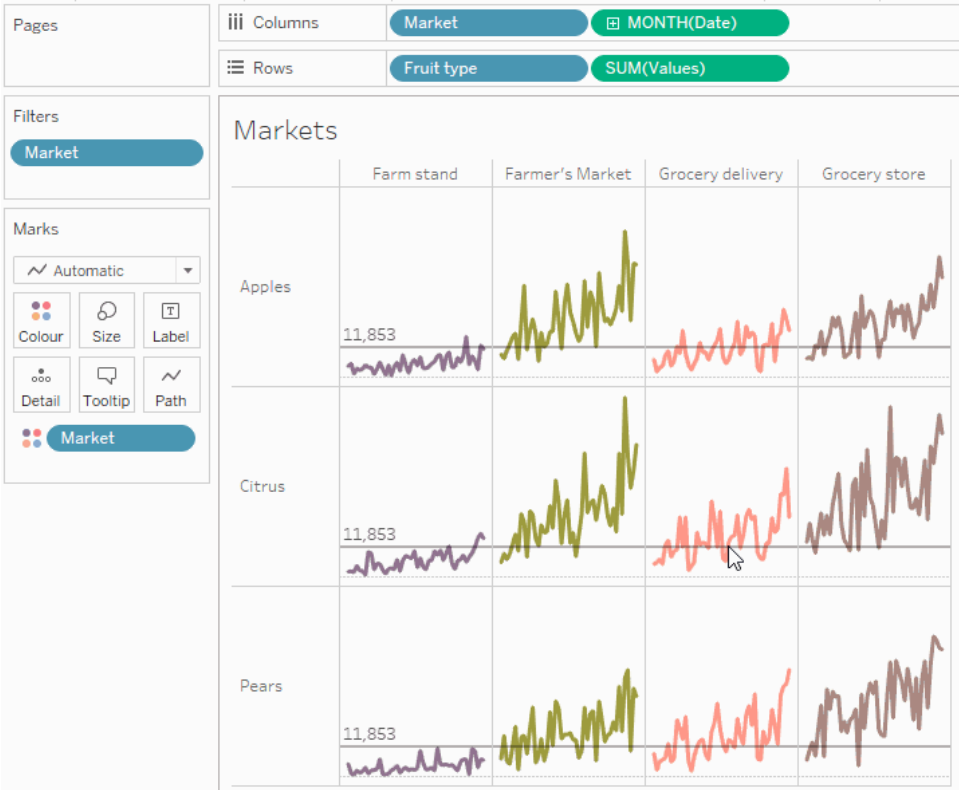

Run action on:

Target Parameter

Value

Field: Aggregation:

4. Test the parameter action in the sheet. Hovering over a mark in the view updates the reference line to see how that value appears in context with the other categories of data.

Display a selective hierarchy

This example demonstrates how you could use a parameter action that is referenced by a calculated field to let your audience control what information is being displayed in a view.

One common use for parameters is using a parameter to change the input value in a calculation. This example uses a parameter *ChooseAType* for the type of fruit and a calculated field *Varieties* that returns the varieties for the type of fruit. The calculated field has been added to the view instead of the original field *Fruit variety*. Users can select a fruit type using a parameter control to change the fruit type and varieties being displayed.

Using a parameter with a calculation and a parameter control to interactively change a parameter value

This is one way to let your users explore the data in the view. Parameter actions make this same scenario possible, but with added functionality and benefits. When you create a parameter action that updates the value of the parameter based on a user interacting with the marks in the view:

- User interaction with the viz is more natural. Your users can stay in the flow of exploring the data. Rather than needing to interact with a parameter control, your users can hover or click in the viz to update the parameter value.
- If the data source is updated at some time in the future, and more fruit type and fruit variety values are added, those values will automatically be displayed in the viz and are automatically available to the parameter.

To incorporate parameter actions, this example makes use of a second sheet (*Fruit Type*) that consists of the names of the fruit types. The two sheets (*Fruit Type* and *Varieties*) are combined into a dashboard (*Fruits*).

Selective hierarchy example details

1. The workbook shown in the image above uses the *ChooseAType* parameter and the *Varieties* calculated field.

The *ChooseAType* parameter is set to allow *All Values*.

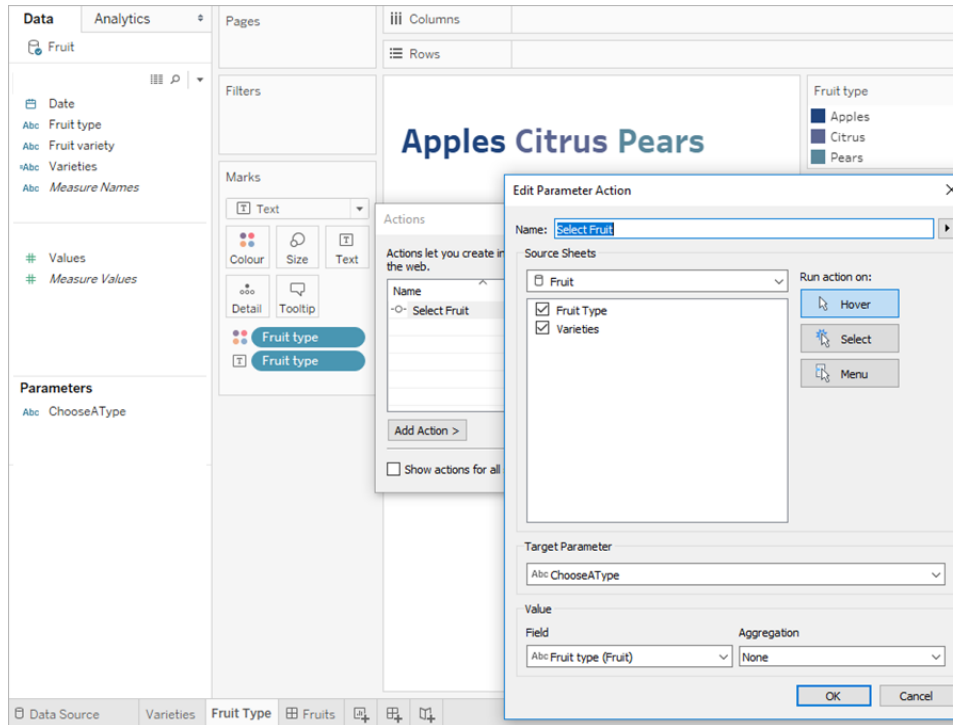

The *Varieties* calculated field references the *ChooseAType* parameter to show the values from the *Fruit variety* field based on the current value selected for *Fruit type*.

2. The workbook uses a parameter action named *Select Fruit*. To create the parameter action, the author clicked a sheet, and then selected **Worksheet > Actions > Add Action > Change Parameter**.

The action uses the *Fruit* data source. Because the parameter and calculation both need to be aware of the *Fruit type* field to function, both the *Fruit Type* and *Varieties* sheets need to be selected.

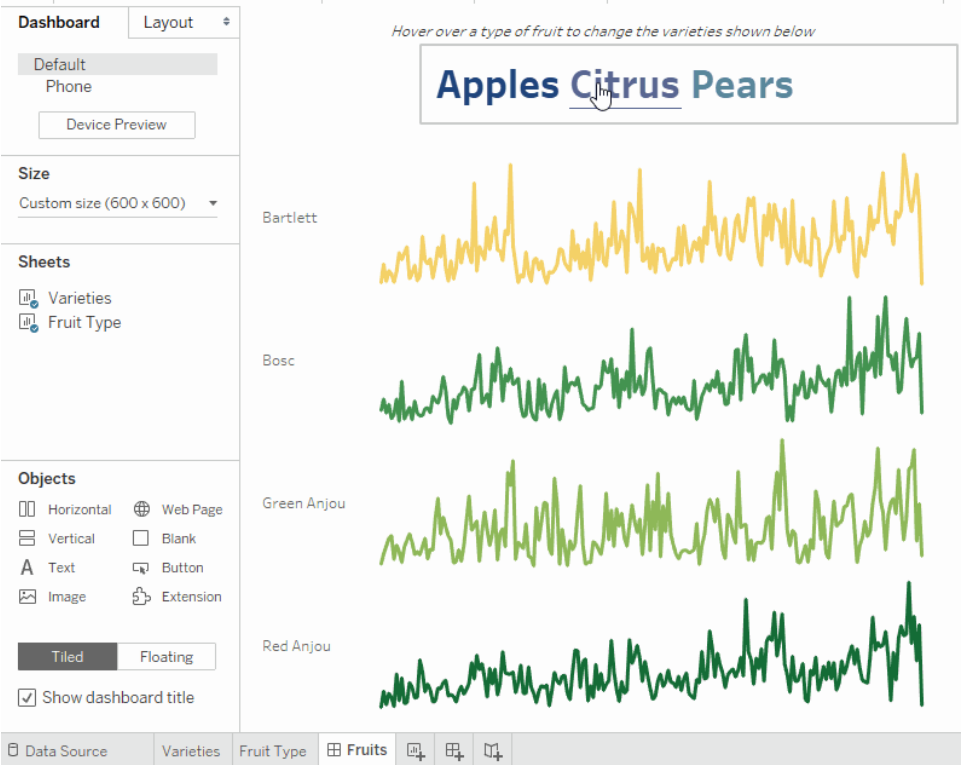

The parameter *ChooseAType* is associated with the *Fruit type* field. The parameter action will run whenever a user hovers over the fruit type text in the *Fruits* dashboard, or in the *Fruit Type* sheet.

In the *Varieties* sheet, the *Fruit type* field is on the Rows shelf, but the Show Header option is unticked for that field to remove the fruit type label from this view.

3. Test the parameter action in the Fruits dashboard. Hovering over the fruit type updates the view to show the varieties of that fruit.

Display summary data for selected marks

Getting summary statistics for a subset of data is a valuable analytical tool. This example shows how you can use aggregated parameter actions for selected marks to automatically generate summary data.

This view of a sheet named Options shows fruit varietals and their intended markets.

The SUM(Values) field needs to be present on both sheets for the parameter to work. SUM (Values) is placed on **Detail** in the Marks card in this view.

The previous Options view will function as a selector for this second view, a scatter plot that plots the same marks against their total value and quantity. SUM(Values) is placed on Rows in this view.

A parameter action will be used to make the two views work together in a dashboard.

Select a fruit and market from the left (by clicking headers or icons) to see the average value and quantity in the scatterplot update for that selection.

Summary data example details

1. Create the parameter. This parameter is named *Average Value*. The data type is set to Float.

Edit Parameter [Average Value] ✕

Name: Comment >>

Properties

Data type: ▼

Current value:

Display format: ▼

Allowable values: ☒ All ☐ List ☐ Range

OK Cancel

2. Create a reference line that uses the Average Value parameter. The label is set to Custom with the text "Average value: <Value>". The Line option is set to a brown colour.

Edit Reference Line, Band, or Box

Line Band Distribution Box Plot

Scope

☒ Entire Table ☐ Per Pane ☐ Per Cell

Line

Value: Average Value

Label: Custom Average value: <Value>

Tooltip: None

Line only 95

Formatting

Line: [Brown Line]

Fill Above: None

Fill Below: None

☒ Show recalculated line for highlighted or selected data points

OK

3. The two sheets are combined in a dashboard. To create the parameter action, click the dashboard tab, and then select **Dashboard > Actions > Add Action > Change Parameter**.

The action is named *Average Value*. The target parameter references the Average Value parameter. The source field is set to SUM(Values) (Fruit).

The setting for aggregation is where the summary statistic information comes into play. By choosing Average, Median, Count, etc., you set the parameter to update with the statistic of your choosing.

The aggregation is set to Average. Also note that the aggregation for the source field in the view can be different from the aggregation that you use for the parameter action.

Edit Parameter Action

Name:

Source Sheets

☐ Dashboard 1

☒ Options

☒ Value x Quantity

Run action on:

Target Parameter

Value

Field:

☐ Dates and Times
☒ All Fields

☐ Fruit type
☐ Fruit variety
☐ Market

4. Test the parameter action in the dashboard. As you select headers and marks, the reference line updates dynamically and displays the average of the values.

Set Actions

Use set actions to let your audience interact directly with a viz or dashboard to control aspects of their analysis. When someone selects marks in the view, set actions can change the values in a set. For examples on how set actions can be used, see [Examples of set actions on page 1449](#).

Set actions take an existing set and update the values contained in that set based on user actions in a viz. You can define the set action to include:

- the source sheet or sheets it applies to.
- the user behaviour that runs the action (hover, select or menu).
- the target set (the data source and set to be used).
- what happens when the selection is cleared.

To change or affect a visualisation, the set referenced in the action must be used somehow in the visualisation. You can do this in different ways, such as using the set in a calculated field that you then use to build the viz, or by placing the set in the view or on a Marks card property.

You can create set actions in Tableau Desktop, Tableau Cloud and Tableau Server. However, set actions can't be used with [Stories on page 2823](#).

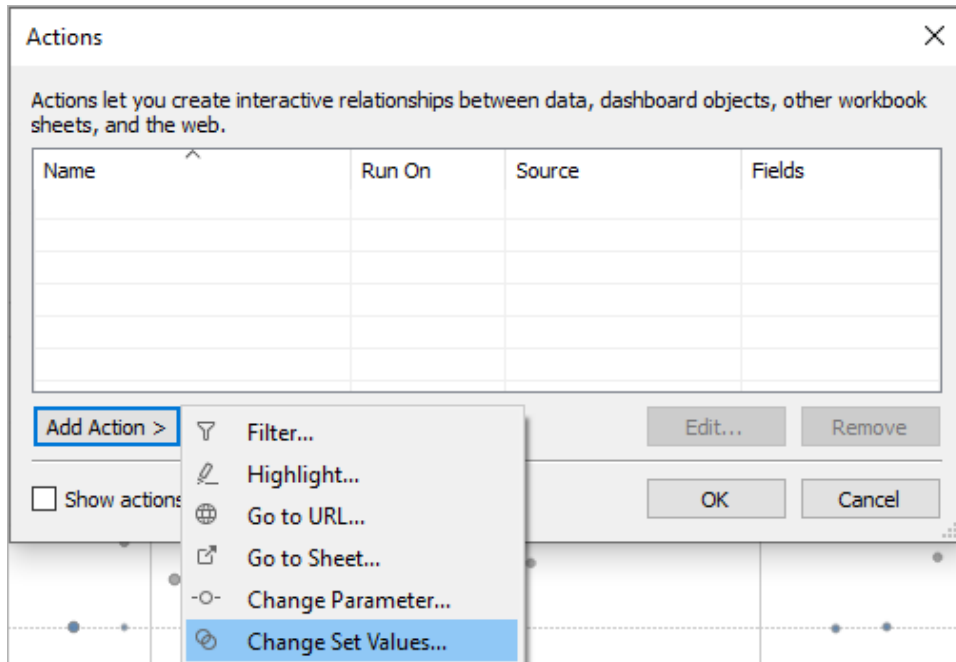

General steps for set actions

1. Create one or more sets. The sets you create will be associated with the data source that is currently selected. For details on creating sets, see [Create Sets on page 1101](#).
2. Create a **set action** that uses one of the sets you created. You can create multiple set actions for different purposes.
3. Depending on the behaviour you want to make available to users for their analysis, you might want to create a calculated field that uses the set. For details on creating calculated fields, see [Create a calculated field on page 2010](#).
4. Build a visualisation that uses a set referenced by a set action. For example, if you create a calculated field that uses the set, build the view using that calculated field. Or, drag the set to Colour in the Marks card.
5. Test the set action and adjust its settings as needed to get the behaviour you want your audience to experience.

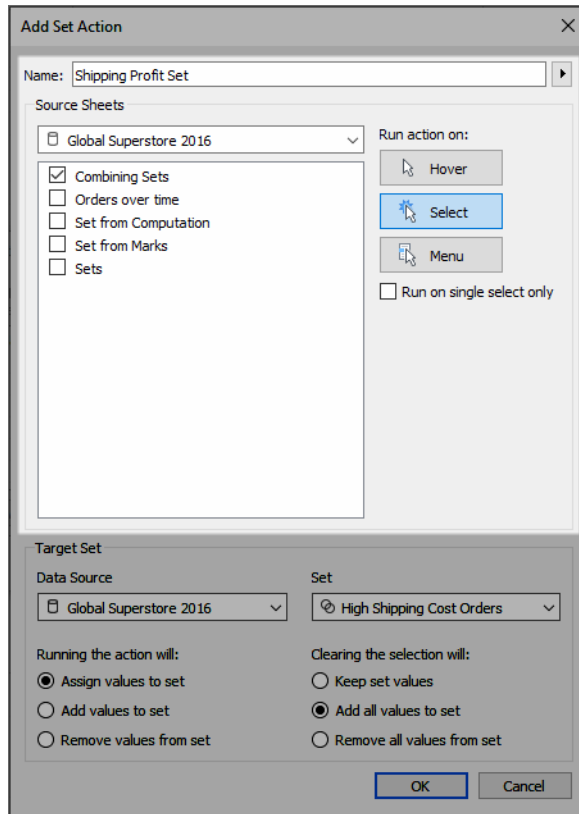

Getting Started: For an overview of what you need to know to create set actions, see [On Your Marks, Get Set, Go: Everything You Need to Know to Get Started with Set Actions](#) on the [Data Viz Linds](#) blog.

Create a set action

1. In a worksheet, select **Worksheet >Actions**. In a dashboard, select **Dashboard >Actions**.
2. In the Actions dialog box, click **Add Action** and then select **Change Set Values**.

3. In the **Add/Edit Set Action** dialog box, specify a meaningful name for the action.
4. Select a source sheet or data source. The current sheet is selected by default. If you select a data source or dashboard you can select individual sheets within it.

5. Select how users will run the action.

- **Hover** - Runs when a user hovers the mouse cursor over a mark in the view.
- **Select** - Runs when a user clicks a mark in the view. This option works well for set actions.
- **Menu** - Runs when a user right-clicks (control-clicks on Mac) a selected mark in the view, then selects an option on the context menu.

6. Specify the target set. First, select the data source, and then select the set.

The sets available in the Target Set lists are determined by the data source that you select and the sets that you have created in the workbook that are associated with that data source.

In this example, the target set is using *Global Superstore 2016* as the data source and *High Delivery Cost Orders* as the set.

7. Specify what happens when the action is run in the view:
 - **Assign values to set** – Replaces all values in the set with the values selected.
 - **Add values to set** – Adds individually selected values to the set.
 - **Remove values from set** – Removes individually selected values from the set.

Note: Selecting **Add values to set** or **Remove values from set** via the Set Action dialog modifies the values selected in the General tab of the set's definition – just like **Assign values to set** does. This differs from the **Add to** and **Remove from** functionality available only in authoring mode via the set's context menu in the tooltip. The latter unions or removes values to and from the set after the condition specified has been applied.

8. Specify what happens when the selection is cleared in the view:

- **Keep set values** - Current values in the set remain in the set.
 - **Add all values to set** - Adds all possible values to the set.
 - **Remove all values from set** - Removes previously selected values from the set.
9. Click **OK** to save your changes and return to the view.
 10. Test the set action by interacting with the visualisation. Tweak some of the settings for the action to adjust the selection behaviour as needed.

Examples of set actions

The following examples show just a few of the ways you can use set actions. To follow along, you will need to be familiar with creating and using sets and calculated fields. For details, see [Create Sets on page 1101](#) and [Create a calculated field on page 2010](#).

Proportional brushing

A classic use case for set actions is proportional brushing, described in [How to do proportional highlighting with set actions](#) on the [Tableau blog](#) and [Tableau Set Actions](#) from [The Information Lab blog](#) (along with other examples).

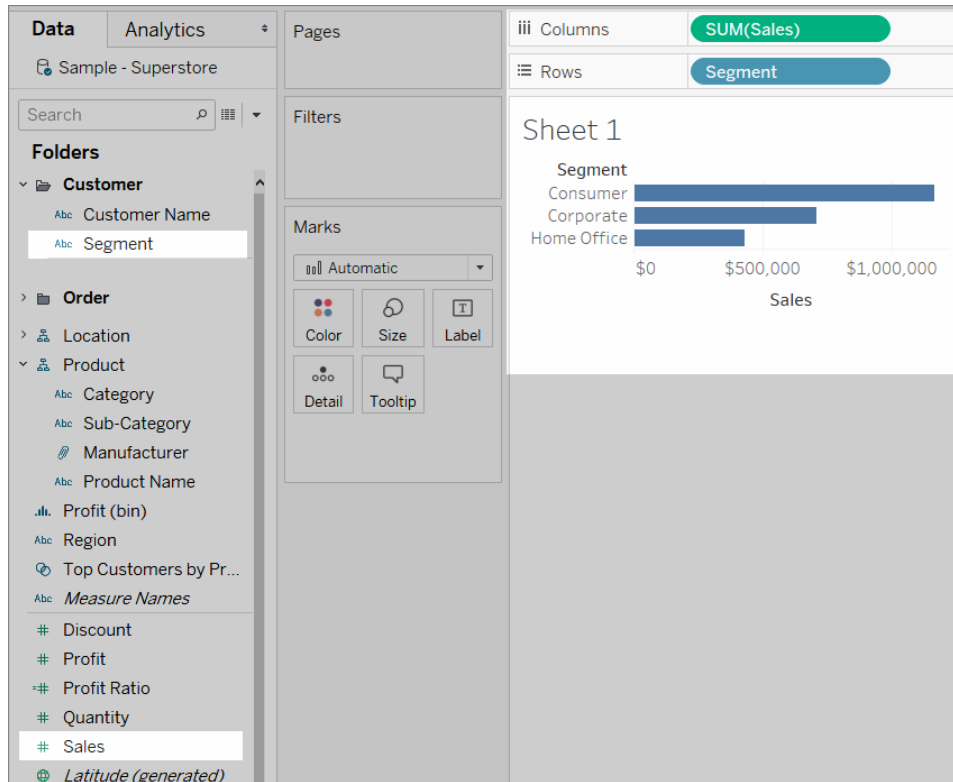

Sales by Subcategory

Proportional brushing example details

This example uses the Sample – Superstore data source. This set action changes the colour of existing marks in the view based on the proportion of the mark that is in or out of the set.

1. Connect to **Sample - Superstore** data in Tableau Desktop.
2. In a new sheet, drag the **Sales** measure to Columns, and drag the **Segment** dimension to Rows.

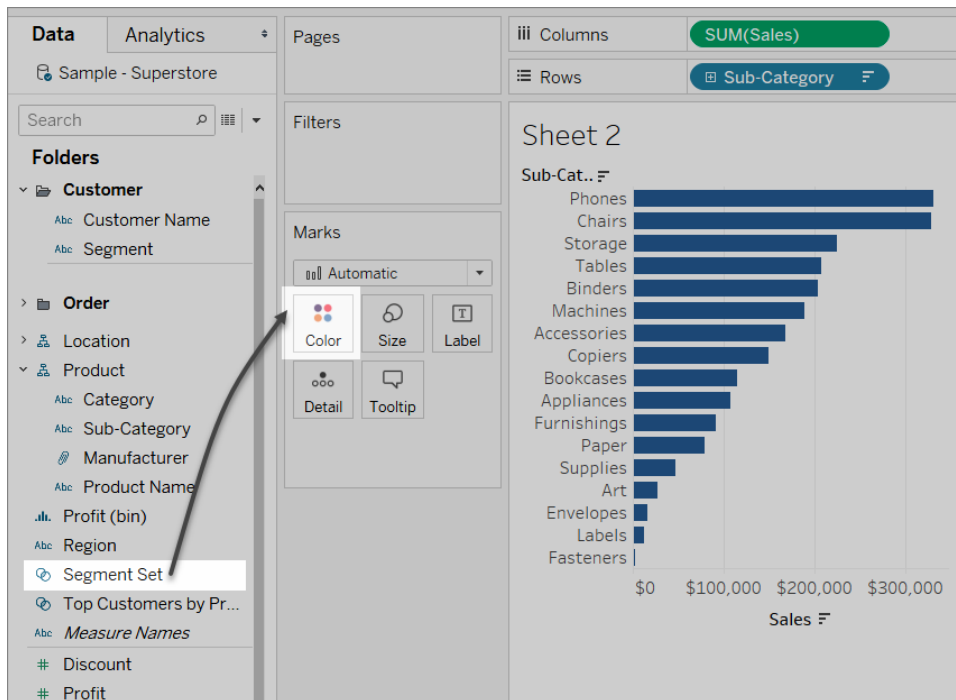

3. In another blank sheet, drag the **Sales** measure to Columns, and drag the **Sub-Category** dimension to Rows.

4. Create a set for the Segment dimension named *Segment Set*.

5. In the sheet that shows Sales by Sub-Category, drag Segment Set onto Colour in the Marks card.

Swap the colours used to show marks IN or OUT of the set.

6. Create a new dashboard. Drag both sheets into the dashboard.

On the **Dashboard** menu, select **Actions**. Click **Add Action**, and then select **Change Set Values**.

7. Configure the action using the same settings as shown in the image below.

8. Click **OK** to save your changes and return to the view.
9. Test the set action by clicking the marks for each segment.

Asymmetric drill down

Set actions can also be used across multiple sets for more complex interactions. If a data set has hierarchical information, such as Category, Sub-Category and Manufacturer, normally drilling down the hierarchy expands all values at a given level. However, you can use set actions for asymmetric drill down, opening only the next hierarchy level for the selected value.

Asymmetric Drill Down

| Category | Asymmetric Sub-Category |
|-----------------|-------------------------|
| Furniture | \$742,000 |
| Office Supplies | \$719,047 |
| Technology | \$836,154 |

Asymmetric drill down example details

This example uses the Sample – Superstore data source.

Set actions are used here in conjunction with two calculated fields to create an asymmetric drill down experience.

1. Create a set for the Category field named *Category set*.

Choose any category to be a member of that set. The membership is temporary and will be overwritten by the set action.

2. Create a calculated field named *Asymmetric Sub-Category*.

Right-click the Sub-Category field in the Data pane, and then select **Create Calculated Field**.

Type the following calculation:

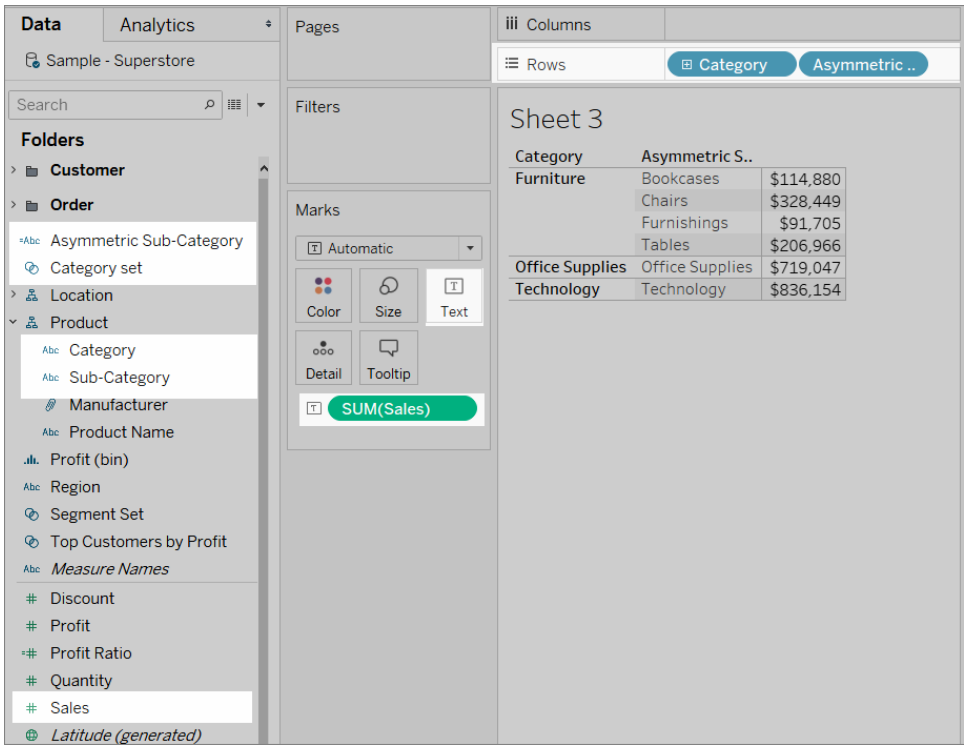

```
IF [Category set] THEN [Sub-Category] ELSE [Category] END
```

If the category of the mark or marks in the view is in the Category Set, the calculation will return the Sub-categories for that Category. Otherwise, it will return the Category again.

The set isn't in use in the view yet and has no action associated with it, so it is static for the moment.

3. Build the view by dragging the Category and Asymmetric Sub-Category fields to Rows (in that order). Then Drag **Sales** to Text in the Marks card.

4. Create a set action.

On the Worksheet menu, select **Actions**. Click **Add Action**, and then select **Change Set Values**.

Name the action *Asymmetric Drill to Sub-Category*.

Add Set Action

Name:

Source Sheets

- ☒ Asymmetric Drill Down
- ☐ Sales by Segment
- ☐ Sales by Subcategory

Run action on:

Target Set

Clearing the selection will:

☐ Keep set values
☐ Add all values to set
☒ Remove all values from set

Select the following options:

- Source Sheets: Make sure the only the current sheet is selected.
- Run action on: Choose **Select**. This will make the action apply when the user selects a mark or marks in the view.
- Target Set: Select the current data source from the first drop-down list and the Category set from the second drop-down list.
- Clearing the selection: Select **Remove all values from set**.

Click **OK** to save your changes.

5. Test the set action.

When you click on a header or mark in the view, it will expand out to the next level. Clicking a category bar will expand its sub-categories.

Colour scaling

Colour values in a viz often can be distorted by outliers. When one country has a significantly higher value than other countries, the nuance of differences between those non-extreme values can be lost.

A set action can update the values in a Country set based on the selection in the viz. That set is then used in a calculated field that computes the value of the relevant measure for only countries in that set, and that calculated field is placed on colour. Now, when countries are selected in the map, the colour palette is based only on those countries, showing greater visual differences between those values.

Colour scaling example details

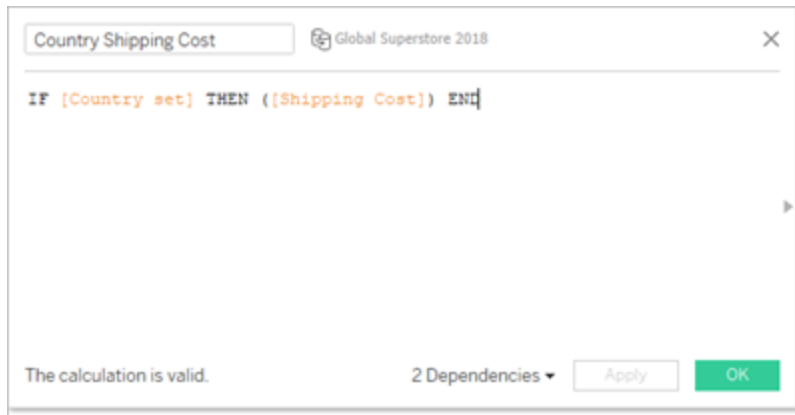

This example uses the [Global Superstore data source](#).

1. Create a set on the Country field named *Country set*. Chose any country to be a member of the set. The membership is temporary and will be overwritten by the set action.
2. Create a calculated field named *Country Shipping Cost*.

Right-click in the Data pane, and then select **Create Calculated Field**.

Type the following calculation:

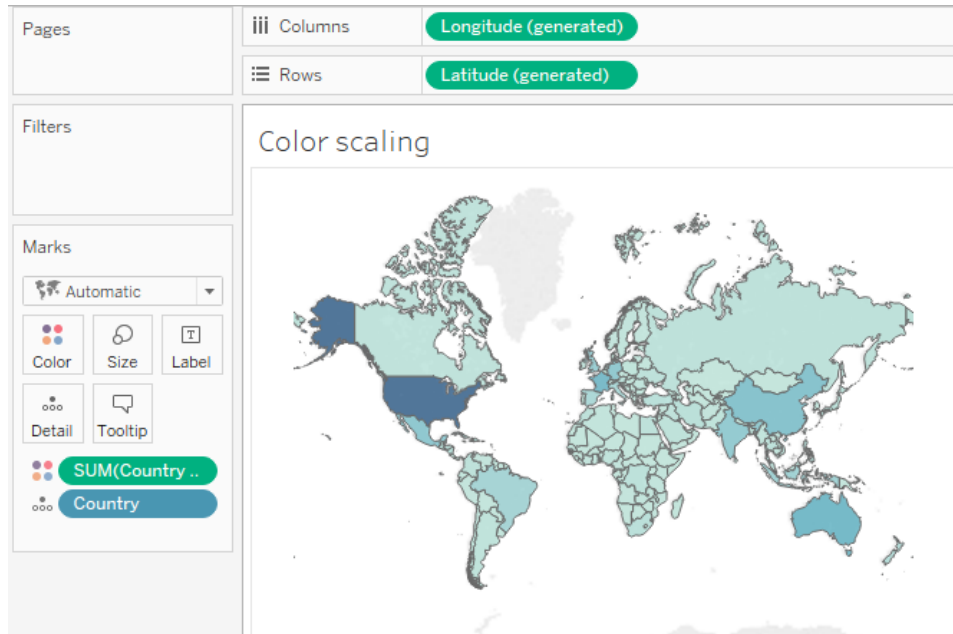

```
IF [Country set] THEN ([Shipping Cost]) END
```

If the country of the mark(s) in the view is in the Country set, the calculation returns the Shipping Cost. Otherwise, it does nothing.

The calculated field ties the set into the view.

3. Double-click the Country dimension to automatically create a map.
4. Drag Country Shipping Cost to Colour in the Marks card. The map should automatically update to a filled map.

5. Create the set action: *Country colour scaling*.

On the Worksheet menu, select **Actions**. Click **Add Action**, and then select **Change Set Values**.

Name the action *Country colour scaling*.

Edit Set Action

Name:

Source Sheets

☒ Color scaling
☐ Default color palette

Run action on:

Target Set

Clearing the selection will:

☐ Keep set values
☒ Add all values to set
☐ Remove all values from set

Select the following options:

- Source Sheets: Select only the current sheet.
- Run action on: Choose **Select**. This will make the action apply when the user selects a mark or marks in the view.
- Target Set: Select the current data source from the first drop-down list and the Category set from the second drop-down list.
- Clearing the selection: Select **Add all values to set**.

6. Click **OK** to save your changes.

7. Test the set action.

When you select a mark or group of marks in the view, the colour palette responds by representing the values for those marks, not the entire data set.

Relative dates

This dashboard example contains multiple relative date calculations. Based on a target date, the dashboard displays the difference from the previous day, the percent change from the same month in the previous year, the Year to Date sales for the current year and Year to Date sales for the previous year.

The set action in this dashboard updates the target date and relevant date calculations in response to a user clicking a mark on a timeline.

Relative date example details

This example uses the [Global Superstore data source](#).

The set action in this example is applied to the Timeline sheet in the dashboard, and uses that sheet to drive the behaviour of the dashboard. When a user selects a mark in the Timeline view, the set action updates the Selected Date set with a single date value.

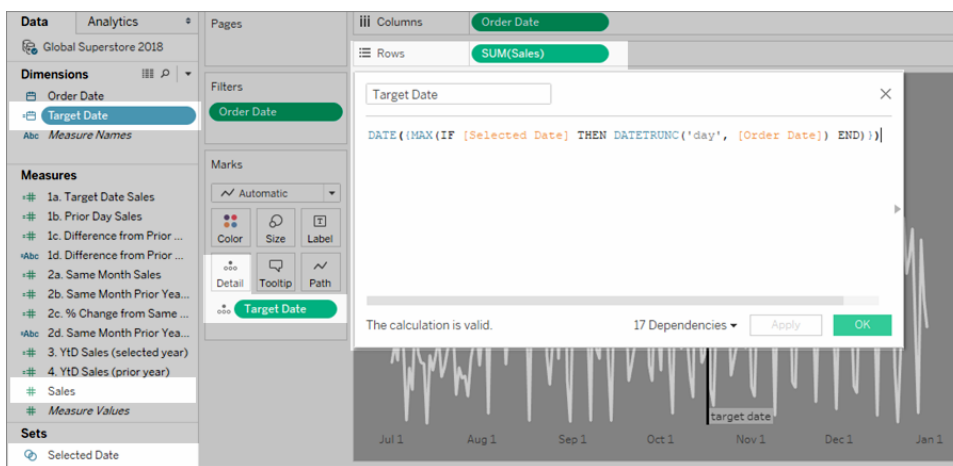

In this example:

- A Selected Date set is built on the Order Date field.
- An Update Target Date set action updates the Selected Date set so the date value for the mark selected in the view is the only value in the set.
- A Target Date calculated field captures the date value from the Selected Date set, and that calculated field is referenced by other relative date calculations in the viz.
- Each sheet in the dashboard uses calculated fields to update its displayed values.

Note: Because this example is more complex, the description below gives a summary of the major steps and settings involved, rather than specific details.

Timeline sheet settings

Sales is on Rows. A calculated field named Target Date is placed on Detail to make it available to the reference line.

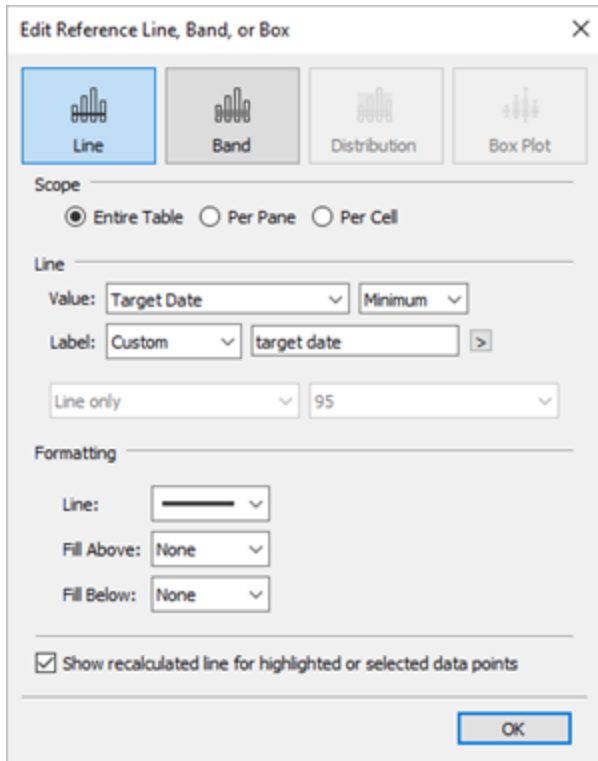

Starting in Tableau 2020.2: The above image doesn't reflect the latest user interface. For each table or folder in the Data pane, a grey line separates dimensions (above line) and measures (below line). The Dimensions and Measures labels are no longer used in the Data pane.

Order Date is on Columns as Exact Date.

The reference line is applied to the Order Date field and is set to be the Minimum of Target Date.

The dialog box is titled "Edit Reference Line, Band, or Box" and has a close button (X) in the top right corner. It contains four tabs: "Line" (selected), "Band", "Distribution", and "Box Plot". Below the tabs is a "Scope" section with three radio buttons: "Entire Table" (selected), "Per Pane", and "Per Cell". The "Line" section includes a "Value" dropdown set to "Target Date" and a "Minimum" dropdown. Below this is a "Label" section with a "Custom" dropdown and a text input field containing "target date", followed by a right-pointing arrow button. Further down is a section with "Line only" and "95" dropdowns. The "Formatting" section includes a "Line" dropdown with a thick black line icon, "Fill Above" and "Fill Below" dropdowns both set to "None". At the bottom is a checked checkbox labeled "Show recalculated line for highlighted or selected data points" and an "OK" button.

A set action is applied to this sheet that updates the Selected Date set based on what mark is selected in the view.

Edit Set Action

Name:

Source Sheets

☒ % change from same month prior year
☒ Difference from Prior Day
☐ Target Date
☒ Timeline
☒ YtD Sales (prior year)
☒ YtD Sales (selected year)

Run action on:

Target Set

Clearing the selection will:

☒ Keep set values
☐ Add all values to set
☐ Remove all values from set

Running Actions

Depending on how the action is created, you can run an action using one of the following three methods:

- **Hover** - Rest the pointer over a mark in the view to run the action. This option works well for highlight and filter actions within a dashboard.
- **Select** - Click on a mark in the view to run the action. This option works well for all types of actions.
- **Menu** - On Tableau Desktop, right-click (control-click on Mac) a selected mark in the view and then select an option on the context menu. On Tableau Server or Tableau Cloud, left-click (click on Mac) on a selected mark in the view to see the context menu. This option works well for filter and URL actions.

Hover

Select

Menu

Links are not always visible for every worksheet and mark. Because links are mapped to specific fields in the data source, links will only be available for the worksheets that use the mapped fields. For example, if you add a hyperlink that uses both Latitude and Longitude as parameters in the link, the link will only be available to worksheets that use Latitude and Longitude in the view. Additionally, the link is only available on marks and headers that contain relevant values.

Actions and Dashboards

Because a dashboard can contain multiple views, a single filter or highlight action can have broad impact. Dashboards can also contain web page objects, which you can target with interactive URL actions.

Use a single view to filter other views in a dashboard

Imagine you have a dashboard that contains three views about profitability: a map, a bar chart, and a table of customer names. You can use a filter action to make one of the views in your dashboard, such as the map, the controlling view for the filter action. When your users select a region in the map, the data in the other views is filtered so that it relates to just that region.

1. On the dashboard, select the view you want to use as a filter.
2. In the shortcut menu of the view, choose **Use as Filter**. You can perform the same action by clicking the Use as Filter icon .

You can also use filter actions to filter the data on a dashboard when the data comes from multiple data sources. For more information, see [Filtering Across Multiple Data Sources Using a Parameter](#) in the Tableau Knowledge Base.

For more information about filter actions, see [Filter Actions](#) on page 1396.

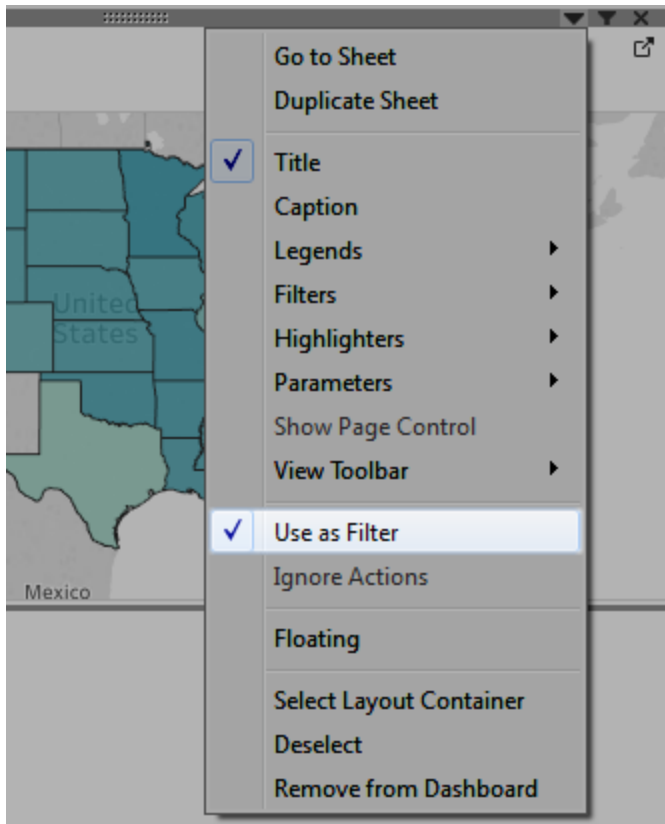

Use multiple views to filter other views in a dashboard

Just as you can use a single view to filter other views in a dashboard, you can also use multiple views as a filter. The trick is to not only use these views as filters, but to also disable their ability to be filtered themselves.

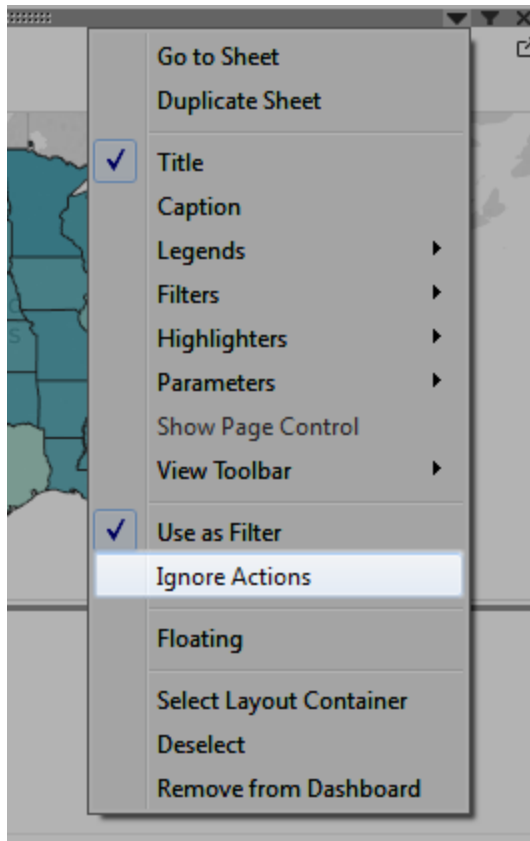

1. Create or open a dashboard that has at least three views.

2. Select the first view that you want to use as a filter (such as a map), and from its shortcut menu, select **Use as Filter**.

3. Open the same view's shortcut menu again and select **Ignore Actions**. This ensures that other filter actions, including the one you'll create next, will not affect this view.

4. Repeat the steps 2 and 3 for any other views you want to use as a filter.

Now, selecting marks in these controlling views filters data in one or more detail views – all without affecting any other controlling views.

Navigate from one view to another view, dashboard or story

Use the Go to Sheet action to let users quickly navigate to a related visualisation – a dashboard, sheet, or story – when they click on a mark or a tooltip menu item in the original view.

Note: To simply navigate from one dashboard to another, without requiring users to interact with data, consider using [the Navigation object](#).

1. From your dashboard, select **Dashboard > Actions**.
2. In the Actions dialog box, click **Add Action** and then select **Go to Sheet**.

3. Specify a name for the action. (If you choose to run the action using a tooltip menu, the name you specify here is what the tooltip displays.)

4. Select a source sheet that will initiate the action.
5. Specify how people viewing your dashboard will run the action. **Select** or **Menu** are the best choices for a navigation action.

If you choose **Select**, consider selecting **Single-select only** so users won't navigate away from the view when multiple marks are selected.

6. For the target sheet, select the navigation destination that appears when users click marks or tooltip menu items in the source sheet. Then click **OK**.

Interactively display a web page in a dashboard (Create in Tableau Desktop)

To interactively display information from the web inside a dashboard, you can use a URL action with a web page object. For example, you might have a dashboard that shows profits by country. In addition to showing the profit data in your dashboard, you also want to display supplemental information about the countries from a web site.

Tip: To easily organise and target multiple web page objects in a dashboard, **rename them**.

1. Drag a **Web Page** object onto your dashboard, and enter a URL.

2. From your dashboard, select **Dashboard > Actions**.
3. In the Actions dialog box, click **Add Action** and then select **Go to URL**.
4. Specify a name for the link. If you choose to run the action using a menu, such as a menu option on a tooltip, the name you specify here is what's displayed.

5. Under Source Sheets, select the view or data source that will initiate the action. For example, if you want the action to be initiated when a user clicks a link on a map's tooltip, select the map view.
6. Specify whether people viewing your dashboard will run the action on hover, select, or menu. For details, see [Running Actions on page 1469](#).
7. Enter the URL, starting with the http:// or https:// prefix, such as `http://www.example.com`.

You can use field values as parameters in your URL. For example, if Country is a field used by a view in your dashboard, you can use `<Country>` as a parameter in your URL. For details, see [URL Actions on page 1412](#).

8. For URL Target, select **Web Page Object**, and select the object you created in step 1.

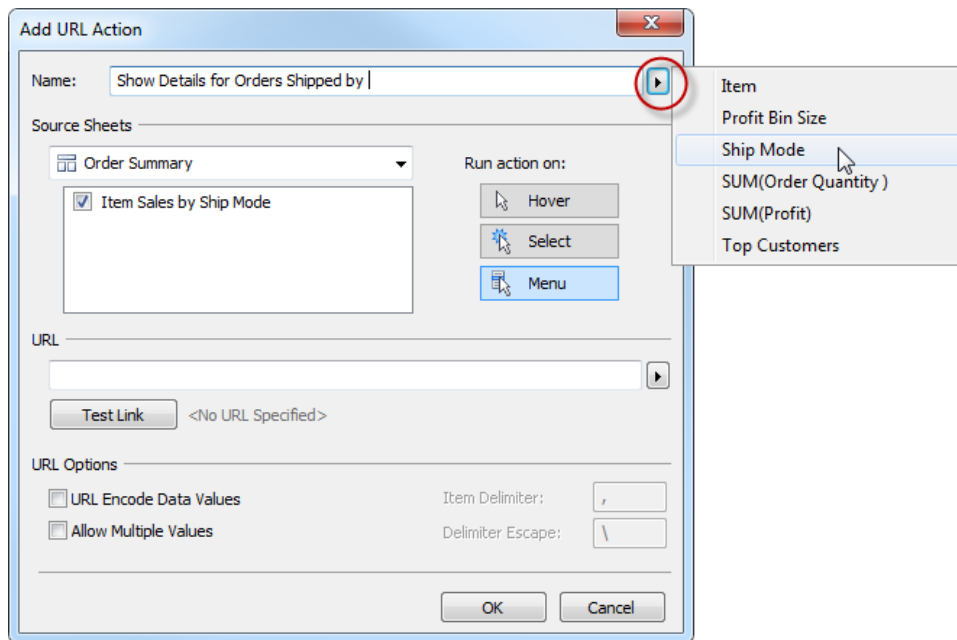

When you launch the action, a web page automatically loads within the dashboard rather than opening a separate browser window.

Using Field and Filter Values in Action Names

In addition to using field, parameter, and filter values in URLs, you can use this information as variables in the action names. The name of the action displays on the context menu when an action is launched using the menu. Using field and filter variables in the name is useful in making the action specific to the selected mark. In a view showing real estate information, you could name a URL action that points at satellite images from an online mapping service, “Show satellite image of <Address>”. When you right-click (control-click on Mac) a specific mark, the <Address> tag is replaced with the location value associated with that mark.

1. In the Add Action dialog box, begin typing the name for the action.
2. Place the cursor where you want to insert the field or filter value.
3. Click the arrow to the right of the text box and select the field or filter you want to add as a variable. The field or filter name is added between angle brackets.

Here's a finished example for an action run from a tooltip menu:

Build Common Chart Types in Data Views

This section includes detailed exercises that guide you through the steps involved in building some common chart types in data views. All exercises use the **Sample - Superstore** data source, which is included with Tableau Desktop. This collection of topics is just a sample of the many types of data views that you can create in Tableau. For details on options for building views from scratch, see [Build Data Views from Scratch on page 1197](#) and [Build a Basic View to Explore Your Data on page 3](#).

Create an Area Chart

An area chart is a line chart where the area between the line and the axis are shaded with a colour. These charts are typically used to represent accumulated totals over time and are the conventional way to display stacked lines.

The basic building blocks for an area chart are as follows:

- **Mark type:** Area
- **Columns shelf:** Dimension
- **Rows shelf:** Measure
- **Colour:** Dimension

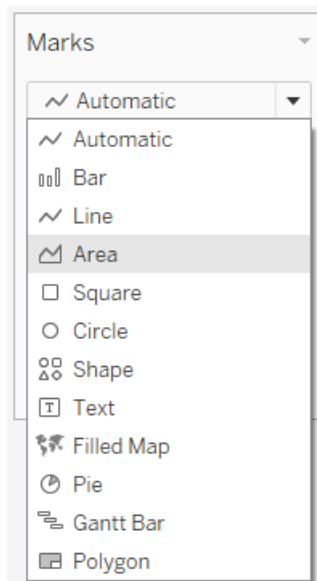

To create an area chart, follow these steps:

1. Connect to the **Sample - Superstore** data source (if necessary, you can download it from the [Tableau Public sample data page](#)).
2. Navigate to a new worksheet.
3. From the **Data** pane, drag **Order Date** to the **Columns** shelf.

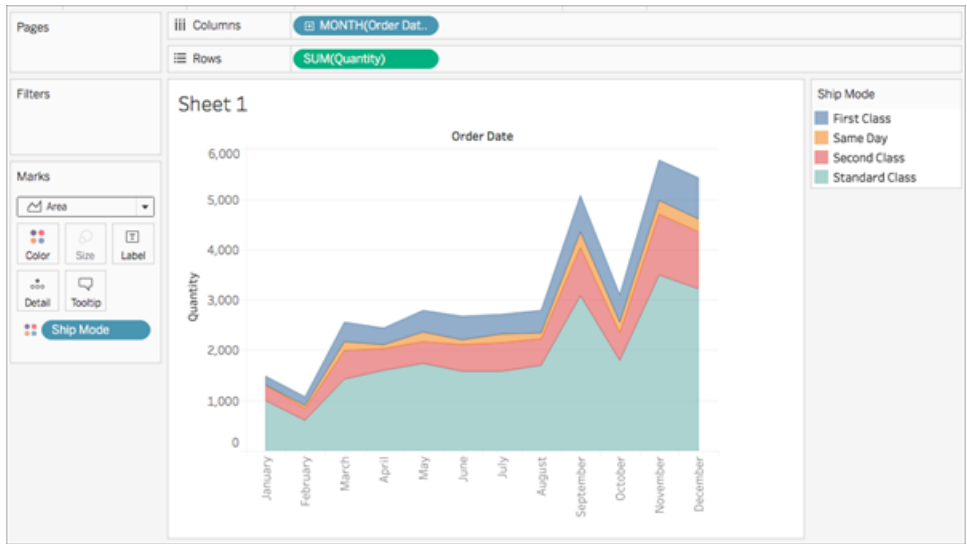

4. On the Columns shelf, right-click **YEAR(Order Date)** and select **Month**.

5. From the **Data** pane, drag **Quantity** to the **Rows** shelf.
6. From the **Data** pane, drag **Ship Mode** to **Colour** on the Marks card.
7. On the Marks card, click the Mark Type drop-down and select **Area**.

The visualisation updates to the following:

You can add formatting to an area chart. For example, you can edit the colour legend and turn on mark labels and borders. For more information, see [Format at the Worksheet Level on page 2932](#).

You can also use highlight actions with area charts. For example, selecting a colour in the legend or turning on the highlighter will highlight the entire area instead of just the line. For more information, see [Highlight Actions on page 1401](#).

Build a Bar Chart

Use bar charts to compare data across categories. You create a bar chart by placing a dimension on the **Rows** shelf and a measure on the **Columns** shelf, or vice versa.

A bar chart uses the **Bar** mark type. Tableau selects this mark type when the data view matches one of the two field arrangements shown below. You can add additional fields to these shelves. For more information about the **Bar** mark type, see [Bar mark on page 1250](#).

Creates Vertical Bars

Creates Horizontal Bars

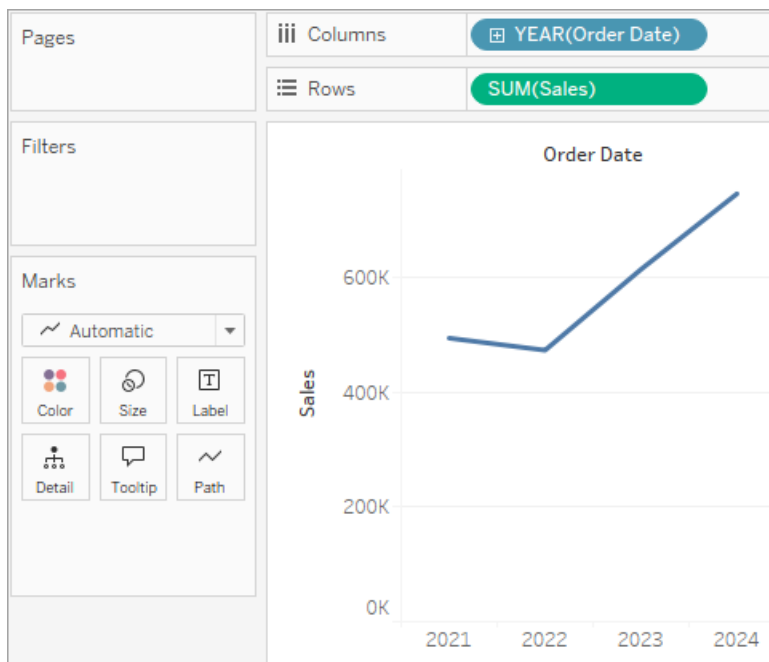

To create a bar chart that displays total sales over a four-year period, follow these steps:

Note: At the end of the procedure, there is an extra step you can take to display totals at the tops of the bars.

1. Connect to the **Sample - Superstore** data source (if necessary, you can download it from the [Tableau Public sample data page](#)).
2. Drag the **Order Date** dimension to **Columns** and drag the **Sales** measure to **Rows**.

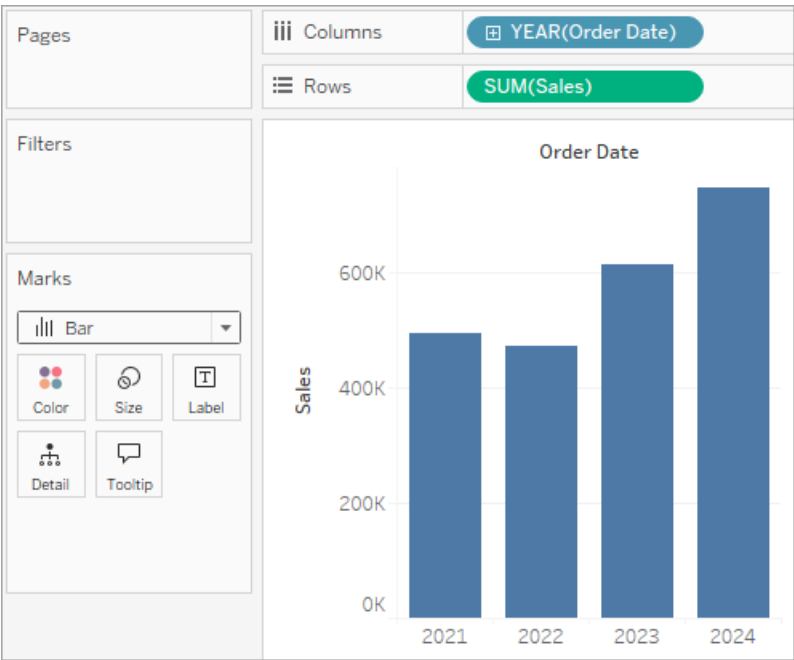

Notice that the data is aggregated by year and column headers appear. The Sales measure is aggregated as a sum and an axis is created, while the column headers move to the bottom of the view. Tableau uses **Line** as the mark type because you added the date dimension.

3. On the **Marks** card, select **Bar** from the drop-down list.

The view changes to a bar chart.

The marks (which are bars in this case) are vertical because the axis is vertical. The length of each mark represents the sum of the sales for that year. The actual numbers you see here might not match the numbers you see – the sample data changes from time to time.

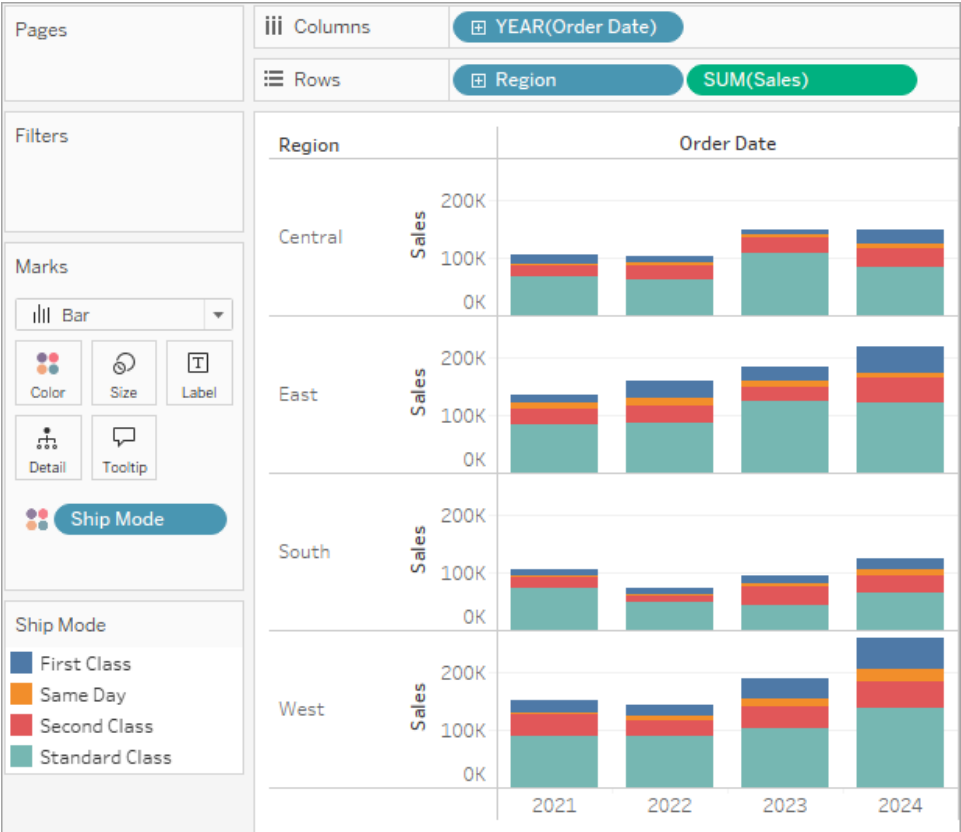

4. Drag the **Ship Mode** dimension to **Colour** on the **Marks** card.

The view shows how different dispatch modes have contributed to total sales over time. The ratios look consistent from year to year.

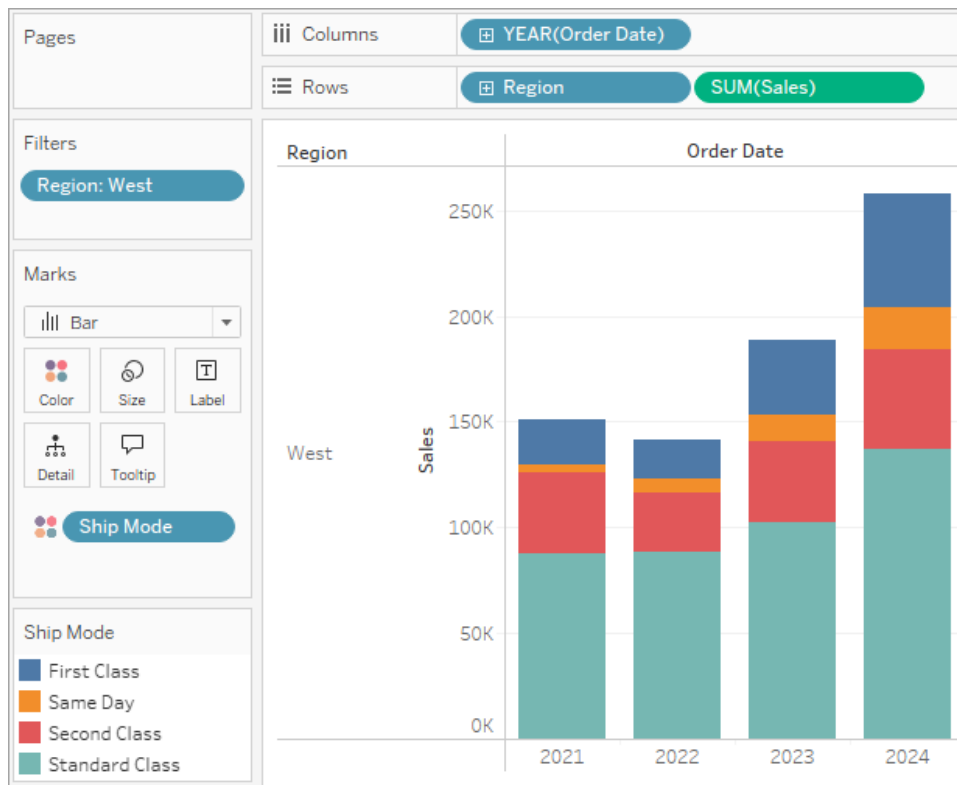

5. Drag the **Region** dimension to **Rows**, and drop it to the left of **Sales** to produce multiple axes for sales by region.

6. To view data in the West region only, you can filter out the other regions. To do this, drag the **Region** dimension again, this time from the **Data** pane to the **Filters** shelf.

7. In the Filter [Region] dialog box, clear the **Central**, **East** and **South** tick boxes, and then click **OK**.

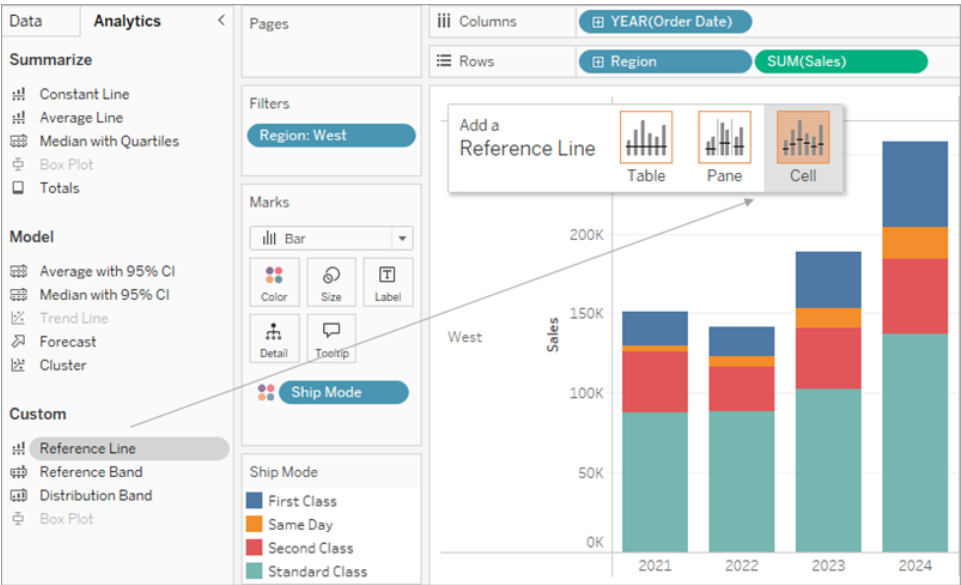

This view gives you insight into your data – for example, how the dispatch mode has changed in the West over the four-year period.

One Step Further: Add Totals To Stacked Bars

Adding totals to the tops of bars in a chart is sometimes as simple as clicking the **Show Mark Labels** icon in the toolbar. But when the bars are broken down by colour or size, each individual segment would be labelled, rather than the total for the bar. With a few steps, you can add a total label at the top of every bar even when the bars are subdivided, as in the view you just created. In the following procedure you will technically be adding a reference line. But by configuring that "line" in a certain way, you end up with the labels you want.

1. From the **Analytics** pane, drag a **Reference Line** into the view and drop it on **Cell**.

2. In the Edit Line, Band, or Box dialog box, set the aggregation for **SUM(Sales)** to **Sum**, set **Label** to **Value**, and set **Line** under Formatting to **None**:

The screenshot shows the **Edit Reference Line, Band, or Box** dialog box. The **Line** tab is selected. Under **Scope**, **Per Cell** is selected. Under **Line**, the **Value** is set to **SUM(Sales)**, the **Sum** aggregation is selected, the **Label** is set to **Value**, and the **Tooltip** is set to **Automatic**. Under **Formatting**, the **Line** is set to **None**, and **Fill Above** and **Fill Below** are also set to **None**.

Then click **OK** to close the Edit Reference Line, Band, or Box dialog box.

Your view now has currency totals at the top of each bar.

You may need to adjust the view to make it look just right. If the bars are too narrow, the numbers will be truncated; to correct this, press **Ctrl + Right** on the keyboard to make the bars wider. Or if you want to centre the totals over the bars – by default, they are left-aligned. Do the following:

3. Right-click any of the totals on the bar chart and select **Format**.
4. In the Format window, in the **Reference Line Label** area, open the **Alignment** control and select the Centre option for Horizontal alignment:

Other resources

Creation of a Grouped Bar Chart: A knowledge base article with embedded videos that describes how to create grouped bar charts, also known as side-by-side bar charts.

Build a Box Plot

Use box plots, also known as box-and-whisker plots, to show the distribution of values along an axis.

Boxes indicate the middle 50 percent of the data (that is, the middle two quartiles of the data's distribution). You can configure lines, called *whiskers*, to display all points within 1.5 times the interquartile range (in other words, all points within 1.5 times the width of the adjoining box), or all points at the maximum extent of the data, as shown in the following image:

The basic building blocks for a box and whisker plot are as follows:

- **Mark type:** Circle
- **Columns shelf:** Dimension
- **Rows shelf:** Measure
- **Detail:** Dimension
- **Reference Line:** Box Plot. For information on how to add a reference line, see [Reference Lines, Bands, Distributions and Boxes on page 2467](#).

To create a box plot that shows discounts by region and customer segment, follow these steps:

1. Connect to the **Sample - Superstore** data source (if necessary, you can download it from the [Tableau Public sample data page](#)).
2. Drag the **Segment** dimension to **Columns**.
3. Drag the **Discount** measure to **Rows**. Tableau creates a vertical axis and displays a bar chart – the default chart type when there is a dimension on the **Columns** shelf and a measure on the **Rows** shelf.
4. Click the **Discount** field on the Rows shelf and hover over **Measure (Sum)**, then change the aggregation to **Average**.
5. Drag the **Region** dimension to **Columns**, and drop it to the right of **Segment**. Now you have a two-level hierarchy of dimensions from left to right in the view, with regions (listed along the bottom) nested within segments (listed across the top).

6. Click **Show Me** in the toolbar, then select the box-and-whisker plot chart type.

Tableau displays the a box plot:

Notice that there are only a few marks in each box plot. Also, Tableau reassigned **Region** from the **Columns** shelf to the **Marks** card. When you changed the chart type to a box plot, Tableau determined what the individual marks in the plot should represent. It determined that the marks should represent regions. We'll change that.

7. Drag **Region** from the **Marks** card back to **Columns**, to the right of **Segment**.

The horizontal lines are flattened box plots, which is what happens when box plots are based on a single mark. Box plots are intended to show a distribution of data, and that can be difficult when data is aggregated, as in the current view.

8. To disaggregate data, select **Analysis > Aggregate Measures**. This turns aggregation on or off, and because data is aggregated by default in Tableau, the first time you select this command, it disaggregates the data. For more information, see [How to Disaggregate Data on page 180](#).

Now, instead of a single mark for each column in the view, you see a range of marks, one for each row in your data source.

The view now shows the information we want to see. The remaining steps make the view more readable and appealing.

- Click the **Swap**  button to swap the axes. The box plots now flow from left-to-right:

10. Right-click (control-click on Mac) the bottom axis and select **Edit Reference Line**.
11. In Edit Reference Line, Band, or Box dialog box, in the **Fill** drop-down list, select an interesting colour scheme.

For more on these options, see [Add a Box Plot on page 2488](#) in the **Reference Lines, Bands, Distributions and Boxes** article.

Now your view is complete:

For more information about box plots, see [Reference Lines, Bands, Distributions and Boxes on page 2467](#).

Build a Bullet Graph

A bullet graph is a variation of a bar graph developed to replace dashboard gauges and meters. A bullet graph is useful for comparing the performance of a primary measure to one or more other measures. It consists of one measure forming the bars and a second measure represented as a reference line with distribution bands. For more information on how to construct or read a bullet graph, see [Bullet Graphs](#) on Tableau's website. Below is a single bullet graph showing how inbound tourism compares to outbound tourism.

The basic building blocks for a bullet graph are as follows:

- **Mark type:** Bar (or automatic)
- **Columns shelf:** First measure
- **Rows shelf:** Dimension
- **Detail and reference line with distribution bands:** Second measure

Follow these steps to create a bullet graph:

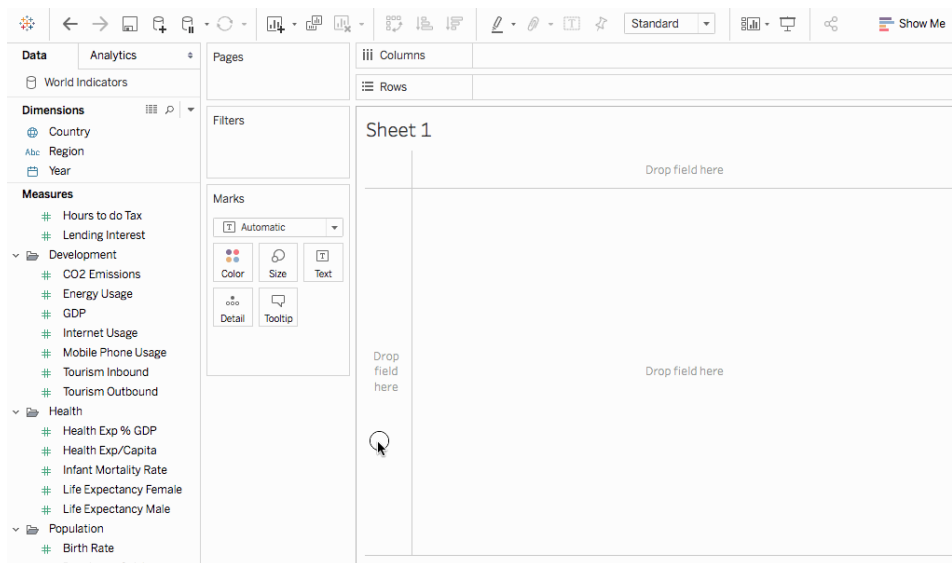

1. Connect to the **World Indicators** data source.
2. Navigate to a new worksheet.
3. In the **Data** pane, in the **Development** folder, multi-select the fields **Tourism Inbound** and **Tourism Outbound** (hold down the Shift key to select multiple fields).
4. In the top right of the toolbar, select **Show Me**.
5. In Show Me, choose **Bullet Graph**.
6. Click **Show Me** again to close it.

7. From the **Data** pane, drag **Region** to the **Rows** shelf.

The graph updates to look like the following:

Check your work! Watch steps 3 - 7 below:

Note: In Tableau 2020.2 and later, the Data pane no longer shows Dimensions and Measures as labels. Fields are listed by table or folder.

Swap reference line fields

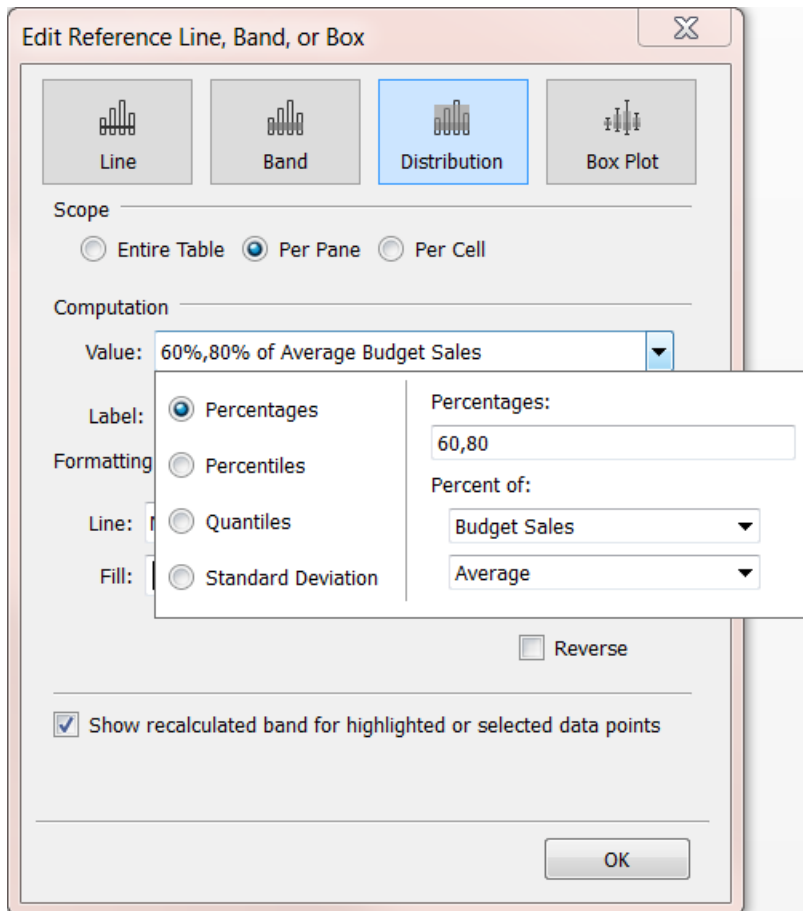

Sometimes you might want to swap the reference lines fields. For example, the inbound tourism is shown as a reference distribution instead of a bar.

To swap the two measures, right-click (control-click on the Mac) the axis and select **Swap Reference Line Fields**.

Edit the distribution

Right-click (control-click on the Mac) the axis in the view and select **Edit Reference Line**, and then select one of the reference lines to modify.

Build with Density Marks (Heatmap)

Use density chart to visualise patterns or trends in dense data with many overlapping marks. Tableau does this by grouping overlaying marks, and colour-coding them based on the number of marks in the group.

Density maps help you identify locations with greater or fewer numbers of data points.

In Tableau, you can create a chart using the density mark by placing at least one continuous measure on the Columns shelf, and at least one dimension or measure on the Rows shelf (or vice versa), and then adding a field to the Marks card.

Note: Density charts work best when used with data sources containing many data points.

The basic building blocks for a density chart are as follows:

- **Mark type:** Density
- **Rows and Columns shelves:** At least one continuous measure, and at least one measure or dimension
- **Marks card:** At least one continuous measure

Density charts use the **Density** mark type. By default, Tableau will use the automatic mark type.

To show how density charts can help make sense of overlapping marks in Tableau, we're going to start with a scatter plot with a large number of marks and re-create it as a density chart.

To use a density chart to see orders by date, follow these steps:

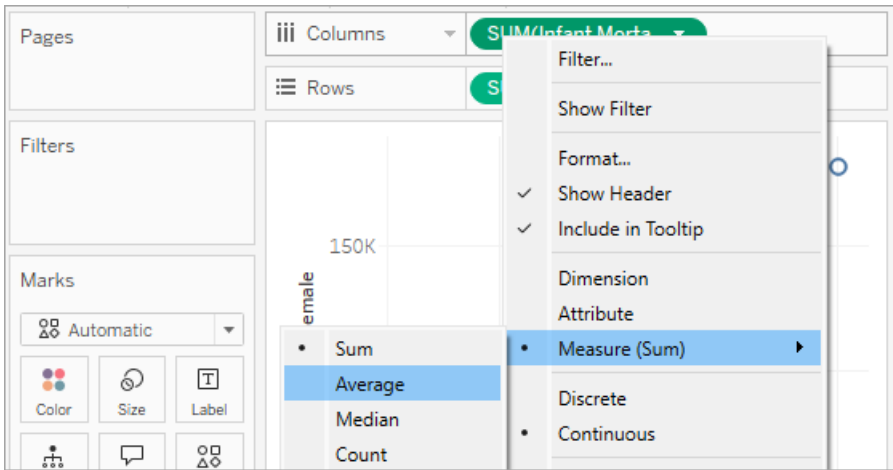

1. Open the **World Indicators** data source from the **Saved Data Sources** section of the Start screen.

2. From the Health folder, drag **Infant Mortality Rate** to the Columns shelf. Tableau aggregates the measure as a sum and creates a horizontal axis.
3. Drag the **Life Expectancy Female** to the **Rows** shelf. Now you have a one-mark scatter plot.

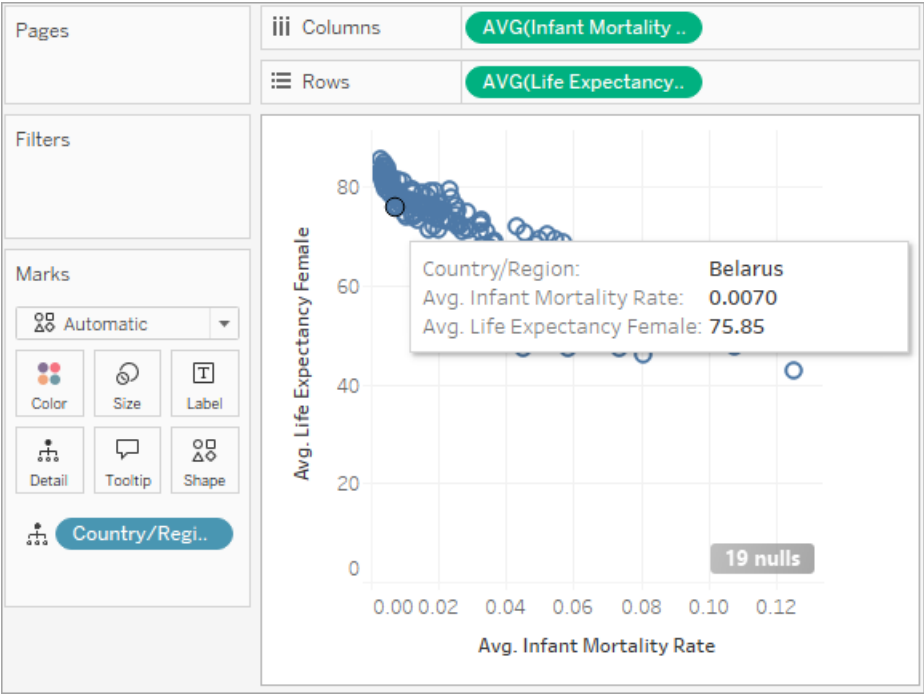

4. Both Infant Mortality and Life Expectancy are aggregated as a **Sum**, rather than average. Right-click on both of these measures and change **Measure (Sum)** to **Average**.

5. Drag the **Country/Region** dimension to **Details** on the Marks card.

Now there are many more marks in your view. The number of marks in your view is now equal to the number of distinct countries in this data set. If you hover over a mark, you can see the country name, female life expectancy and infant mortality rate.

We've created a basic scatter plot, but there are lots of overlapping marks in the view and it's hard to see where the marks are most dense.

6. On the **Marks** card, select **Density** from the menu to change this scatter plot into a density chart.

Tableau created a density chart by overlaying marks, called kernels, and colour-coding where those kernels overlap. The more overlapping data points, the more intense the colour is.

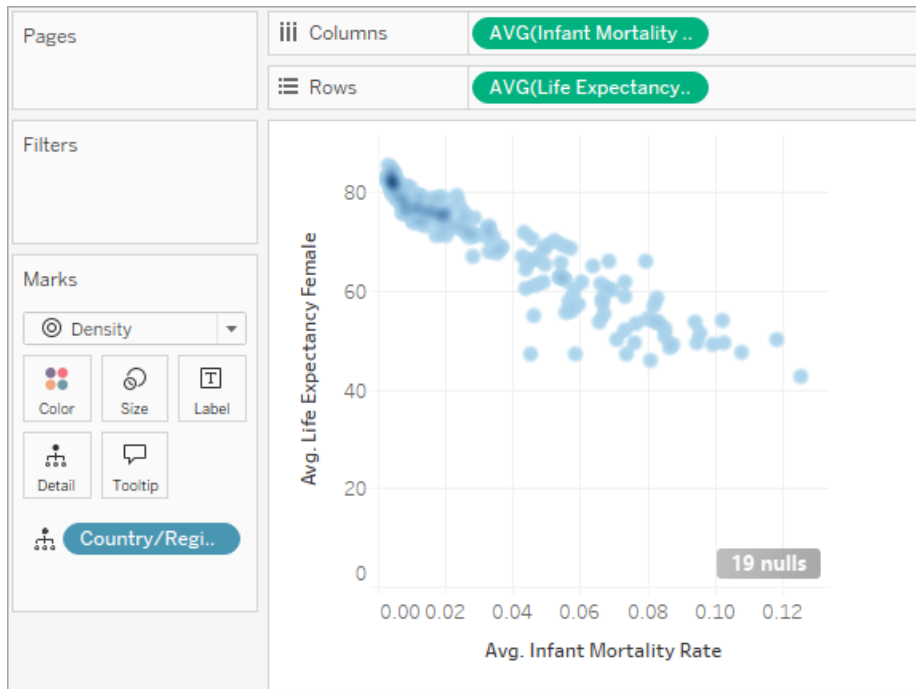

Tableau selected a blue colour palette by default, but you can choose from ten density colour palettes or any of the existing colour palettes.

7. Select **Colour** from the **Marks** card and select **Density Multi-colour Light** from the menu.

The names of the colour palettes indicate whether they're designed for use on charts with dark or light backgrounds. Since our chart has a light background, we picked a "Light" palette. This changes the colour palette on your chart. More concentrated areas will appear red, while areas without overlapping marks will appear green.

Note: Colour legends are not available for density marks.

8. In the Colour menu, use the Intensity slider to increase or decrease the vividness of the density marks. For example, increasing intensity, or vividness, lowers the "max heat" spots in your data, so that more appear.

9. Select **Size** from the Marks card to adjust the size of the density's kernel.

For more information, see [Change the Type of Mark in the View](#) on page 1245 and [Create Heatmaps that Show Trends or Density in Tableau](#) on page 1790.

Build a Gantt Chart

Use Gantt charts to show the duration of events or activities.

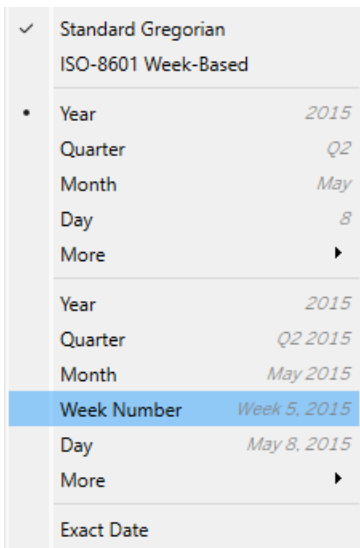

In a Gantt chart, each separate mark (usually a bar) shows a duration. For example, you might use a Gantt chart to display average delivery time for a range of products.

The basic building blocks for a gantt chart are as follows:

- **Mark type:** Automatic or Gantt Bar. For more information about the Gantt bar mark type, see [Gantt Bar mark on page 1264](#).
- **Columns shelf:** Date or Time field (continuous measure)
- **Rows shelf:** Dimension(s)
- **Size:** Continuous measure

To create a Gantt chart that shows how many days elapse on average between order date and ship date, follow these steps:

1. Connect to the **Sample - Superstore** data source (if necessary, you can download it from the [Tableau Public sample data page](#)).
2. Drag the **Order Date** dimension to **Columns**. Tableau aggregates the dates by year and creates column headers with labels for the years.
3. On the **Columns** shelf, click the **Year (Order Date)** drop-down arrow, and then select **Week Number**.

The column headers change. Individual weeks are indicated by tick marks because there are 208 weeks in a four-year span – too many to show as labels in the view.

4. Drag the **Sub-Category** and **Ship Mode** dimensions to the **Rows** shelf. Drop **Ship Mode** to the right of **Sub-Category**. This builds a two-level nested hierarchy of dimensions along the left axis.

Next, we'll size the marks according to the length of the interval between the order date and the ship date. To do this, create a calculated field to capture that interval.

7. In the toolbar menu, click **Analysis > Create Calculated Field**. You can also right-click (Control-click on Mac) any field in the **Data** pane and select **Create > Calculated Field**.
8. In the calculation dialog box, name your calculated field **OrderUntilShip**.
9. In the **Formula** box, enter the following formula and then click **OK**:

```
DATEDIFF('day',[Order Date],[Ship Date])
```

The formula creates a custom measure that captures the difference between the **Order Date** and **Ship Date** values, in days.

10. Drag the **OrderUntilShip** measure to **Size** on the **Marks** card.

The default aggregation for **OrderUntilShip** is **Sum**, but in this case it makes more sense to average the values.

11. Right-click (Control-click on Mac) the **SUM(OrderUntilShip)** field on the **Marks** card, and then select **Measure (Sum) > Average**.

The view is coming along. But there are too many marks squeezed into the view.

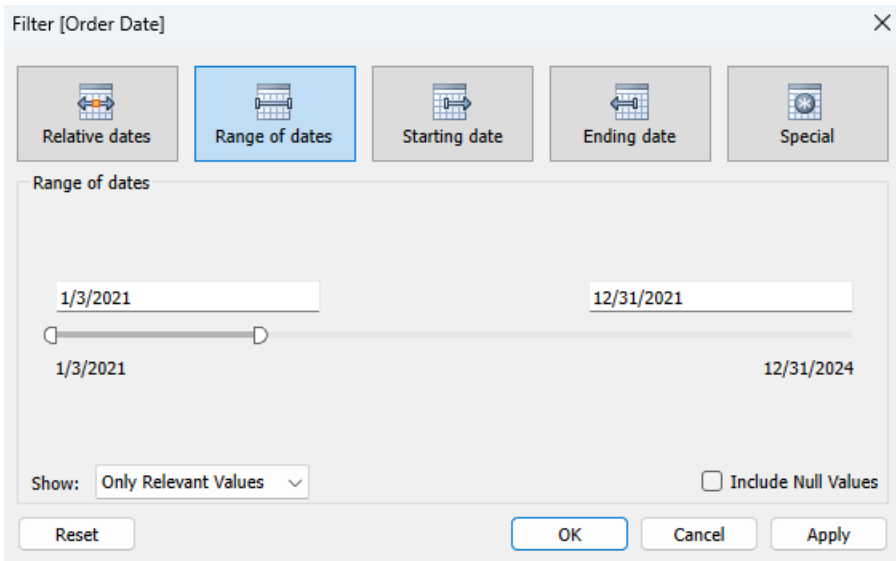

We can make our data more readable by filtering down to a smaller time window.

12. Hold down the Ctrl key (Option key on the Mac) and drag the **Week(Order Date)** field from the **Columns** shelf to the **Filter** shelf.

By holding down the Ctrl key (or the Option key), you tell Tableau that you want to copy the field to the new location, with whatever customisations you have added, without removing it from the old location.

13. In the Filter Field dialog box, select **Range of Dates** and then click **Next**.
14. Set the range to a three-month time interval, such as 1/1/2021 to 31/3/2021, and then click **OK**.

It can be difficult to get the exact date using the sliders – it's easier just to enter the numbers you want directly into the date boxes or use the calendar to select the dates.

15. Drag the **Ship Mode** dimension to **Colour** on the **Marks** card. Now your view shows you all sorts of information about the lag between order times and ship times.

For example, you can see which ship modes are more prone to longer lag times, whether lag times vary by category and whether lag times are consistent over time.

Note: If you publish this view to Tableau Server, you can include filters that let users interact with the view by varying the time window, or filtering out various sub-categories or

ship modes. For more information, see [Publish Data Sources and Workbooks on page 3113](#).

Build a Highlight Table or Heat Map

Use highlight tables to compare categorical data using colour.

In Tableau, you create a highlight table by placing one or more dimensions on the **Columns** shelf and one or more dimensions on the **Rows** shelf. You then select **Square** as the mark type and place a measure of interest on the **Colour** shelf.

You can enhance this basic highlight table by setting the size and shape of the table cells to create a heat map.

To create a highlight table to explore how profit varies across regions, product sub-categories, and customer segments, follow these steps:

1. Connect to the **Sample - Superstore** data source (if necessary, you can download it from the [Tableau Public sample data page](#)).
2. Drag the **Segment** dimension to **Columns**.

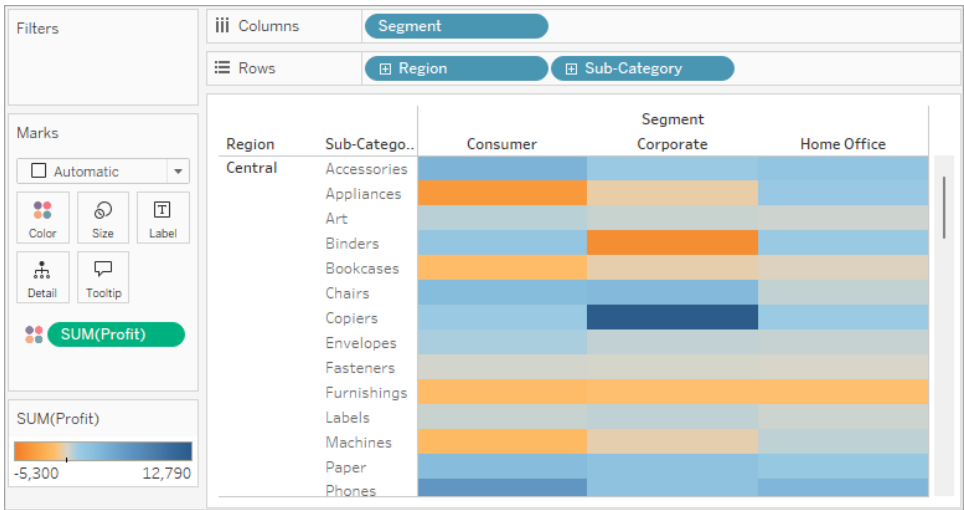

Tableau creates headers with labels derived from the dimension member names.

3. Drag the **Region** and **Sub-Category** dimensions to **Rows**, dropping **Sub-Category** to the right of **Region**.

Now you have a nested table of categorical data (that is, the **Sub-Category** dimension is nested within the **Region** dimension).

4. Drag the **Profit** measure to **Colour** on the **Marks** card.

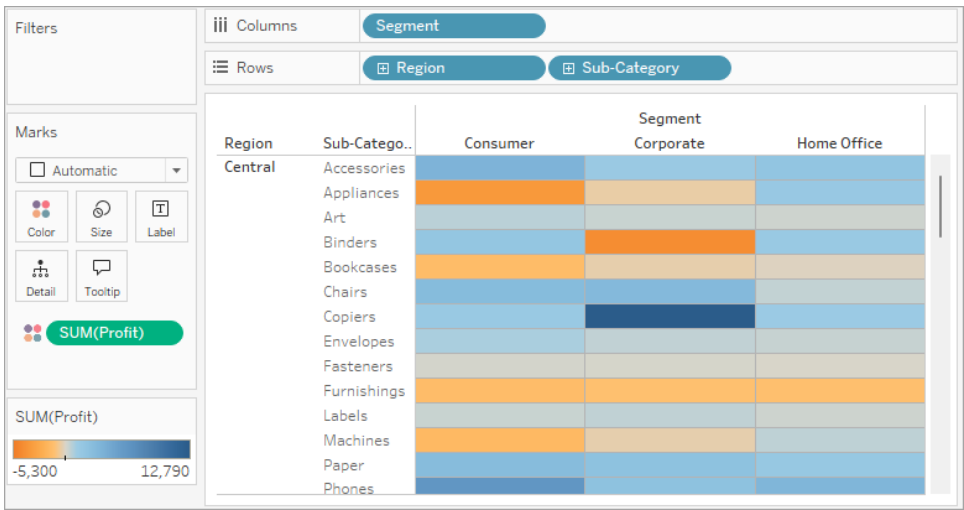

Tableau aggregates the measure as a sum. The colour legend reflects the continuous data range.

In this view, you can see data for only the Central region. Scroll down to see data for other regions.

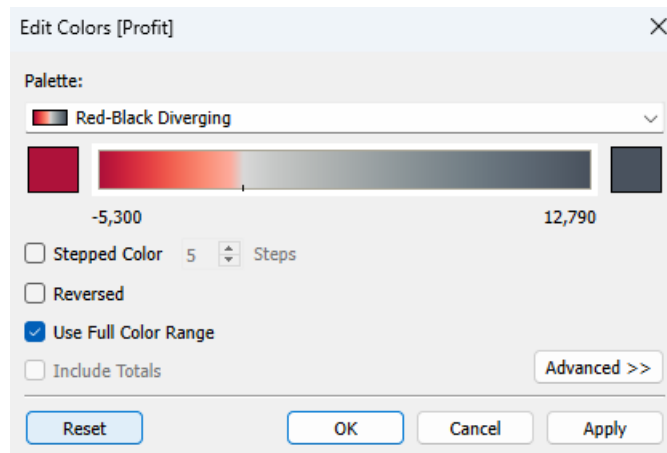

In the Central region, copiers are shown to be the most profitable sub-category (dark blue) and binders and appliances the least profitable (dark orange).

5. Click **Colour** on the **Marks** card to display configuration options. In the **Border** dropdown list, select a medium grey colour for cell borders. Now it's easier to see the individual cells in the view:

6. The default colour palette is Orange-Blue Diverging. A Red-Black Diverging palette might be more appropriate for profit. To change the colour palette and to make the colours more distinct, do the following:

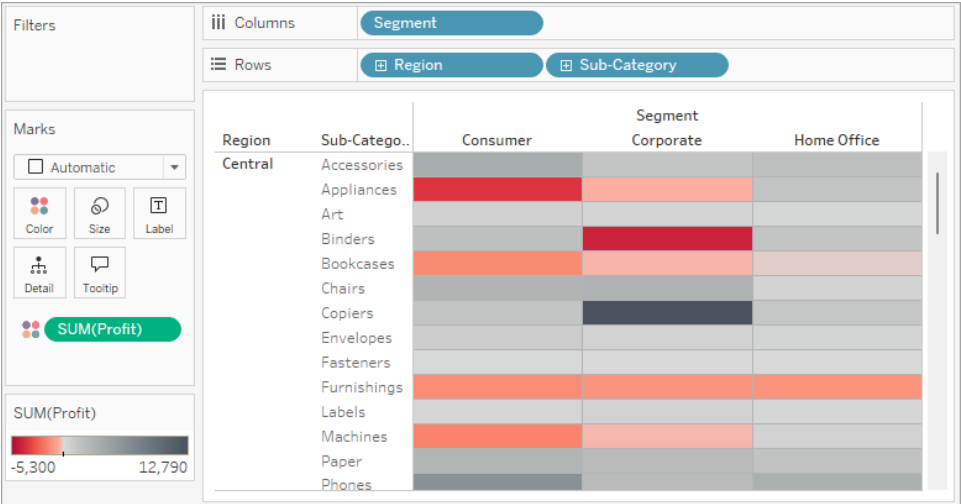

- Hover over the **SUM(Profit)** colour legend, then click the drop-down arrow that appears and select **Edit Colours**.
- In the **Edit Colours** dialog box, in the **Palette** field, select **Red-Black Diverging** from the dropdown list.
- Select the **Use Full Colour Range** tick box and click **Apply** and then click **OK**.

When you select this option, Tableau assigns the starting number a full intensity and the ending number a full intensity. If the range is from -10 to 100, the colour representing negative numbers changes in shade much more quickly than the colour representing positive numbers.

When you do not select **Use Full Colour Range**, Tableau assigns the colour intensity as if the range was from -100 to 100, so that the change in shade is the same on both sides of zero. The effect is to make the colour contrasts in your view much more distinct.

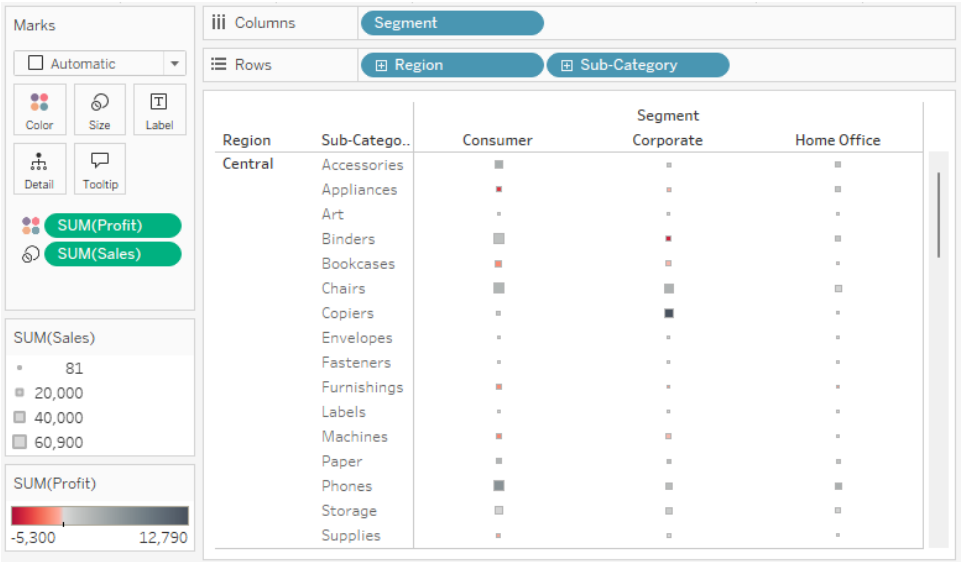

For more information about colour options, see [Colour Palettes and Effects on page 1300](#).

Modify the size to create a heat map

7. Drag the **Sales** measure to **Size** on the **Marks** card to control the size of the boxes by the Sales measure. You can compare absolute sales numbers (by size of the boxes) and profit (by colour).

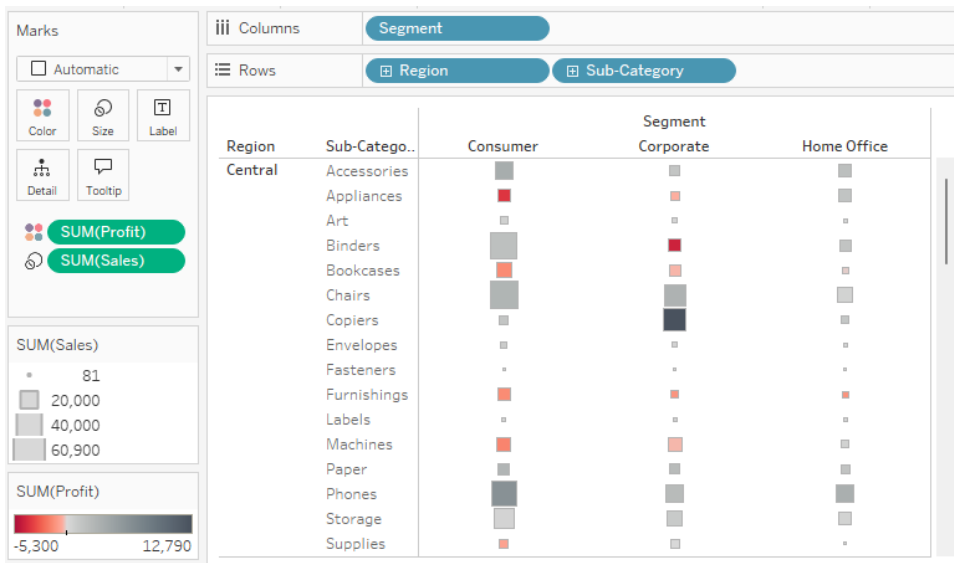

Initially, the marks look like this:

8. To enlarge the marks, click **Size** on the **Marks** card to display a size slider:

9. Drag the slider to the right until the boxes in the view are the optimal size. Now your view is complete:

Build a Histogram

A histogram is a chart that displays the shape of a distribution. A histogram looks like a bar chart but groups values for a continuous measure into ranges, or bins.

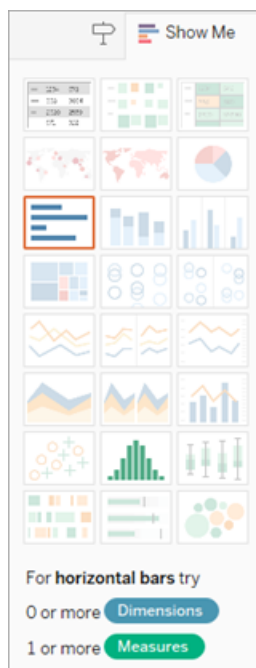

The basic building blocks for a histogram are as follows:

- **Mark type:** Automatic
- **Rows shelf:** Continuous measure (aggregated by Count or Count Distinct)

- **Columns shelf:** Bin (continuous or discrete). **Note:** *This bin should be created from the continuous measure on the Rows shelf. For more information on how to create a bin from a continuous measure, see [Create Bins from a Continuous Measure on page 1583](#).*

In Tableau you can create a histogram using **Show Me**.

1. Connect to the **Sample - Superstore** data source (if necessary, you can download it from the [Tableau Public sample data page](#)).
2. Drag **Quantity** to **Columns**.
3. Click **Show Me** on the toolbar, then select the histogram chart type. The histogram chart type is available in **Show Me** when the view contains a single measure and no dimensions.

Three things happen after you click the histogram icon in **Show Me**:

- The view changes to show vertical bars, with a continuous x-axis (1 - 14) and a continuous y-axis (0 - 5,000).
- The **Quantity** measure you placed on the **Columns** shelf, which had been aggregated as SUM, is replaced by a continuous **Quantity (bin)** dimension. (The green colour of the field on the **Columns** shelf indicates that the field is continuous.)
- The **Quantity** measure moves to the **Rows** shelf and the aggregation changes from SUM to CNT (Count).

The **Quantity** measure captures the number of items in a particular order. The histogram shows that about 4,800 orders contained two items (the second bar), about 2,400 orders contained 4 items (the third bar), and so on. The bin size is 1.77, so the bars don't align with the axis tick marks. (To see or change the bin size, in the Data pane, right-click the bin and select **Edit....**)

Let's take this view one step further and add **Segment** to **Colour** to see if we can detect a relationship between the customer segment (consumer, corporate or home office) and the quantity of items per order.

4. Drag **Segment** to **Colour**.

The colours don't show a clear trend. Let's show the percentage of each bar that belongs to each segment.

5. Hold down the Ctrl key and drag the **CNT(Quantity)** field from the **Rows** shelf to **Label**.

Holding down the Ctrl key copies the field to the new location without removing it from the original location.

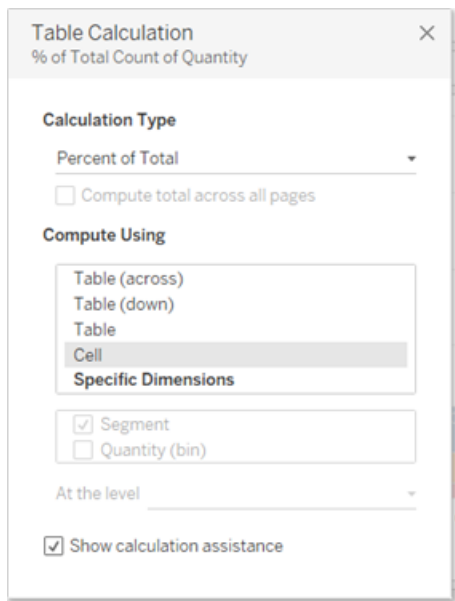

6. Right-click (Control-click on a Mac) the **CNT(Quantity)** field on the **Marks** card and select **Quick Table Calculation > Percent of Total**.

Now each coloured section of each bar shows its respective percentage of the total quantity:

But we want the percentages to be on a per-bar basis.

- Right-click the **CNT(Quantity)** field on the **Marks** card again and select **Edit Table Calculation**.
- In the Table Calculation dialog box, change the value of the **Compute Using** field to **Cell**.

Now we have the view that we want:

There's still no evidence that the percentages by customer segment show any trend as the number of items in an order increases.

Building Line Charts

Line charts connect individual data points in a view. They provide a simple way to visualise a sequence of values and are useful when you want to see trends over time, or to forecast future values. For more information about the line mark type, see [Line mark on page 1251](#).

Note: In views that use the line mark type, you can use the **Path** property in the Marks card to change the type of line mark (linear, step or jump), or to encode data by connecting marks using a particular drawing order. For details, see [Path properties](#) in the [Control the Appearance of Marks in the View on page 1268](#)

To create a view that displays the sum of sales and the sum of profit for all years, and then uses forecasting to determine a trend, follow these steps:

1. Connect to the **Sample - Superstore** data source (if necessary, you can download it from the [Tableau Public sample data page](#)).
2. Drag the **Ship Date** dimension to **Columns**. Tableau aggregates the date by year, and creates column headers.
3. Drag the **Sales** measure to **Rows**. Tableau aggregates **Sales** as SUM and displays a simple line chart.

4. Drag the **Profit** measure to **Rows** and drop it to the right of the **Sales** measure. Tableau creates separate axes along the left margin for **Sales** and **Profit**.

Notice that the scale of the two axes is different – the **Sales** axis scales from \$0 to \$700,000, whereas the **Profit** axis scales from \$0 to \$100,000. This can make it hard to see that sales values are much greater than profit values.

When you are displaying multiple measures in a line chart, you can align or merge axes to make it easier for users to compare values.

- For more information about aligning the axes, see [Compare two measures using dual axes](#) on page 1212.
- For more information about enforcing a single axis across multiple measures, see [Blend axes for multiple measures into a single axis](#) on page 1210.

With either of these options, you can create a combination chart to change the mark type for one of your measures. For more information, see [Create a combo chart \(assign different mark types to measures\)](#) on page 1216.

5. Drag the **SUM(Profit)** field from **Rows** to the **Sales** axis to create a blended axis. The two pale green parallel bars indicate that **Profit** and **Sales** will use a blended axis when you release the mouse button.

The view updates to look like this:

The view is rather sparse because we are looking at a summation of values on a per-year basis. Additionally, the trend seems to dip at the end because there is limited data for 2025.

- Click the drop-down arrow in the **YEAR([Ship Date])** field on the **Columns** shelf and select **Month** in the lower part of the context menu to see a continuous range of values over the four-year period.

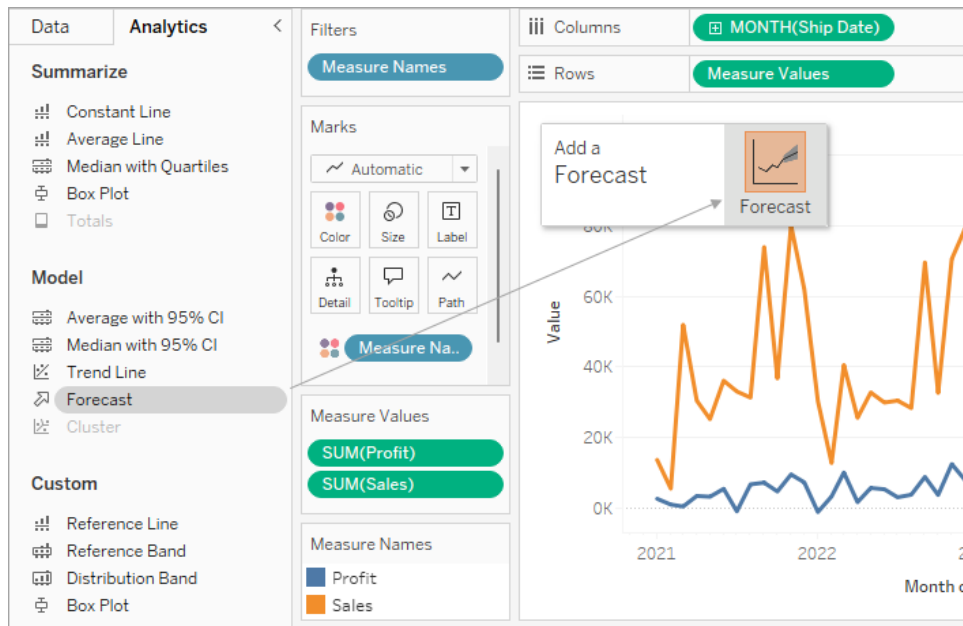

| | | |
|---|---------------------|--------------|
| ✓ | Standard Gregorian | |
| | ISO-8601 Week-Based | |
| • | Year | 2015 |
| | Quarter | Q2 |
| | Month | May |
| | Day | 8 |
| | More | ► |
| | Year | 2015 |
| | Quarter | Q2 2015 |
| | Month | May 2015 |
| | Week Number | Week 5, 2015 |
| | Day | May 8, 2015 |
| | More | ► |
| | Exact Date | |

The resulting view is a lot more detailed than the original view:

Notice that the values seem to go much higher just before the end of each year. A pattern like that is known as *seasonality*. If we turn on the forecasting feature in the view, we can see whether we should expect that the apparent seasonal trend will continue in the future.

7. To add a forecast, in the **Analytics** pane, drag the **Forecast** model to the view, and then drop it on **Forecast**.

We then see that, according to Tableau forecasting, the seasonal trend does continue into the future:

Build a Packed Bubble Chart

Use packed bubble charts to display data in a cluster of circles. Dimensions define the individual bubbles, and measures define the size and colour of the individual circles.

The basic building blocks for a packed bubble chart are as follows:

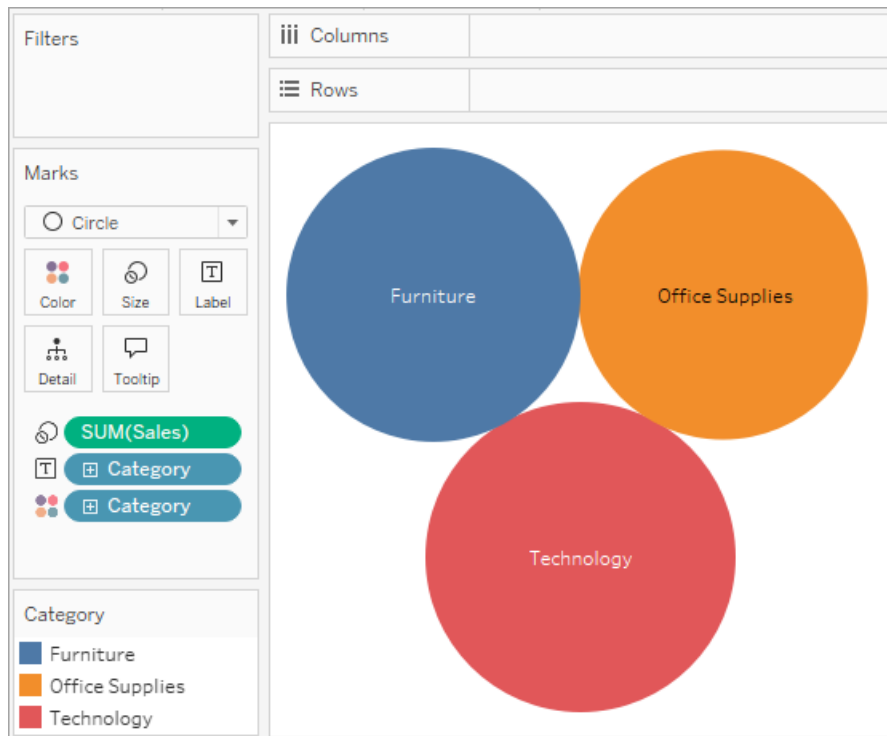

- **Mark type:** Circle
- **Detail:** Dimension
- **Size:** Measure
- **Colour:** Dimension or Measure
- **Label (optional):** Dimension or Measure

To create a basic packed bubble chart that shows sales and profit information for different product categories, follow these steps:

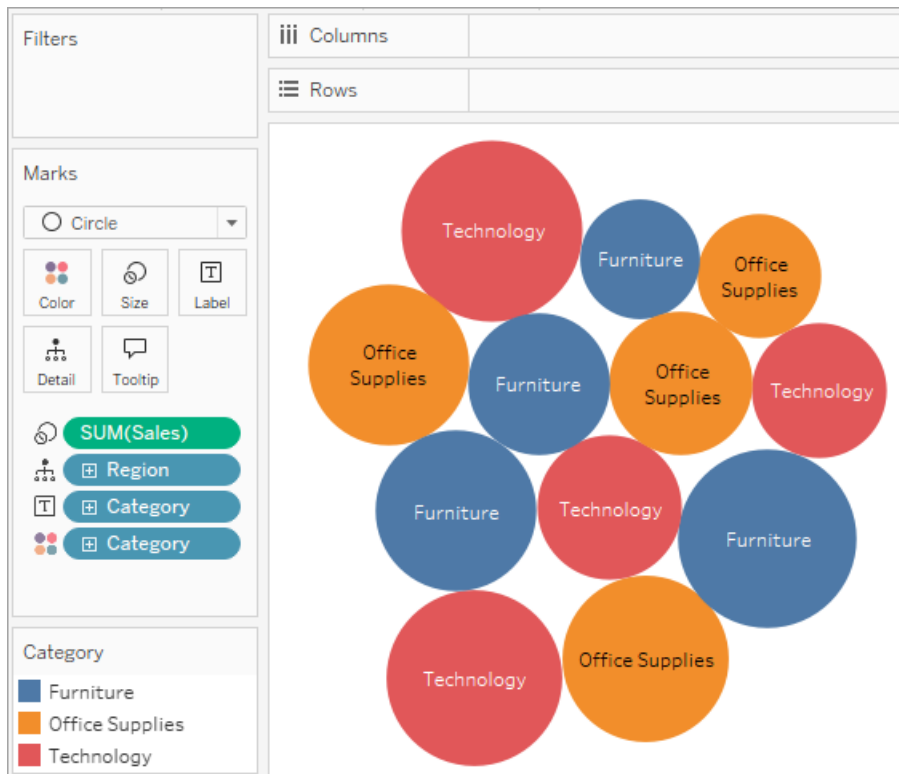

1. Connect to the **Sample - Superstore** data source (if necessary, you can download it from the [Tableau Public sample data page](#)).
2. Drag the **Category** dimension to **Columns**. A horizontal axis displays product categories.
3. Drag the **Sales** measure to **Rows**. The measure is aggregated as a sum and a vertical axis appears. Tableau displays a bar chart – the default chart type when there is a dimension on the **Columns** shelf and a measure on the **Rows** shelf.
4. Click **Show Me** on the toolbar, then select the packed bubbles chart type.

Tableau displays the following packed bubble chart:

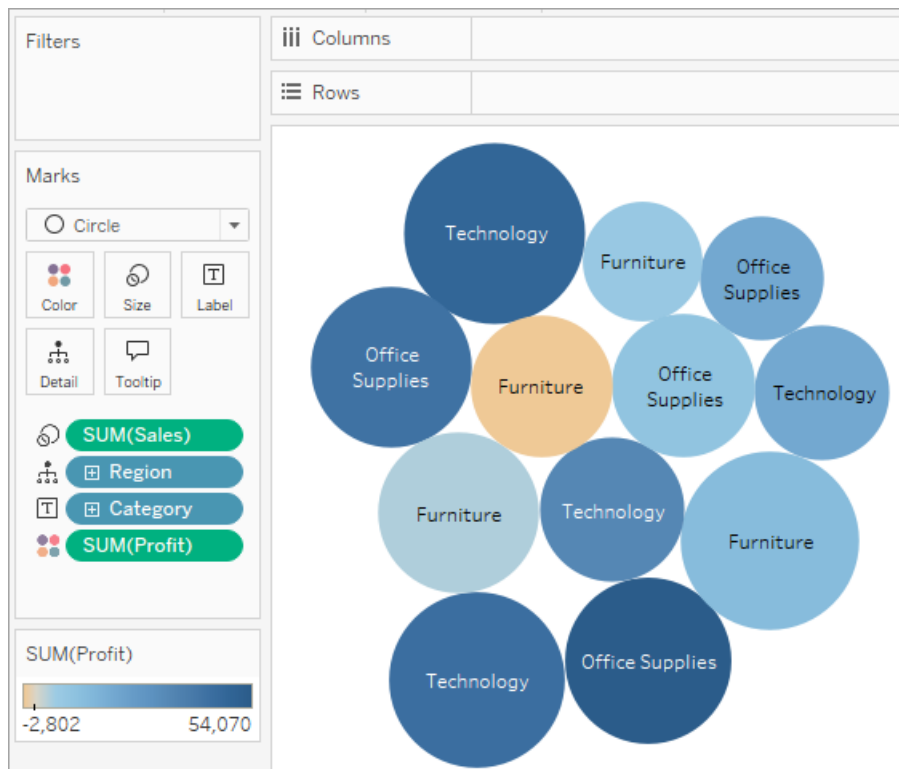

5. Drag **Region** to **Detail** on the **Marks** card to include more bubbles in the view.

Next we'll add another layer of information to the view.

6. Drag **Profit** to **Colour** on the **Marks** card:

7. Drag **Region** to **Label** on the **Marks** card to clarify what each bubble represents.

The size of the bubbles shows the sales for different combinations of region and category. The colour of the bubbles shows the profit (the darker the blue, the greater the profit).

For information about formatting mark labels, see [Show, Hide and Format Mark Labels](#) on page 1291.

To further develop this view, you might edit the colours for **Profit** to show negative profit in a different colour, or create a calculated field to show profit divided by sales (that is, profit margin) and then drop that on **Colour** instead of absolute profit. For more information, see [Colour Palettes and Effects](#) on page 1300.

Build a Pie Chart

Use pie charts to show proportions of a whole. It's a best practice to only use pie charts with a small number of slices.

The basic building blocks for a pie chart are as follows:

- **Mark type:** Pie
- **Colour:** Dimension.
 - Each member of the dimension is represented as a slice or wedge in the pie. Try to use a dimension with no more than five unique values.
- **Angle:** Measure. The **Angle** property appears on the Marks card when the mark type is set to Pie.

To create a pie chart view that shows how different product categories contribute to total profit, follow these steps:

1. Connect to the **Sample - Superstore** data source (if necessary, you can download it from the [Tableau Public sample data page](#)).
2. Drag the **Profit** measure to **Columns** and drag the **Category** dimension to **Rows**.

Tableau aggregates the **Sales** measure as a sum. By default, Tableau displays a bar chart.

3. Click **Show Me** on the toolbar, then select the pie chart type. Pie charts require at least one dimension and one or two measures. Aggregate fields, such as Profit Ratio, don't contribute to those requirements.

Three things happen after you click the pie icon in Show Me:

- The mark type changes to **Pie**.
- The **Profit** measure you placed on the **Columns** shelf, which had been aggregated as SUM, moves to both the **Size** and **Angle** properties on the Marks card.
- The **Category** dimension you placed on the **Rows** shelf moves to the **Colour** property on the Marks card.

The result is a rather small pie. To make the chart bigger:

- a. Navigate to the Fit menu in the toolbar and select **Entire View**.
 - b. Click the **Size** property on the Marks card and drag the slider until the pie chart is the size you want.
4. Add labels by dragging the **Category** dimension from the **Data** pane to **Label** on the **Marks** card.

Note: Pie charts can also be used as a mark type in a visualisation. For more information, see [Pie mark on page 1263](#).

Build a Scatter Plot

Use scatter plots to visualise relationships between numerical variables.

In Tableau, you create a scatter plot by placing at least one measure on the **Columns** shelf and at least one measure on the **Rows** shelf. If these shelves contain both dimensions and measures, Tableau places the measures as the innermost fields, which means that measures are always to the right of any dimensions that you have also placed on these shelves. The word "innermost" in this case refers to the table structure.

Creates Simple Scatter Plot

| | |
|---------|-------------|
| Columns | SUM(Sales) |
| Rows | SUM(Profit) |

Creates Matrix of Scatter Plots

| | | |
|---------|----------|-------------|
| Columns | Region | SUM(Sales) |
| Rows | Category | SUM(Profit) |

A scatter plot can use several mark types. By default, Tableau uses the shape mark type. Depending on your data, you might want to use another mark type, such as a circle or a square. For more information, see [Change the Type of Mark in the View on page 1245](#).

To use scatter plots and trend lines to compare sales to profit, follow these steps:

1. Open the **Sample - Superstore** data source (if necessary, you can download it from the [Tableau Public sample data page](#)).
2. Drag the **Sales** measure to **Columns**.

Tableau aggregates the measure as a sum and creates a horizontal axis.

3. Drag the **Profit** measure to **Rows**.

Tableau aggregates the measure as a sum and creates a vertical axis.

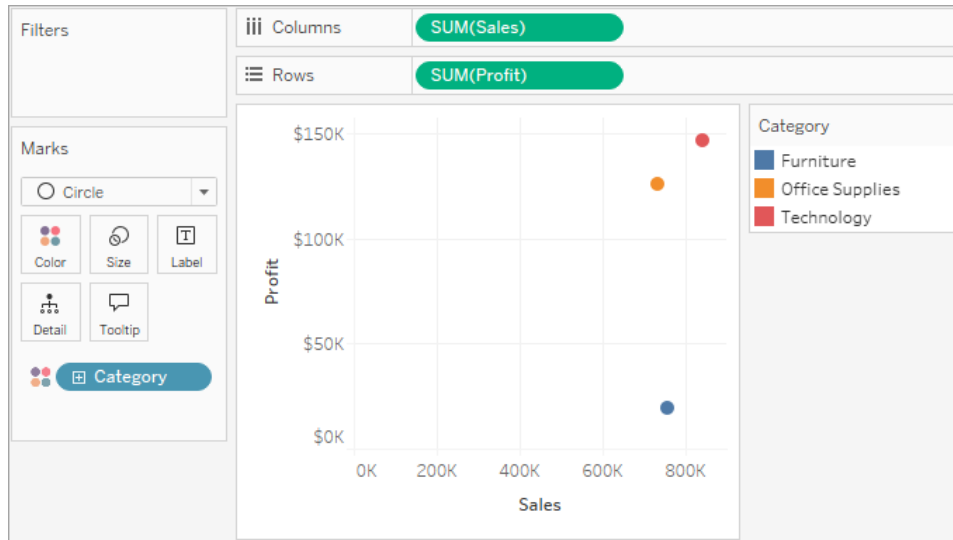

Measures can consist of continuous numerical data. When you plot one number against another, you are comparing two numbers; the resulting chart is analogous to a Cartesian chart, with x and y coordinates.

Now you have a one-mark scatter plot:

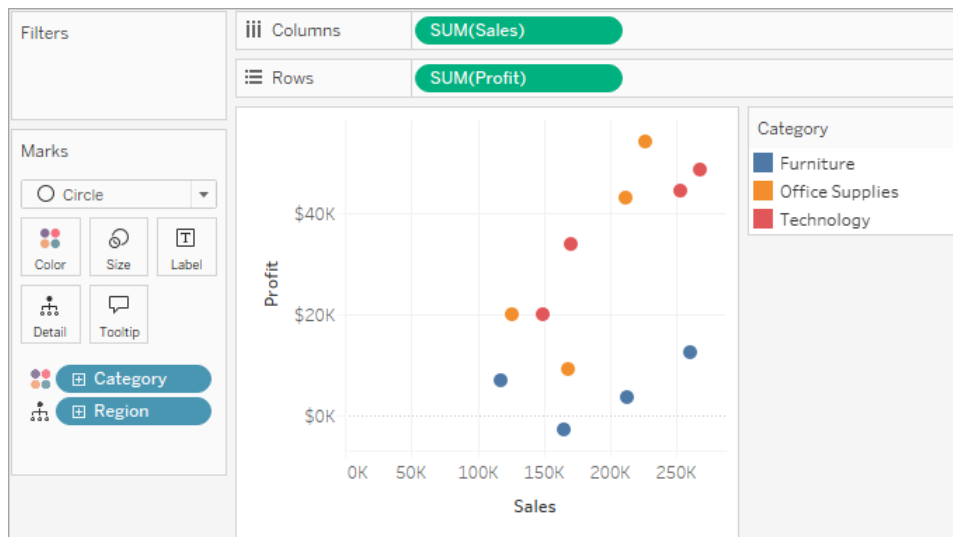

4. Drag the **Category** dimension to **Colour** on the Marks card.

This separates the data into three marks – one for each dimension member – and encodes the marks using colour.

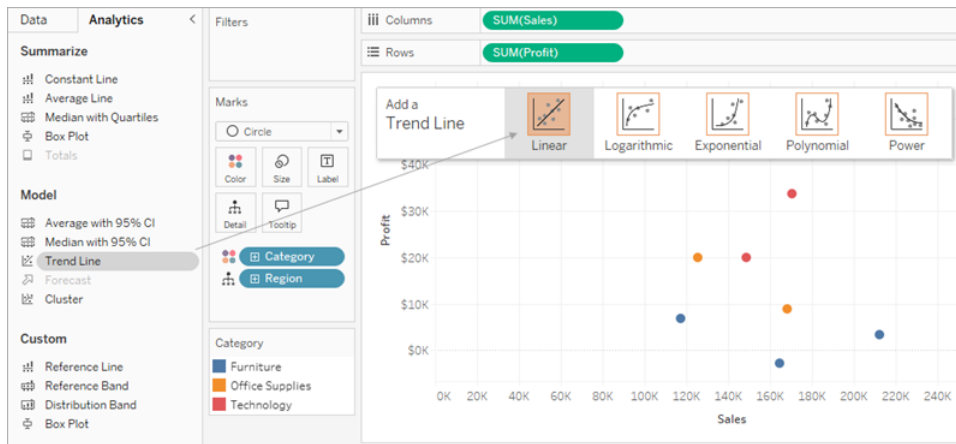

5. Drag the **Region** dimension to **Detail** on the **Marks** card.

Now there are many more marks in the view. The number of marks is equal to the number of distinct regions in the data source multiplied by the number of categories. (If you're curious, use the **Undo** button on the toolbar to see what happens if you drop the **Region** dimension on **Shape** instead of **Detail**.)

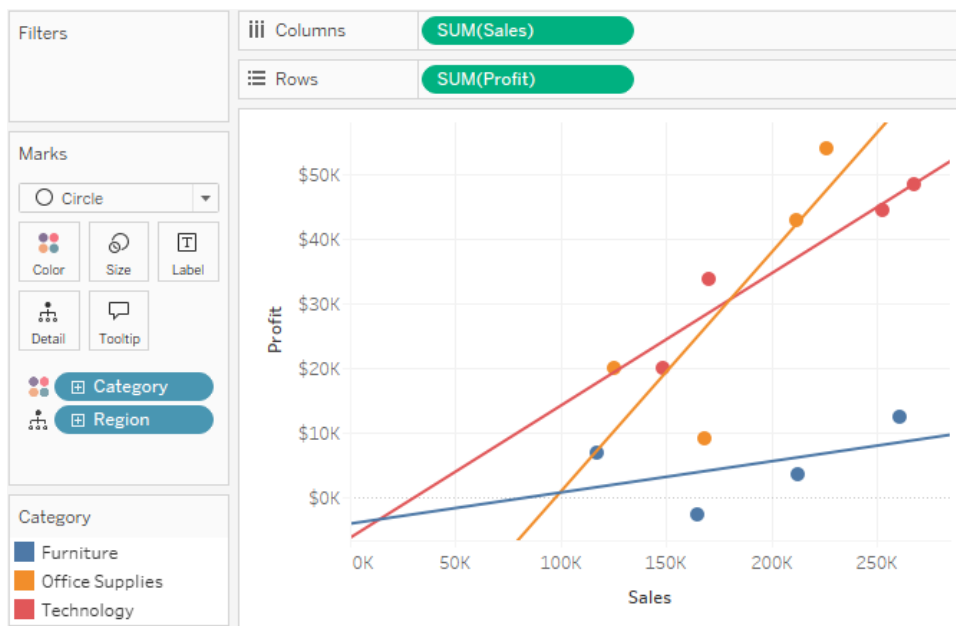

6. To add trend lines, from the **Analytics** pane, drag the **Trend Line** model to the view, and then drop it on the model type.

A trend line can provide a statistical definition of the relationship between two numerical values. To add trend lines to a view, both axes must contain a field that can be interpreted as a number – by definition, that is always the case with a scatter plot.

Tableau adds three linear trend lines – one for each colour that you are using to distinguish the three categories.

7. Hover the cursor over the trend lines to see statistical information about the model that was used to create the line:

For more information, see [Assess Trend Line Significance on page 2505](#). You can also customise the trend line to use a different model type or to include confidence bands. For more information, see [Add Trend Lines to a Visualisation on page 2493](#).

[Example: Scatter Plots, Aggregation and Granularity on page 181](#)

Build a Text Table

In Tableau, you typically create text tables (also called cross-tabs or pivot tables) by placing one dimension on the **Rows** shelf and another dimension on the **Columns** shelf. You then complete the view by dragging one or more measures to **Text** on the **Marks** card.

A text table uses the text mark type. Tableau uses this mark type automatically if the view is constructed using only dimensions (assuming the mark type is set to **Automatic**). For more information about the text mark type, see [Text mark on page 1258](#).

Build a text table with raw values

To create a text table that shows sales totals by year and category, follow these steps:

1. Connect to the **Sample - Superstore** data source (if necessary, you can download it from the [Tableau Public sample data page](#)).
2. Drag the **Order Date** dimension to **Columns**.

Tableau aggregates the date by year and creates column headers.

3. Drag the **Sub-Category** dimension to **Rows**.

Tableau creates row headers. Columns with headers plus rows with headers means that a valid table structure now exists. For more information about changing the layout for row and column headers, see [Define Table Structure on page 3006](#).

Now you can add a measure to the view to see actual data.

4. Drag the **Sales** measure to **Text** on the **Marks** card.

Tableau aggregates the measure as a sum.

| Tables | 47,016 | 39,170 | 60,835 | 60,999 |

Tableau uses text as the mark type. Each cell in the table displays the sum of sales for a particular year and sub-category. We can see that the chairs and phones sub-categories had the highest sales in every year.

5. Drag the **Region** dimension to **Rows** and drop it to the left of **Sub-Category**. A small triangle will appear to indicate that the new field will be inserted to the left of the existing field.

| Paper | 15,322 | 15,316 | 20,729 | 28,174 |

The view now breaks down sales by region, in addition to year and sub-category. Regions are listed alphabetically.

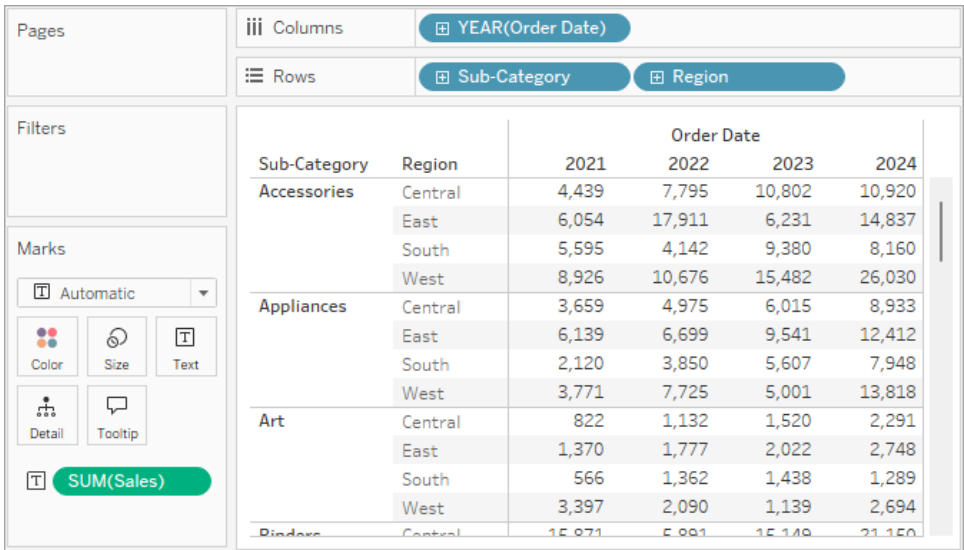

The screenshot shows the Tableau interface with the following configuration:

- Columns:** YEAR(Order Date)
- Rows:** Region, Sub-Category
- Marks:** SUM(Sales)

The resulting table shows sales data grouped by Region and Sub-Category, with columns for the years 2021, 2022, 2023, and 2024.

| Region | Sub-Category | Order Date | | | |
|---------|--------------|------------|--------|--------|--------|
| | | 2021 | 2022 | 2023 | 2024 |
| Central | Paper | 2,347 | 3,544 | 5,366 | 6,235 |
| | Phones | 9,926 | 19,364 | 19,902 | 23,211 |

| | Employees | 1,248 | 877 | 1,205 | 847 |
| | Supplies | 440 | 324 | 4,295 | 4,408 |

You can drag **Region** to the right of **Sub-Category** to organise the view first by sub-category, and then by region.

The screenshot shows the Tableau interface with the following configuration:

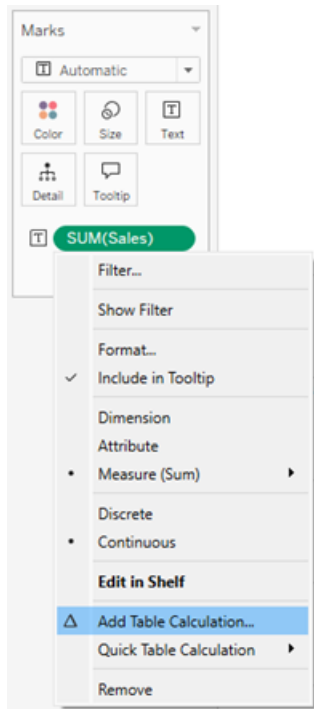

- Columns:** YEAR(Order Date)
- Rows:** Sub-Category, Region
- Marks:** SUM(Sales)

The resulting table shows sales data grouped by Sub-Category and Region, with columns for the years 2021, 2022, 2023, and 2024.

| Sub-Category | Region | Order Date | | | |
|--------------|---------|------------|--------|--------|--------|
| | | 2021 | 2022 | 2023 | 2024 |
| Accessories | Central | 4,439 | 7,795 | 10,802 | 10,920 |
| | East | 6,054 | 17,911 | 6,231 | 14,837 |
| | South | 5,595 | 4,142 | 9,380 | 8,160 |
| | West | 8,926 | 10,676 | 15,482 | 26,030 |
| Appliances | Central | 3,659 | 4,975 | 6,015 | 8,933 |
| | East | 6,139 | 6,699 | 9,541 | 12,412 |
| | South | 2,120 | 3,850 | 5,607 | 7,948 |
| | West | 3,771 | 7,725 | 5,001 | 13,818 |
| Art | Central | 822 | 1,132 | 1,520 | 2,291 |
| | East | 1,370 | 1,777 | 2,022 | 2,748 |
| | South | 566 | 1,362 | 1,438 | 1,289 |
| | West | 3,397 | 2,090 | 1,139 | 2,694 |

Change the values to percentages

1. To create a table calculation to show percentages, right-click (control-click on Mac) the **SUM(Sales)** field on the **Marks** card, and then select **Add Table Calculation**.

2. In the Table Calculation dialog box, set **Calculation Type** to **Percent of Total**.

The options in the dialog box change depending on the type of calculation you choose.

For more information about using table calculations, see [Transform Values with Table Calculations](#) on page 2355.

☒ Show calculation assistance

Pane (Down) is the appropriate choice because it specifies that the calculation should be performed vertically within each pane of the table, or per year.

The table has two vertical dimensions, so **Table (Down)** would have calculated the percent of total from top to bottom for the entire table, ignoring the **Sub-Category** dimension:

| Sub-Category | Region | Order Date | | | |
|--------------|---------|------------|--------|--------|--------|
| | | 2021 | 2022 | 2023 | 2024 |
| Accessories | Central | 0.899% | 1.648% | 1.760% | 1.465% |
| | East | 1.225% | 3.787% | 1.015% | 1.990% |
| | South | 1.133% | 0.876% | 1.528% | 1.094% |
| | West | 1.807% | 2.257% | 2.522% | 3.491% |
| Appliances | Central | 0.741% | 1.052% | 0.980% | 1.198% |
| | East | 1.243% | 1.416% | 1.554% | 1.665% |
| | South | 0.429% | 0.814% | 0.913% | 1.066% |
| | West | 0.763% | 1.633% | 0.815% | 1.853% |
| Art | Central | 0.166% | 0.239% | 0.248% | 0.307% |

Pane would compute across the pane, computing across the years:

| Sub-Category | Region | Order Date | | | |
|--------------|---------|------------|--------|-------|--------|
| | | 2021 | 2022 | 2023 | 2024 |
| Accessories | Central | 2.65% | 4.66% | 6.45% | 6.52% |
| | East | 3.62% | 10.70% | 3.72% | 8.86% |
| | South | 3.34% | 2.47% | 5.60% | 4.88% |
| | West | 5.33% | 6.38% | 9.25% | 15.55% |
| Appliances | Central | 3.38% | 4.60% | 5.56% | 8.26% |
| | East | 5.67% | 6.19% | 8.82% | 11.47% |
| | South | 1.96% | 3.56% | 5.18% | 7.34% |
| | West | 3.49% | 7.14% | 4.62% | 12.77% |

Build a Treemap

Use treemaps to display data in nested rectangles. You use dimensions to define the structure of the treemap, and measures to define the size or colour of the individual rectangles. Treemaps are a relatively simple data visualisation that can provide insight in a visually attractive format.

The basic building blocks for a treemap are as follows:

- **Mark type:** Automatic or Square
- **Colour:** Dimension or Measure
- **Size:** Measure
- **Label or Detail:** Dimension(s)

To create a treemap that shows aggregated sales totals across a range of product categories, follow the steps below.

1. Connect to the **Sample - Superstore** data source (if necessary, you can download it from the [Tableau Public sample data page](#)).

2. Drag the **Sub-Category** dimension to **Columns**.

A horizontal axis appears, which shows product categories.

3. Drag the **Sales** measure to **Rows**.

Tableau aggregates the measure as a sum and creates a vertical axis, making a bar chart – the default chart type when there is a dimension on the **Columns** shelf and a measure on the **Rows** shelf.

4. Click **Show Me** on the toolbar, then select the treemap chart type.

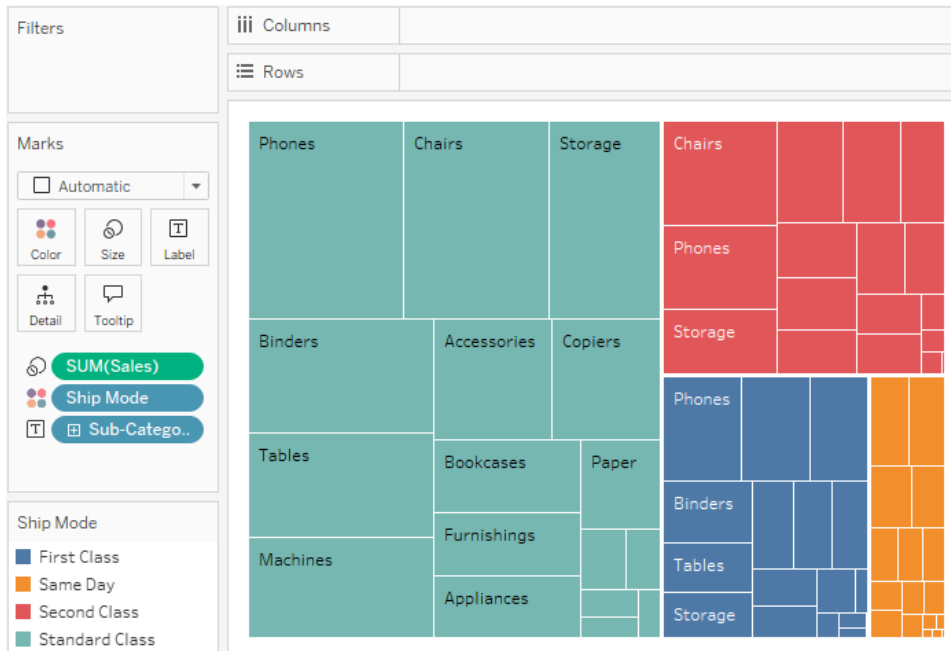

Tableau displays the following treemap:

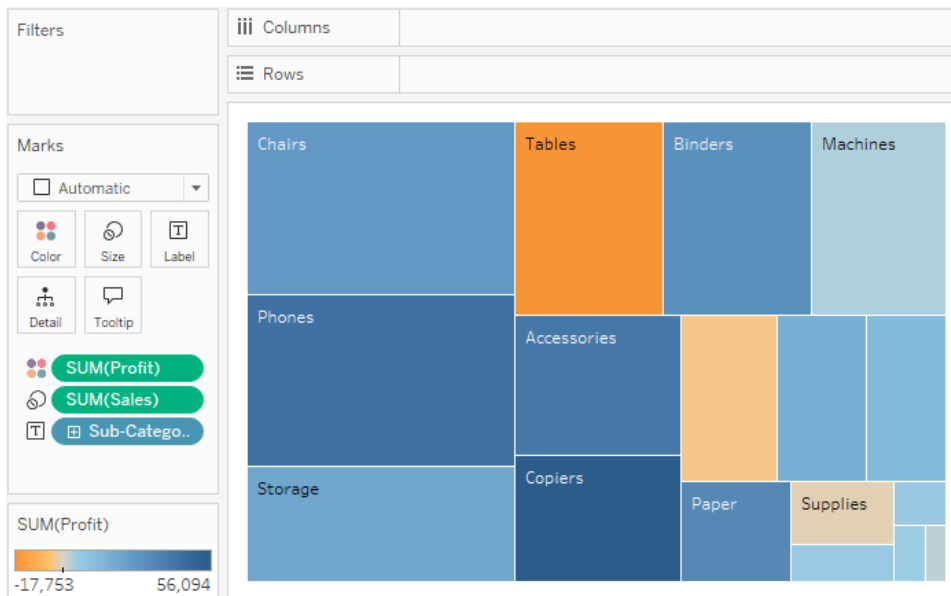

In this treemap, both the size of the rectangles and their colour are determined by the value of **Sales** – the greater the sum of sales for each category, the darker and larger its box.

5. Drag the **Ship Mode** dimension to **Colour** on the **Marks** card. In the resulting view, **Ship Mode** determines the colour of the rectangles – and sorts them into four separate areas accordingly. **Sales** determines the size of the rectangles:

6. Try another option to modify the treemap: click the **Undo** button to remove **Ship Mode** from view.
7. Drag the **Profit** measure to **Colour** on the **Marks** card. Now **Profit** determines the colour of the rectangles, and **Sales** determines their size:

With treemaps, **Size** and **Colour** are the crucial elements. You can place measures on **Size** and **Colour**, but placing a measure anywhere else has no effect. Treemaps can accommodate any number of dimensions, including one or even two on **Colour**. But beyond that, adding dimensions

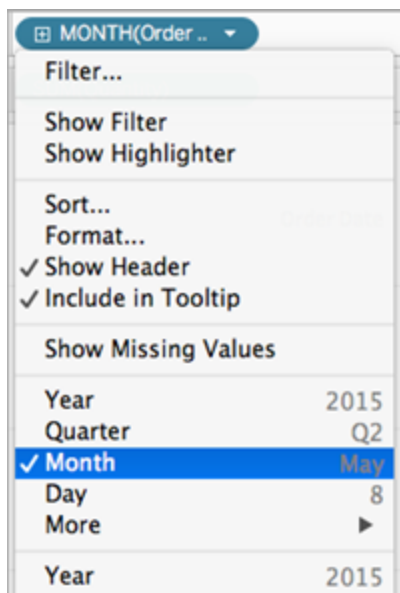

only breaks the map into an ever greater number of smaller rectangles. For information on how to place two dimensions on **Colour** in a treemap, see [Example – Multiple Fields on Colour on page 1310](#).

Build a Combination Chart

Combination charts are views that use multiple mark types in the same visualisation. For example, you may show sum of profit as bars with a line across the bars showing sum of sales. You can also use combination charts to show multiple levels of detail in the same view. For example, you can have a line chart with individual lines showing average sales over time for each customer segment, then you can have another line that shows the combined average across all customer segments.

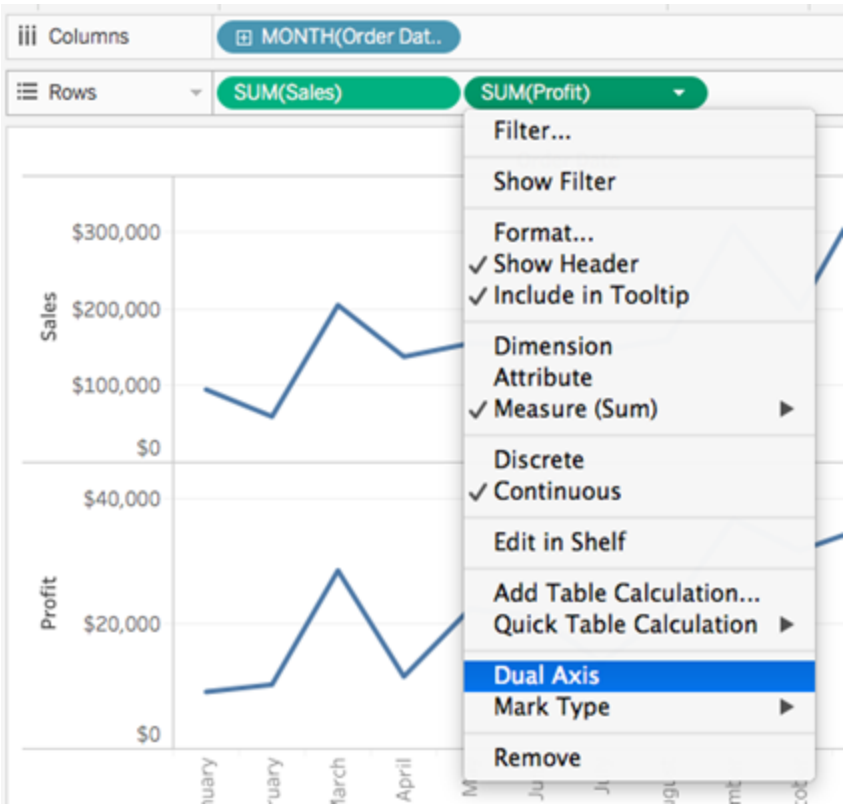

To create a combination chart, follow the steps below:

1. Connect to the Sample - Superstore data source (if necessary, you can download it from the Tableau Public sample data page).
2. Navigate to a new worksheet.
3. From the **Data** pane, drag **Order Date** to the **Columns** shelf.
4. On the Columns shelf, right-click **YEAR(Order Date)** and select **Month**.

5. From the **Data** pane, drag **Sales** to the **Rows** shelf.
6. From the **Data** pane, drag **Profit** to the **Rows** shelf and place it to the right of SUM (Sales).

7. On the Rows shelf, right-click **SUM(Profit)** and select **Dual-Axis**.

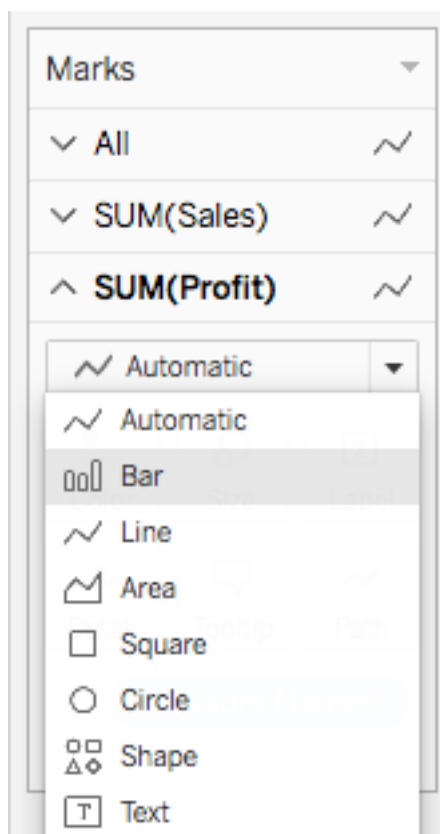

The view updates. Measure Names is added to Colour on the Marks card to differentiate the lines.

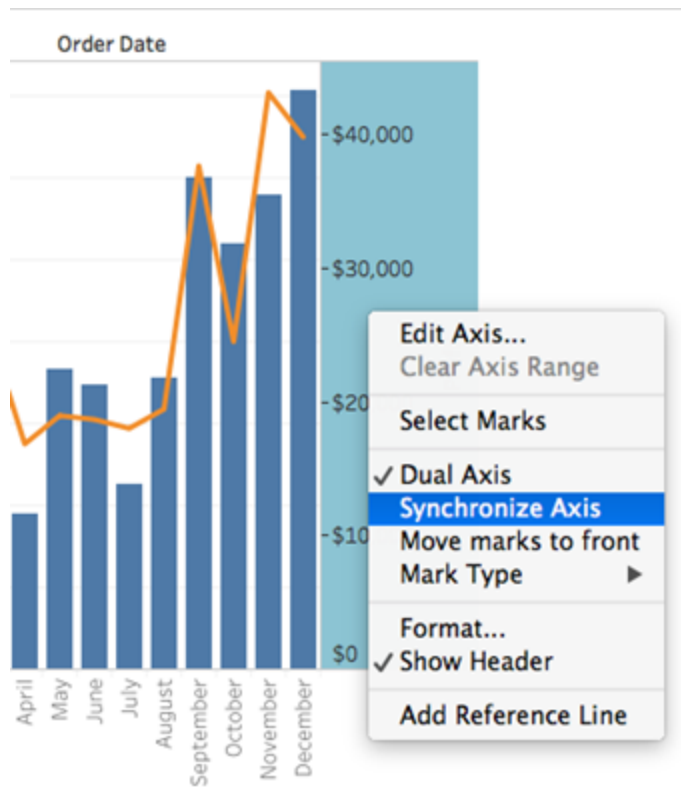

Note: Some marks can be hidden behind others. To move the marks forward or backward, right-click one of the axes in the visualisation and select **Move Marks to Back** or **Move Marks to Front**.

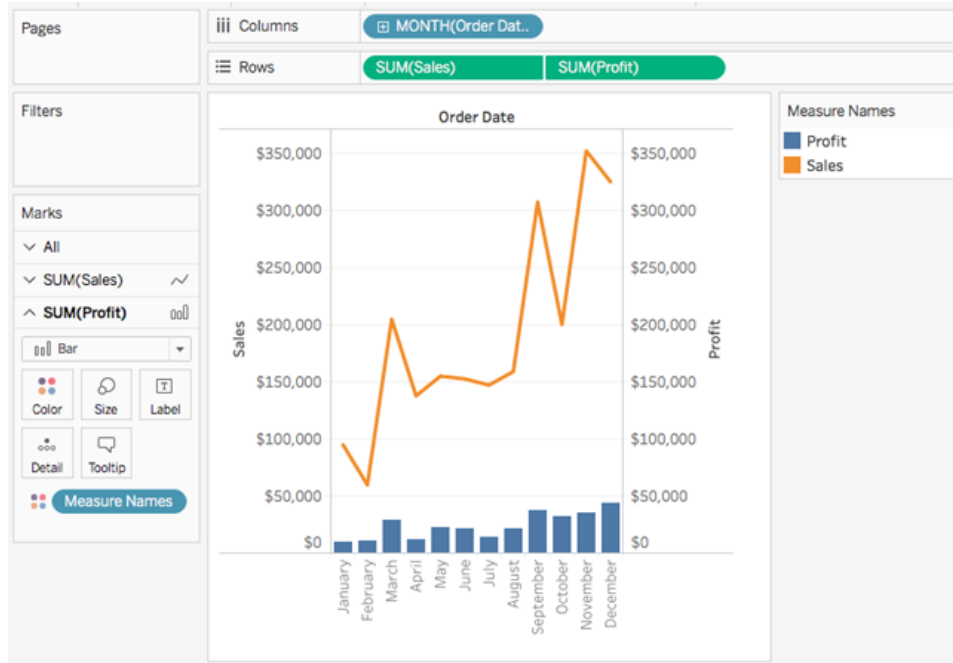

8. On the SUM(Profit) Marks card, click the Mark Type drop-down and select **Bar**.

9. In the visualisation, right-click the **Profit** axis and select **Synchronise Axis**.

The view updates to look like this:

Build Advanced Chart Types

The topics in this section illustrate how to create views that include industry-standard analytical benchmarks and visualisation types.

Note: Most of these examples can only be built in Tableau Desktop – not as you edit views on the web. Before attempting to follow the steps in one of these topics, check the Applies To line at the top of the topic to determine whether the procedure is valid for editing on the web. If Tableau Server and Tableau Cloud are not listed, the procedure will not work on the web.

Add a Calculated Column to a View

Sometimes your data may not have all the pieces you need for your analysis. A common way to handle this is to create a calculated column (also referred to as a calculated field or just a calculation) that modifies the existing data. Calculations can be created by opening the **Analysis** menu and selecting **Create Calculated Field...**

It's important to note that there are often several different ways to achieve the same results for a calculated field. Additionally, the correct value of a calculation may depend on how the data is

shaped and how the visualisation is set up. Make sure you understand your data structure and how the viz will be built when determining how to write a calculation.

Examples of when a calculation might be useful

Combine first and last name

You may have First name and Last name in two different columns and want a single field for name.

| Abc Names First name | Abc Names Last name | Abc Names Real person |
|----------------------------|---------------------------|-----------------------------|
| James | Herriot | no |
| Helen | Alderson | no |
| Siegfried | Farnon | no |
| Tristan | Farnon | no |
| Donald | Sinclair | yes |
| Alfred | Wight | yes |
| Joan | Danbury | yes |
| Brian | Sinclair | yes |

The calculation:

```
[First name] + " " + [Last name]
```

A finished viz might look like this

Find a sequence inside a string

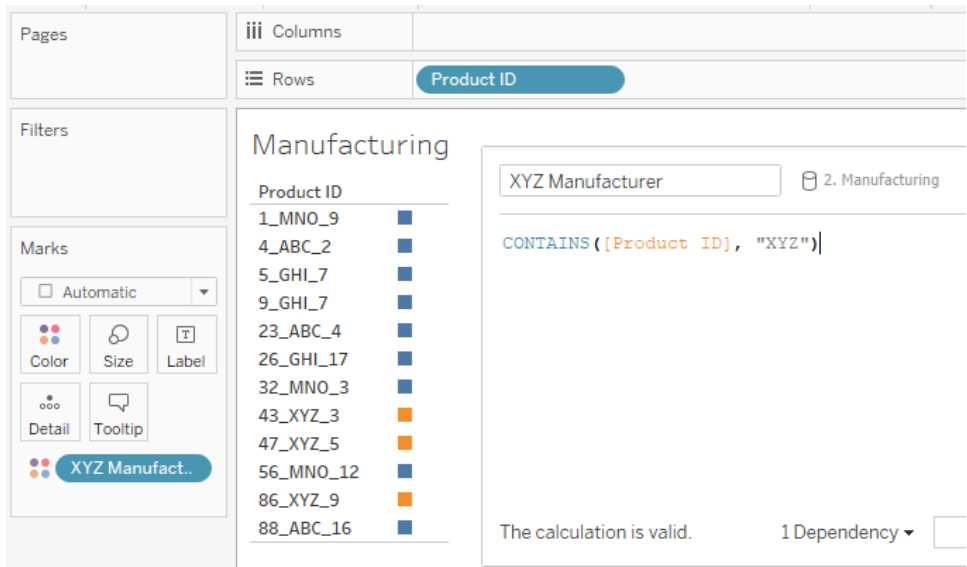

You may want to flag every record that has a certain manufacturing code XYZ in the Product ID field.

| Abc Manufacturing Product ID | Abc Manufacturing Unit Cost | # Manufacturing Number on hand |
|------------------------------------|-----------------------------------|--------------------------------------|
| 4_ABC_2 | \$44 | 277 |
| 47_XYZ_5 | \$20 | 193 |
| 9_GHI_7 | \$30 | 41 |
| 56_MNO_12 | \$34 | 103 |
| 88_ABC_16 | \$11 | 67 |
| 86_XYZ_9 | \$43 | 216 |
| 26_GHI_17 | \$11 | 198 |
| 1_MNO_9 | \$19 | 213 |
| 23_ABC_4 | \$14 | 39 |
| 43_XYZ_3 | \$16 | 185 |
| 5_GHI_7 | \$4 | 252 |
| 32_MNO_3 | \$1 | 273 |

The calculation will return "true" if the code is present and "false" if not.

```
CONTAINS([Product ID], "XYZ")
```

A finished viz might look like this, with the calculation on Colour.

Assign categories for value ranges

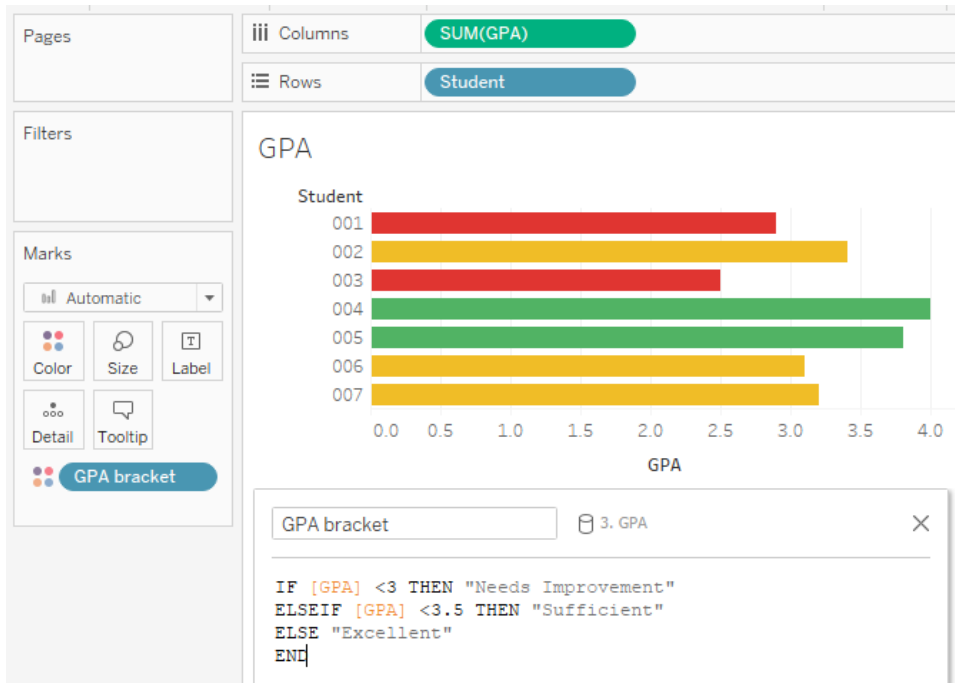

You want to assign categories based on several thresholds.

| Abc Grades Student | # Grades GPA |
|--------------------------|--------------------|
| 001 | 2.90000 |
| 002 | 3.40000 |
| 003 | 2.50000 |
| 004 | 4.00000 |
| 005 | 3.80000 |
| 006 | 3.10000 |
| 007 | 3.20000 |

The calculation will evaluate each student's GPA against the cutoff value and assign a label.

```
IF [GPA] <3 THEN "Needs Improvement" ELSEIF [GPA] <3.5 THEN  
"Sufficient" ELSE "Excellent" END
```

A finished viz might look like this, with the calculation on Colour.

Calculate percent change

You want to display the year-over-year (YOY) percentage change in the weight of children from age 1 to age 2.

| Abc Babies Baby | # Babies Age | # Babies Weight |
|-----------------------|--------------------|-----------------------|
| A | 1 | 19.3600 |
| A | 2 | 26.4000 |
| B | 1 | 22.6600 |
| B | 2 | 30.1400 |
| C | 1 | 17.3800 |
| C | 2 | 24.1000 |
| D | 1 | 21.3400 |
| D | 2 | 24.2000 |

This calculation is for the *difference/original* for each child.

```
(SUM((IF [Age] = 2 THEN [Weight] ELSE 0 END)) - SUM((IF [Age] = 1 THEN [Weight] ELSE 0 END)))/SUM(IF [Age] = 1 THEN [Weight] ELSE 0 END)
```

A finished viz might look like this.

This example is one where the calculation could change quite a lot based on the structure of the data. If there was a field for weight at age 1 and weight at age 2, for example, the calculation would only need to be $([\text{Weight at age 2}] - [\text{Weight at age 1}]) / [\text{Weight at age 1}]$. However, the data structure detailed above is more standard and more likely to be encountered.

Follow along: create a YOY calculation

Objective

To create a view like the following, that shows sales results for two years in the first two columns, and then the year-over-year change, as a percentage, in the third column. The scenario uses the **Sample - Superstore** data source provided with Tableau Desktop to show how to build the viz.

The screenshot shows the Tableau Desktop interface. On the left, the 'Columns' shelf contains 'Measure Names' and the 'Rows' shelf contains 'Sub-Category'. The 'Marks' card is set to 'Automatic'. Below the 'Marks' card, the 'Measure Values' section shows three green buttons: 'SUM(2013)', 'SUM(2014)', and 'AGG(YOY Change)'. The main view, 'Sheet 1', displays a table with the following data:

| Sub-Catego.. | 2013 | 2014 | YOY Change |
|--------------|----------|----------|------------|
| Accessories | \$25,014 | \$40,524 | 62.00% |
| Appliances | \$15,314 | \$23,241 | 51.77% |
| Art | \$6,058 | \$6,237 | 2.95% |
| Binders | \$43,488 | \$37,453 | -13.88% |
| Bookcases | \$20,037 | \$38,544 | 92.37% |
| Chairs | \$77,242 | \$71,735 | -7.13% |
| Copiers | \$10,850 | \$26,179 | 141.29% |
| Envelopes | \$3,856 | \$4,512 | 17.02% |
| Fasteners | \$661 | \$545 | -17.56% |
| Furnishings | \$13,826 | \$21,090 | 52.53% |
| Labels | \$2,841 | \$2,956 | 4.05% |
| Machines | \$62,023 | \$27,764 | -55.24% |
| Paper | \$14,835 | \$15,288 | 3.05% |
| Phones | \$77,391 | \$68,314 | -11.73% |
| Storage | \$50,329 | \$45,048 | -10.49% |
| Supplies | \$14,394 | \$1,952 | -86.44% |
| Tables | \$46,088 | \$39,150 | -15.05% |

Create the necessary calculated fields

1. Connect to the **Sample - Superstore** data source.
2. Choose **Analysis > Create Calculated Field** to open the calculation editor. Name the calculation **2013** and type or paste the following in the formula area:

```
IF YEAR([Order Date]) = 2013 THEN [Sales] ELSE 0 END
```

3. Create a second calculated field and name it **2014**; the formula is the same except with 2014 instead of 2013:

```
IF YEAR([Order Date]) = 2014 THEN [Sales] ELSE 0 END
```

4. Create a third calculated field, **YOY Pct. Change**, to calculate the change from 2013 to

2014:

$$(SUM([2014]) - SUM([2013])) / SUM([2013])$$

Format the calculated fields

1. Click **2013** in the Measures area of the **Data** pane and choose **Default Properties > Number Format**.
2. In the Default Number Format dialog box, set the format to **Currency (Custom)** and the **Decimal places** to **0**.

3. Format the **2014** measure the exact same way.
4. Format the **YOY Pct. Change** field as **Percentage**, with **2** decimal places.

Build the view

1. Drag **2013** to Text on the Marks card.
2. Double-click **2014** and then **YOY Pct. Change**.
3. Drag **Measure Names** from **Rows** to **Columns**.
4. Drag **Sub-Category** to **Rows**.

Your view should now look like the one at the beginning of this section.

Calculate Z-scores

In statistics, the z-score (or standard score) of an observation is the number of standard deviations that it is above or below the population mean.

To calculate a z-score you must know the population mean and the population standard deviation. In cases where it is impossible to measure every observation of a population, you can estimate the standard deviation using a random sample.

Create a z-score visualisation to answer questions like the following:

- What percentage of values fall below a specific value?
- What values can be considered exceptional? For example, in an IQ test, what scores represent the top five percent?
- What is the relative score of one distribution versus another? For example, Michael is taller than the average male and Emily is taller than the average female, but who is relatively taller within their gender?

As a general rule, z-scores lower than -1.96 or higher than 1.96 are considered unusual and interesting. That is, they are statistically significant outliers.

This article demonstrates how to calculate a z-score in Tableau.

1. Connect to the **Sample - Superstore** data source provided with Tableau Desktop.
2. Create a calculated field to calculate average sales.

Choose **Analysis > Create Calculated Field** to open the calculation editor. Name the calculation **Average Sales** and type or paste the following in the formula area:

```
WINDOW_AVG(SUM([Sales]))
```

3. Create another calculated field to calculate the standard deviation. Name the calculation **STDEVP Sales** and type or paste the following in the formula area:

```
WINDOW_STDEVP(SUM([Sales]))
```

4. Create one more calculated field, this one to calculate the z-score. Name the calculation **Z-score** and type or paste the following in the formula area:

```
(SUM([Sales]) - [Average Sales]) / [STDEVP Sales]
```

5. Drag **Z-Score** from the **Data** pane to **Columns** and **State** to **Rows**.

Notice that the **Z-score** field on Columns has a table calculation icon on the right side (that is, a small triangle):

The **STDEVP Sales** function is based on the **WINDOW_STDEVP** function, which is a table calculation function. The **Z-Score** function, in turn, is a table calculation function because it includes **STDEVP Sales** in its definition. When you use a calculated field that includes a table calculation function in a view, it's the same as adding a table calculation to a field manually. You can edit the field as a table calculation. In fact, that's what you do next.

6. Click the **Z-score** field on Columns and choose **Compute Using > State**.

This causes the z-scores to be computed on a per-state basis.

7. Click the **Sort Descending** icon on the toolbar:

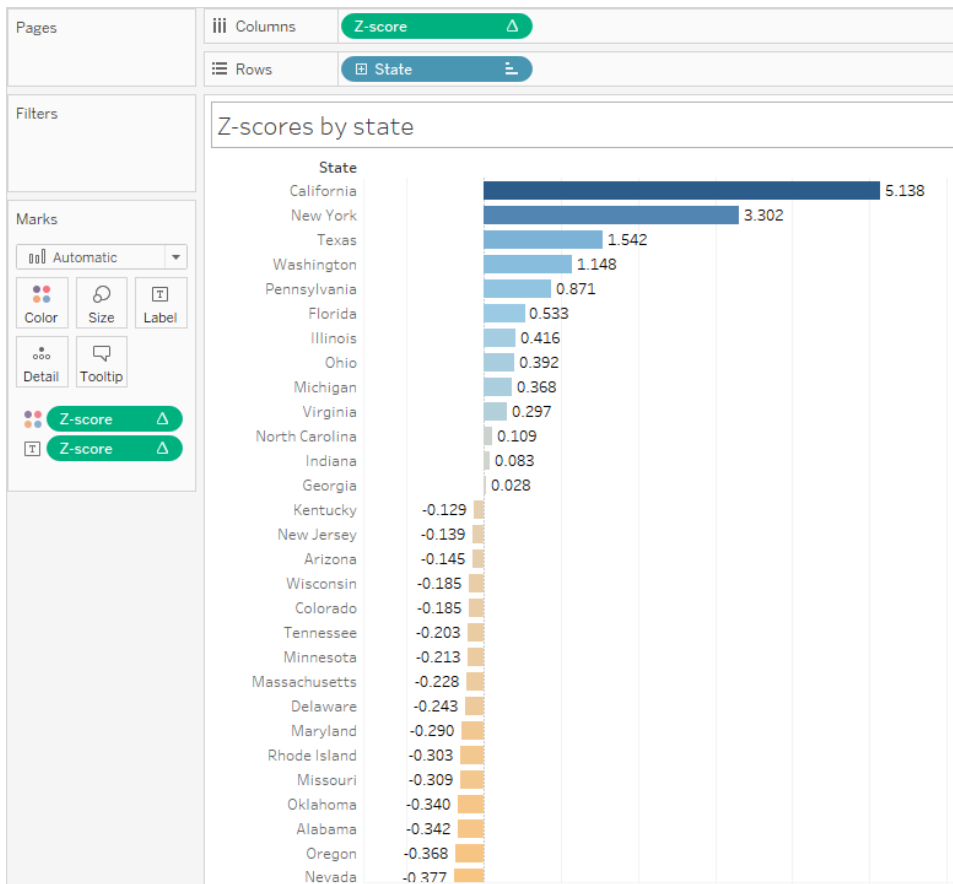

8. Hold down the Ctrl key and drag the **Z-score** field from **Columns** to **Colour**.

Ctrl + Drag copies a field as currently configured to an additional location.

9. Ctrl + Drag **Z-score** from Columns once again. This time drop it on **Label**.

You now have a distribution of z-scores broken out by state. California and New York both have z-scores greater than 1.96. You could conclude from this that California and New York have significantly higher average sales than other states.

Visualise Key Progress Indicators

This article shows how to create a view that shows Key Progress Indicators (KPIs). A Key Performance Indicator is a measurable value that shows how effectively a company is achieving key business objectives. At a high level, the procedure requires you to do the following:

1. Create a view that includes the field or fields (measures) you want to assess.
2. Create a calculated field that establishes the threshold that demarcates success from failure.
3. Update the view to use KPI-specific shape marks to show which values are above the threshold and which are below.

Note: When connected to Microsoft Analysis Services, any KPI calculations defined in the cube are not available in Tableau. But as the procedure below demonstrates, you can write your own KPI calculations directly inside Tableau, and then use Tableau parameters

to create highly flexible what-if KPI analysis. For more on special considerations for cube data sources, see [Cube Data Sources on page 985](#).

The scenario uses the **Sample - Superstore** data source provided with Tableau Desktop to show how to build a KPI view that displays a green tick for any sales figure over \$25,000, and a red X for any sales figure under \$25,000.

Create a view that includes the field you want to assess

In this case, that field is **Sales**.

1. Connect to the **Sample - Superstore** data source.
2. From the Data pane, drag **Sub-Category** to **Rows** and **Region** to **Columns**.
3. From the Data pane, drag **Sales** to **Text** on the Marks card.

Create a calculated field that establishes the threshold that demarcates success from failure

1. In the **Analysis** menu, select **Create Calculated Field** to open the calculation editor. Name the calculation KPI and type or paste the following in the formula area

```
IF SUM ([Sales]) > 25000 THEN "Above Benchmark" ELSE "Below  
Benchmark" END
```
2. Click **OK**.

Update the view to use KPI-specific shape marks

1. On the Marks card, select Shape from the drop-down list of views:

2. Drag the **KPI** field from the **Measures** area of the **Data** pane to **Shape** on the Marks card.
3. Click **Shape** on the Marks card to open the **Edit Shape** dialog box.
4. From the **Select Shape Palette** drop down list, choose **KPI**.

Now you are ready to associate specific values for the KPI field with specific shapes.

5. Click **Above Benchmark** under **Select Data Item** and then click the tick mark in the palette.
6. Click **Below Benchmark** under **Select Data Item** and then click the red X in the palette.

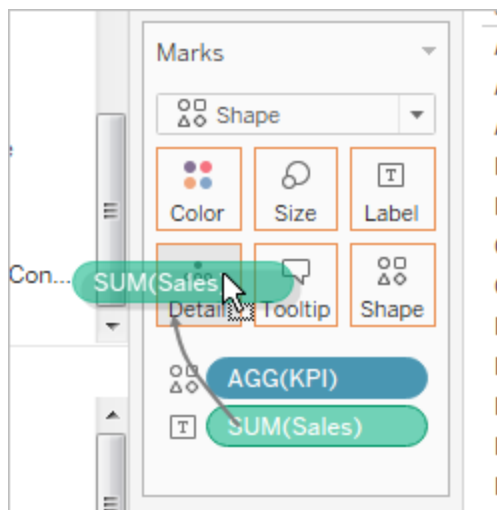

The Edit Shape dialog box should now look like this:

7. Click **OK** to close the Edit Shape dialog box.

The shapes in the view show the correct indicators. Now you just need to hide the sales numbers.

8. Drag **SUM(Sales)** on the Marks card to **Detail**.

You now have a completed view that show how individual products (sub-categories) are performing across all four regions:

The view may not be terribly exciting on its own, but it would make a nice addition to a dashboard that showed other performance metrics.

Create a Pareto Chart

A Pareto chart is a type of chart that contains both bars and a line graph, where individual values are represented in descending order by bars, and the ascending cumulative total is represented by the line. It is named for Vilfredo Pareto, an Italian engineer, sociologist, economist, political scientist, and philosopher, who formulated what has become known as the Pareto principal.

Pareto made the observation that 80% of land was typically owned by 20% of the population.

Pareto extended his principle by observing that 20% of the peapods in his garden contained 80% of the peas. Eventually, the principal was further extrapolated by others to propose that for

many events, roughly 80% of the effects come from 20% of the causes. In business, for example, 80% of the profits often derive from 20% of the available products.

In Tableau, you can apply a table calculation to sales data to create a chart that shows the percentage of total sales that come from the top products, and thus identify the key segments of your customer base that are most important for the success of your business.

The procedure uses the **Sample - Superstore** data source provided with Tableau Desktop.

Preparing for the analysis

Before starting your analysis, decide what questions you want to answer. These questions determine the category (dimension) and number (measure) on which to base the analysis. In the example to follow, the question is which products (captured by the **Sub-Category** dimension) account for the most total sales.

At a high level, the process requires you to do the following:

1. Create a bar chart that shows **Sales** by **Sub-Category**, in descending order.
2. Add a line chart that also shows **Sales** by **Sub-Category**.
3. Add a table calculation to the line chart to show sales by Sub-Category as a **Running Total**, and as a **Percent of Total**.

The scenario uses the **Sample - Superstore** data source provided with Tableau Desktop

Create a bar chart that shows Sales by Sub-Category in descending order

1. Connect to the **Sample - Superstore** data source.
2. From the **Data** pane, drag **Sub-Category** to **Columns**, and then drag **Sales** to **Rows**.
3. Click **Sub-Category** on **Columns** and choose **Sort**.

In the Sort dialog box, do the following:

- a. Under **Sort order**, choose **Descending**.
- b. Under **Sort by**, choose **Field**.
- c. Leave all other values unchanged, including **Sales** as the selected field and **Sum** as the selected aggregation.
- d. Click **OK** to exit the Sort dialog box.

Products are now sorted from highest sales to lowest.

Add a line chart that also shows Sales by Sub-Category

1. From the Data pane, drag **Sales** to the far right of the view, until a dotted line appears.

Note: In Tableau 2020.2 and later, the Data pane no longer shows Dimensions and Measures as labels. Fields are listed by table or folder.

2. Drop Sales, to create a dual-axis view. It's difficult to see that there are two instances of the Sales bars at this point, because they are configured identically.
3. Select **SUM(Sales) (2)** on the Marks card, and change the mark type to **Line**.

This is what the view should look like at this point:

Add a table calculation to the line chart to show sales by Sub-Category as a running total, and as a percent of total

1. Click the second copy of **SUM(Sales)** on **Rows** and choose **Add Table Calculation**.
2. Add a primary table calculation to **SUM(Sales)** to present sales as a running total.

Choose **Running Total** as the **Calculation Type**.

Do not close the Table Calculation dialog box.

3. Add a secondary table calculation to present the data as a percent of total.

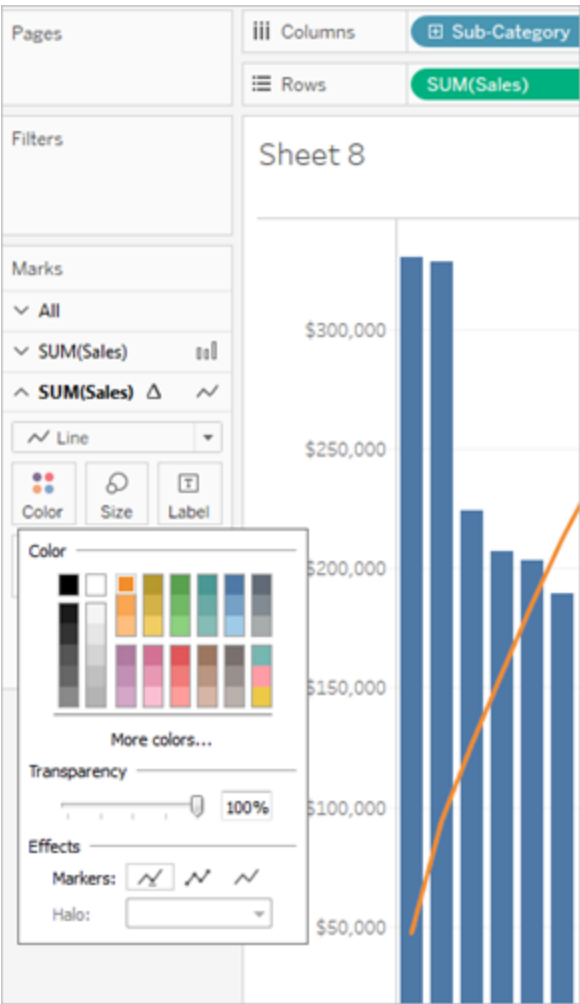

Click **Add Secondary Calculation** and choose **Percent of Total** as the **Secondary Calculation Type**.

This is what the Table Calculation dialog box should look like at this point:

The image shows the 'Table Calculation' dialog box with the title '% of Total Running Sum of Sales'. It is divided into two main columns: 'Primary Calculation Type' and 'Secondary Calculation Type'. Under 'Primary Calculation Type', 'Running Total' is selected in the dropdown, and 'Sum' is selected in the 'Compute Using' list. Under 'Secondary Calculation Type', 'Percent of Total' is selected in the dropdown, and 'Table (across)' is selected in the 'Compute Using' list. Both columns have a 'Sub-Category' checkbox which is checked. At the bottom left, there is a 'Restarting every' dropdown and an 'Add secondary calculation' checkbox which is checked. At the bottom right, there is an 'At the level' dropdown.

| Primary Calculation Type | Secondary Calculation Type |
|---|---|
| Running Total | Percent of Total |
| Sum | <input type="checkbox"/> Compute total across all pages |
| Compute Using | Compute Using |
| Table (across) | Table (across) |
| Cell | Table (down) |
| Specific Dimensions | Table |
| <input checked="" type="checkbox"/> Sub-Category | Cell |
| Restarting every | Specific Dimensions |
| | <input checked="" type="checkbox"/> Sub-Category |
| <input checked="" type="checkbox"/> Add secondary calculation | At the level |

4. Click the X in the upper-right corner of the Table Calculations dialog box to close it.
5. Click Colour in the Marks card to change the colour of the line.

The result is now a Pareto chart:

Create a Population Pyramid

A population pyramid, also known as an age structure diagram, shows the distribution of various age groups in a population.

A common distribution often used with this type of visualisation is female and male populations by age. To create a population pyramid using Tableau, first separate the population (measure) into two groups, females and males, and then create "bins" for the age cohorts you want to represent in the population pyramid.

For example, suppose you are working with a table from the United States Census Bureau that contains population, gender and age data.

To create a bin and divide a measure into two groups.

1. Download and open the following workbook from Tableau Public.
 1. Go to
<https://public.tableau.com/profile/tableau.docs.team#!/vizhome/CreateaPopulationPyramid/Sheet1>.
 2. Click **Download Workbook** in the upper-right corner and then open the workbook.
2. Select **Worksheet > Clear > Sheet**.
3. In the Data pane, right-click the **Age** field and select **Create > Bins**.
4. In the Create Bins dialog box, enter a bin size based on the age groups you're interested in focusing on, and then click **OK**.

In this example, the bin size is 10. This means that the age cohorts are defined by increments of 10 years.

The screenshot shows the 'Edit Bins [Age]' dialog box. It has a title bar with a close button. Inside, there's a text field for 'New field name:' containing 'Age (bin)'. Below that is a 'Size of bins:' dropdown menu set to '10' and a 'Suggest Bin Size' button. A 'Range of Values:' section contains four input fields: 'Min:' (0), 'Diff:' (85), 'Max:' (85), and 'CntD:' (86). At the bottom are 'OK' and 'Cancel' buttons.

5. Drag the bin you just created to the Rows shelf.

| | |
|---------|-----------|
| Columns | |
| Rows | Age (bin) |
| 0 | Abc |
| 10 | Abc |
| 20 | Abc |
| 30 | Abc |
| 40 | Abc |
| 50 | Abc |
| 60 | Abc |
| 70 | Abc |
| 80 | Abc |

6. Select **Analysis > Create a Calculated Field**, and then do the following:

- Enter a name for the calculation. For this example, enter **Male Population**.
- Enter a formula similar to the following to isolate the male constituent from population:

```
IF [Gender] = 1 THEN [ESTBASE2010] END
```

In this case, the census data has defined the Gender value for male as "1." The field "ESTBASE2010" contains estimated population values.

7. Similar to the step 5, select **Analysis > Create a Calculated Field**, and then do the following:

- Enter a name for the calculation. For this example, enter **Female Population**.
- Enter a formula similar to the following to isolate the female constituent from population:

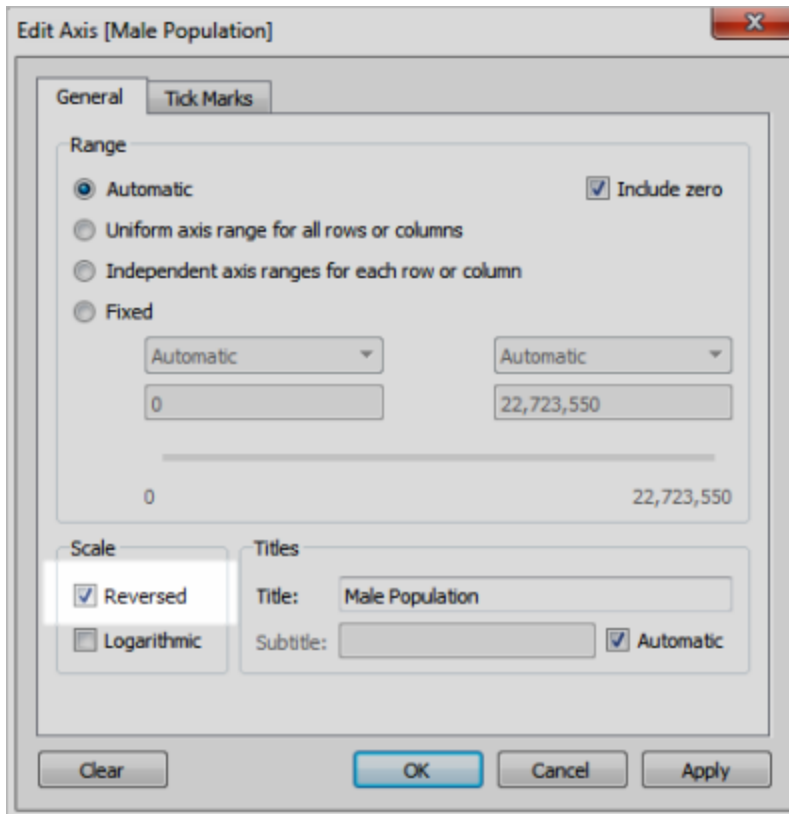

```
IF [Gender] = 2 THEN [ESTBASE2010] END
```

In this case, the census data has defined the Gender value for female as "2." The field "ESTBASE2010" contains estimated population values.

8. Drag the calculated fields you created to the Columns shelf and the **Gender** field to the Colour shelf.

Note: To change the colour assignments, click the Colour shelf and then click **Edit Colours**.

9. Right-click the axis for Male Population, select **Edit Axis**, and then tick the box for **Reversed** to reverse the order the values display on the axis, and then click **OK**.

After changing the sort order of the bin, the population pyramid looks like the following:

Create a Co-Occurrence Visualisation Using a Parameter and a Set

You can create co-occurrence visualisations in Tableau. With a co-occurrence visualisation, users can pick one field value and then see which other fields values it co-occurs with, and how often. One practical application of this analysis is a market basket analysis, which you can use to discover and understand customer purchasing behaviour. You can use a market basket analysis to answer questions like the following:

- How many people bought both Product A and Product B?
- What other products do people who purchased Product A generally buy?
- Which other courses do students who enrolled in Course A frequently enroll in?

Follow the steps in this article to create a co-occurrence visualisation (in this case, a market basket analysis view) using a parameter, calculated fields, and a set. At a high level, the steps involved are:

1. Create a parameter that you will use to dynamically modify the view based on the item you select.
2. Create calculated fields that you will use to return which items are also ordered when a particular item is ordered.

3. Create a set to determine whether an order has the item that was selected in the parameter control.
4. Build the view to display which items are also contained in an order with the selected item.

The scenario uses the **Sample - Superstore** data source provided with Tableau Desktop. The details are covered in the following sections.

Create a Parameter

Follow these steps to create a parameter and then display a parameter control that users can use to pick a **Sub-Category** value.

1. Connect to the **Sample - Superstore** data source.
2. Right-click (control-click on a Mac) in the **Data** pane and select **Create > Parameter**.
3. In the Create Parameter dialog box, do the following:
 - a. Name the parameter **Order Contains**.
 - b. For the **Data Type**, select **String**.
 - c. For **Allowable Values**, choose **List**.
 - d. In the **List of values** section click **Add from Field > Sub-Category**.
 - e. Click **OK**.
4. Right-click the **Order Contains** parameter in the Data pane and select **Show Parameter Control**.

Create Calculated Fields

Follow these steps to create the calculated fields that you will use to show which items are also ordered when the item selected by the user (via the parameter control) is ordered.

1. Create a calculated field to identify products that the order also contains (in addition to the one that the user selects).

Choose **Analysis > Create Calculated Field** to open the calculation editor. Name the calculated field **Then Order Also Contains** and type or paste the following in the formula area:

```
IF [Sub-Category] <> [Order Contains] THEN [Sub-Category] END
```

You may have to replace `<>` with `<>` after you have pasted.

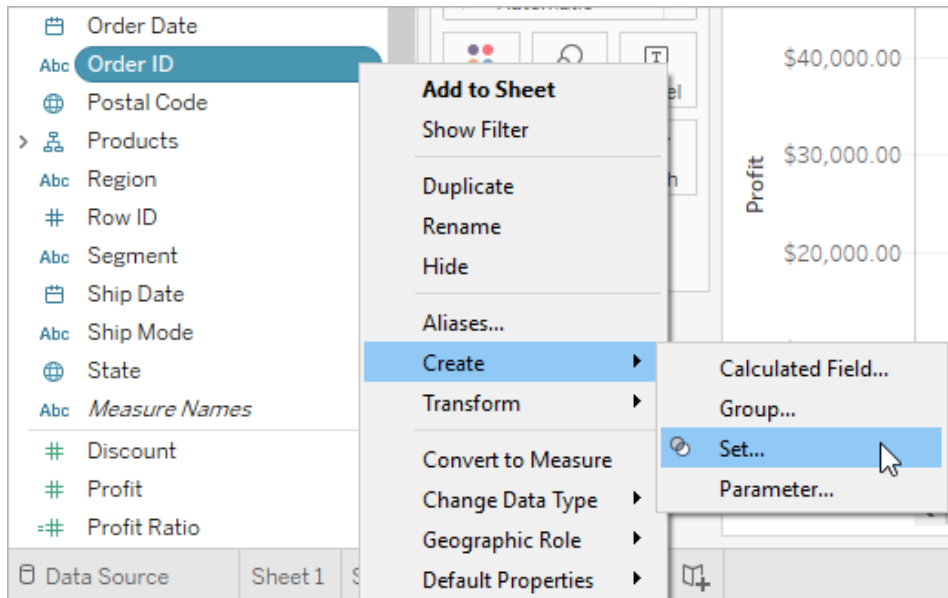

2. Create another calculated field to identify matching products.

Name the field **Product Matches** and type or paste the following in the formula area:

```
IF [Sub-Category] = [Order Contains] THEN 1 END
```

Create a Set

1. Now create a set to determine whether an order has the item that was selected in the parameter control.
2. Hover the cursor over the **Order ID** dimension in the Data pane, click the down arrow at the right end of the field, and choose **Create > Set**.

3. In the Create Set dialog box, type **Order Has Selected Product** in the **Name** text box.
4. Go to the Condition tab, select **By field**, and in the drop-down lists make the following selections and entries to build the condition:
 - a. In the first drop-down list, select **Product Matches**.
 - b. In the second drop-down list, select **Sum**.
 - c. In the next drop-down list, select **>=**.
 - d. In the last text box, type **1**.
 - e. Click **OK**.
5. Click **OK**.

Build the View

Finally, build the view to display which items are also contained in an order with the selected item.

1. Drag **Then Order Also Contains** to **Columns**.
2. Drag **Order ID** to Rows.

In the warning dialog box, click **Add all members**.

3. Click the **Order ID** field on Rows and choose **Measure > Count (Distinct)** to change the aggregation.
4. Right-click (control-click on a Mac) the Null bar on the x-axis and choose **Exclude**.
5. Drag the **Order Has Selected Product** set to the **Filters** shelf.
6. Press Ctrl+W to swap the fields on Rows and Columns.

You (or your users) can now use the **Order Contains** parameter control to select an item in an order, and then see a bar chart showing which other items are also included in orders with the selected item.

Visualise Benford's Law

Benford's Law is a mathematical law that states that the leading, or left-most, digit in many real-life data sources is distributed in a very specific manner. Specifically, the number 1 occurs as the leading digit about 30% of the time, and as numbers get larger they occur less frequently, with the number 9 occurring less than 5% of the time. When fraudsters are fabricating data, they may not know to create fake data that conforms to Benford's law, and in some cases this makes it possible to detect fake data or at least to create doubt about its veracity.

This article describes how to apply Benford's Law to Sales data, using the **Sample - Superstore** data source provided with Tableau Desktop.

The process requires you to do the following:

1. Create calculated fields to use in your view.
2. Set up the view.

The following sections break these procedures down into specific instructions.

Create calculated fields to use in your view

1. In the **Analysis** menu, select **Create Calculated Field** to open the calculation editor. Name the calculation **Leftmost Integer** and type or paste the following in the formula area:

```
LEFT(STR([Sales]),1)
```

2. Create a second calculated field and name it **Benfords Law**. Type or paste the following in the formula area:

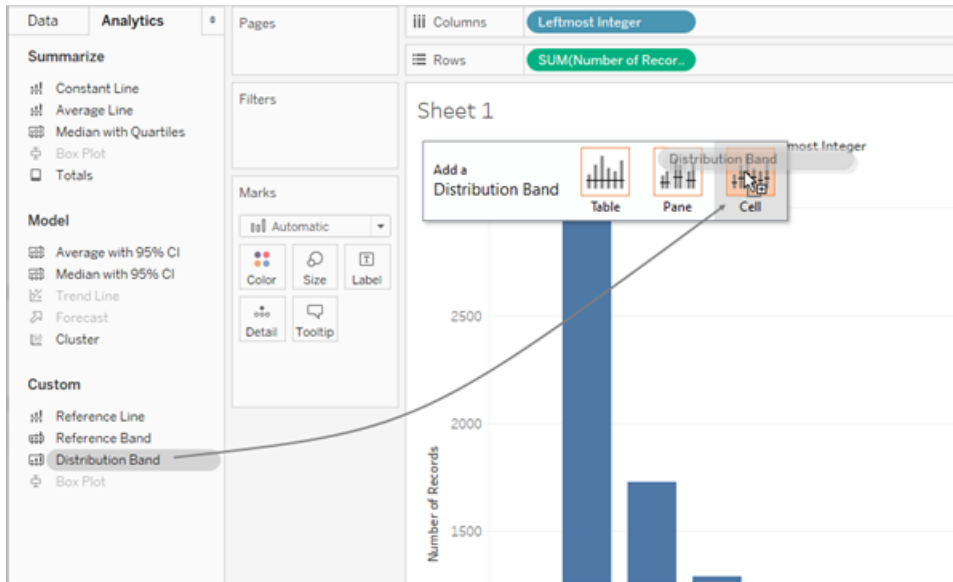

```
LOG(INT([Leftmost Integer])+1)-LOG(INT([Leftmost Integer]))
```

Set up the view

1. From the **Data** pane, drag **Leftmost Integer** to **Columns**, and then drag **Orders(Count)** to **Rows**.
2. Click **CNT(Orders)** on Rows and choose **Quick Table Calculation > Percent of Total**.

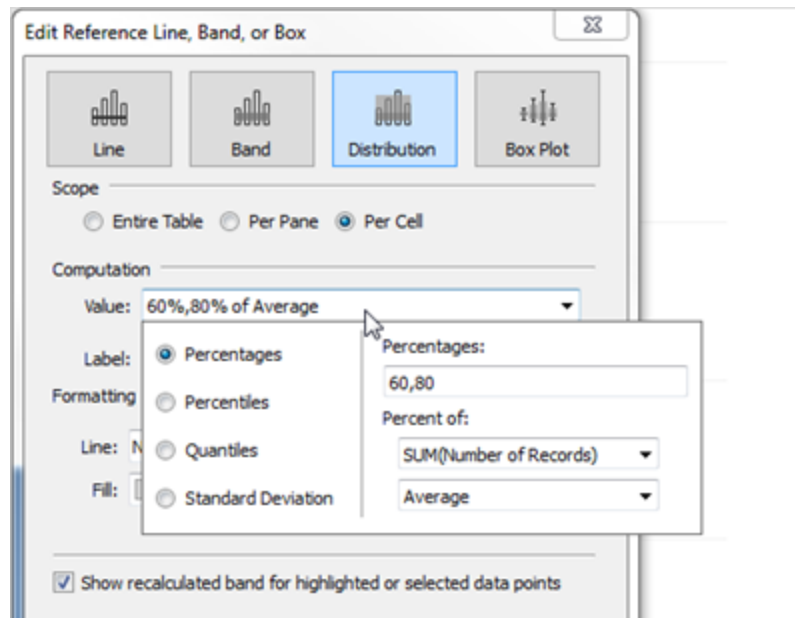

Your view now shows the distribution of first digits, and the size of the bars (decreasing from left to right) suggests that the data in this case conforms to Benford's law. But we can do more to frame the data by adding reference distributions.

3. From the **Data** pane, drag **Benfords Law** to Detail on the Marks card. Click **Benfords Law** on the Marks card and select **Measure > Minimum**.
4. Switch from the **Data** pane to the **Analytics** pane and drag **Distribution Band** into the view. Drop it on **Cell**.

Note: Distribution Bands are supported on web platforms starting with Tableau 10.2.

5. In the Edit Reference Line, Band, or Box dialog box, do the following:
 - a. Click in the Value field to view an additional set of options:

- b. In the Percentages area, type 80, 100, 120.

This specifies that you want bands spanning from 80 to 100 percent, and from 100 to 120 percent. Next you will specify what value the percentages are referencing.

- c. In the **Percent of** field, choose **MIN(Benfords Law)**.

The Value field should now read 80%, 100%, 120% of Average Min.
Benfords Law.

The remaining steps configure the appearance of the reference bands:

- d. Set **Label** to **None**.
- e. Set **Line** to the thinnest available line.
- f. Choose **Fill Below**.
- g. From **Fill**, select **Stoplight**.
- h. Click **OK** to exit the Edit Reference Line, Band or Box dialog box.

- 6. Click the toolbar button to display mark labels: 

The finished view should look like this:

Even though Superstore is demo data, it's realistic as far as conforming to Benford's law. The blue bars that indicate actual percentages of initial digits align very well with the 100% value (that is, the line that separates the green zone from the yellow zone in the distribution bands) that shows expected Benford values in the view.

Create Bins from a Continuous Measure

Sometimes it's useful to convert a continuous measure (or a numeric dimension) into bins.

Any discrete field in Tableau can be considered as a set of bins. For example, suppose you create a view with **Profit** on **Rows** and **State** on **Columns**. You could consider the **State** field as a set of bins – each profit value is sorted into a bin corresponding to the state from which the value was recorded. But if you want to see values for **Profit** assigned to bins without reference to

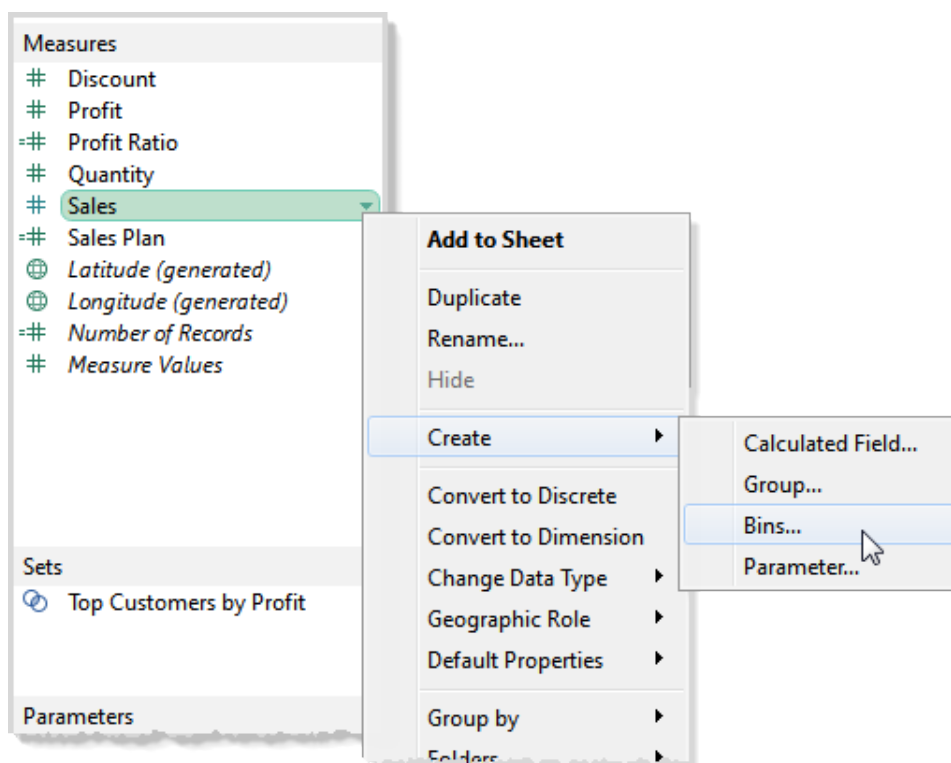

a dimension, you can create a numeric bin, with each individual bin corresponding to a range of values.

Note: You can bin data only for relational data sources and binned fields cannot be used in calculations. However, it is possible to create a calculated field that will replicate a bin of a specific size. For example: `(FLOOR([Sales]/1000)*1000)` will create bins with a size of 1,000 that can be used with cube data sources and calculated fields.

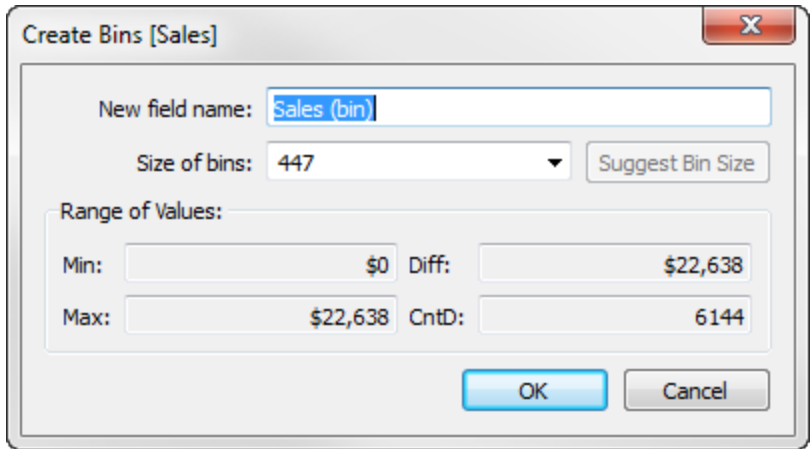

When you create bins from a measure you create a new dimension. That's because you are creating a field with a limited and discrete set of possible values out of a field with an unlimited, continuous range of values. However, once the dimension is created, you can convert it to a continuous dimension. This can be useful, for example, if you want to create a histogram. See [Create a Histogram from a Binned Dimension on page 1586](#).

Create a Binned Dimension:

1. In the **Data** pane, right-click (control-click on Mac) a measure and select **Create > Bins**.

2. In the Create Bins dialog box, accept the proposed New field name or specify a different name for the new field.

On the web, the dialog box is named Edit Bins and has a slightly different appearance, but the options are the same.

3. Either enter a value in the **Size of bins** field or have Tableau calculate a value for you.
 - If Tableau can perform the optimising calculation quickly enough, the value you see initially in **Size of bins** is Tableau's estimate of the optimal bin size.
 - If Tableau cannot perform the optimising calculation quickly, the **Size of bins** field defaults to 10. In this case you can click **Suggest Bin Size** to have Tableau perform the optimising calculation. The formula that Tableau uses to calculate an optimal bin size is $\text{Number of Bins} = 3 + \log_2(n) * \log(n)$.

In the formula, n is the number of distinct rows in the table. The size of each bin is determined by dividing the difference between the smallest and the largest values by the number of bins.

The four read-only fields in the lower part of the Create Bins dialog box show you the data that Tableau uses to suggest a bin size. You can also consider these values if you want to set a bin size manually. The values are:

| | |
|------|---|
| Min | The minimum value of the field. |
| Max | The maximum value of the field. |
| Diff | The difference between the minimum and maximum values of the field. |
| CntD | The number of distinct values (rows) in the data. |

After you click **OK** to dismiss the Create Bins dialog box, a new binned field appears in the **Data** pane.

When you add a binned dimension to the view, each bin acts as an equal-sized container that summarises data for a specific range of values. Column or row headers are created, where each bin label designates the lower limit of the range of numbers that is assigned to the bin. Note that the lower limit is inclusive.

Create a Histogram from a Binned Dimension

If you create a binned dimension, you can use it as the starting point for creating a histogram. Using the **Sales (bin)** dimension created according to the instructions above, use the following steps to create a histogram.

Note: A quicker way to create a histogram is using Show Me. See [Build a Histogram on page 1516](#) in the Build-It-Yourself Exercises section for information on creating a histogram using Show Me.

1. Click the **Sales (bin)** dimension in the Data pane and choose **Convert to continuous**.
2. Drag the **Sales (bin)** dimension from the Data pane and drop it on the **Columns** shelf.
3. Drag the original **Sales** field from the Data pane and drop it on the **Rows** shelf.
4. Click **SUM(Sales)** on **Rows** and change the aggregation from Sum to Count.

The result is a histogram:

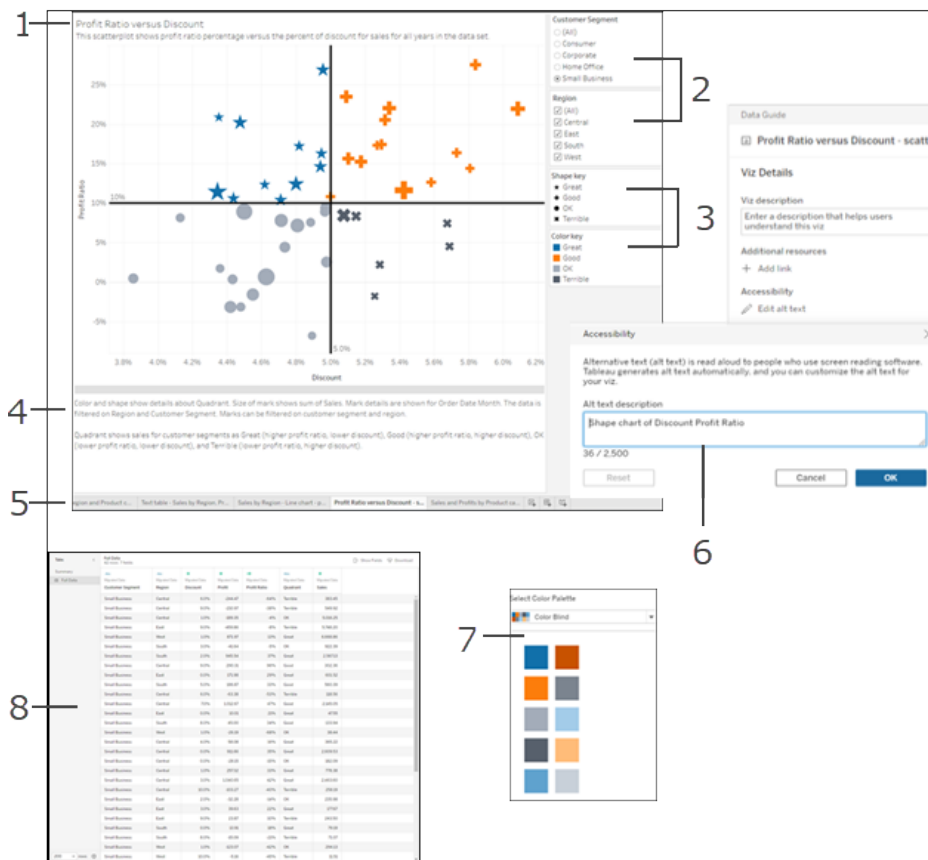

Build Data Views for Accessibility

If you want to make your views accessible to as many people as possible, or if you work in an environment that is subject to US Section 508 requirements, other accessibility-related laws and regulations, you can use Tableau to build data views that help you align to the Web Content Accessibility guidelines (WCAG 2.2 AA). This includes building views that are accessible to users who use screen readers, Braille keyboards, keyboard-only navigation and so on.

View controls that support accessibility

You can use Tableau Desktop to create an accessible view that includes elements that align with Web Content Accessibility guidelines (WCAG 2.1 AA), and then publish and embed that view in a web page that similarly aligns with WCAG 2.2 AA.

The example below shows a view with a scatter plot chart and includes various elements that improve accessibility. For more details, see [Best Practices for Designing Accessible Views on page 1589](#) and [Author Views for Accessibility on page 1596](#).

Title (1), single and multi-value filters (2), categorical legends (3), captions (4), tabs (5), alt text for vizzes (6), Colour Blind palette (7), View Data window (8).

Note: The colour blind palette can help you select colours that can be recognised by users with visual impairments. When you assign colours to different dimension values make sure that they provide enough contrast and aren't too close to each other on the light-dark spectrum.

Additional support for accessible views

In addition to the controls shown in the illustration, Tableau also supports the following features to help you create accessible views:

- Keyboard navigation
- Programmatic context for assistive technologies (using ARIA roles)
- A text equivalent for charts and visualisations
- Compliance with contrast standards

- Authentication when signing in to Tableau Server for embedded views
- Alt text for visualisations (Tableau Cloud version 23.2 and later)

Note: If you use a data source that requires authentication, you can embed the credentials for the data source when you publish to prevent the authentication page from showing and make it more accessible. For information about how to embed credentials for the data source, see [Set Credentials for Accessing Your Published Data on page 3153](#), "Set the authentication type," Embedded password section.

Additional resources

The following external resources can help you when designing your views for accessibility.

- [Web Content Accessibility Guidelines \(WCAG 2.2 AA\)](#)
- [Colour Contrast Tips and Tools](#)
- [Colour Contrast Analyser](#)

Disclaimer: Although we make every effort to ensure these links to external websites are accurate, up to date and relevant, Tableau cannot take responsibility for the accuracy or freshness of pages maintained by external providers. Contact the external site for answers to questions regarding its content.

For information, guidelines and examples about how to create accessible views, refer to the following topics in this section.

Best Practices for Designing Accessible Views

You created a great view, and you want to make it more accessible to make sure that all of your users can see and understand the data that you've put together.

Tableau supports several controls to enable you to build accessible views and help you align with US Section 508 requirements and the Web Content Accessibility guidelines (WCAG 2.2 AA).

Ensure that content shared from Tableau Cloud or Tableau Server follows the steps in [Author Views for Accessibility on page 1596](#) and aligns with the following WCAG 2.2 AA principles:

- **Perceivable** - Information and user interface components must be presented to users in a way that they can perceive. Consider including text alternatives and alternate ways to present the content.

- **Operable** - The user interface components and navigation must be accessible to users from the different devices or methods that they use to interact with the view.
- **Understandable** -The information presented in the view must be understandable to your users. For example, using clearly distinguishable names and labels for different elements shown in your view.

Follow the best practices described in this article and incorporate the steps described in [Author Views for Accessibility on page 1596](#) to build views that are accessible to all of your users when published on Tableau Server or Tableau Cloud.

Keep it simple

WCAG 2.1 AA principle: Understandable

You might have a lot of information that you want to communicate with your view. However, dense views can be difficult to understand or navigate using a screen reader or keyboard. Use the following guidelines to help you communicate everything that you want to without overwhelming your users with an over-packed view.

- Aggregate your data whenever possible to help reduce the number of marks you're showing. Also, showing more than 1000 marks in the view can cause the view to be rendered by the server instead of the browser and server-rendered views aren't yet supported for WCAG alignment.

Users can also access the **View Data** page (enabled by default) to review the underlying data for the marks or can download the data from that page to an accessible application to view it that way.

Example: This example shows two different bar chart views to illustrate the difference between a detailed and aggregated view.

Not easily accessible - Too many marks More accessible - Aggregated view

- This much detail makes the view harder to understand.
- The view is showing over 5,000 marks and doesn't include enough text to indicate what the different marks represent.
- It's too difficult to use for users who need screen readers.
- This example shows the same view with the data aggregated at a higher level.
- Key data points are still included, but they're now easier for users to read and understand.
- The number of marks is reduced from over 5000 to about 20.
- Users can still read the underlying details for the marks by placing focus on the view and then pressing **Enter** to open the **View Data** page.
- Consider using simple graphic elements like bar charts or line charts that allow you to use text, colour and shapes to add more context to the view.
- Limit the number of marks to only those that emphasise the most important data points.

For information and examples about how to build this type of view, see [Keep it simple on page 1597](#) in [Author Views for Accessibility on page 1596](#).

Titles and captions

WCAG 2.1 AA principle: Perceivable, Understandable

Providing good descriptive text in titles and captions provides context to users who are using assistive technology, and can help them understand the data in your view. Use the following guidelines to adapt the visual nature of Tableau to meet the needs of all of your users.

- Think about your views as a supplement to the text you use to describe it.
- Use text in titles and captions to describe your visualisations and what you are showing.
- Use simple, easy-to-understand language. Avoid jargon, acronyms or abbreviations.
- Don't include words like 'image of' or 'picture of' in your text descriptions, because screen readers sometimes already include this information.
- Avoid using all capital letters (for example in headings or titles), because they can be difficult to read.

Example: This example shows two different bar charts. One using very little text and the other using titles and captions to add context

Not easily accessible - Too little text

More accessible - Adding descriptive text to provide context

- A one-word title isn't descriptive enough.
- The marks are differentiated by colour and size. But without additional text, the context for these marks can be difficult to

- This example shows the same view, but includes additional explanatory text in both the title and the caption.
- The same contrast colour scale and size differentiators are used, but

understand.

- There's no caption or other explanatory text to help explain this view.

labels are added to the bar marks to give additional context.

For information and examples about how to build a view that includes text for context, see [Show more text and make it helpful](#) on page 1608 in [Author Views for Accessibility](#) on page 1596.

Additional text

WCAG 2.1 AA principle: Perceivable, Understandable

Using text beyond just titles and captions throughout your view can help users understand the context of the different elements that you're showing, as well as help describe the relationship between the different controls (such as legends and filters) and your data.

Use the following guidelines when adding additional text:

- Use text in headings on legends or filters to describe the control and what it does. You can also use text zones on a dashboard to add additional context for your visualisations to further describe what you are showing.
- Add alternative text (alt text) to visualisations. Tableau started automatically generating alt text for vizs in Tableau 23.1. In Tableau 23.2 and later, you can edit the auto-generated alt text to add additional context that you know is important to your audience.
- Refer to controls by label whenever possible. For example, changing the label for a legend from **Subcategory** to **Colour key for product type** can help users understand the relationship between the controls and the data.
- If you include link text in your view, use text that describes where the link takes the user. For example, use link text like "Global Warming statistics for 1990-2000". Avoid wording like "Click here", "More" or "More information". These link text examples are too generic and can be confusing to users.
- **Example:** The following example shows two bubble charts. One view uses only the text that shows by default when creating a view and one view has additional text that adds context throughout the view to help convey meaning.

Not easily accessible - Too little text

More accessible - More descriptive text

- This view uses only default text for the sheet title and default labels for the filters and legend.
- The marks are differentiated by size and colour only.
- There's no caption or other explanatory text included in the view to help provide context.
- This example shows the same view, but includes additional explanatory text.
- Additional text was added to the title and caption to explain the relationship of the marks and provide additional context about what the view is showing.
- Mark labels are added to show profit numbers so that users don't have to rely on the colour only to understand this information.

For information and examples about how to build a view that includes additional text for context, see [Show more text and make it helpful](#) on page 1608 and [Author Views for Accessibility](#) on page 1596 in [Author Views for Accessibility](#) on page 1596.

Colour and contrast

WCAG 2.1 AA principle: Perceivable, Understandable

You can use colour to help distinguish marks in your view. However, for users with visual impairments, using colour alone doesn't always provide enough of a distinction, especially when there are many marks in a view. Use the following guidelines when using colour in your views:

- Tableau provides a colour-blind palette that you can use to help you select appropriate colours for your view. For any colour palette that you use, try to provide enough contrast and assign colours that differ from each other on the light-dark spectrum.
- For line marks, use additional options like shapes, size and labels to help distinguish them.
- Use **contrast analyser** tools to help select the best text colours and backgrounds with sufficient contrast ratios. Make sure that colour contrast for text is strong and meets the contrast ratio standards of 4.5:1 (3:1 for large text).

Example: This example shows two line charts. One that uses colour only to differentiate the lines and the other that uses more appropriate colours plus shapes to differentiate marks

Not easily accessible - Using only colour to differentiate marks

- This view uses only colour to distinguish the lines from one another.
- The marks in the view aren't using a colour palette that is fully accessible to users with visual impairments.

More accessible - Using colour and shape to differentiate marks

- This example shows the same view, but uses both colour and shape to identify the marks.
- A colour legend and a shape legend with clear titles identify what the colours and shapes represent in the view.

For information and examples about how to build a view that uses colour to help distinguish marks, see [Author Views for Accessibility](#) below in [Author Views for Accessibility](#) below.

Publishing your view

WCAG 2.1 AA principle: Perceivable, Operable, Understandable

To make your views available to your users, publish your view to Tableau Server or Tableau Cloud, in the toolbar menu, click **Share**. Users can interact with the view and toolbar buttons using a screen reader or a keyboard. For more information, see [Keyboard Accessibility for Tableau on the Web](#) on page 3255.

For information about how to publish and embed workbooks, find the embed code to copy into your web pages, and turn off the toolbar, see [Publish and share the view](#) on page 1630 in [Author Views for Accessibility](#) below.

Author Views for Accessibility

This article provides more detail on the design guidelines discussed in [Best Practices for Designing Accessible Views](#) on page 1589, and the steps to create these views in Tableau Desktop (version 10.2 and later).

General steps

As a content author, you can create views that help you align with Web Content Accessibility Guidelines (WCAG) following these general steps:

Step 1: Author views following accessibility best practices.

Step 2: Publish the views to Tableau Server or Tableau Cloud (version 10.2 and later).

Step 3: Share the link for users to access the content in Tableau Cloud or Tableau Server, or embed the views in a web page for users to access the content.

Creating views using best practices guidelines can make them more accessible; they're treated by screen readers as images with a title and a description. Users will be able to use keyboard navigation to open the View Data pane and access the underlying data for the view.

Building the views

Many of the principles that apply to creating effective views in Tableau also apply to creating accessible views. The main difference in creating accessible views is that you should always

provide other types of mark encoding when you use colour in the view. You also want to use text more liberally in the view to provide context for the view and its marks.

Keep it simple

When creating accessible views, keep it simple. Simplicity helps people more easily see the relationships and intersections in your data.

How can you make a view more simple? Emphasise only the most relevant and important data. Reduce the marks in the view to only show what is needed. Limit the level of detail and granularity in the view to prevent cognitive overload.

When designing your views, keep in mind that your users will be accessing the underlying data in the view. The data you include in the view is what screen readers read when users access the underlying data in the Summary tab of the View Data pane.

Guidelines that support simplicity:

- Limit the number of marks in the view
- Orientate your views for legibility
- Limit the number of colours and shapes in a single view
- Use filters to reduce the number of marks in the view at a given time

Limit the number of marks in the view

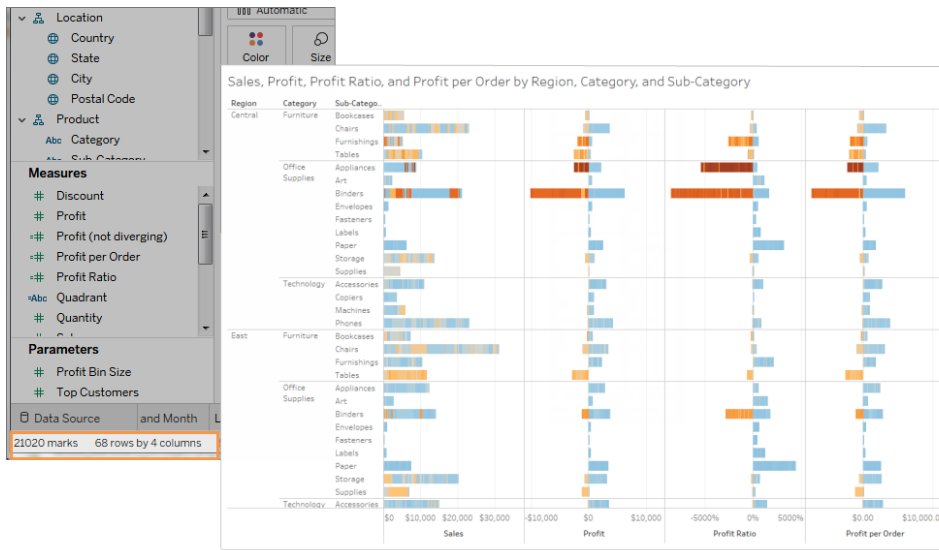

Keep the number of marks below 1000 to ensure the view will be rendered in the browser and not on the server.

Note: Client-rendered views can be more accessible than server-rendered views. To ensure an embedded view is rendered in the browser, make sure the view has fewer than 1,000 marks, including items in legends and filters.

You can see the number of marks a view has when you're authoring the view in Tableau Desktop (bottom-left corner of the window).

Example of a view with too many marks

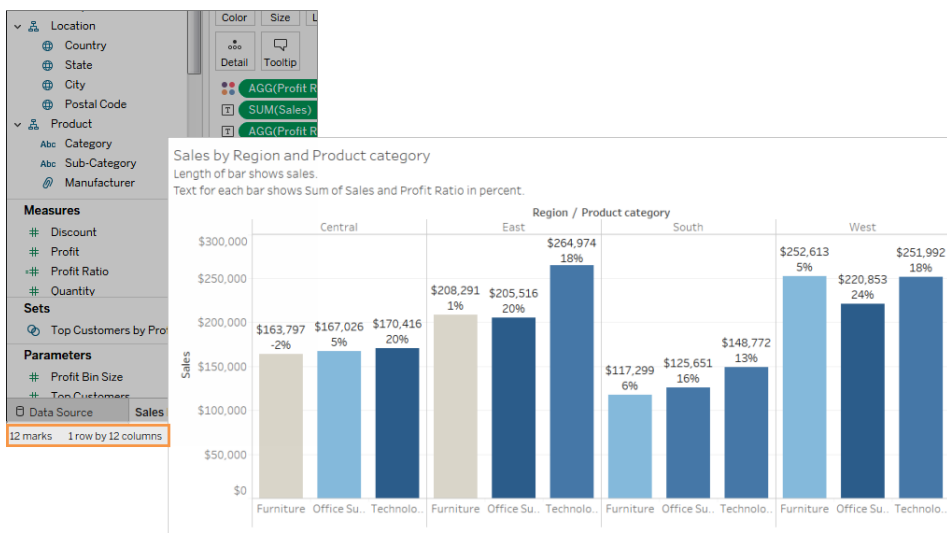

The following example shows a view with over 20,000 marks. The view shows a more granular level of detail in the data (versus aggregated). Multiple dimensions (Region, Category, Sub-Category) and measures (Sales, Profit, Profit per Order, and Profit Ratio) have been added to the view. Product Name is on Detail, which adds a mark for every product included in the data set.

Example of a view with fewer marks

The next example shows a more accessible view (fewer than 100 marks). The data is aggregated and shows a less granular level of detail in the data. Two dimensions (Region and Product Category) and one measure (Sales) are used in the view.

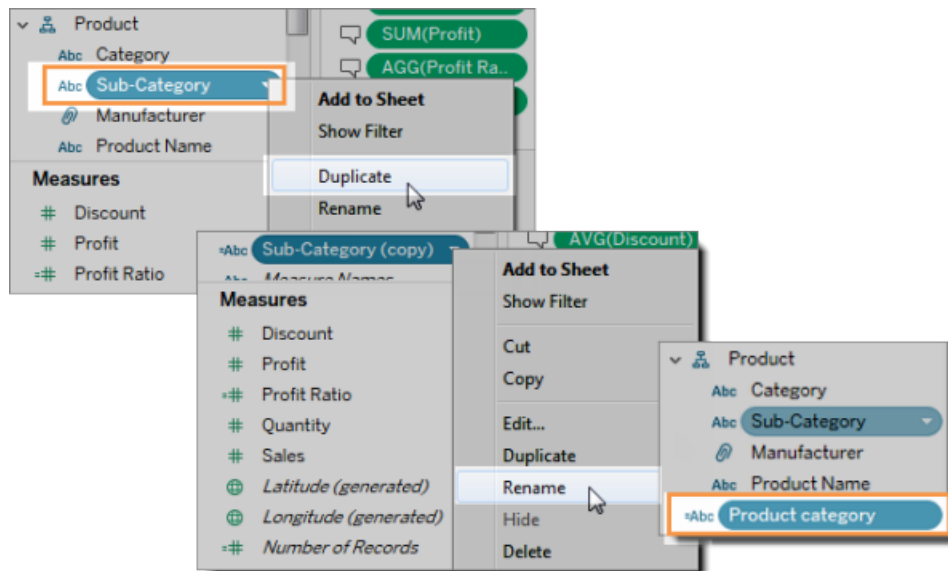

For more details about these concepts, see [Data Aggregation in Tableau on page 171](#) and [How dimensions affect the level of detail in the view on page 150](#).

There are several ways you can limit the number of marks:

- Create views of aggregated data rather than showing more granular levels of detail in the view. Don't place dimensions that contain thousands of values on **Detail** in the Marks card.
- If you want to use a dimension that is in a hierarchy, but not make the hierarchy available in the view, use a copy of that particular dimension. Copy the field you want to use from the hierarchy and build the view with the copied version of the dimension.

This will prevent users from expanding the hierarchy in the embedded view, which could increase the number of marks in the view and result in the view being rendered on the server instead of the browser.

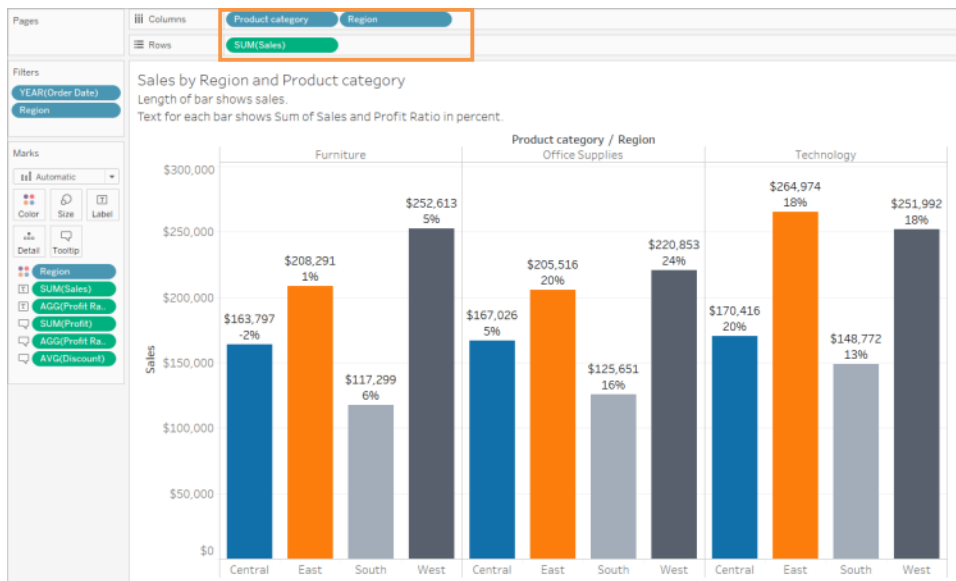

1. Right-click a dimension in the hierarchy, and then select **Duplicate**. A copy of the dimension appears.
 2. Right-click the copied dimension, and then select **Rename**. Give the copied dimension a unique, meaningful name. Now use that dimension to build the view.
- Limit the number of measures and dimensions used to create the view.

Less accessible: The next example shows a view with four measures on Rows and three dimensions on Columns. More fields create a more complex view.

More accessible: This view has two dimensions on Columns and one measure on Rows. Fewer fields in the view structure reduces cognitive overload.

Orientate your views for legibility

Horizontally oriented labels and headers are easier to read than vertically oriented labels.

Less accessible: In this example, the text is displayed vertically.

More accessible: In this example, space has been added to the view to allow the text to be displayed horizontally.

To change the orientation of the view and its headers and labels, you can click the **Swap** button on the toolbar, or you can resize the view to allow more room for horizontal labels. In this example, the table was resized. For details, see [Resize Tables and Cells](#) on page 3003.

Limit the number of colours and shapes in a view

If you're showing a dimension on Colour or Shape, don't use more than 10 colours and shapes in one view so that users can distinguish each colour and shape and see important patterns.

Don't do this: In the following example, the line colours have started repeating after the 10th mark applied to Product type.

Do this: In the next example, filters have been used to limit the number of marks that can be shown at a time. As a result, the number of colours and shapes in the view is never more than ten.

Use filters to reduce the number of marks in a view

Using filters helps to focus the number of marks in the view to only what you want users to see.

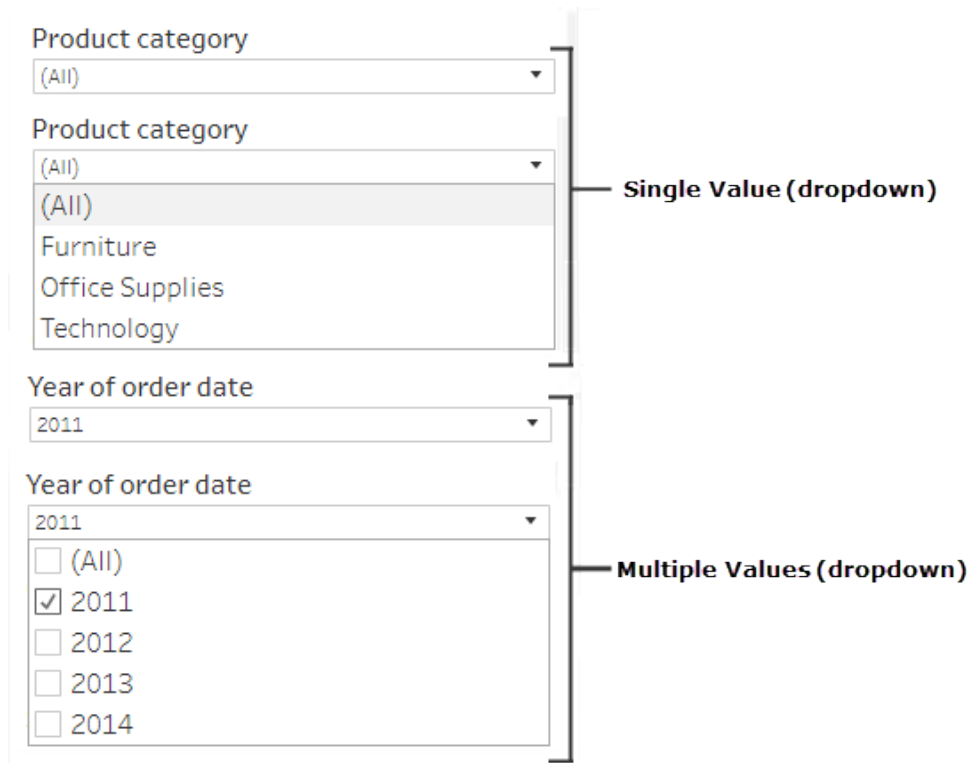

For more details about creating filters, see [Filter Data from Your Views](#).

You can also show the following filter modes to allow users to control what data is in the view. The filter modes that support more accessible views in Tableau are:

- **Single Value (list):** a filter with radio buttons. Only one item can be selected at a time. Giving your users single-value filters is a great way to reduce the number of marks in the view.
- **Multiple Values (list):** a filter with a list of items (with tick boxes) that can be selected at the same time. Multiple-value filters will allow more marks to be shown at the same time.

- **Single Value (dropdown):** a filter with a dropdown list of items. Only one item can be selected at a time. Giving your users single-value filters is a great way to reduce the number of marks in the view.
- **Multiple Values (dropdown):** a filter with a dropdown list of items that can be selected at the same time. Multiple-value filters allow more marks to be shown at the same time.

To show a filter, right-click the field you want to use as a filter, and then select **Show Filter**.

To select the filter mode, in the drop-down menu for a filter, select a **Single Value (list)**, **Single Value (dropdown)**, **Multiple Values (list)**, or **Multiple Values (dropdown)** filter.

For a Single Value (list) or Single Value (dropdown filter), you can remove the **All** option from the filter. In the drop-down menu for the filter, select **Customise** and then clear the **Show "All" Value** option.

The following image shows the **Customise** option in a filter.

When you're using multiple filters in a worksheet, keep the following guidance in mind:

- When you're creating a view, test the browser zoom up to 200% to make sure all of the components in the view display as intended.
- Avoid positioning filters horizontally in a worksheet. In instances where the browser window isn't wide enough, components in the view (such as filters) will overlap with the visualisation.
- Don't reposition the filters after you have added them to the view. If you reposition the filters or change their order, the tab order may change.

This example shows a view with a **Single Value (list)** filter for the Product category and a **Multiple Values (list)** filter for Product order date. The **Single Value (list)** filter only allows one product type to be shown at a time (**All** is hidden).

Show more text and make it helpful

In your views, make sure you show titles, captions, and mark labels. You can edit titles and captions to provide more context and details to help users understand the view.

- Be precise and consistent in how you name every object in the view.
- Provide text that explains how components of a visualisation relate.
- Simplify text to remove redundancies.

You can also rename measures and dimensions in the Data pane to make sure field names in the view are meaningful.

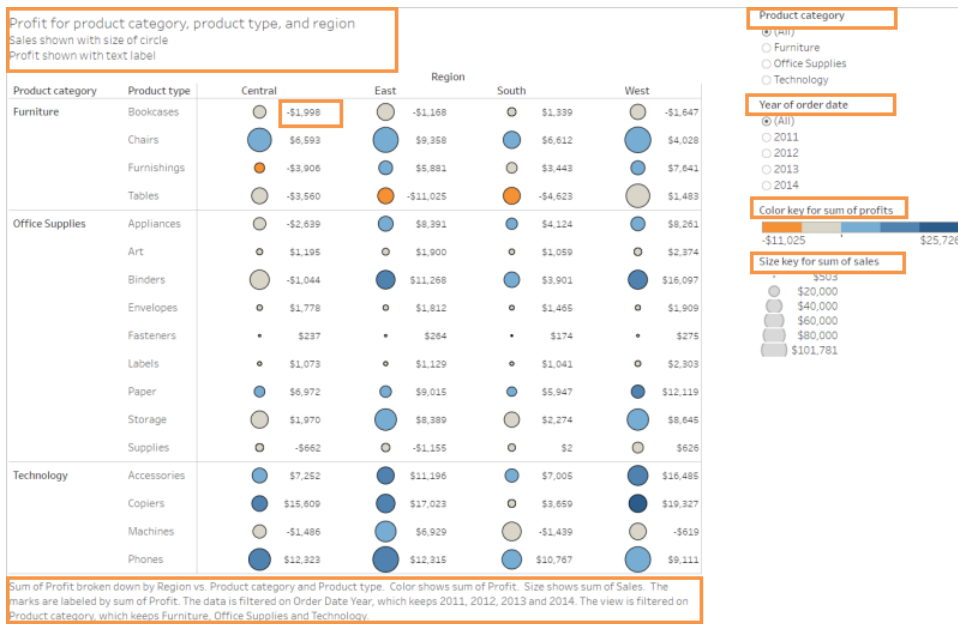

Here are the different elements in a view that you can show and edit:

- **Titles (worksheet, filters, and legends).** Show titles for the worksheet, filters, and legends. The default title text is the sheet name or field name referenced by the filter or legend. You can edit any title to provide more context.
- **Captions (in worksheets).** Show the caption in the worksheet. The default caption text gives a summary of what is shown the view. You can add to this text to provide more context.
- **Labels (Marks card, Label button).** By default, labels aren't shown in a view, so you must select the option to show them.

Less accessible: This example shows a view with limited text. Many text elements aren't shown: the worksheet caption, mark labels, a descriptive title and additional text about the view in the Title area. Also, the filter and legend titles haven't been edited to provide more context.

More accessible: This example shows the same view with multiple text elements shown to provide more detail and context. Titles and captions are shown in the worksheet. The worksheet title was edited to include text that describes how data is indicated in the view. The worksheet caption includes the default summary text that is automatically generated by Tableau. The legend titles have been edited to make more sense in this view. Mark labels show Profit values so that users don't have to rely only on seeing the colour.

You also can build views that show only text, such as this example of a Text Table view that shows similar data.

Sales by Region, Product category, and Product type

| Product category | Product type | Region | | | |
|------------------|--------------|----------|-----------|----------|-----------|
| | | Central | East | South | West |
| Furniture | Bookcases | \$24,157 | \$43,819 | \$10,899 | \$36,004 |
| | Chairs | \$85,231 | \$96,261 | \$45,176 | \$101,781 |
| | Furnishings | \$15,254 | \$29,071 | \$17,307 | \$30,073 |
| | Tables | \$39,155 | \$39,140 | \$43,916 | \$84,755 |
| Office Supplies | Appliances | \$23,582 | \$34,188 | \$19,525 | \$30,236 |
| | Art | \$5,765 | \$7,486 | \$4,656 | \$9,212 |
| | Binders | \$56,923 | \$53,498 | \$37,030 | \$55,961 |
| | Envelopes | \$4,637 | \$4,376 | \$3,346 | \$4,118 |
| | Fasteners | \$778 | \$820 | \$503 | \$923 |
| | Labels | \$2,451 | \$2,603 | \$2,353 | \$5,079 |
| | Paper | \$17,492 | \$20,173 | \$14,151 | \$26,664 |
| | Storage | \$45,930 | \$71,613 | \$35,768 | \$70,533 |
| | Supplies | \$9,467 | \$10,760 | \$8,319 | \$18,127 |
| Technology | Accessories | \$33,956 | \$45,033 | \$27,277 | \$61,114 |
| | Copiers | \$37,260 | \$53,219 | \$9,300 | \$49,749 |
| | Machines | \$26,797 | \$66,106 | \$53,891 | \$42,444 |
| | Phones | \$72,403 | \$100,615 | \$58,304 | \$98,684 |

Sum of Sales broken down by Region vs. Product category and Product type. The data is filtered on Order Date Year, which keeps 2011, 2012, 2013 and 2014. The view is filtered on Region, which keeps Central, East, South and West.

Region
☒ (All)
☒ Central
☒ East
☒ South
☒ West

Year of Order Date
☒ (All)
☐ 2011
☐ 2012
☐ 2013
☐ 2014

To show and edit titles and captions for the worksheet

1. Select **Worksheet > Show Title**, and then select **Worksheet > Show Caption**.

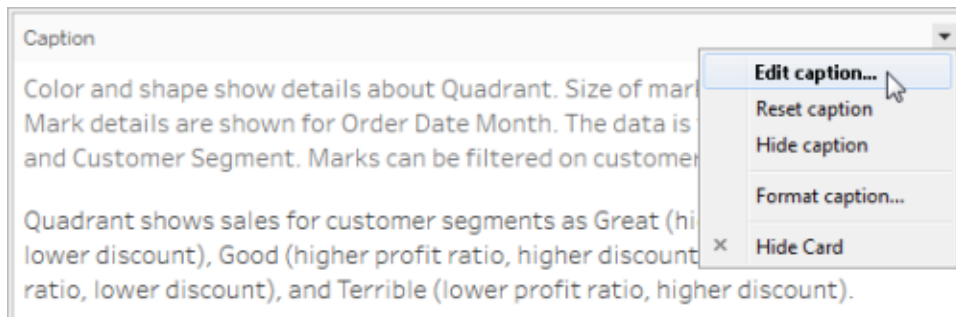

2. In the Title box at the top of the view, click the drop-down menu, and then click **Edit title**.

Type text in the text area and format it, and then click **OK**. You can add text in addition to markup text, or replace the markup text.

3. In the Caption box, click the drop-down menu, and then click **Edit caption**.

Type text in the text area and format the text, click the drop-down menu, and then click **OK**. You can add text in addition to the default text, or replace the default text.

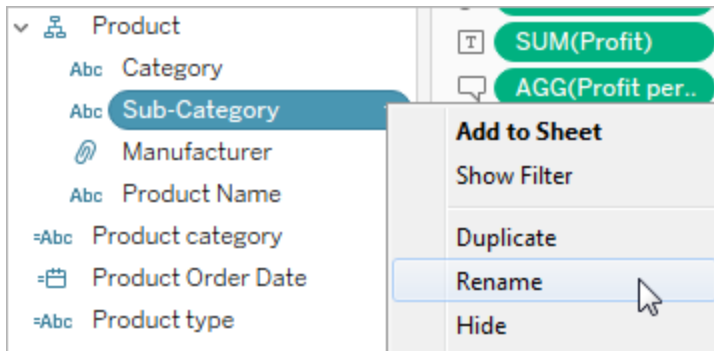

To show mark labels in the view

- Click **Label** in the Marks card, and then click **Show mark labels**.

To edit field names in the Data pane

1. Right-click the dimension or measure, and then click **Rename**.

2. Edit the name, and then press **Enter**.

For more details, see [Rename fields](#).

To edit filter or legend titles

The text associated with legends and filters should clearly describe their purpose. Edit titles for filters and legends to indicate function. Refer to filters by name in any instructions that you provide in the worksheet title or caption.

1. Click the drop-down menu for the filter, and then click **Edit Title**.

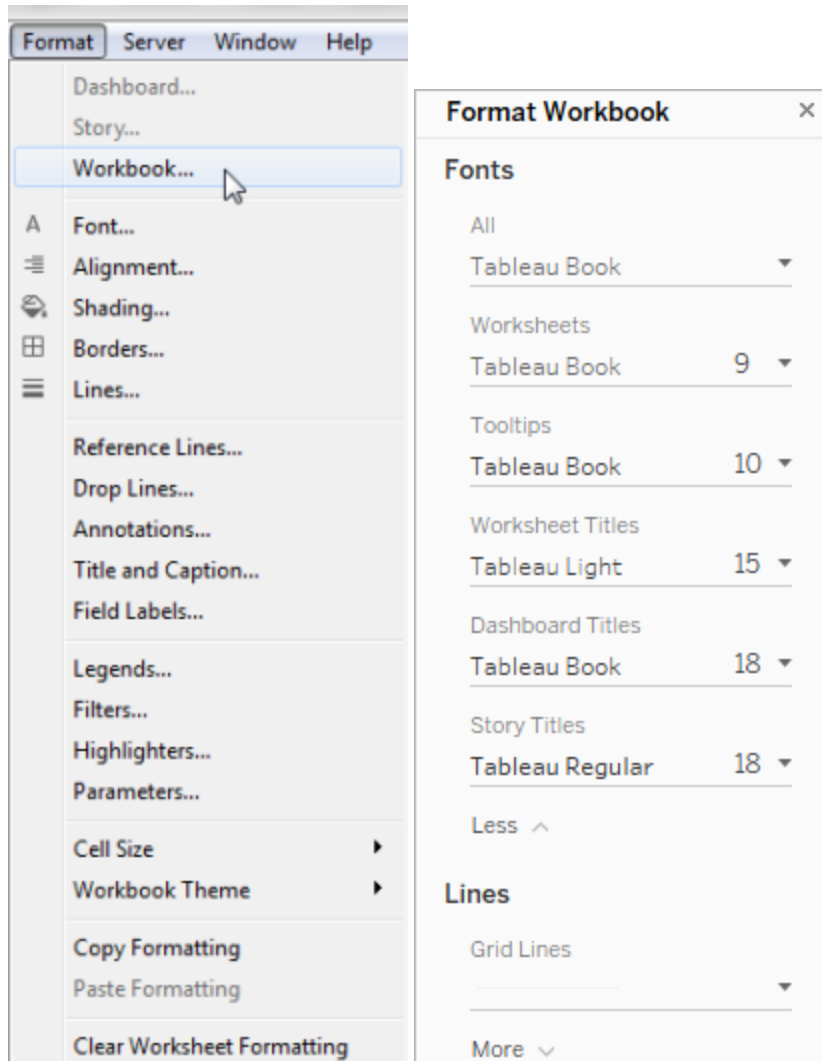

2. Edit the text, and then select **OK**.

Font Size

Increasing the font size of your text can make it more accessible. Select **Format > Workbook** to change the default text sizes for the entire workbook. For more details, see [Format Your Work](#).

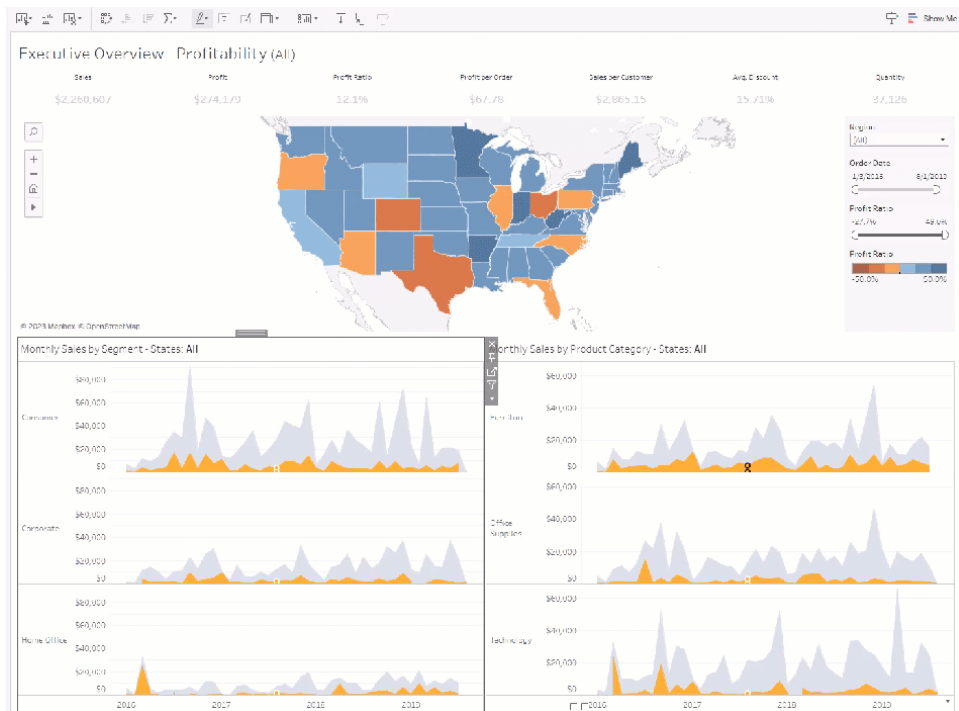

You can also change the font size at the worksheet level.

Edit alt text to make it more descriptive (Tableau Cloud and Tableau Desktop)

Starting in Tableau Cloud 23.2 and Tableau Desktop 23.3, you can customise the alt text auto-generated by Tableau, which can help make it more descriptive and meaningful to your audience.

In a dashboard, you can access the alt text editor through the context menu.

1. Tap the viz to select it, expand the More Options menu, and choose **Accessibility**.
2. Update the alt text in the alt text description box, and then select **OK**.

In a worksheet, you can access the alt text editor through the toolbar or the Data Guide pane.

From the toolbar:

1. Select Worksheet and choose **Accessibility**.
2. Update the alt text in the alt text description box, and then select **OK**.

From the Data Guide pane:

1. In authoring mode, open the Data Guide pane by clicking the Data Guide  icon.
2. Under Accessibility, select **Edit alt text**.

3. Update the alt text in the alt text description box, and then select **OK**.

Note: You must be in authoring mode to edit alt text. If you don't have access to the Data Guide, check with your administrator. They may have hidden the Data Guide for your organisation.

Use colour thoughtfully and provide contrast

Different colour palettes are available depending on the type of field being placed on Colour in the Marks card. For any colour palette that you use, make sure that you're providing enough contrast and assign colours that differ from each other on the light-dark spectrum.

- For dimensions (discrete), a suggested practice is to use the **Colour Blind** palette. You may need to adjust the colours assigned to different dimension values. Try to provide enough contrast and assign colours that differ from each other on the light-dark spectrum. For monochromacy, try using the **Seattle Greys** palette with **Stepped Colour** set to 5.
- For measures (continuous), try using the **Blue** or **Orange-Blue Diverging** palette with the **Stepped Colour** option set to 5. You may need to adjust the number of steps used. For monochromacy, consider using the **Grey** palette with **Stepped Colour** set to 5.

For text colour, general guidelines are that the visual presentation of text and images of text has a contrast ratio of at least 4.5:1 (large text 3:1). Tableau's default colour formatting follows these prescribed contrast ratios. You can use a [contrast analyser](#) tool to test the contrast ratios of text colours and backgrounds.

Important: When you use colour in the view, you must also provide other types of encoding for marks, such as labels, size, shape, and position. Don't rely on colour alone to communicate differences in marks.

Dimension on Colour

Less accessible: This view shows an example of a discrete dimension being placed on Colour, which is set to the Tableau 20 palette. The line path provides helpful position information, but the colours don't provide a clear distinction between the line marks.

More accessible: In the next example, the Colour Blind palette is being used. Shape is also being used to reinforce what is being shown in colour.

Measure on Colour

Less accessible: This view shows an example of a continuous measure placed on Colour, which is set to the Blue-Teal palette with gradient colours. The view doesn't provide enough contrast between colours and there's insufficient contrast on the light-dark spectrum. The use of

size helps this view, but this colour palette can make it hard for people with colour vision deficiencies to see contrast differences between marks.

More accessible: This view uses the Orange-Blue Diverging palette with stepped colours. This palette provides improved contrast between marks.

To select a palette

You must already have a measure or dimension on Colour in the view for this option to be available.

- 1. Click **Colour** in the Marks card, and then click **Edit Colours**.
- 2. For **Select Colour Palette**, click the drop-down arrow and select the palette.

This example shows selecting the Colour Blind palette.

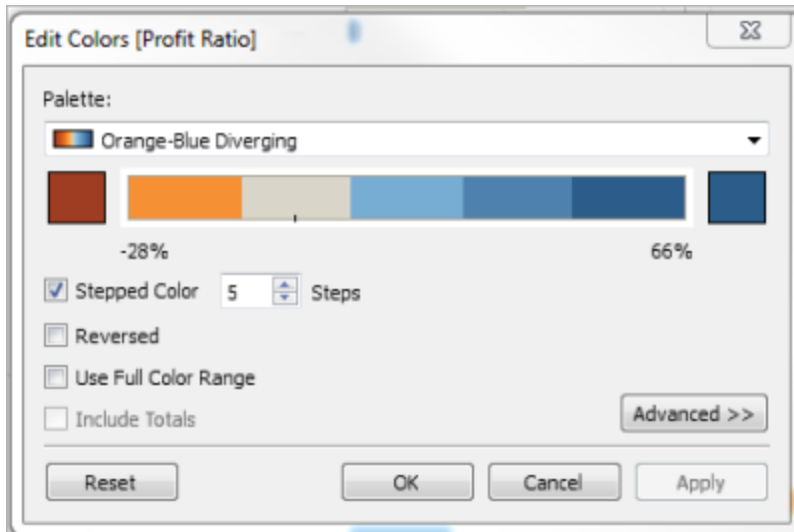

For the Colour Blind palette, click **Assign Palette** and then click **OK**. Otherwise, click **OK**.

To change the colour of a value:

1. Click a value on the left, under **Select Data Item**.
2. Click a new colour in the palette on the right. Hover over a swatch to identify the colour. Repeat for many values that you want to change.
3. Click **OK** to exit the Edit Colours dialog box.

The following example shows the Orange-Blue Diverging palette with Stepped Colour set to 5 steps.

3. For the Colour Blind palette, click **Assign Palette** and then click **OK**. Otherwise, click **OK**.

For details about colours and palettes, see [Colour Properties](#).

Provide visual cues beyond colour: position, size, and shape

When you use colour for field values, you must also provide other types of encoding for marks, [such as labels](#), and position, size, and shape. Use position, size, or shape for the same field values to reinforce the differences between marks. These mechanisms all communicate information about the data to your users.

If you're using colour to show measure or dimension values, make sure that you provide enough light-dark spectrum contrast for the colours that you assign to different marks.

Less accessible: This example shows the same scatter plot with no use of colour, shape, or size to create contrast. The position of the marks provides meaningful information, but the view could make use of more visual cues.

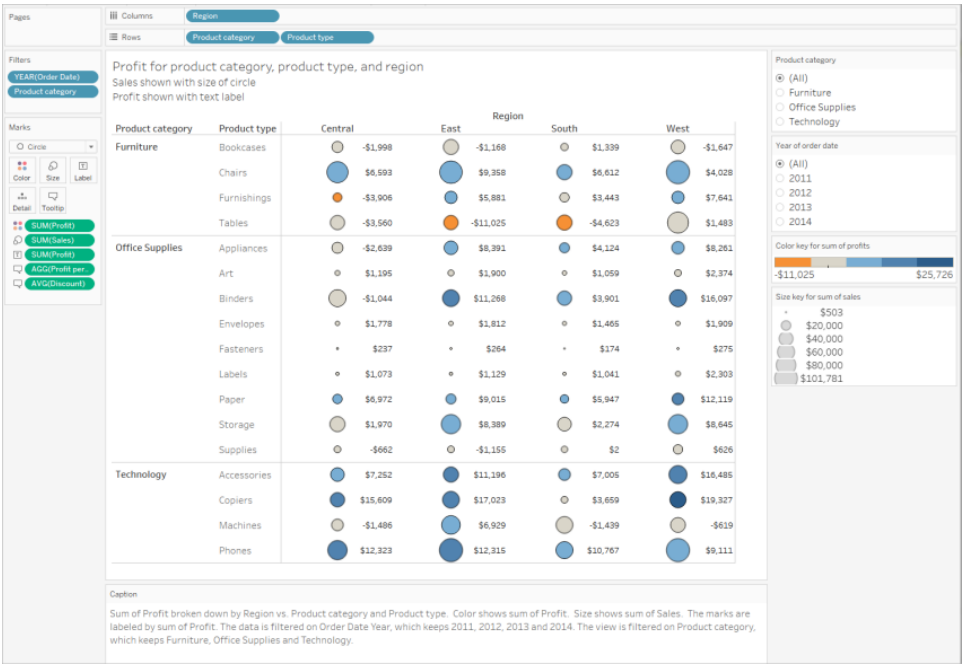

More accessible: This example shows a calculated field named Quadrant being used on colour and shape. Position, colour, and shape are used to distinguish each mark. The axes also clarify the mark position and meaning.

Putting it all together

This next example shows how text, shape, colour, and size can all work together to create an accessible view. Sales are represented by the size of each circle (mark). Profit is represented by colour and text. The title and caption for the view are shown. These have been edited to provide more context. The filter and legend titles have also been edited to provide more context.

Walkthrough: The journey from less accessible to more accessible

Let's convert a viz that isn't very accessible into one that is. The data in this starting view has a more granular level of detail and a structure that could contribute to cognitive overload with a screen reader.

This view is designed to show total sales for each sales region, along with the profit ratio, to determine which types of products seem to be selling well but aren't actually profitable. Profit and Profit per Order are also shown.

We'll make changes to it **based on the concepts and best practices** mentioned previously in this article.

Step 1: Reduce the level of detail in the view.

Because the Product Name dimension is on Detail, every product in the data set is being represented with a mark in the view.

- Remove Product Name from Detail. This change reduces the number of marks in the view from over 20,000 to 272.

Reducing the number of marks in the view helps to ensure the embedded view will be rendered on the browser instead of the server.

Step 2: Create a more aggregated view of the data.

1. Reduce the number of measures on Columns and the number of dimensions on Rows.
2. Remove Region (we can use a filter for Region). The number of marks changes to 68.
3. Replace Category and Sub-Category (both dimensions that are part of the Product hierarchy) with copies (not part of a hierarchy) that have been renamed Product category and Product type. Remove the Sub-Category filter.

This will prevent users from expanding the hierarchy in the embedded view, which could increase the number of marks in the view and result in the view being rendered on the browser instead of the server.

The view is already more aggregated and simplified, but we'll keep going.

- Move the Profit, Profit per Order, and Profit Ratio from the Columns shelf to **Tooltip**.

The number of marks is now 17. The underlying details in the data will still be available in the View Data window, but the reduced number of marks ensures the view will be more accessible because it will be rendered in the browser.

Step 3: Check the colour palette settings.

The palette is set to Orange-Blue Diverging.

- Set **Stepped Colour** to 5.

Step 4: Update and show text in the view.

1. Change the Title to make sense with the new view.
2. Show the worksheet Caption.
3. Show Mark labels.
4. Drag Profit Ratio to Label in the Marks card.
5. Edit the filter and legend titles.

Step 5: Open the View Data window to the Summary tab.

This is the text that screen readers will read for this view. The four measures are included in the underlying data for each product type.

| Tabs | | Summary 17 rows 6 fields | | | | |
|-----------|---------|--------------------------|-------------------|-------------------|-------------------|-------------------|
| Full Data | Summary | ABC Migrated Data | ABC Migrated Data | ABC Migrated Data | ABC Migrated Data | ABC Migrated D... |
| | | Product category | Product type | Profit per Order | Profit Ratio | Profit |
| | | Furniture | Tables | \$-81.41 | -13% | \$-8,141 |
| | | Furniture | Furnishings | \$14.04 | 14% | \$4,099 |
| | | Furniture | Chairs | \$43.93 | 8% | \$7,644 |
| | | Furniture | Bookcases | \$-7.68 | -2% | \$-584 |
| | | Office Supplies | Supplies | \$-16.19 | -6% | \$-955 |
| | | Office Supplies | Storage | \$27.29 | 11% | \$7,368 |
| | | Office Supplies | Paper | \$29.82 | 43% | \$12,049 |
| | | Office Supplies | Labels | \$15.86 | 45% | \$1,745 |
| | | Office Supplies | Fasteners | \$4.76 | 36% | \$305 |
| | | Office Supplies | Envelopes | \$20.31 | 43% | \$1,442 |
| | | Office Supplies | Binders | \$17.83 | 11% | \$7,737 |
| | | Office Supplies | Art | \$8.70 | 25% | \$2,227 |
| | | Office Supplies | Appliances | \$49.47 | 18% | \$7,865 |
| | | Technology | Phones | \$45.97 | 12% | \$12,872 |
| | | Technology | Machines | \$-89.66 | -7% | \$-2,869 |
| | | Technology | Copiers | \$1,137.81 | 40% | \$25,032 |
| | | Technology | Accessories | \$62.44 | 26% | \$15,672 |

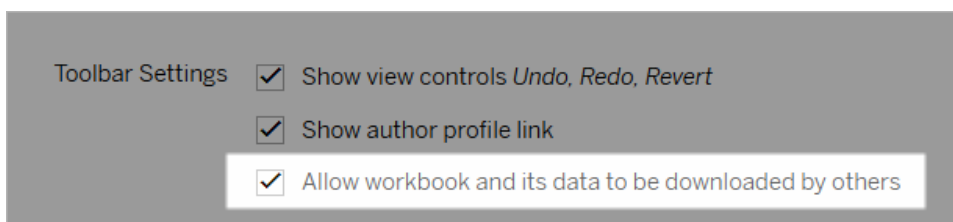

Publish and share the view

After you create your views, to make them more accessible, you can:

- Publish views to Tableau Server or Tableau Cloud and share the link, or embed the view in an accessible web page. For information about how to publish a view, see [Comprehensive Steps to Publish a Workbook on page 3120](#).
- Make sure users have permissions to access to the views and are able to view the underlying data in the View Data window.

Publishing to Tableau Public

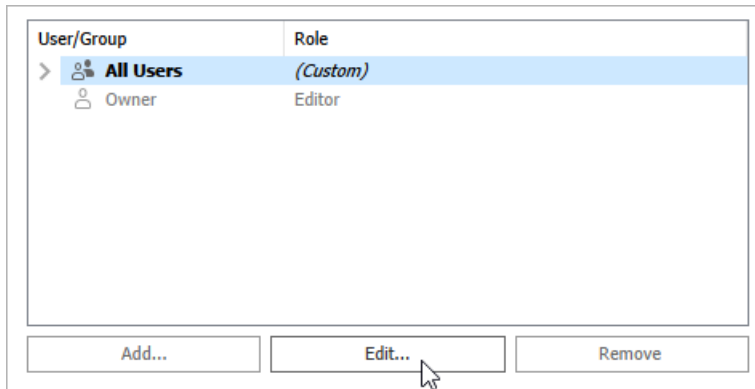

After creating your workbook and saving to Tableau Public, the "Allow workbook and its data to be downloaded by others" option must be enabled in order for the end user to be able to open the View Data window.

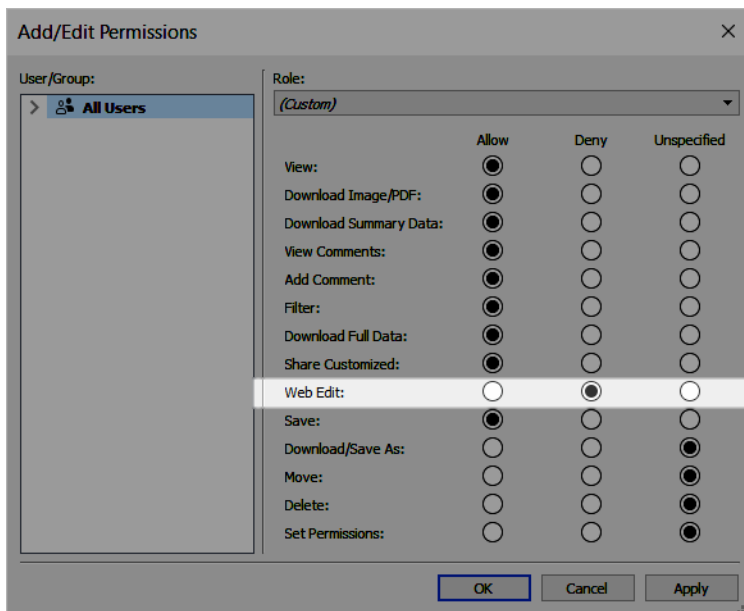

Turn off Web Edit permissions

To prevent your users from seeing the Edit option in the view toolbar, set the Web Edit permission to Deny when you publish your workbook. You should also let your Tableau Cloud administrator know when you publish workbooks that they should not allow users to access web editing mode.

1. In Desktop, select **Server > Publish Workbook**.
2. Under **Permissions**, select **Edit**, select **All Users**, and then select **Edit** again.

3. For the Web Edit permissions, select **Deny**. Click **Apply**, then click **Ok**.

Share or embed the view

When you're ready to share, go to the view in Tableau Server or Tableau Cloud and click the **Share** button in the view toolbar to copy the link or share with a user on the site. The view toolbar and navigation panel are supported for conformance, and include a "Skip to Content" option for keyboard navigation as well as a focus indicator.

Alternately, views can be embedded in the HTML code of a WCAG-conformant web page. For more information about how to embed views, see [Embed Views into Webpages on page 3362](#).

Sample embed code

```
<script type='text/javascript' src='http://Your_
Server/javascripts/api/viz_v1.js'></script>
<div class='tableauPlaceholder' style='width: 1256px; height:
818px;'>
  <object class='tableauViz' width='1256' height='818'
style='display:none;'>
    <param name='host_url' value='http%3A%2F%2FYour_Server%2F' />
    <param name='site_root' value='' />
    <param name='name' value='name of the visualization' />
    <param name='tabs' value='yes' />
    <param name='showShareOptions' value='true' />
  </object>
</div>
```

In a view URL:

```
https://myserver/t/Sales/views/MyCoSales/SalesScoreCard?embed=y
```

Embedded views must be rendered on the browser (not the server)

Server-rendered views are less accessible than client-rendered views. To ensure an embedded view is rendered in the browser, make sure the view has fewer than 1,000 marks, or set *render* to *true* in the URL for the embedded view.

For example:

```
http://localhost/views/Supplies/MyView?:render=true
```

Client-side rendering is enabled (*true*) by default.

About permissions

Users who need access to the underlying data will need the proper site role and permissions to view and interact with your embedded views. This includes having access to the projects and workbooks that contain the views. At the minimum, your users need View and Download Summary Data permissions. The ability to view the underlying data is necessary for users who use screen readers.

Users viewing the embedded view should have:

- Site role of Explorer, Viewer or Guest.

Note: The Viewer site role is more limited and won't be able to use filters or view the Full Data tab.

- **View** permission for the project that the workbook is in.
- **View** permissions for the workbook and its views.
- **Download Summary Data** permission to read the underlying data in the view on the **Summary** tab of the View Data window.
- **Download Full Data** permission if the user needs to be able to read all of the available data in the data source on the **Full Data** tab of the View Data window.

For information about how to set permissions for workbooks and views, see [Set Content Permissions](#) in the Tableau Cloud help.

Test the view

Test your embedded view using [keyboard shortcuts for embedded views](#). Provide your users with this information in your user documentation.

Maps and Geographic Data Analysis in Tableau

When it comes to plotting your data on a map, Tableau has got you covered. This section provides all the documentation you need to get started with creating maps in Tableau.

Start with these topics

[Get Started Mapping with Tableau](#) below

[Mapping Concepts](#)

[The Mapping Workspace in Tableau](#) on page 1669

[Map Data](#)

[Build Maps](#)

[Customise Maps](#)

Get Started Mapping with Tableau

This tutorial walks you through some of the most common tasks you might perform when creating maps in Tableau.

You'll learn how to connect to and join geographic data; format that data in Tableau; create location hierarchies; build and present a basic map view; and apply key mapping features along the way.

If you're new to building maps in Tableau, this a great place to start.

Step 1: Connect to your geographic data

Geographic data comes in many shapes and formats. When you open Tableau Desktop, the start page shows you the connectors available in the left **Connect** pane. These are how you will connect to your data.

You can work with geographic data by connecting to spatial files, or you can connect to location data stored in spreadsheets, text files or on a server.

Spatial files, such as a shapefile or geoJSON file, contain actual geometries (points, lines or polygons), whereas text files or spreadsheets contain point locations in latitude and longitude coordinates, or named locations that, when brought into Tableau, connect to the Tableau geocoding (stored geometries that your data references).

For a complete list of connections Tableau supports, see the list of [Data Connections](#) on the Tableau website.

For this tutorial, you are going to connect to an Excel file that comes with Tableau Desktop. It contains location names that Tableau can geocode. When you build a map view, the location names reference the geometries stored in the Tableau Map Service based on the geographic role you assign to the field. You'll learn more about geographic roles later in this tutorial.

1. Open Tableau Desktop.
2. In the Connect pane, click **Excel**.
3. Navigate to **Documents > My Tableau Repository > Data Sources**, and then open the **Sample - Superstore.xls** file.

Once you connect to the data source, your screen will look like this:

This is called the Data Source page, and it is where you can prepare your location data for use in Tableau.

Some of the tasks you can perform on the Data Source page include the following, but you don't have to do all these things to create a map view:

- Adding additional connections and joining your data
- Adding multiple sheets to your data source
- Assigning or changing geographic roles to your fields
- Changing the data type of your columns (from numbers to strings, for example)
- Renaming columns
- Splitting columns, such as splitting a full address into multiple columns for street, city, state and postcode

For more information about the Data Source page and some of the tasks you can perform while on it, see the topics in the [Set Up Data Sources on page 602](#) section.

Step 2: Join your data

Your data is often held in multiple data sources or sheets. As long as those data sources or sheets have a column in common, you can join them in Tableau. Joining is a method for combining the related data on those common fields. The result of combining data using a join is a virtual table that is typically extended horizontally by adding columns of data.

Joining is often necessary with geographic data, particularly spatial data. For example, you can join a KML file that contains custom geographies for school districts in Oregon, U.S. with an Excel spreadsheet that contains demographic information about those school districts.

For this example, you will join two sheets in the Sample-Superstore data source.

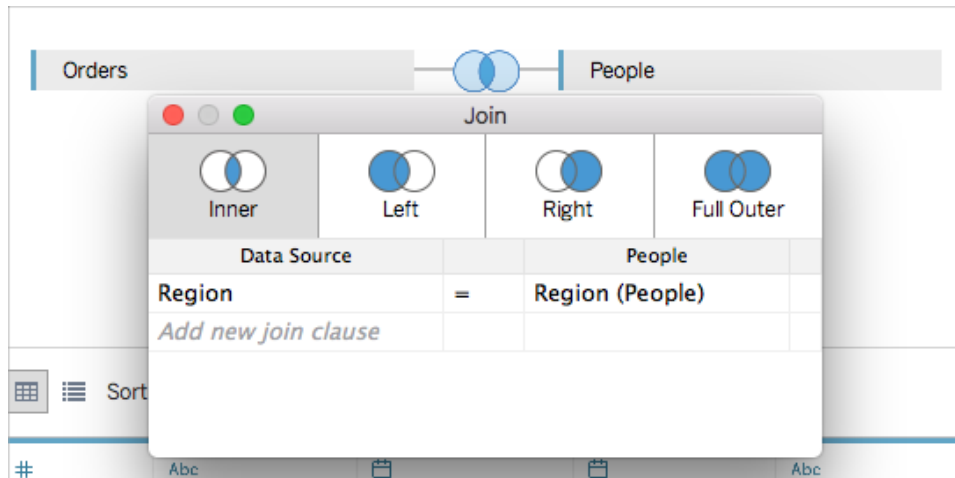

1. On the left side of the Data Source page, under Sheets, double-click **Orders**.
2. Under Sheets, double-click **People**.

Tableau creates an inner-join between the two spreadsheets, using the Region column from both spreadsheets as the joining field. Now there is a sales person assigned to every location in your data source, as well as to regions.

To edit this join, click the join icon (the two circles). You can edit the join in the Join dialog box that opens. For more information about joining data in Tableau, see [Join Your Data](#)

on page 796.

Step 3: Format your geographic data in Tableau

After you set up your data source, you might need to prepare your geographic data for use in Tableau. Not all of these procedures will always be necessary to create a map view, but it's important information to know when it comes to preparing geographic data for use in Tableau.

Depending on the type of map you want to create, you must assign certain data types, data roles and geographic roles to your fields (or columns).

For example, in most cases, your latitude and longitude fields should have a *data type* of **number (decimal)**, a *data role* of **measure**, and be assigned the **Latitude** and **Longitude** *geographic roles*. All other geographic fields should have a *data type* of **string**, a *data role* of **dimension** and be assigned the appropriate geographic roles.

Note: If you are connecting to a spatial file, a Geometry field is created. It should have a data role of measure.

This step demonstrates how to format your geographic data to meet this criteria.

Change the data type of a column

When you first connect to geographic data, Tableau assigns data types to all of your columns. These data types include Number (decimal), Number (whole), Date and Time, Date, String and Boolean. Sometimes Tableau does not get these data types right, and you must edit them. For example, Tableau might assign a Postcode column a data type of Number (whole). To create map views, your Postcode data must have a data type of String.

To change the data type of a column:

1. On the Data Source page, click the data type icon (the globe) for Postcode and select **String**.

|  Orders State |  Orders Postal Code | Abc Orders Region | ▼ Abc Orders Product ID |
|---|---|-------------------------|----------------------------------|
| Kentucky | 42420 | South | FUR-BS-10001798 |
| Kentucky | 42420 | South | FUR-CH-10000454 |
| California | 90036 | West | OFF-LA-10000240 |
| Florida | 33311 | South | FUR-TA-10000577 |
| Florida | 33311 | South | OFF-ST-10000760 |
| California | 90032 | West | FUR-FU-10001487 |
| California | 90032 | West | OFF-AR-10002833 |
| California | 90032 | West | TEC-PH-10002275 |
| California | 90032 | West | OFF-BI-10003910 |
| California | 90032 | West | OFF-AP-10002892 |

For more information about data types, see [Data Types](#) on page 156.

Assign geographic roles to your geographic data

In Tableau, a *geographic role* associates each value in a field with a latitude and longitude value. When you assign the correct geographic role to a field, Tableau assigns latitude and longitude values to each location in that field by finding a match that is already built in to the installed geocoding database. This is how Tableau knows where to plot your locations on the map.

When you assign a geographic role to a field, such as State, Tableau creates a Latitude (generated) field and a Longitude (generated) field.

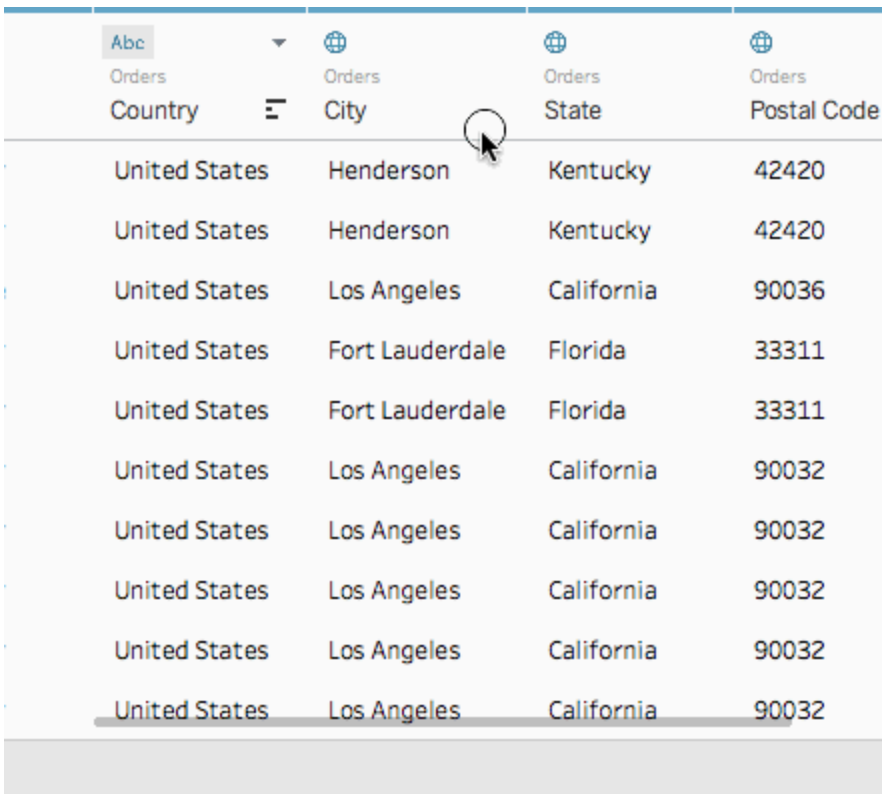

Geographic roles are sometimes automatically assigned to your data, such as in this example. You can tell a geographic role has been assigned to your data because the column includes a globe icon.

If a geographic role is not automatically assigned, you can manually assign one to your field. You don't need to do so for this example, but it's important to know how so you can do it for your own data.

To assign or edit a geographic role:

1. On the Data Source page, click the globe icon.
2. Select **Geographic Role**, and then select a role that best matches your data.

For example, in this case, the Country column does not have a geographic role assigned to it, so the Country/Region geographic role is assigned.

The screenshot shows the Tableau Data Source page with four columns: Country, City, State, and Postal Code. Each column has a globe icon in the header, indicating a geographic role. The City column is highlighted with a mouse cursor. The data rows show various locations, including Henderson, Los Angeles, Fort Lauderdale, and California.

| Country | City | State | Postal Code |
|---------------|-----------------|------------|-------------|
| United States | Henderson | Kentucky | 42420 |
| United States | Henderson | Kentucky | 42420 |
| United States | Los Angeles | California | 90036 |
| United States | Fort Lauderdale | Florida | 33311 |
| United States | Fort Lauderdale | Florida | 33311 |
| United States | Los Angeles | California | 90032 |
| United States | Los Angeles | California | 90032 |
| United States | Los Angeles | California | 90032 |
| United States | Los Angeles | California | 90032 |
| United States | Los Angeles | California | 90032 |

Note: If you have difficulties assigning geographic roles to your data, or have data that is not built in to the Tableau map server, there are a few things you can do to get that data into Tableau. See [Assign Geographic Roles](#) on page 1717.

Change from dimensions to measures

When you connect to geographic data, Tableau also assigns data roles to all of your columns. A column can be a *dimension* or *measure*. In most cases, your latitude and longitude columns

should be measures. For special cases, such as if you want to plot every location in your data source on a map without the ability to drill up or down a level of detail (such as from City to State), they can be dimensions. A great example of this is a [point distribution](#) map.

The rest of your geographic data should be dimensions.

You don't need to change the data role of a column for this example, but it's important to know how so you can do it for your own data. Feel free to practise here. You can always undo any changes you make.

To change the data role of a column:

1. On the Data Source page, click **Sheet 1**.

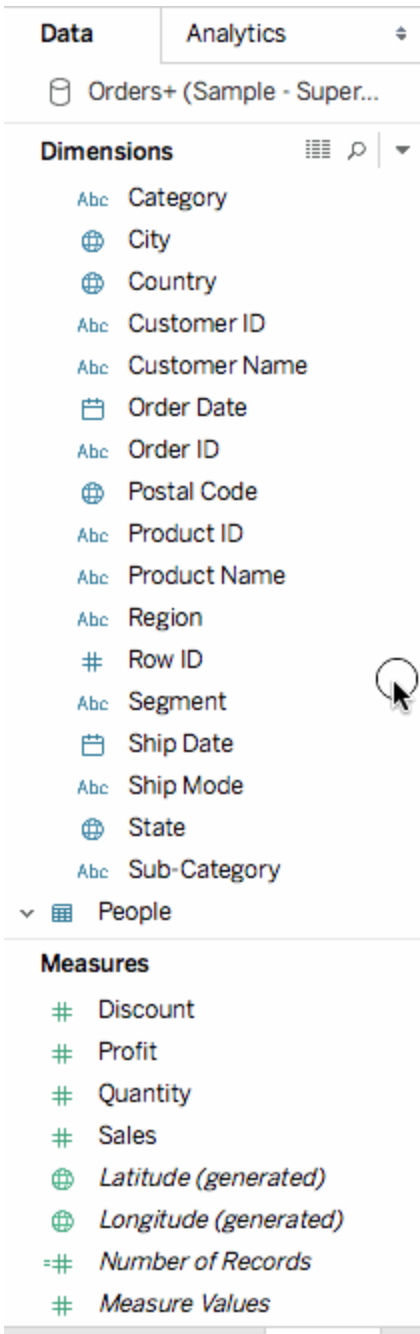

Your workspace updates to look like this:

This is called a **worksheet**, and it is where you will build your map. On the left-side of the screen is the **Data** pane. All of the columns in your data source are listed as fields in this pane. For example, Country and State. These fields contain all the raw data in your columns. Note that Tableau has generated a Latitude and Longitude field (*Latitude (generated)* and *Longitude (generated)*). This is because you assigned geographic roles to your data.

The fields in the data pane are divided into measures and dimensions. The fields placed in the Dimensions section of the Data pane are often categorical data, such as Date and Customer ID, while the fields placed in the Measures section of the Data pane are often quantitative data, such as Sales and Quantity.

2. In the **Data** pane, under Dimensions, select a field, such as Row ID, and drag it down to the Measures section.

The field is added to the Measures section and changes from blue to green. You just converted a Dimension to a Measure. To convert a field from a measure to a dimension, drag the field from the Measures section up to the Dimensions section.

For more information, see [Dimensions and Measures, Blue and Green](#) on page 146.

Step 4: Create a geographic hierarchy

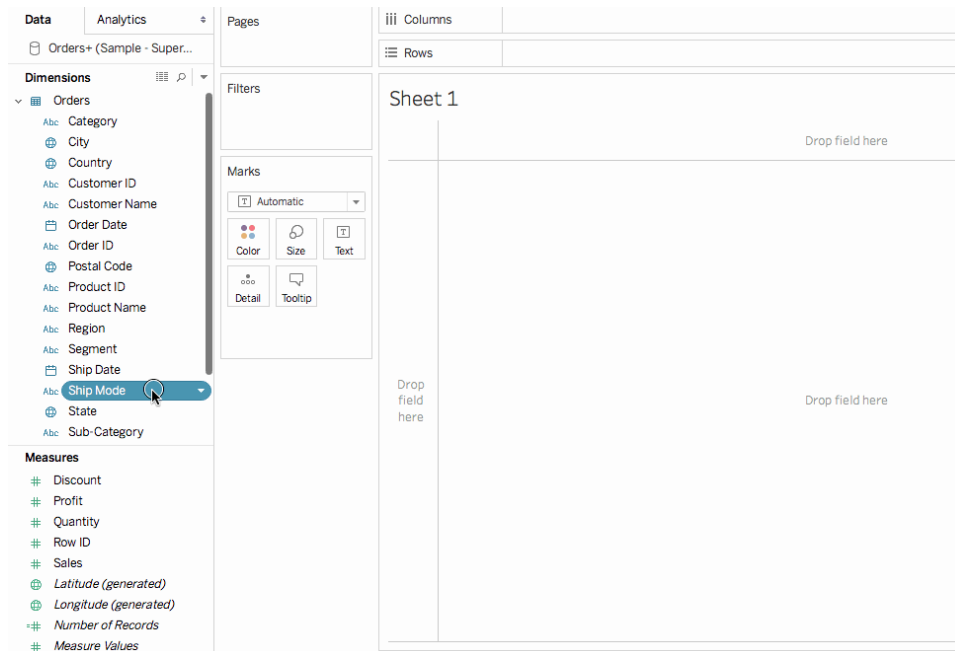

Now that you are in the worksheet space, you can create geographic hierarchies. This is not required to create a map view, but creating a geographic hierarchy will allow you to quickly drill into the levels of geographic detail your data contains, in the order you specify.

To create a geographic hierarchy:

1. In the Data pane, right-click the geographic field, **Country**, and then select **Hierarchy > Create Hierarchy**.
2. In the Create Hierarchy dialog box that opens, give the hierarchy a name, such as Mapping Items, and then click **OK**.

At the bottom of the Dimensions section, the Mapping Items hierarchy is created with the Country field.

3. In the Data pane, drag the State field to the hierarchy and place it below the Country field.
4. Repeat step 3 for the City and Postcode fields.

When you are finished, your hierarchy should be in the following order:

- Country
- State
- City
- Postcode

Step 5: Build a basic map

Now that you have connected to and joined your data, formatted your data and built a geographic hierarchy, you are now ready to start building your map. You will start by building a basic map view.

1. In the Data pane, double-click **Country**.

The Country field is added to Detail on the Marks card, and Latitude (generated) and Longitude (generated) are added to the Columns and Rows shelves. A map view with one data point is created. Since a geographic role is assigned to Country, Tableau creates a map view. If you double-click any other field, such as a dimension or measure, Tableau adds that field to the Rows or Columns shelf, or the Marks card, depending on what you already have in the view. Geographic fields are always placed on Detail on the Marks card, however.

Since this data source only contains one country, (United Kingdom), that is the only data point shown. You will need to add more levels of detail to see additional data points. Since you created a geographic hierarchy, this is easy.

2. On the Marks card, click the **+** icon on the **Country** field.

The State field is added to Detail on the Marks card and the map updates to include a data point for every state in the data source.

If you did not create a hierarchy, the **+** icon on the Country field will not be available. In this case, to add State as another level of detail, manually drag **State** from the **Data** pane to **Detail** on the Marks card.

Congratulations! You now have a basic map view that you can customise and build upon in the next steps.

Step 6: Change from points to polygons

The default map type in Tableau is often a point map. When you have geographic roles assigned to your geographic data, however, it's easy to change those data points to polygons.

Note: Filled maps are not available for cities or airports.

1. On the Marks card, click the Mark Type drop-down and select **Filled Map**.

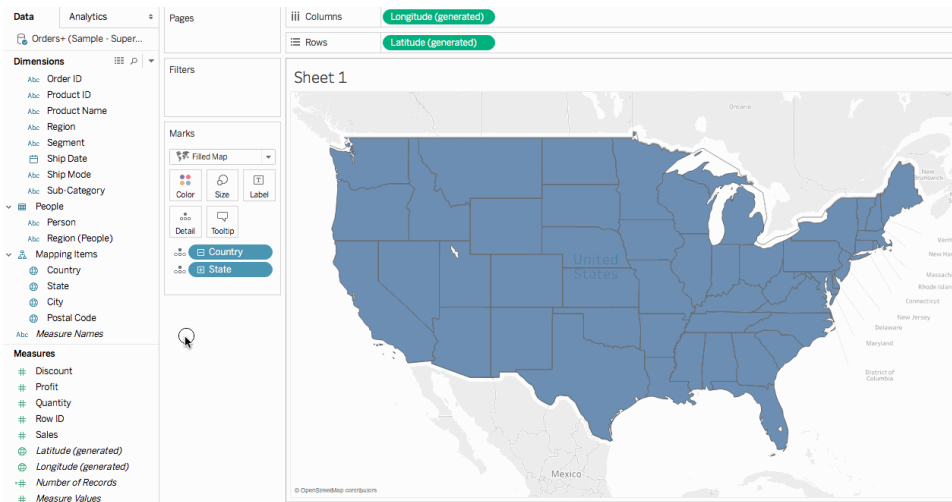

The map updates to a polygon map.

Step 7: Add visual detail

You can add measures and dimensions to the Marks card to add visual detail to your view. In this example, you will add colour and labels to the view.

Add colour

- From Measures, drag **Sales** to **Colour** on the Marks card.

Each state is coloured by sum of sales. Since Sales is a measure, a qualitative colour palette is used. If you place a dimension on colour, then a categorical colour palette is used.

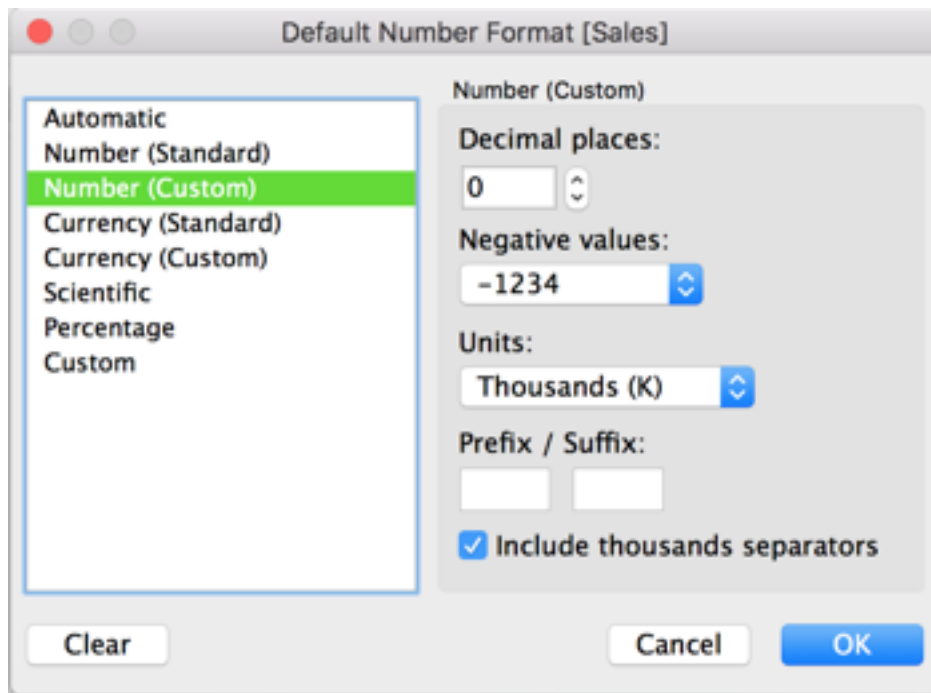

Add labels

- From Measures, drag **Sales** to **Label** on the Marks card.

Each state is labelled with sum of sales. The numbers need a little bit of formatting, however.

- In the Data pane, right-click **Sales** and select **Default Properties > Number Format**.
- In the Default Number Format dialog box that opens, select **Number (Custom)**, and then do the following:
 - For **Decimal Places**, enter **0**.
 - For **Units**, select **Thousands (K)**.
 - Click **OK**.

The labels and the colour legend update with the specified format.

Step 8: Customise your background map

The background map is everything behind your marks (borders, oceans, location names, etc.) You can customise the style of this background map, as well as add map layers and data layers. In addition to customising the background maps, you can also connect to your own WMS server or Mapbox map. For more information, see [Use Web Map Service \(WMS\) Servers on page 1876](#) and [Use Mapbox Maps on page 1873](#).

To customise your background map:

1. Select **Map > Map Layers**.

The Map Layers pane appears on the left side of the workspace. This is where all background map customisation happens.

2. In the Map Layers pane, click the **Style** drop-down and select **Normal**.

The background map updates to look like this:

3. In the Map Layers pane, under Map Layers, select **Coastlines**, and then clear **Country/Region Borders**, **Country/Region Names**, **State/Province Borders**, and **State/Province Names**.

3. Right-click the new group you just created and select **Rename**.
4. Rename the group, **West Coast**.
5. For the next territory, select **Alabama, Florida, Georgia, Louisiana, Mississippi, South Carolina** and **Texas**, and then click **Group**.
6. Rename this group, **South**.

7. For the third territory, select **Connecticut, Delaware, District of Columbia, Main, Maryland, Massachusetts, New Hampshire, New Jersey, New York, Pennsylvania, Rhode Island, Vermont** and, finally, **West Virginia** and then click **Group**.
8. Rename this group, **East Coast**.
9. Select **Include Other** to group the remaining states.
10. Rename the **Other** group, **Central**.

11. Click **OK**.

A **State (group)** field appears in the **Data** pane beneath your other mapping items.

12. From the Data pane, drag **State (group)** to **Colour** on the Marks card.

The view updates to look like this:

Notice that each group has a different colour.

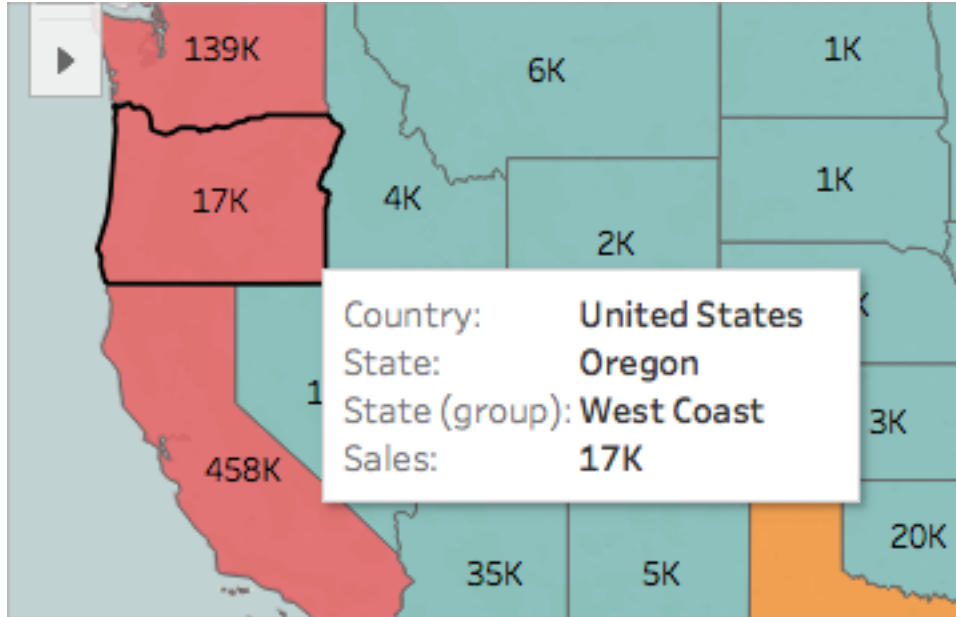

13. On the Marks card, click the **Colour** icon and select **Edit Colours**.
14. In the Edit Colours dialog box that appears, select **Assign Palette**, and then click **OK**.

The marks update with new colours.

15. From Measures, drag **Sales** to **Tooltip** on the Marks card.

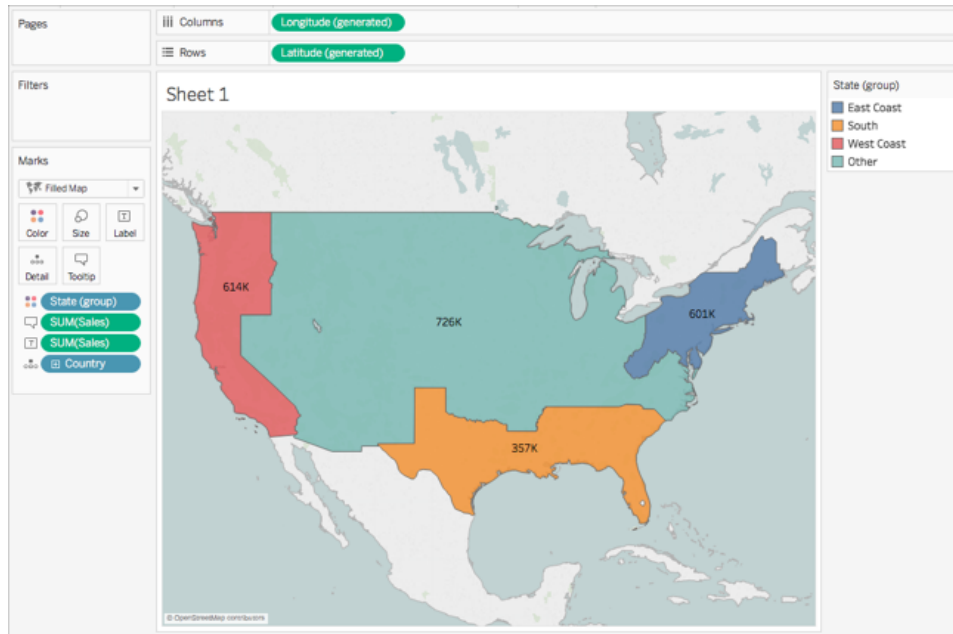

When you hover over a state, a tooltip appears with the sales for that state, among other information. You'll learn how to edit this tooltip later.

16. On the Marks card, click the minus (-) icon on the **Country** field to remove State from the level of detail.

If you did not create a hierarchy, you can drag **State** from the view to remove it. You can remove any field by dragging it from the view.

The states no longer appear on the map. Notice how the sum of sales has updated for the labels and in the tooltip? This is because custom territories aggregate at the level of the group, rather than separately for each location within the group. So the sum of sales you are seeing in the West Coast group, for example, are the total sales for California, Oregon and Washington combined.

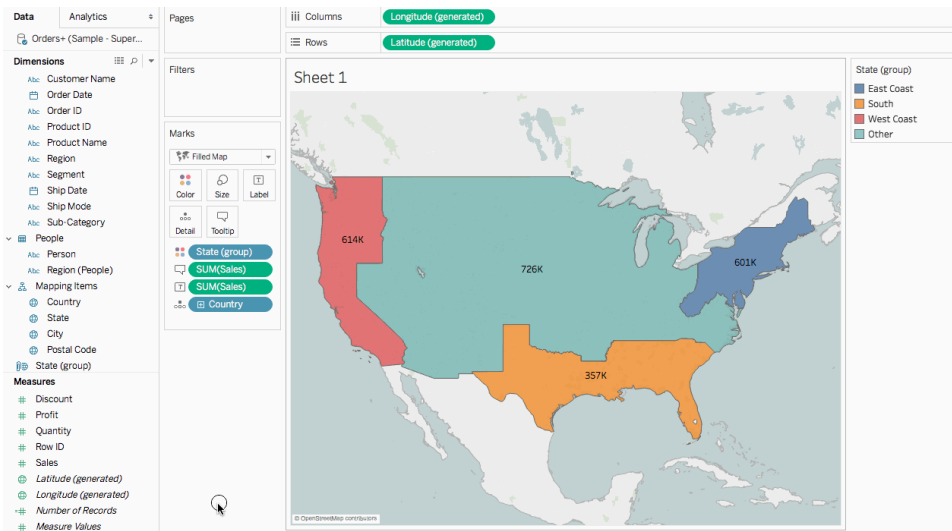

Step 10: Create a dual axis map

So far you have created two map views: one that shows the sales per state, and one that shows the sales per region. Could you layer these maps on top of one another? Yes! In Tableau, you can create a map with two layers of marks. This is called a dual axis map in Tableau, and is often used to layer points over polygons. In this example, you will layer two polygons maps.

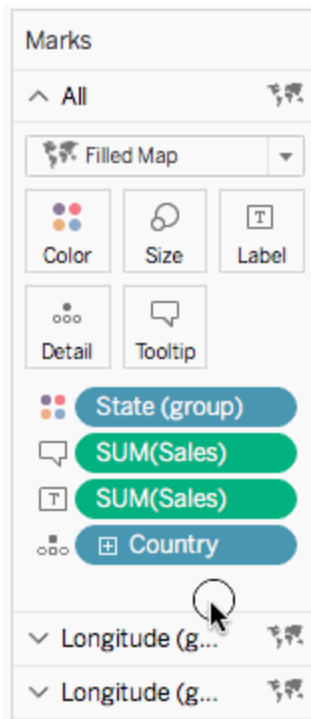

To create a dual axis map:

1. From the Data pane, drag **Longitude (generated)** to the **Columns** shelf and place it to the right of the first Longitude field.

The view updates with two identical maps.

There are now three tabs on the Marks card: one for each map view, and one for both views (All). You can use these to control the visual detail of the map views. The top Longitude tab corresponds to the map on the left of the view, and the bottom Longitude tab corresponds to the map on the right of the view.

2. On the Marks card, select the top **Longitude (generated)** tab.

3. From Measures, drag **Sales** to **Colour** on the top Longitude (generated) Marks card.
The map on the left updates.
4. On the top Longitude (generated) Marks card, click the **+** icon on the **Country** field to drill back down to the State level of detail.
5. On the Marks card, click **Colour**, and then select **Edit Colours**.
6. In the Edit Colours dialog box that opens, click the Palette drop-down, select **Grey**, and then click **OK**.

At this point, your maps look like this:

7. On the Columns shelf, right-click the **Longitude (generated)** field on the right and select **Dual Axis**.

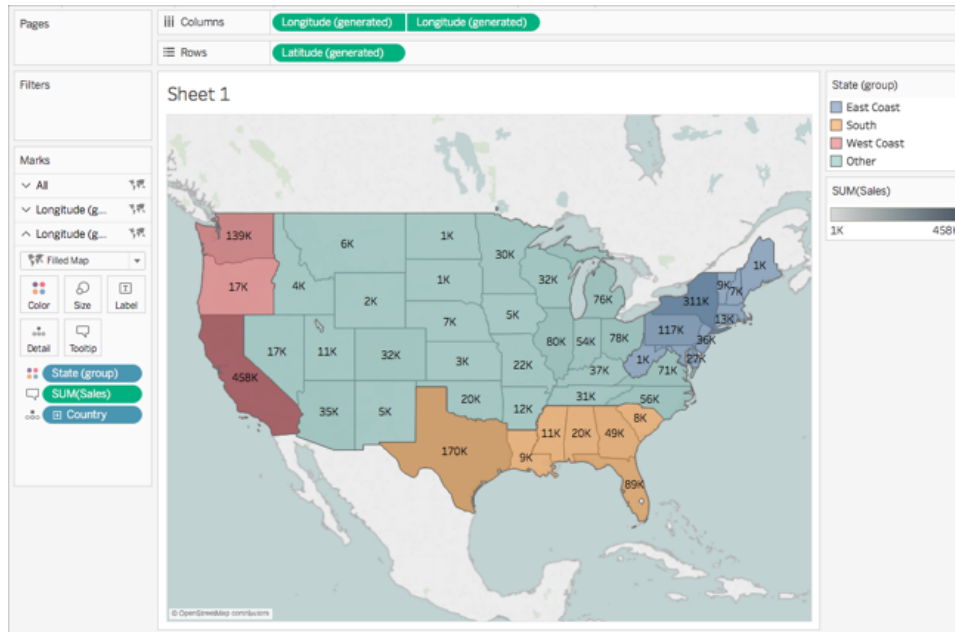

8. On the Marks card, select the bottom **Longitude (generated)** tab.
9. On the bottom **Longitude (generated)** Marks card, drag both **SUM(Sales)** fields from the view to remove them.

The labels for each map no longer overlap.

10. On the bottom **Longitude (generated)** Marks card, click **Colour**, and then, for **Opacity**, enter **50%**.

This is a crucial step if you want to be able to see the map on the bottom layer.

The map view updates to look like this:

You can now see how each state performed within each group.

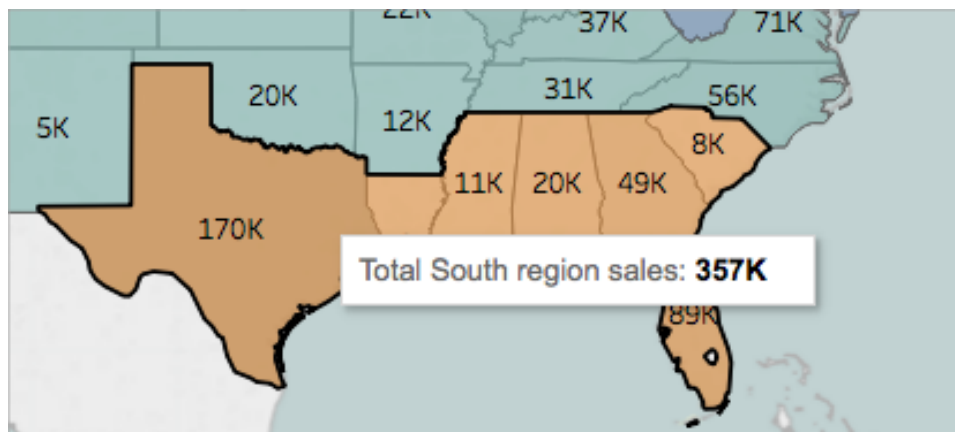

11. On the bottom **Longitude (generated)** Marks card, click **Tooltip**.

An Edit Tooltip dialog box opens.

12. Copy the following text and paste it into the Edit Tooltip dialog box, and then click **OK**:

Total <State (group)> region sales: **<SUM(Sales)>**

The tooltip looks similar to this:

Congrats! You've created a dual axis map! There's only one thing left to do.

For more information about dual axis maps, see [Dual Axis Mapping - Many Ways](#) on the Tableau Community.

Step 11: Customise how others can interact with your map

Now that you have created your map view, you can customise how people will interact with it. For example, you might now want anyone to be able to zoom in or out of your map, or pan. Or perhaps you want to display a map scale? You can customise these two options and more in the Map Options dialog box.

To customise how others can interact with your map:

1. Select **Map > Map Options**.
2. In the Map Options dialog box that appears, do the following:
 - Select **Show Map Scale**.
 - Clear **Show Map Search**.
 - Clear **Show View Toolbar**.

A scale appears in the bottom-right corner of the map, and the map search icon and the toolbar in the top left corner of the map disappear. You can still pan and zoom using keyboard shortcuts. For more information, see [Zoom and Pan Views and Select Marks on page 1982](#).

And that's a wrap! Your map view is now ready to be presented or combined with another view in a dashboard. For more information about dashboards, see [Create a Dashboard on page 2693](#).

Want to check your work? Download the [example workbook](#) from Tableau Public.

Mapping Concepts in Tableau

If you want to analyse your data geographically, you can plot your data on a map in Tableau. This topic explains why and when you should put your data on a map visualisation. It also describes some of the types of maps you can create in Tableau, with links to topics that demonstrate how to create each one.

If you're new to maps in Tableau, this is a great place to start learning.

Why put your data on a map?

There are many reasons to put your data on a map. Perhaps you have some location data in your data source? Or maybe you think a map could really make your data pop? Both of those are good enough reasons to create a map visualisation, but it's important to keep in mind that maps, like any other type of visualisation, serve a particular purpose: they answer spatial questions.

You make a map in Tableau because you have a spatial question, and you need to use a map to understand the trends or patterns in your data.

But what is a spatial question? Some examples might be:

- Which state has the most farmers markets?
- Where are the regions in the U.S. with the high obesity rates?
- Which metro station is the busiest for each metro line in my city?
- Where did the storms move over time?
- Where are people checking out and returning bikes from their local bike share program?

All of these are spatial questions. However, is a map the best way to answer them?

When should you use a map to represent your data?

If you have a spatial question, a map view might be a great way to answer it. However, that might not always be the case.

Take, for example, the first question from the previous list: Which state has the most farmers markets?

If you had a data source with a list of farmers markets per state, you might create a map view like the one below. Can you easily tell the difference between New York and California? Which one has more farmers markets?

What if you create a bar chart instead? Now is it easy to spot the state with the most farmers markets?

The above example is one of many where a different type of visualisation would be better to answer a spatial question than a map.

So when do you know if you should use a map view?

One general rule is to ask yourself whether you could answer your question faster, or easier with another visualisation. If the answer is yes, then perhaps a map view isn't the best visualisation for the data you're using. If the answer is no, then take the following into account:

Maps that answer questions well have both appropriate data representation, and attractive data representation. In other words: the data isn't misleading, and the map is appealing.

If your map is beautiful, but the data is misleading, or not insightful, you run the risk of people misinterpreting your data. That's why it's important to create maps that represent your data accurately, as well as attractively.

What types of maps can you build in Tableau?

With Tableau, you can create the following common map types:

- **Proportional symbol maps** below
- **Choropleth maps (filled maps)** on the next page
- **Point distribution maps** on the next page
- **Density maps (heatmaps)** on page 1665
- **Flow maps (path maps)** on page 1666
- **Spider maps (origin-destination maps)** on page 1667

Proportional symbol maps

Proportional symbol maps are great for showing quantitative data for individual locations. For example, you can plot earthquakes around the world and size them by magnitude.

For more information about proportional symbol maps, and to learn how to create them in Tableau, see [Create Maps that Show Quantitative Values in Tableau](#) on page 1763.

Choropleth maps (filled maps)

Also known as filled maps in Tableau, Choropleth maps are great for showing ratio data. For example, if you want to see obesity rates for every county across the United States, you might consider creating a choropleth map to see if you can spot any spatial trends.

For more information about choropleth maps, and to learn how to create them in Tableau, see [Create Maps that Show Ratio or Aggregated Data in Tableau](#) on page 1774.

Point distribution maps

Point distribution maps can be used when you want to show approximate locations and are looking for visual clusters of data. For example, if you want to see where all the hailstorms were in the U.S. last year, you can create a point distribution map to see if you can spot any clusters.

For more information about point distribution maps, and to learn how to create them in Tableau, see [Create Maps that Highlight Visual Clusters of Data in Tableau](#) on page 1769.

Density maps (heatmaps)

Density maps, also called heatmaps, can be used when you want to show a trend for visual clusters of data. For example, if you want to find out which areas of Manhattan have the most taxi pickups, you can create a density map to see which areas are most popular.

For more information about density maps, and to learn how to create them in Tableau, see [Create Heatmaps that Show Trends or Density in Tableau](#) on page 1790.

[Back to top](#)

Flow maps (path maps)

You can use flow maps to connect paths across a map and to see where something went over time. For example, you can track the paths of major storms across the world over a period of time.

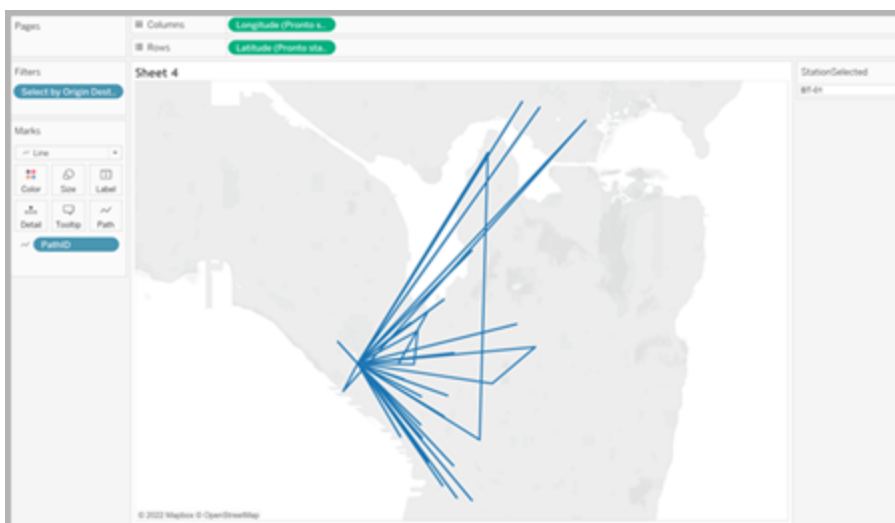

For more information about flow maps, and to learn how to create them in Tableau, see [Create Maps that Show a Path Over Time in Tableau](#) on page 1782.

Spider maps (origin-destination maps)

You can use a spider map to show how an origin location and one or more destination locations interact. For example, you can connect paths between metro stations to plot them on a map, or you can track bike share rides from an origin to one or more destinations.

For more information about spider maps, and to learn how to create them in Tableau, see [Create Maps that Show Paths Between Origins and Destinations in Tableau](#) on page 1796.

Resources to help you get started

Before you get started with building map views in Tableau, review some of the following resources.

Get your geographic data into Tableau

- **Create Tableau Maps from Spatial Files** on page 1735: If you have Esri Shapefiles, Mapinfo tables, or KML files, start here.

- **Geocode Locations Tableau Does Not Recognise and Plot Them on a Map** on page 1703: If you have data that Tableau doesn't recognise, start here.
- **Blend Geographic Data** on page 1709: If you have geographic data you want to blend with another data source, start here.

Format your geographic fields

- **Assign Geographic Roles** on page 1717: After you bring your geographic data into Tableau, you'll need to format that data for use in Tableau.

Build-It-Yourself: Build a map view

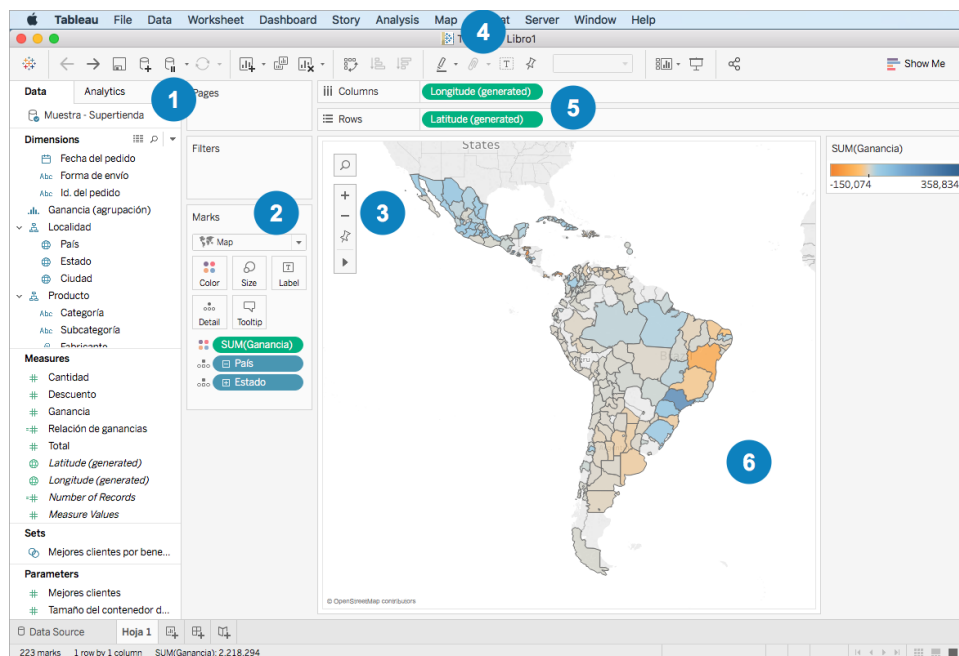

Customise How Your Map Looks on page 1845

Use Mapbox Maps on page 1873

Use Web Map Service (WMS) Servers on page 1876

The Mapping Workspace in Tableau

The mapping workspace in Tableau consists of the following elements.

The Data Pane

The Data pane organises your location data into dimensions and measures. Typically, your location fields (country, state, and city names, for example) should be dimensions, and your latitude and longitude fields should be measures. However, there are some scenarios where latitude and longitude fields can be dimensions.

In the Data pane, a globe icon next to a location field means that a geographic role is assigned to that field. For more information, see [Assign Geographic Roles](#) on page 1717.

A: Globe icon - indicates that a field is a geographic field and can be automatically mapped by Tableau.

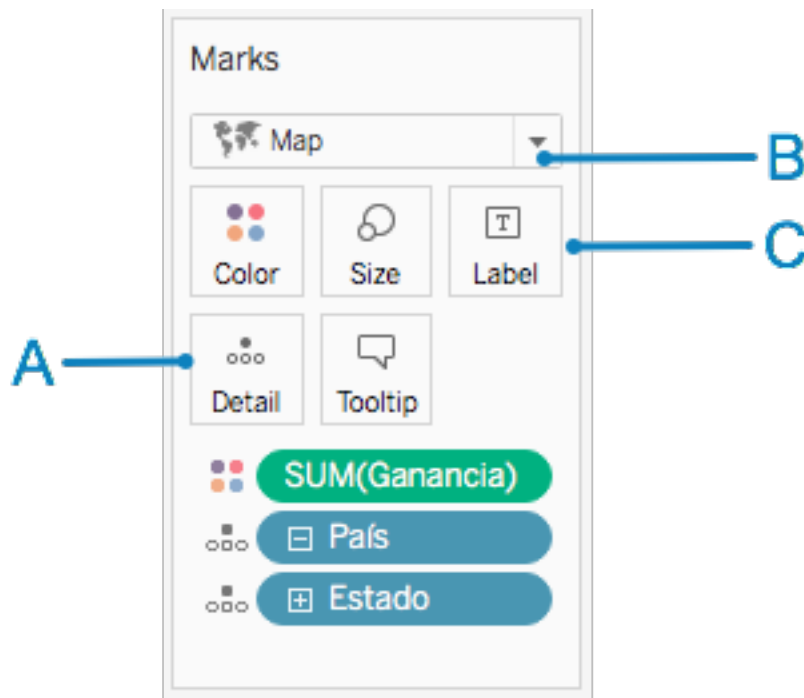

B: Location fields - These categorical fields, often location names, can be found under Dimensions. They are often recognised by Tableau.

C: Latitude and Longitude generated fields - When you have geographic fields in your data source, Tableau often generates Latitude and Longitude fields. You can use these to build your map, or you can include your own latitude and longitude fields.

2

The Marks Card

The Marks card is where you control the granularity and visual detail of your map view. In the Marks card, you can drag locations to Detail to add more granularity, drag fields to Colour, Size, or Label to add visual detail, or change the map type from a point map to a polygon map.

A: Add location fields to Detail to create a map and add granularity to the view.

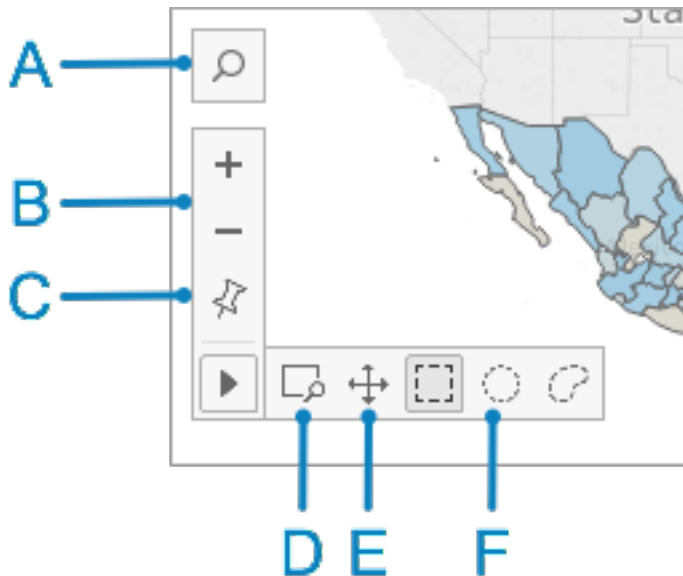

B: Select the Automatic mark type for a point map and the Map mark type for a polygon (filled) map.

C: Add fields to Colour, Size, and Label to change the visual detail of the marks (data points) in the view.

3

The View Toolbar

The view toolbar holds many of the tools you might need to explore your map data.

A: Use the map search icon to search for locations in your map.

B: Use the plus and minus icons to zoom in and out of the map.

D: Use the zoom area icon to zoom in to a specific area in the map.

E: Use the pan icon to pan around the map.

F: Use the selection tools to select data points within a rectangle, circle, or drawn area. You can also measure distances with the circle selection tool. For more information, see [Measure Distances Between Data Points and Locations on a Map](#) on page 1886.

4

The Map Menu

The Map menu holds several maps-specific options:

- Select **Map > Background Maps** to add a map service (such as Mapbox or a WMS server) or to switch between the background maps you have available in your workbook. For more information, see [Import your own background map on page 1847](#).
- Select **Map > Background Images** to add a static image instead of a background map to your view.
- Select **Map > Geocoding** to import locations that Tableau does not recognise into your workbook. For more information, see [Geocode Locations Tableau Does Not Recognise and Plot Them on a Map on page 1703](#).
- Select **Map > Edit Locations** to edit your location data to match the Tableau map data. For more information, see [Edit Unknown or Ambiguous Locations on page 1721](#).
- Select **Map > Map Layers** to customise your background map style, add or remove map layers, or add U.S. data layers. For more information see [Customise How Your Map Looks on page 1845](#).
- Select **Map > Map Options** to control if people can pan and zoom, search for locations, or use the view toolbar. For more information, see [Customise How People Interact with your Map on page 1869](#)

5

The Columns and Rows Shelves

The Columns and Rows shelves are where you put your latitude and longitude fields. Longitude is placed on the Columns shelf, and Latitude is placed on the Rows shelf, regardless of whether they are your latitude and longitude fields, or the generated fields Tableau creates.

The Map Visualisation

This is your map. As you makes changes to your map, the viz updates. This visualisation is dynamic and can be interacted with. Hover over the marks to learn more information about each location. You can edit the information that displays in the tooltip that appears using the Tooltip button on the Marks card. For more information, see [Add tooltips to marks on page 1278](#) and [Create Views in Tooltips \(Viz in Tooltip\) on page 1378](#).

In addition to the options available in the mapping workspace, Tableau provides many other options for analysing your data. You can [create custom territories](#), [filter data from your view](#), [set up parameters](#), [create sets](#), and much more.

See Also

[Get Started Mapping with Tableau on page 1635](#)

Location Data that Tableau Supports for Building Map Views

Tableau supports worldwide airport codes, cities, countries, regions, territories, states, provinces and some postcodes and second-level administrative districts (county-equivalents). US area codes, Core Based Statistical Areas (CBSA), Metropolitan Statistical Areas (MSA), Congressional districts and Zip codes are also supported by Tableau. Additionally, any latitude and longitude coordinates are supported, as long as they are in decimal degrees.

Note: See [About Tableau Maps](#) on the Tableau website for a complete list of location data by country that Tableau supports.

What to do if Tableau doesn't recognise your location data

- **If Tableau recognises your location data and automatically assigns geographic roles to your fields** (you'll know this has happened because there will be a globe icon  next to them in the **Data** pane), then you're ready to build a map view. Just double-click one of those geographic fields and you've got a map.

- **If Tableau does not immediately recognise your location data**, and you can't build a map view, you'll need to assign geographic roles to your fields. See the [Assign a geographic role to a field on page 1718](#) section to learn how.

Note: This procedure only works if your location data is supported by Tableau. If your data isn't supported by Tableau, there are a couple of things you can try in the meantime to map that data in Tableau:

- [Edit location names in your data source to match Tableau location names](#)
- [Custom geocode your data](#)
- [Blend your geographic data](#)
- [Use spatial data to build a map view](#)

Note: Connecting to spatial data is only supported on Tableau Desktop version 10.2 and later.

[About Tableau Maps Partners](#)

Spatial File

This topic describes how to connect Tableau to Shapefiles, MapInfo tables, KML (Keyhole Markup Language) files, TopoJSON files, GeoJSON files and Esri File Geodatabases.

Note: Connecting to spatial data is supported in Tableau Desktop version 10.2 and later.

Before you connect

Before you can connect to spatial files, make sure to include all of the following files in the same directory:

- **For Esri shapefiles:** The folder must contain `.shp`, `.shx`, `.dbf`, and `.prj` files as well as `.zip` files of the Esri shapefile.

For Esri File Geodatabases: The folder must contain the File Geodatabase's `.gdb` or the `.zip` of the File Geodatabases's `.gdb`.

- **For MapInfo tables** (Tableau Desktop only): The folder must contain `.TAB`, `.DAT`, `.MAP`, and `.ID` or `.MID` and `.MIF` files.
- **For KML files**: The folder must contain the `.kml` file. (No other files are required.)
- **For GeoJSON files**: The folder must contain the `.geojson` file. (No other files are required.)
- **For TopoJSON files**: The folder must contain the `.json` or `.topojson` file. (No other files are required.)

Note: Flat files will pull in the contents of the entire folder. For performance reasons, remove unneeded files and reduce the amount of data in the files.

You can connect only to point geometries, linear geometries and polygons in current versions of Tableau. You cannot connect to mixed geometry types.

If your data does not display diacritics (accent marks on characters) properly, check to make sure the file is **UTF-8** encoded.

Make the connection and set up the data source

In Tableau Desktop: click the New Data Source icon and select **Spatial file**.

In Tableau Cloud or Tableau Server (Creator role): Select **Create > Workbook**. Select the **Files** tab.

Then do the following:

1. Navigate to the folder that contains your spatial data and select the spatial file you want to connect to.
2. Select **Open**.

Spatial file data source example

Here is an example of a spatial file data source using Tableau Desktop on a Mac computer:

| Binomial | Presence | Origin | Year | Island | Family Nam | Friendly N | Geometry |
|-----------------------|----------|--------|------|------------------|----------------|-----------------------|--------------|
| Phyllomys unicolor | 1 | 1 | 2008 | null | ECHIMYIDAE | Phyllomys unicolor | POLYGON |
| Coendou rufescens | 1 | 1 | 2016 | null | ERETHIZONTIDAE | Coendou rufescens | MULTIPOLYGON |
| Echiothrix leucura | 1 | 1 | 2008 | Sulawesi | MURIDAE | Echiothrix leucura | MULTIPOLYGON |
| Echiothrix leucura | 2 | 1 | 2008 | Sulawesi | MURIDAE | Echiothrix leucura | POLYGON |
| Echymipera clara | 1 | 1 | 2008 | New Guinea | PERAMELIDAE | Echymipera clara | POLYGON |
| Echymipera clara | 1 | 1 | 2008 | Japen Island | PERAMELIDAE | Echymipera clara | POLYGON |
| Echymipera echinis... | 1 | 1 | 2008 | New Guinea | PERAMELIDAE | Echymipera echinis... | MULTIPOLYGON |
| Echymipera davidi | 1 | 1 | 2008 | Kiriwina Isla... | PERAMELIDAE | Echymipera davidi | POLYGON |
| Echymipera kalubu | 1 | 1 | 2016 | Waigeo | PERAMELIDAE | Echymipera kalubu | POLYGON |
| Echymipera kalubu | 1 | 1 | 2016 | Vokeo | PERAMELIDAE | Echymipera kalubu | POLYGON |
| Echymipera kalubu | 1 | 1 | 2016 | Umbol | PERAMELIDAE | Echymipera kalubu | POLYGON |
| Echymipera kalubu | 1 | 1 | 2016 | Tolokiwa | PERAMELIDAE | Echymipera kalubu | POLYGON |
| Echymipera kalubu | 1 | 1 | 2016 | Su Mios | PERAMELIDAE | Echymipera kalubu | POLYGON |

Work with the Geometry column

There are many tasks that you can optionally perform on your data before you start your analysis, such as hiding or renaming fields. Note, however, the following restrictions apply when working with the Geometry column:

- You can't hide the Geometry column.
- You can't split the Geometry column.
- On the data source page, you can't create a calculated field using the Geometry column.

About .ttde and .hhyper files in Tableau Desktop

You might notice .ttde or .hhyper files when navigating your computer's directory. When you create a Tableau data source that connects to your data, Tableau creates a .ttde or .hhyper file. This file, also known as a shadow extract, is used to help improve the speed your data source loads in Tableau Desktop. Although a shadow extract contains underlying data and other information similar to the standard Tableau extract, a shadow extract is saved in a different format and can't be used to recover your data.

Note: .tde files are no longer supported for Tableau versions beyond 2024.2. All extracts are now in .hyper format.

[Create Tableau Maps from Spatial Files](#) on page 1735

Connect to Spatial Data in a Database

You can use spatial columns stored in your database to build map visualisations in Tableau. You can connect to supported spatial data sources and build visualisations with them to analyse spatial data, or you can connect to custom SQL or RAWSQL queries to perform advanced spatial analysis.

Tableau supports direct connections to spatial data using these connectors:

- Amazon Redshift
- Microsoft SQL Server
- PostgreSQL + PostGIS
- Pivotal Greenplum + PostGIS
- Oracle
- Snowflake

For information on using these connectors, see the [Microsoft SQL Server](#) on page 383, [PostgreSQL](#) on page 411, [Pivotal Greenplum Database](#) on page 410, [Oracle](#) on page 396 or [Snowflake](#) on page 471 connector examples.

Supported spatial data and SRIDs

For Microsoft SQL Server, only **Geography-type** spatial data is supported.

PostgreSQL + PostGIS, **Oracle** and **Pivotal Greenplum + PostGIS** support Geography- and Geometry-type fields. Geometry fields must specify the geo-type (for example, POINT, LINESTRING) and SRID to be recognised as a spatial field. Geography fields must specify the geo-type to be recognised.

Note: In PostgreSQL + PostGIS, you can connect to tables with both mixed geometry types (points, lines and polygons), but Tableau won't render these simultaneously.

The following **SRIDs** are supported by these connectors:

- NAD83 (EPSG:4269)
- ETRS89 (EPSG:4258)

- WGS84 (EPSG:4326)

In PostgreSQL + PostGIS, SRID always defaults to WGS84 (EPSG: 4326).

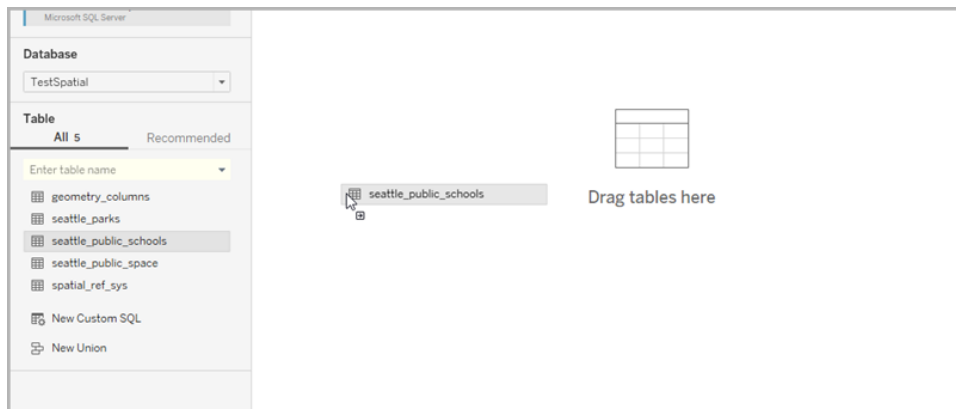

Tableau supports both live and extract connections using these connectors.

Connect to spatial columns

1. Open Tableau and connect to your data.

For more information on how to connect to data using supported connectors, see the [Microsoft SQL Server](#) on page 383, [PostgreSQL](#) on page 411, [Oracle](#) on page 396, [Pivotal Greenplum Database](#) on page 410 or [Snowflake](#) on page 471 connector examples.

2. On the Data Source page, in the left pane under Table, drag a table that contains spatial data onto the canvas.

Spatial columns display the same name they have in your database.

You're now ready to build a map in Tableau using spatial data. For more information on how to create maps from spatial files, see [Build a map view from spatial data on page 1737](#).

Use Custom SQL and RAWSQL to perform advanced spatial analysis

Connect to a Custom SQL query

1. Open Tableau and connect to your database.
2. On the Data Source page, in the left pane, drag **New Custom SQL** onto the canvas.
3. Type or paste your query into the Edit Custom SQL dialog box that appears. For examples of Custom SQL you can use with spatial data, see [Custom SQL query](#)

[examples](#) on the facing page.

4. When finished, click **OK**.

For more information, see [Connect to a Custom SQL Query](#) on page 868

Custom SQL query examples

The following queries are examples. Note that Custom SQL queries will vary from data source to data source.

If your data has two sets of points, such as schools and parks, and you want to show where they intersect:

```
SELECT S.[name] as SchoolName, P.[name] as PubSpaceName, S.geog_
schools.STBuffer(<Parameters.Radius>) as Geog_School, P.geog_pub_space as Geog_
Pub_Space FROM TestSpatial.dbo.seattle_public_schools S LEFT JOIN
TestSpatial.dbo.seattle_pub_space P ON S.geog_schools.STBuffer
(<Parameters.Radius>). STIntersects(P.geog_pub_space) = 1
```

This example query produces a row for each case where a public space polygon is within Radius distance (meters) from a school. The result of the query looks like this in the data grid:

| Field Name | Physical Table | Item... |
|----------------|------------------|-----------|
| SchoolName | Custom SQL Query | School... |
| PubSpaceName | Custom SQL Query | PubSpc... |
| Geog_School | Custom SQL Query | Geog_S... |
| Geog_Pub_Space | Custom SQL Query | Geog_P... |

| Row | SchoolName | PubSpaceName | Geog_School | Geog_Pub_Space |
|-----|------------------|------------------------------|-------------|----------------|
| 1 | Beacon Hill Int1 | BEACON HILL INTERNATIONAL... | Polygon | Polygon |
| 2 | Beacon Hill Int1 | BEACON HILL PLAYGROUND... | Polygon | Polygon |
| 3 | Concord Int1 | CONCORD INTERNATIONAL... | Polygon | Polygon |
| 4 | Nathan Hale | JANE ADDAMS MIDDLE SCH... | Polygon | MultPolygon |
| 5 | Nathan Hale | NATHAN HALE HIGH SCHOOL... | Polygon | Polygon |
| 6 | Olympic Hills | OLYMPIC HILLS ELEMENTARY | Polygon | Polygon |

Note: This example references a parameter named "Radius". It measures distance (meters) and has the following settings:

- Data type: Float
- Current Value: 600
- Allowable values: Range
- Minimum: 100

- Maximum 2,000
- Step size: 50

Using the parameter, you can adjust the relationship between schools and public spaces dynamically.

For more information, see [Use parameters in a custom SQL query](#) on page 878.

If you only want data around a certain point

```
SELECT * FROM [Test_spatial_<username>].[dbo].[SDOT_Collisions]
C WHERE C.geom.STIntersects(geography::STGeomFromText('POINT(-
122.344706 47.650388)', 4326).STBuffer(1000))=1
```

This example query limits data to 1000 meters around the POINT. The radius can be a parameter, such as [the parameter used in the first example](#).

Or, rather than a point and radius, a rectangle can be used. For example:

```
SELECT * FROM [Test_spatial_<username>].[dbo].[SDOT_Collisions]
C
WHERE C.geom.STIntersects(geography::STGeomFromText('POLYGON ((-
122.3625 47.6642,-122.3625 47.6493,-122.3427 47.6493,-122.3422
47.6642,-122.3625 47.6642))', 4326))=1
```

The winding order of the polygon points (clockwise vs anticlockwise) determines which set of points you get. You can reverse the winding order with the SQL Server function `ReorientObject()`.

If you get an error about mixed data types

```
SELECT *, F.geom.STGeometryType() as geomtype FROM [Test_
spatial_<username>].[dbo].[us_historic_fire_perimeters_dd83] F
WHERE F.geom.STGeometryType() = 'MultiPolygon' OR
F.geom.STGeometryType() = 'Polygon'
```

This example query filters out the geometry-type spatial data, since Tableau can't render geometry-type spatial data for Microsoft SQL Server connections. You can select other spatial types as well.

If your data renders too slowly in Tableau

```
SELECT [Id], [OBJECTID], [fire_num], [year_], [acres], [fire_
name], [unit_id], [Shape_Leng], [Shape_Area], [geom].Reduce(500)
as SimpleGeom
FROM [Test_spatial_<username>].[dbo].[us_historic_fire_
perimeters_dd83]
WHERE [geom].Reduce(500).STGeometryType() = 'MultiPolygon' OR
[geom].Reduce(500).STGeometryType() = 'Polygon'
```

This example query may greatly reduce data size. (Some objects are reduced to Points, and these are discarded.)

Use RAWSQL

To use RAWSQL with spatial data, you can create a calculated field using either the RAWSQL_SPATIAL or RAWSQLAGG_SPATIAL functions. For example:

```
RAWSQL_SPATIAL("Select %1.STIntersection(%2.STBuffer(200))",
[school_geom], [park_geom])
```

This formula returns unique spatial data based on the intersection of two values.

```
RAWSQLAGG_SPATIAL("ST_ConvexHull(ST_Collect(%1))", [Geog])
```

```
RAWSQLAGG_SPATIAL("ST_ConcaveHull(ST_Collect(%1), %2, false)",
[Geog], [ParameterValue])
```

Each of these return a bounding area around the supplied data points. ConcaveHull is a minimum bounding area based on the precision, which in this function is the parameter value.

For more information about using RAWSQL with spatial data, see [Pass-Through Functions \(RAWSQL\) on page 2117](#). For more information about how to create calculated fields, see [Create a calculated field on page 2010](#).

Note: RAWSQL spatial functions aren't available when connected to **Oracle**.

Note: It's possible to cause errors when using RAWSQL specific to PostGIS functions when using PostgreSQL + PostGIS.

Troubleshooting spatial connections

Performance issues

When working with joined spatial columns with a large number of records, duplicate marks can occur. This can result in slow performance.

To improve performance, extract the joined data source. For more information, see [Extract Your Data](#) on page 925.

Microsoft SQL Server error messages and solutions

When the spatial table is using an unsupported spatial reference

Error message:

An error occurred while communicating with the Microsoft SQL Server data source '<data source name>'.

Bad Connection: Tableau couldn't connect to the data source.

[Microsoft][ODBC Driver 13 for SQL Server][SQL Server]Operand type clash: geometry is incompatible with geography

[Microsoft][ODBC Driver 13 for SQL Server][SQL Server]Statement(s) could not be prepared.

Solution:

- Export the spatial data from Microsoft SQL Server to a Shapefile and connect to it in Tableau. Spatial file connections go through a data transformation process that supports thousands of projections.
- Export the data from Microsoft SQL Server and transform the data using a GIS tool like QGIS or ArcGIS. Then reload the table back into Microsoft SQL Server.

When the spatial table includes multiple types of spatial objects

Error message:

Unable to complete action

The spatial operation resulted in a MixedGeometry or MixedGeography, which Tableau doesn't support yet.

The spatial operation resulted in a MixedGeometry or MixedGeography, which Tableau doesn't support yet.

Solution:

Use Custom SQL to filter the data. For more information, see [If you get an error about mixed data types on page 1682](#) Custom SQL example.

When measures are being aggregated in the visualisation

Error message:

An error occurred while communicating with the Microsoft SQL Server data source '<data source name>'

Bad Connection: Tableau could not connect to the data source.

Cannot perform an aggregate function on an expression containing an aggregate or a subquery.

Solution:

Disaggregate measures in the visualisation: Select **Analysis**, and then clear **Aggregate Measures**.

PostgreSQL + PostGIS, Oracle and Pivotal Greenplum + PostGIS error messages and solutions

When using mixed SRIDs and one of the SRIDs is unsupported

Error message:

An error occurred while communicating with the PostgreSQL data source '<data source name>'.

Bad Connection: Tableau could not connect to the data source.

Error: Operation on mixed SRID geometries;

Error while executing the query

<query> from <datasource>

HAVING (COUNT(1) > 0)

Solution:

Disaggregate measures in the visualisation: Select **Analysis**, and then clear **Aggregate Measures**. This eliminates the error message and the data where the SRID is unsupported.

When the spatial table is using an unsupported spatial reference

In PostgreSQL + PostGIS, you can connect to a table with unsupported SRIDs, but the Geometry column will display as "Unknown".

Solution:

- Export the spatial data from PostgreSQL + PostGIS to a Shapefile and connect to it in Tableau. Spatial file connections go through a data transformation process that supports thousands of projections.
- Export the data from PostgreSQL + PostGIS and transform the data using a GIS tool like QGIS or ArcGIS. Then reload the table back into PostgreSQL + PostGIS.

When a query result exceeds the limit of 1 GB

Error message:

ERROR: array size exceeds the maximum allowed (1073741823); Error while executing the query"

```
SELECT ST_Collect(geom) FROM <data source>
```

Solution:

Rewrite the calculation to be more efficient. See [Best Practices for Creating Calculations in Tableau](#) on page 2451 or [Create Efficient Calculations](#) on page 3066.

Example - Build a map from Microsoft SQL Server spatial data

The following example demonstrates how to create the map below, which shows schools within 600 meters of parks in Seattle, Washington.

This example uses a Microsoft SQL Server connection to a database called, TestSpatial. The following tables from this database are used:

- seattle_schools
- seattle_public_space

Step 1: Connect

1. Open Tableau Desktop and connect to Microsoft SQL Server.
2. On the Data Source page, in the left pane, drag **New Custom SQL** onto the canvas.
3. Type or paste a query into the Edit Custom SQL dialog box that appears.

For this example, the following query is used:

```
SELECT S.[name] as SchoolName, P.[name] as PubSpaceName, S.geog_
schools.STBuffer(<Parameters.Radius>) as Geog_School, P.geog_pub_space as
Geog_Pub_Space FROM TestSpatial.dbo.seattle_public_schools S FULL JOIN
TestSpatial.dbo.seattle_public_space P ON S.geog_schools.STBuffer
(<Parameters.Radius>). STIntersects(P.geog_pub_space) = 1
```

Note: This example references a parameter named "Radius". For more information, see [Use parameters in a custom SQL query on page 878](#).

The result of this query looks like the following:

The screenshot shows the Tableau Desktop interface for a Custom SQL Query named 'TestSpatial'. The left pane shows the 'Database' section with 'TestSpatial' selected. The main view displays a data preview table with 5 fields and 107 rows. The table has columns for Name, Type, Field Name, Physical Table, and Name. The data includes school names like 'BEACON HILL INTERNATIONAL' and 'CONCORD INTERNATIONAL', and their corresponding geospatial fields like 'Geog_School' and 'Geog_Pub_Space'.

| Name | Type | Field Name | Physical Table | Name |
|------------------|-------|----------------|------------------|----------------|
| Custom SQL Query | Table | SchoolName | Custom SQL Query | SchoolName |
| Custom SQL Query | Table | PubSpaceName | Custom SQL Query | PubSpaceName |
| Custom SQL Query | Table | Geog_School | Custom SQL Query | Geog_School |
| Custom SQL Query | Table | Geog_Pub_Space | Custom SQL Query | Geog_Pub_Space |

Step 2: Build the map

1. Go to a new worksheet.
2. In the **Data** pane, double-click a spatial field.

In this example, **Geog_School** is used. When double-clicked, it's automatically added to Detail on the Marks card and a map view is created.

3. From the **Data** pane, drag a dimension field to **Label** on the Marks card. In this example, **School Name** is used.
4. Select **Analysis > Create Calculated field**.
5. In the Calculation editor that opens, do the following:
 - Name the calculated field. In this example, the calculated field is named **Intersection**.
 - Enter a RAWSQL formula. This example uses the following formula:
`RAWSQL_SPATIAL ("Select %1.STIntersection(%2)", [Geog_School], [Geog_Pub_Space])`
 This formula returns unique spatial data based on the intersection of two geometries.
 - When finished, click **OK**.
6. Select **Analysis**, and then clear **Aggregate Measures**.
7. From the **Data** pane, drag the new calculated field (in this case, **Intersection**) to a new layer on the worksheet.

The map updates with a new layer of polygons from the Intersection field. The marks are unique spatial shapes because of the RAWSQL formula.

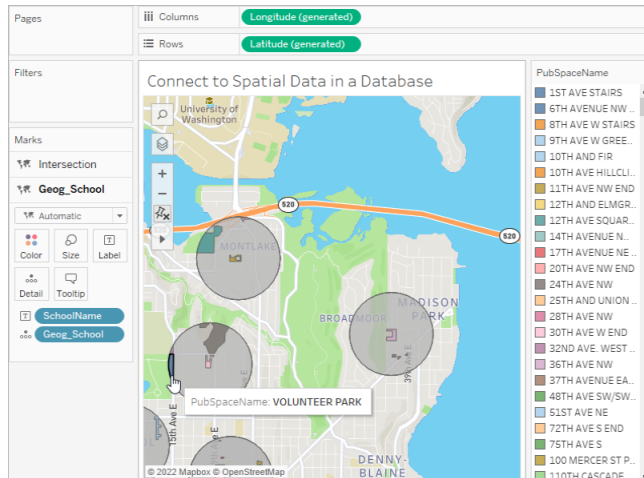

8. From the **Data** pane, drag a dimension field to **Detail** on the Marks card. This disaggregates the marks.

In this example, the dimension **PubSpaceName** is used.

9. From the **Data** pane, drag the same dimension field to **Colour** on the Marks card.

In this example, each public space is now assigned a colour.

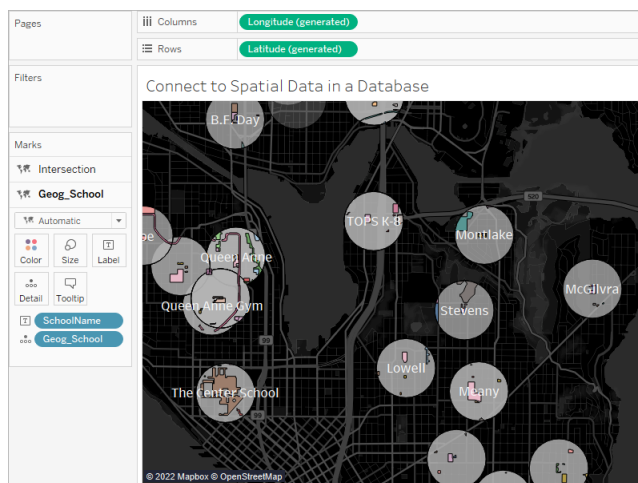

1. Format the map. For more information, see [Customise How Your Map Looks on page 1845](#)

In this example, the following formatting is applied:

- The School buffer marks (Geog_School) are coloured grey.
- The School Name mark labels are coloured white.
- The map background style is set to Dark.
- The Streets and Highways/Motorways layer is shown on the background map.

The map is now finished.

[Get Started with Calculations in Tableau](#) on page 2009

[Spatial Join Slow and Returns Inverted Results Using KML or SQL Spatial Data Imported from Shapefile or GeoJSON](#)

Join Spatial Files in Tableau

You can use spatial data to create maps or other chart types in Tableau. If you have two spatial data sources, you can join them using their spatial features (geography or geometry). You can either join two spatial files together or use a spatial calculation to join a spatial file with non-spatial data that includes latitude and longitude fields.

Tableau supports connection to the following spatial data sources:

- Shapefiles
- MapInfo tables
- Keyhole Markup Language (KML) files
- GeoJSON files
- TopoJSON files
- Esri File Geodatabases

If you have WKT (well known text) in a CSV or Excel file, you can import the data and then translate it to spatial data on the Data Source page. You can also use MAKEPOINT to convert data that has latitude and longitude coordinates into spatial data. See [Create a spatial data source using MAKEPOINT](#) on page 2174.

For more information on the types of spatial files you can connect to in Tableau, and how to connect to them, see the [Spatial File on page 1676](#) connector example.

Important note: In Tableau 2021.3 or later, you can create spatial joins between point/polygon, polygon/line, polygon/polygon and line/polygon features. In Tableau 2021.2 and earlier versions, you can only create spatial joins between points and polygons.

Join spatial files

Tip: To create, edit or view spatial joins, you must first open a logical table in the relationship canvas – the area you see when you first open or create a data source – and access the join canvas.

1. Open Tableau and connect to the first spatial data source.
2. Open the join canvas for your data source by double-clicking on the table on the canvas to open the join canvas (physical layer).
3. On the upper-left side of the Data Source page, under Connections, click **Add**.
4. In the Add a Connection menu that appears, connect to your second data source. Drag the second data source onto the join canvas.

5. Click on the **Join** icon.
6. In the Join dialog box that appears, do the following:

- Select a join type.

For more information about each of these types, see [Join Your Data on page 796](#).

- Under **Data Source**, select a spatial field to join by.

Note: Geometry is the default field name for spatial file sources except in SQL

Server, where users create field names. Spatial fields have a globe icon  next to them.

- For the second data source, select another spatial field. If your second data source isn't a spatial file and contains latitude and longitude fields, select **Create Join Calculation** as the join clause so that your data can be used in a spatial join. For more information, see [Spatial Functions on page 2168](#).
- Click the **=** sign and then select **Intersects** from the drop-down menu. You can only

intersect two spatial fields.

- When finished, close the Join dialog box.

The map updates to show the count of waterfowl sightings in each basin, and you're ready to start analysing your spatial data.

For more information on building different chart types, see [Build Charts and Analyse Data](#) on page 1009.

Troubleshoot spatial joins

SQL Server error: Geometry is incompatible with geography

Although SQL Server supports both a geography and a geometry data type, Tableau only supports geography data type from SQL Server from the following geographies: EPSG:WGS84

= 4326, EPSG:NAD83 = 4269, EPSG:ETRS89=4258. If you try to add a different geography, or a geometry field from SQL Server to your analysis, you'll receive an error.

Vertex ordering

Different spatial systems may order their vertices differently. If two spatial files contain two different vertex orders, it may cause problems with your analysis. Tableau interprets ordering specification according to the order of the spatial data source.

For more information, see [Spatial Join Slow and Returns Inverted Results Using KML or SQL Spatial Data Imported from Shapefile or GeoJSON](#) and [Supporting advanced spatial analytics with changes to lines and polygon edges in Tableau](#) in the Tableau Knowledge Base.

Spatial Parameters and Operators

Spatial parameters

You can create a spatial parameter to use in calculations from spatial data. You can load spatial parameters from a data source, or you can use well-known text (WKT) to create spatial parameters in Tableau. A spatial parameter can be a point, polygon, multipolygon, line or a homogeneous collection of these types. You can use spatial parameters the same way you use other parameters in Tableau, such as parameter controls, parameter actions and dynamic values.

As of Tableau 25.2, you can use a dynamic map viewport parameter to set a spatial data value parameter to the rectangle that is your map viewport. This feature enables you to create more interactive and responsive map visualisations. To learn more, see [Map Viewport Parameters](#).

Note: Spatial parameters can only be created with fields from spatial data, such as latitude and longitude coordinates. They can't be created with text string fields. For example, a

country field is a text string that may have a geographic role applied, but it's still a text string.

Create a spatial parameter

To create a parameter from the Data pane:

1. Click the drop-down arrow in the upper-right corner and select **Create Parameter**.

Alternatively, you can right-click a field and select **Create Parameter**.

2. In the Create Parameter dialog box, name your spatial parameter.
3. Open the Data Type drop-down, and select **Spatial**.

4. Under Allowable Values, select **All** or **List**.
Choosing List allows you to populate the values by using WKT or from a field. For List domain parameters, we recommend using an alias when naming your parameter. For example, instead of naming your spatial parameter POINT(-73.9856 40.7484079), name it Empire State Building. The use of an alias is only available for List domain parameters.
5. Open the drop-down menu next to **Add values from** and select a field. You can also type the WKT values directly into the grid
6. Select **OK**.

The spatial parameter appears at the bottom of the Data pane under the Parameters section.

Visualise your spatial parameter

To visualise the spatial parameter, the parameter needs to be used in a calculation.

1. Select **Analysis > Create Calculated Field**.
2. In the Calculation Editor that opens, name your calculated field.
3. In the Calculation Editor, drag your parameter and drop it in the formula.
4. Select **OK**.

The new calculated field is added to the Data pane. It has an = in front of the data type icon to show it's a calculated field. You can now visualise your parameter by dropping onto a map layer or double-clicking the pill.

You can change the parameter values by using a parameter control, a parameter action or a dynamic parameter.

Show a spatial parameter control on the viz

A parameter control is a worksheet card that lets you modify the parameter value. They're similar to filter cards in that they contain controls that modify the view.

To show the spatial parameter control, right-click (Control-click on Mac) the parameter in the Data pane and select **Show Parameter**.

You can use the spatial parameter control in several different ways. As a type-in control, you can type in WKT to set your parameter value, or you can type in the parameter's alias. You can also use list or drop-down controls to view your spatial parameter.

To learn more about Parameters and how to use them, see [Create Parameters](#).

Spatial operators

Starting in Tableau version 24.3, you can use spatial operators in a calculation.

To learn more about calculated fields and how to use them, see [Create a Simple Calculated Field in Tableau](#).

Create a calculated field using a spatial operator

1. In a worksheet in Tableau, select **Analysis > Create Calculated Field**.
2. In the Calculation Editor that opens, name your calculated field.
3. In the Calculation Editor, use a spatial operator in the formula.

For example: `UNION([Geometry])`

4. Select **OK**.

The new calculated field is added to the Data pane with an  icon in front of the data type icon to indicate it's a calculated field used with a spatial operator.

Spatial operators available in Tableau

DIFFERENCE

| | |
|------------|---|
| Operator | DIFFERENCE |
| Definition | Computes the portions of regions remaining when all regions in the second argument are carved out of the first argument in areas that overlap. Discards regions from the second argument in areas that don't overlap. |
| Example |  |

INTERSECTION

| | |
|------------|---|
| Operator | INTERSECTION |
| Definition | Computes and returns the portions of regions in the second argument that overlap regions in the first argument. |

| | |
|---------|---|
| Example |  |
|---------|---|

SYMDIFFERENCE

| | |
|------------|---|
| Operator | SYMDIFFERENCE |
| Definition | Computes any portions of regions from the second argument that overlap regions in the first argument and discards from both. Returns the remaining portions of regions from both arguments. |
| Example |  |

UNION

| | |
|------------|---|
| Operator | UNION |
| Definition | Returns spatial data points, polygons and lines that overlap or intersect as an outline of the whole. |
| Example |  |

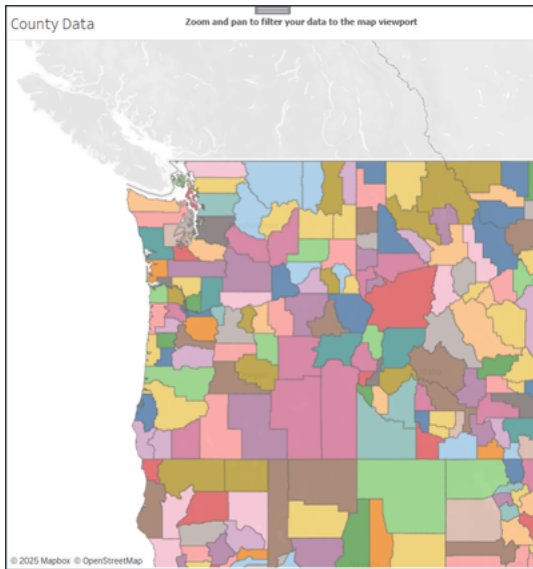

Map Viewport Parameters

What is a map viewport?

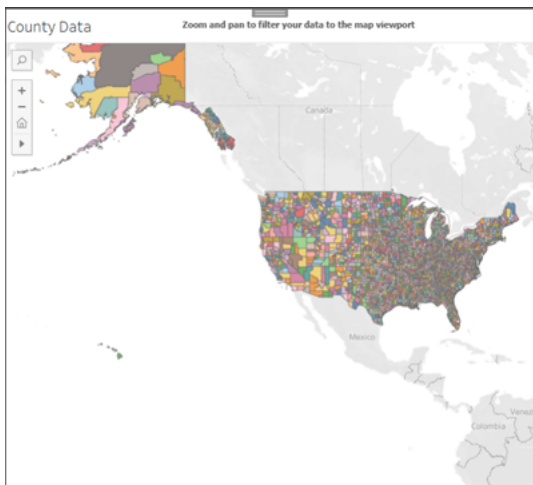

A map viewport in Tableau is the area of the map that is currently visible. Each instance of a map, whether on a worksheet or a dashboard, has its own viewport. Think of a viewport as a window that can vary in size and shape, allowing you to see different portions of the map. For example,

you can view a map zoomed in on a specific region, or you can view it zoomed out to show a larger amount of geography. It's the same map, but the area that you can see is different.

Map viewport zoomed in on a specific region.

Map viewport zoomed out to show a larger amount of geographic information.

By understanding and using dynamic map viewport parameters, you can create more engaging and interactive map visualisations in Tableau.

Why use dynamic map viewport parameters?

You can use dynamic map viewport parameters in Tableau to set a spatial data value parameter to the rectangle that is your map viewport. This parameter updates automatically with every zoom and pan action on the map, not just when the workbook is opened. The viewport will also work when you use the map search functionality. This feature enables you to create more interactive and responsive map visualisations.

Here are some ways you can use dynamic map viewport parameters:

Filter points: Use the **Intersects calculation** to filter points that intersect with the current map viewport.

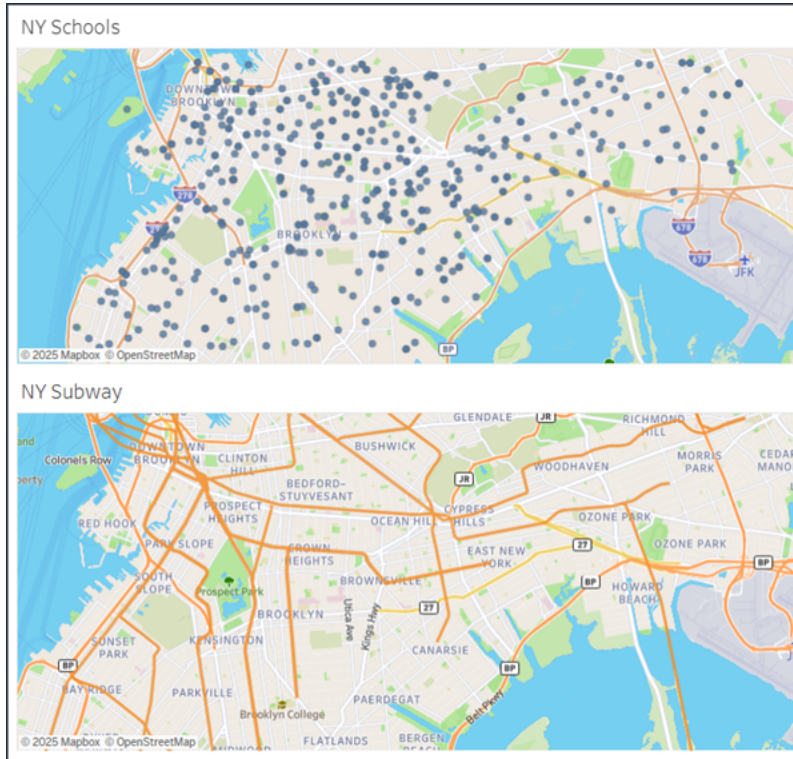

Adjust mark sizes: Use the **Area calculation** to adjust mark sizes based on the size of your viewport.

Create new map polygons: Use **spatial operators** to compare different map polygons, generating new polygons based on the current viewport.

Visualise the parameter directly: You can visualise the parameter by using it in a calculation to see the current viewport.

Sync multiple maps: Select one map as your viewport and use the viewport to filter the data of the other map. This makes sure that the second map updates based on the area shown in the first map.

In this image, one map is used as the viewport parameter. If you zoom and pan on the NY Subway map, the changes happen to the NY Schools map at the same time.

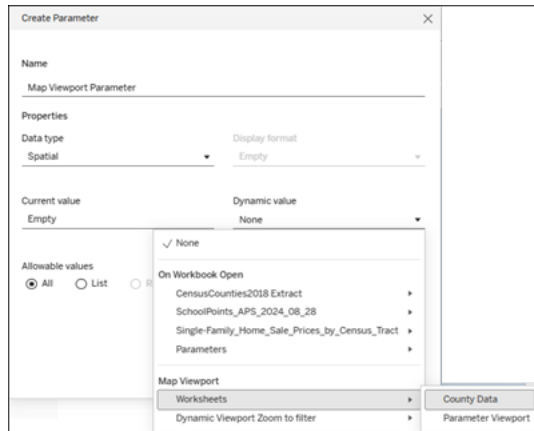

How do you create a dynamic map viewport parameter?

1. In the Data pane, select the drop-down arrow in the upper-right corner and select **Create Parameter**.
2. In the Create Parameter dialog box, name your parameter.
3. Set the data type to **Spatial**.
4. Set the Allowable values to **All**.

Note: **List** is not compatible with dynamic map viewport parameters

5. Under Dynamic value, expand the Map Viewport menu and select the map that you'd like to use as a viewport.

Tip: If you don't see the map that you'd like to use, go to the worksheet to initialise the viewport. Then, you can reopen the parameter dialog and you will see your map viewport listed.

Avoid setting the parameter value through a control or action. Parameter values change with every zoom and pan on the map. Any value set through controls or actions will be overwritten with the map viewport value.

To learn more about creating parameters and showing a parameter control on a viz, see [Create Parameters](#).

To learn more about spatial parameters and operators, see [Spatial Parameters and Operators](#).

Geocode Locations Tableau Does Not Recognise and Plot Them on a Map

If you have locations that Tableau can't map, such as street addresses, you can custom geocode those locations. Custom geocoding means that you assign latitude and longitude coordinates to your locations so Tableau can plot them accurately. It also allows you to create custom geographic roles that you can use as you create map views in Tableau.

For example, if your data contains country, state/province and street address data, Tableau Desktop geocodes your data to the country and state/province level, but won't recognise the street address data. In this case, you can create a custom geographic role for the street address data so that you can plot it on a map view in Tableau.

Follow these steps to learn how to custom geocode your data.

Before you start: Custom geocoding your data can be tricky. We recommend that you check out the [Assign Geographic Roles on page 1717](#) topic to learn more about geographic roles and the types of data Tableau recognises before you get started.

Step 1: Create a CSV file with your location data

The first step to custom geocoding your data is creating a CSV file to import into Tableau. The contents of this file differ depending on whether you're [extending an existing geographic hierarchy](#), [adding a new geographic role](#) or [adding a new hierarchy](#) to Tableau.

However, the following applies to all custom geocoding files:

- The .csv file must contain Latitude and Longitude columns.
- The latitude and longitude values you add must be real numbers. Make sure to include at least one decimal place when specifying these values.

Extend an Existing Role

The built-in geographic roles in Tableau contain hierarchies that can be extended to include locations relevant to your data. For example, the existing hierarchy of Country > State/Province may not contain all of the states or provinces in your data. You can extend this level to include missing states or provinces.

The import file for this type of geocoding should contain every level of the hierarchy above the level you are extending. For example, if you're extending (adding data to) the State/Province geographic role, the existing State/Province hierarchy has a column for Country and State/Province, along with Latitude and Longitude.

| | A | B | C | D |
|---|-----------------------|-----------------------|-----------------|------------------|
| 1 | Country (Name) | State/Province | Latitude | Longitude |
| 2 | England | United Kingdom | 51.5000 | 0.1167 |
| 3 | Scotland | United Kingdom | 55.9500 | 3.1833 |
| 4 | Wales | United Kingdom | 51.4833 | 3.1833 |
| 5 | Northern Ireland | United Kingdom | 54.6000 | 5.9167 |

In the import file, the names of the columns define the geographic roles. When extending an existing role, the column names must match the existing geographic roles in the hierarchy that you're extending. This ensures that the new locations are added to the proper roles and hierarchies.

See the following table for information on how to organise hierarchies in your import file.

| Built-In Hierarchy | Columns to include in the .csv file (in order; left to right) |
|--|--|
| Country (Name) | Country (Name) Latitude Longitude |
| Country (Name), State/Province | Country (Name) State/Province Latitude Longitude |
| Country (Name), State/Province, City | Country (Name) State/Province City Latitude Longitude |
| Country (Name), State/Province, County | Country (Name) State/Province County Latitude Longitude |
| Country (Name), ZIP Code/Post-code | Country (Name) ZIP Code/Postcode Latitude Longitude |
| Country (Name), Area Code | Country (Name) Area Code |

| | |
|----------------------|----------------|
| | Latitude |
| | Longitude |
| Country (Name), CBSA | Country (Name) |
| | CBSA |
| | Latitude |
| | Longitude |

In addition to the Country (Name) column, you can optionally include the following columns: Country 2 char (ISO 3166-1), Country 3 char (ISO 3166-1), and Country (FIPS 10). If you include these columns, they should be just to the right of the Country (Name) column in any order.

Note: The highest level in the hierarchy is Country and can't be extended to include higher levels such as Continent, etc.

Add New Roles

To add new geographic roles to the existing geographic hierarchy in Tableau, format your import file to include the new roles along with their parent roles.

When adding new roles to an existing hierarchy, the import file for those roles needs to contain the columns for each level in the existing hierarchy. For more information on the columns to include in each geographic hierarchy, see the [built-in hierarchy table](#) in the Extend an Existing Role section.

The following table is an example of an import file containing the locations of crater impacts in North America. Importing the following file would add the geographic role Crater Name to the existing Country (Name), State hierarchy. Notice that the column name for country matches the existing Country (Name) geographic role.

| A | B | C | D | E |
|----------------|--------------|----------------|-----------|-------------|
| Crater Name | State | Country (Name) | Latitude | Longitude |
| Ames | Oklahoma | U.S.A. | 35.007752 | -97.092877 |
| Arak | Alaska | U.S.A. | 64.200841 | -149.493673 |
| Barringer | Arizona | U.S.A. | 34.048928 | -111.093731 |
| Beaverhead | Montana | U.S.A. | 46.879682 | -110.362566 |
| Brent | Ontario | Canada | 51.253775 | -85.323214 |
| Calvin | Michigan | USA | 44.314844 | -85.602364 |
| Carwell | Saskatchewan | Canada | 52.939916 | -106.450864 |
| Charlevoix | Quebec | Canada | 46.813878 | -71.207981 |
| Chesapeake Bay | Virginia | U.S.A. | 37.431573 | -78.656894 |
| Chicxulub | Yucatan | Mexico | 20.709879 | -89.094338 |

After you've created your import file, save the file as a Comma-Delimited (.csv) file (Windows Comma-Separated if on a Mac) in a folder on your computer.

Step 2: Import custom geocoding files into Tableau Desktop

After you've created a .csv file with custom geocoding, you can import that file into Tableau.

1. Open Tableau Desktop and navigate to a new or existing worksheet.
2. Select **Map > Geocoding > Import Custom Geocoding**.
3. In the Import Custom Geocoding dialog box, click the button to the right of the text field to browse to the folder your import file is saved in. All files in the folder will be imported into Tableau.

4. Click **Import**.

The custom geocoding data is imported into the workbook and the new geographic roles become available.

Where does Tableau store my custom geocoding data?

When you import custom geocoding, the data is stored in the Local Data folder in your Tableau Repository. To import custom geocoding, your Tableau Repository must be on a local hard drive. The custom geocoding is then available for all workbooks.

Save custom geocoding files in a separate folder on your local computer. If you have several different sets of custom geocoding files, save each of them under their own folder names.

You can remove the custom geocoding stored in your Tableau Repository by clicking **Map > Geocoding > Remove Custom Geocoding**. This won't remove the geocoding from a packaged workbook, but it will remove it from the Local Data folder in your My Tableau Repository.

What happens to my custom geocoding data when I save my workbook?

When you save your workbook as a packaged workbook, the custom geocoding data is packaged with the workbook. When you open a packaged workbook you can import the custom geocoding from that workbook into your own Tableau Repository.

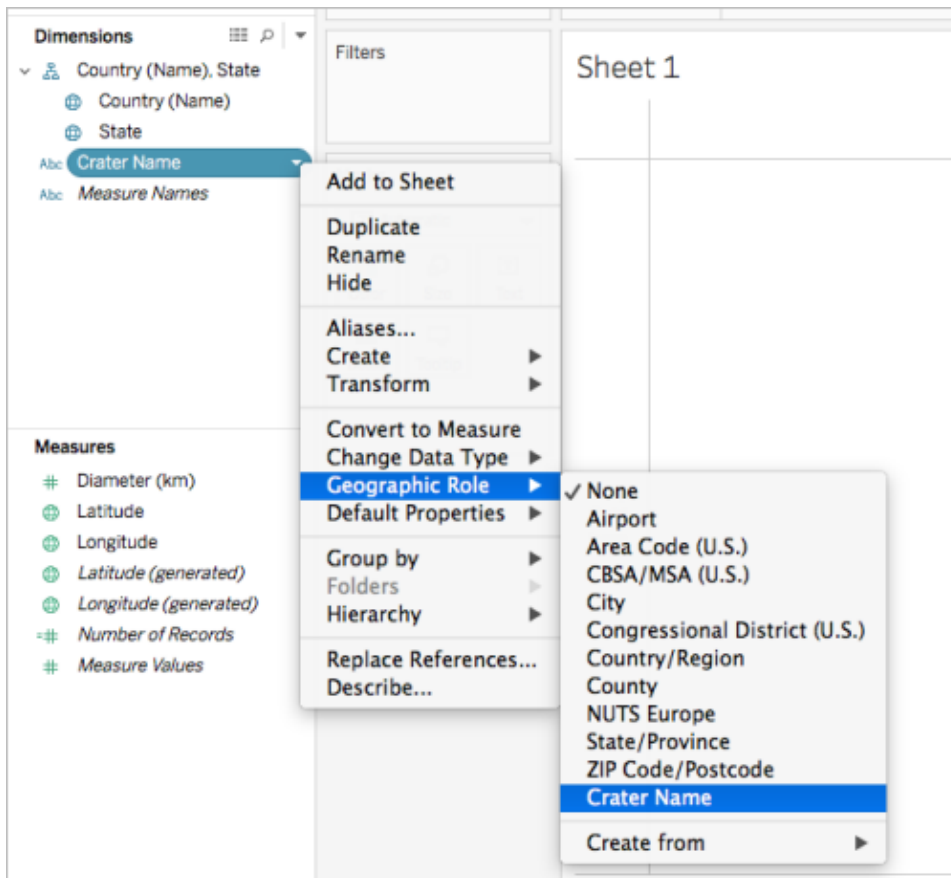

Note: Importing a new custom geocoding file will replace any custom geographic roles previously imported into Tableau.

Step 3: Assign geographic roles to your fields

After you import custom geocoding into your workbook, the custom geographic roles become available. The next step is to assign those geographic roles to fields in your data source.

For example, if you decided to add a new geographic role that lists the latitude and longitude coordinates of crater impacts in North America, you can assign that geographic role to a field in your data source that lists the names of craters so when you create a map view with that field, the crater impacts are plotted in the correct locations on the map view.

To assign a custom geographic role to a field, in the Data pane, click the data type icon next to the field and select **Geographic Role**. Next, select a custom geographic role from the list.

You're now ready to start building a map view with your custom geographic roles. For more information on how to build a map view, see [Mapping Concepts in Tableau](#) on page 1661.

See also

[Data Blending vs. Custom Geocoding](#) on page 1715

[Blend Geographic Data](#) below

Blend Geographic Data

This example demonstrates how to blend geographic data in Tableau using two small sample data sources. Follow the steps in this topic to learn how to create a file that defines your geographic data, blend two data sources, and build the map view below using the two data sources.

The embedded view below shows famous theatres around the world, and was created by blending geographic data with another data source. Hover over the marks in the view to see information about each theatre. If you would like to follow along with the steps in this topic, click

Download in the view below, and then select **Tableau Workbook**. This will open the view in Tableau Desktop.

Step 1: Create a file that defines your geographic data

When you have a data source that contains geographic information that is not automatically geocoded in Tableau, the first step is to create a second data source that defines the latitudinal and longitudinal values for that information. You will later connect to this file in Tableau Desktop and blend it with your original data source.

Create a second data source with the following information:

- **Geographic name column:** This column includes any geographic information you want to plot on a map view and typically matches a geographic column name in your original data. For example, if your original data source has a column called Street Address, your second data source should also have a column called Street Address. The data in this column would then be all of the street addresses you want to plot on a map view.

If the column does not match a geographic column name in your original data source, you may need to edit the relationships between your two data sources in Tableau Desktop.

For more information, see [Step 3](#).

Finally, this column should not match the names of any geographic roles already in Tableau, such as **County**, **Area Code**, or **CBSA/MSA**.

Note: The data in these columns can be strings or numbers. However, if your locations are numbers, especially numbers with leading zeros (for example, 00501), make sure the data type of the field is set to **String** in Tableau. For more information, see [Data Types on page 156](#).

- **Latitude and Longitude columns:** The values in these columns need to be in decimal degrees (for example, 47.651808, -122.356881).

Below is an example of an original data source with geographic locations, and a second data source that defines those geographic locations.

Original data source

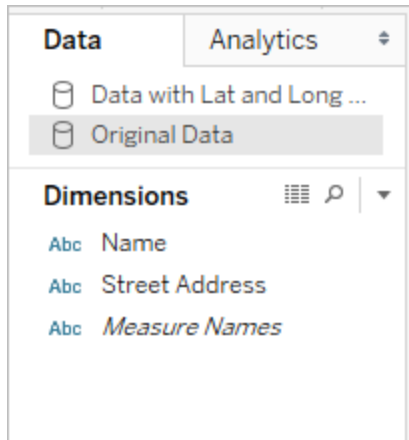

| | A | B |
|---|-----------------------|------------------------|
| 1 | Name | Estimated Seats |
| 2 | La Scala | 3,000 |
| 3 | Teatro di San Calo | 1,397 |
| 4 | Teatro Colon | 2,500 |
| 5 | The Royal Opera House | 2,256 |
| 6 | The Bolshoi | 2,200 |

Second data source

| | A | B | |
|---|--|-----------------|------------|
| 1 | Street Address | latitude | lon |
| 2 | Via Filodrammatici, 2 20121 Milan, Italy | 45.46731 | 9. |
| 3 | Via San Carlo, 98 80132 Naples, Italy | 40.83832 | 1 |
| | Cerrito 628 Buenos Aires | -34.6011 | -5 |
| 4 | Ciudad Autónoma de Buenos Aires | | |
| 5 | Bow St London WC2E 9DD | 51.5137 | -0 |
| 6 | Theatre Square, 1 Moscow 125009 | 55.76016 | 37 |

Step 2: Connect to the data sources

1. Connect to the original data source.
2. Connect to the data source that defines your geographic data.

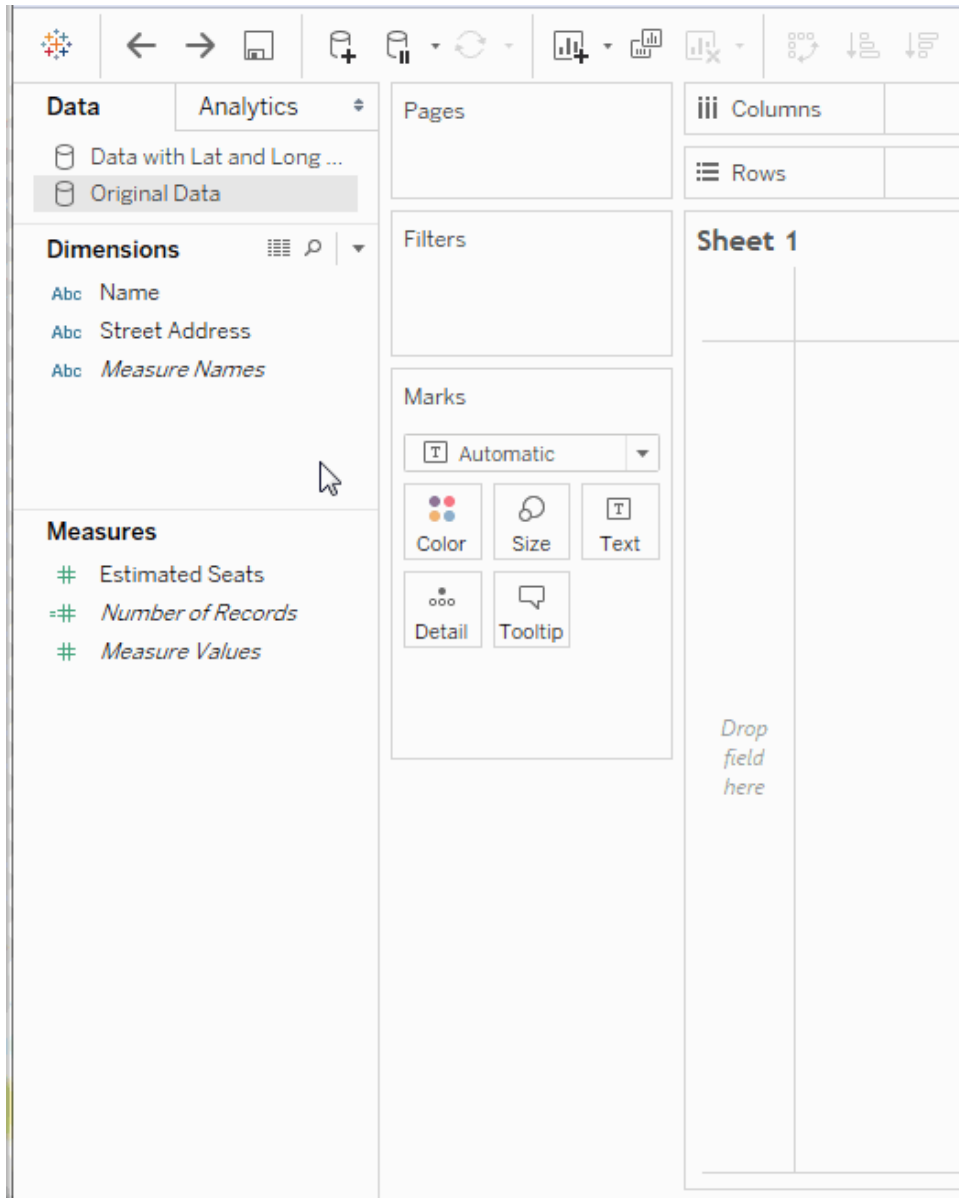

Step 3: Edit Relationships

(Optional) If the two data sources share the same column names, your data should blend automatically when you add fields to the view. However, if the file you created to define your geographic data does not share the same column name as the geographic data in your original data source, you will need to create a relationship between those two fields using the **Edit Relationships** option. For information about how to edit relationships, see [Blend Your Data on page 821](#).

Step 4: Plot the data on a map view

1. In the **Data** pane, select the second data source that defines your geographic data. Under **Measures**, assign the **Latitude** geographic role to the **Latitude** field and the **Longitude** geographic role to the **Longitude** field. For more information, see [Assign Geographic Roles on page 1717](#).

2. In the **Data** pane, select the original data source, and then drag the field you want to plot on a map to **Detail** on the **Marks** card.

Note: This field should have a data type of String, and should be a dimension. For more information on how to change the data type of a field, see [Data Types on page 156](#).

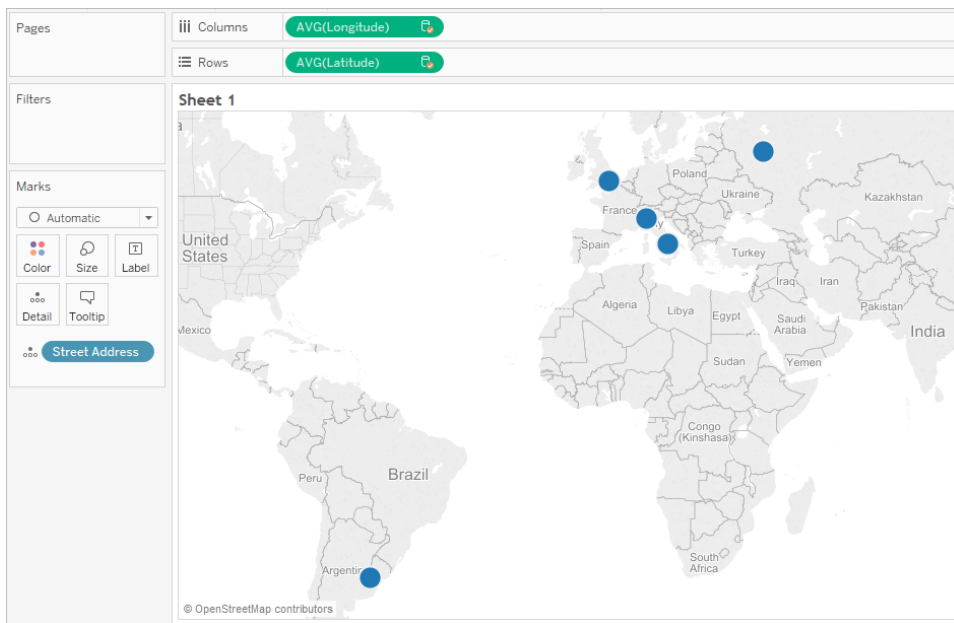

3. In the **Data** pane, select the second data source , and then double-click **Latitude** and **Longitude** to add them to the **Columns** and **Rows** shelves.

The link icon  indicates that the **Street Address** field is blended with the **Street**

Address field in the original data source. A broken link icon  indicates that the **Street Address** field is not blended with the **Street Address** field in the original data source.

The view is now complete. Each mark represents an address from the original data source.

[Data Blending vs. Custom Geocoding](#) below

Data Blending vs. Custom Geocoding

If you have geographic locations in your data that are not automatically geocoded in Tableau, there are two ways to plot them on a map view – data blending and custom geocoding. Both data blending and custom geocoding allow you to plot your own locations on a map. Data blending is easier to set up and you can work with data from any data source. Custom geocoding lets you

add to existing roles, and create hierarchies. Custom geocoding can be easier to use once it is set up and imported.

This topic explains the difference between blending geographic information with another data source and importing custom geocoding data into Tableau.

The following is a quick comparison of data blending and custom geocoding.

| Capability | Data Blending | Custom Geocoding |
|---------------------------------------|---------------|---------------------|
| Plot your own locations on a map view | Yes | Yes |
| Use any data | Yes | No, text files only |
| Add new geographic roles | No | Yes |
| Add to an existing geographic role | No | Yes |
| Create new geographic hierarchies | No | Yes |
| Can be reused for other workbooks | No | Yes |

Data Blending

Data blending is the easiest way to plot your data on a map view. Data blending works great if you are adding a single level of geographic information with a latitude and longitude. You can use any data source, unlike Custom geocoding where you can only use text files. You can share the geographic data source with other workbooks on Tableau Server. You can also speed up your map performance by creating an extract that contains only your geocoding data.

The following is a high-level procedure for blending geographic data. For a more detailed example, see [Blend Geographic Data on page 1709](#).

To blend geographic data

1. Create a data source that defines your geographic data.
2. In Tableau Desktop, connect to the original data you want to map, and then connect to the data source that defines your geographic data.
3. Blend the two data sources together. For more information, see [Blend Your Data on page 821](#).
4. Plot the data on a map view.

Custom Geocoding

Custom geocoding is a more flexible way to plot your data on a map. Custom geocoding is available for all workbooks on a computer once the custom geocoding data is imported. The custom geocoding data will be copied into any packaged workbook (.twbx) or published workbook that uses a custom geographic role. This will make the workbooks about 40 MB larger.

If you upgrade Tableau Desktop, you may need to refresh your custom geocoding to take advantage of any fixes made to the geocoding data in Tableau.

In custom geocoding, you can use additional columns to define larger geographic locations. For instance, if you are creating a set of US census tracts, you may need to define which US county they fall in. You can include additional columns to define larger geographic locations in the import file.

You can also use multiple files for multiple geographic roles that have a matching relationship, meaning they share larger geographic data, such as country or state/province. Once the custom geocoding data is imported, you will see additional geographic roles that can be assigned to your geographic data.

Finally, custom geocoding lets you add additional places to an existing geographic role, such as adding new cities to the city role. It also allows you to define a hierarchy of geographic roles that extends the built-in hierarchies (e.g. census tracts in counties) or defines a new hierarchy (e.g. sub-territories in territories).

For more information about custom geocoding, see [Geocode Locations Tableau Does Not Recognise and Plot Them on a Map](#) on page 1703.

[Assign Geographic Roles](#) below

Assign Geographic Roles

This article describes how to assign a geographic role to a field in Tableau so that you can use it to create a map view.

A *geographic role* associates each value in a field with a latitude and a longitude value. When you assign a geographic role to a field, Tableau assigns latitude and longitude values to each location in your data based on data that is already built into the Tableau map server.

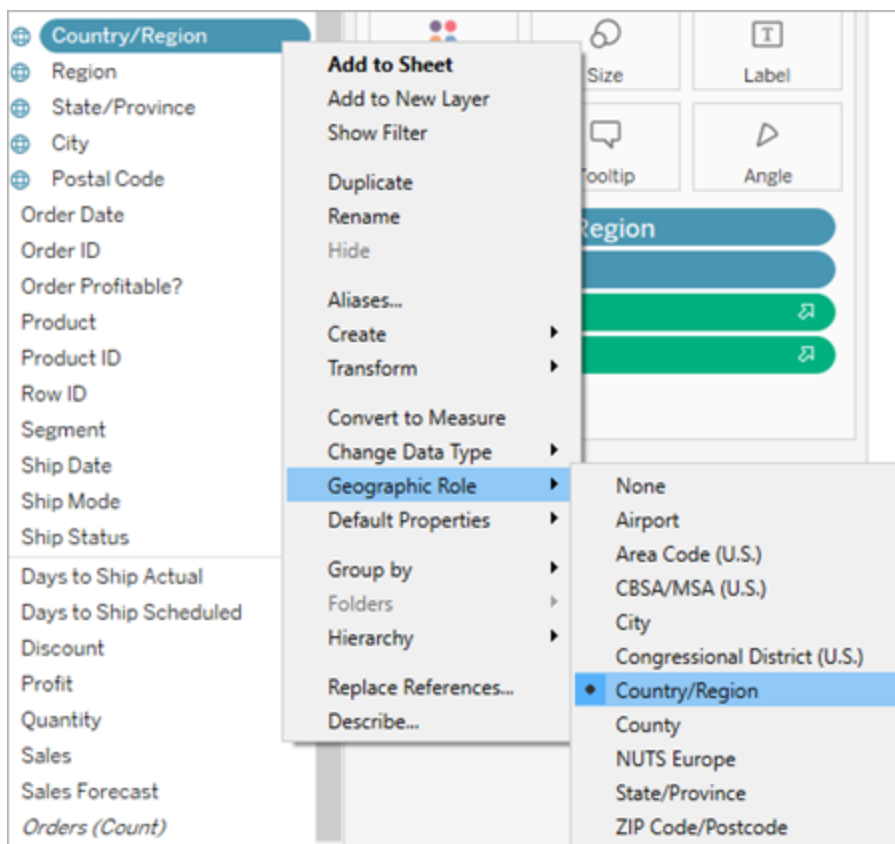

Assign a geographic role to a field

Assigning a geographic role based on the type of location (such as state versus postcode) helps ensure that your data is plotted correctly on your map view. For example, you can assign the City geographic role to a field that contains a list of city names.

When a field is assigned a geographic role, Tableau creates a map view when you add the field to **Detail** on the **Marks** card. In other words, Tableau *geocodes* the information in that field.

To assign a geographic role to a field:

- In the Data pane, click the data type icon next to the field, select **Geographic Role**, and then select the geographic role you want to assign to the field.

When you assign a geographic role to a field, Tableau adds two fields to the measures area of the Data pane: Latitude (generated) and Longitude (generated).

These fields contain latitude and longitude values and are assigned the Latitude and Longitude geographic roles. If you double-click each of these fields, Tableau adds them to the Columns

and Rows shelves and creates a map view using the Tableau background map.

Types of geographic roles in Tableau

The following table describes the geographic roles available in Tableau. Many of the roles are international, but some are limited to the US only.

You can assign geographic roles to your fields based on the type of geographic data they contain. For example, you can assign the Airport geographic role to a field that contains International Air Transport Association (IATA) codes.

If your location data does not fit into one of these roles, you may have to import custom geocoding to plot the data on a map. For more information, see [Geocode Locations Tableau Does Not Recognise and Plot Them on a Map](#) on page 1703.

| Geographic Role | Assign this role to a field if it contains: |
|-----------------|--|
| Airport | International Air Transport Association (IATA) or International Civil Aviation Organisation (ICAO) airport codes. |
| Area Code (US) | US telephone area codes; numbers only. |
| CBSA/MSA (US) | US Core-Based Statistical Areas (CBSA), which includes Metropolitan Statistical Areas (MSA), as defined by the US Office of Management and Budget. CBSA/MSA Codes and Names are recognised. |
| City | Worldwide cities with population of 15,000 or more. Names are in English (UK or US), French, German, Spanish, Brazilian-Portuguese, Japanese, Korean and Chinese (Simplified and Traditional). |

| | |
|-----------------------------|--|
| Congressional District (US) | US congressional districts. |
| Country/Region | Worldwide countries, regions, and territories. Names are in English (UK or US), French (Canada and France), German, Spanish, Brazilian-Portuguese, Japanese, Korean, Chinese (Simplified and Traditional), Swedish, Thai and Dutch. Tableau also recognises, FIPS 10, ISO 3166-1 alpha 2, and ISO 3166-1 alpha 3. Names are included in various forms, including long, short, and various abbreviations. |
| County | <p>Second-level administrative divisions for select countries. For example, US counties, French départements, German kreise, etc.</p> <p>Note: Second-level administrative division definitions vary by country. In Tableau, all second-level administrative divisions are geocoded with the County geographic role. For more information, see the Location Data that Tableau Supports for Building Map Views on page 1675 section.</p> |
| NUTS Europe | NUTS (Nomenclature of Territorial Units for Statistics) levels 1–3 codes. Codes and names, including synonyms, are supported. |
| Latitude | Latitude in decimal degrees. Only available for numeric fields. |
| Longitude | Longitude in decimal degrees. Only available for numeric fields. |
| State/Province | Worldwide state, province, and other first-level administrative divisions. Names are in English (UK or US), French, German, Spanish, Brazilian-Portuguese, Japanese, Korean and Chinese (Simplified and Traditional). Note: Some names are available only in their local form. |
| ZIP Code/Post-code | ZIP codes and postcodes for select countries. For example, US five-digit zip codes, Australian four-digit postcodes, German five-digit postcodes, etc. For more information, see the Location Data that Tableau Supports for Building Map Views on page 1675 section. |

[Create Tableau Maps from Spatial Files](#) on page 1735

[Edit Unknown or Ambiguous Locations](#) below

Edit Unknown or Ambiguous Locations

Sometimes Tableau will not recognise one or more of the location names in your data. When this happens those values are marked as **unknown** in the lower right corner of the map view. This may happen if there is a location or abbreviation that Tableau does not recognise, or if the location is ambiguous and could exist in multiple places.

When this happens, you can add additional information to the view to define locations, or can edit the unknown location names to map to known locations.

Add more fields to view

If your data set includes ambiguous locations (for example, "Aberdeen," which could appear in multiple states or countries), adding another geographic field, like State or Country, to the view defines the correct location for that data. If there is a hierarchy in the data pane, Tableau will automatically use the appropriate levels of the hierarchy to solve location ambiguities.

Edit locations in the Special Values menu

Sometimes, unknown locations can be prompted because there's a misspelling or another issue. When this happens, you can correct the unknown or ambiguous locations in your data using the **Special Values** menu. To do this:

1. In the bottom right corner of the view, click the special values indicator that lists the number of unknown locations in your map. This opens the Special Values menu.

2. In the Special Values dialog box, select **Edit Locations**.

Note: If the special values indicator is not visible, you can also select **Map > Edit Locations**

The Edit Locations dialog lets you clarify unrecognised and ambiguous values to locations in Tableau.

Edit ambiguous locations

Both unrecognised and ambiguous locations can be listed in the Edit Locations dialog box.

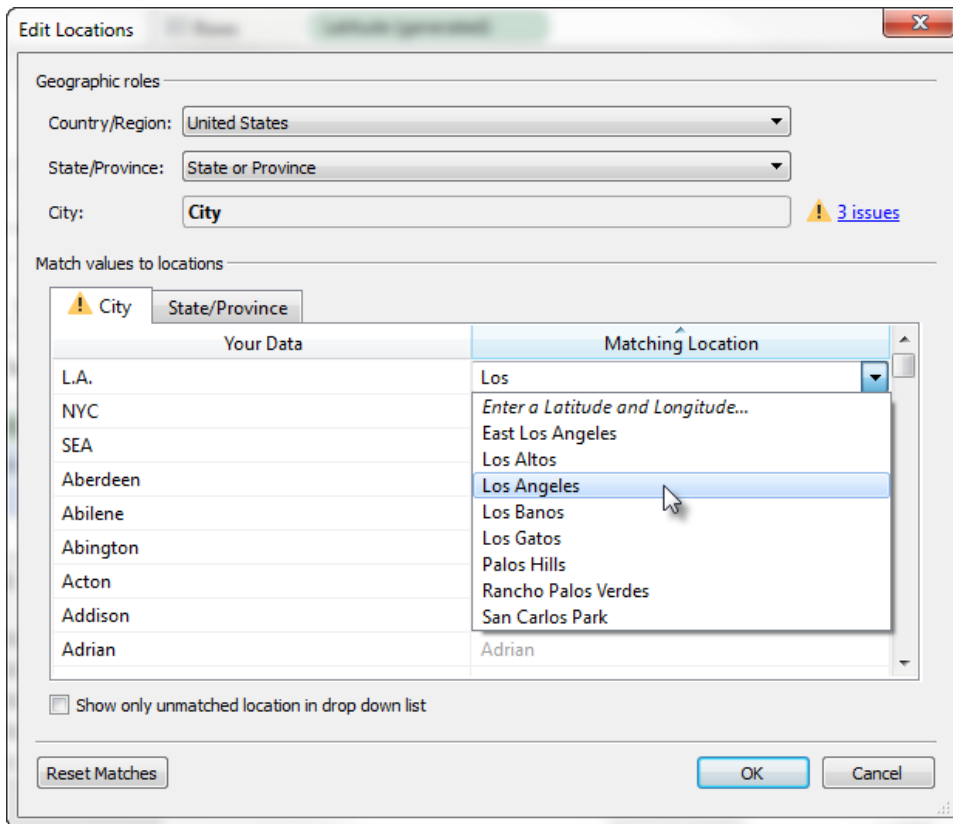

You can fix some ambiguous locations by specifying the **Country/Region** and/or **State/Province** for each city from a specific field in your data, either by hard-coding a value if your data only spans one state or country, or by telling Tableau which fields to refer to for that information. This option is in the Geographic Roles section of the Edit Locations dialog box. For example, if you have several cities that are ambiguous, you can specify a State/Province to fix them.

If there are ambiguous or unknown locations in the Country/Region or State/Province tabs in the Edit Locations menu, fixing those first may resolve some ambiguous locations in smaller geographic roles, such as cities.

Edit unknown locations

In the Edit Locations dialog box, click on one of the **Unrecognised** cells to match a known location to your unknown data. When you click on an unrecognised cell, a search box appears. As you begin typing in the search box, Tableau generates a list of possible locations. Select a location from the list.

Alternatively, you can enter latitude and longitude to manually map a value to a point location on the map. To do this, begin typing into the unrecognised cell and select **Enter Latitude and Longitude** from the drop-down menu.

Note: When you type a latitude and longitude, enter the values in decimal format. For example, Addis Ababa is Latitude: 9.033140, Longitude: 38.750080.

Restrict Locations in the List

By default, all possible locations are listed in the drop-down menu. To restrict the list to locations that have not yet been matched to your data, select the **Show only unmatched locations in drop-down list** option in the bottom left corner of the Edit Locations dialog box.

[Assign Geographic Roles on page 1717](#)

[Location Data that Tableau Supports for Building Map Views on page 1675](#)

Build Maps in Tableau

What type of map do you want to create?

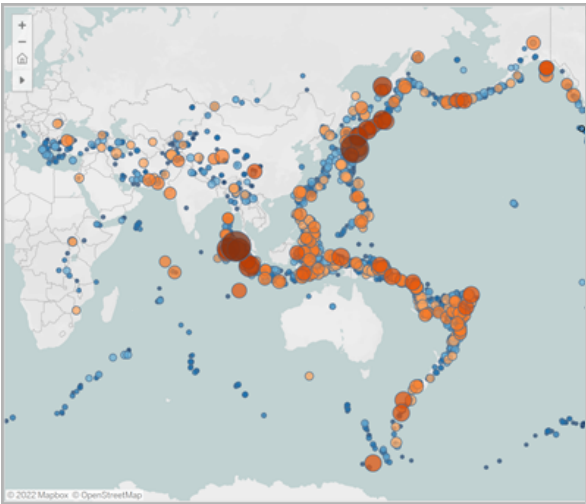

Simple Map

Map from Spatial Files

Proportional Symbol Map

Point Distribution Map

Heatmap (Density Map)

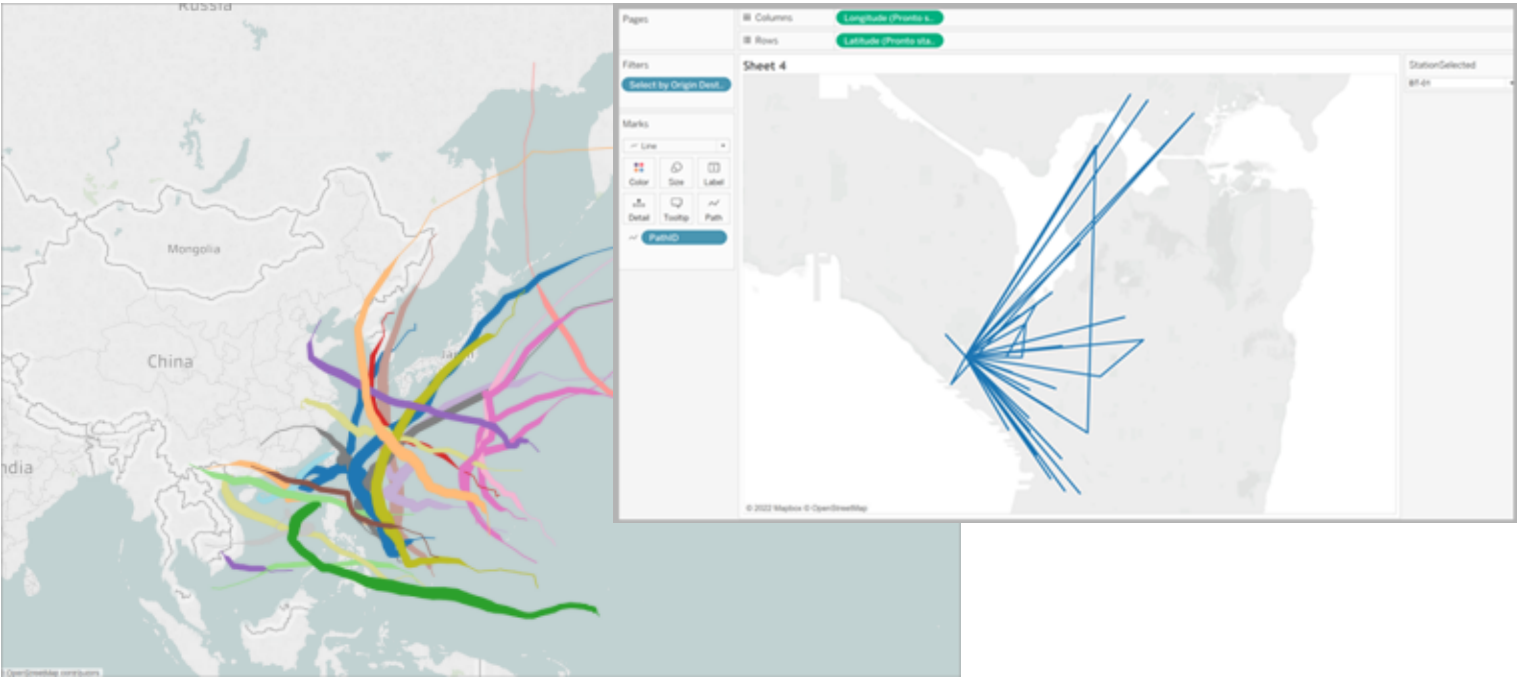

Filled (Choropleth) Map

Flow (Path) Map

Origin-Destination Map

Dual Axis (Layered) Map

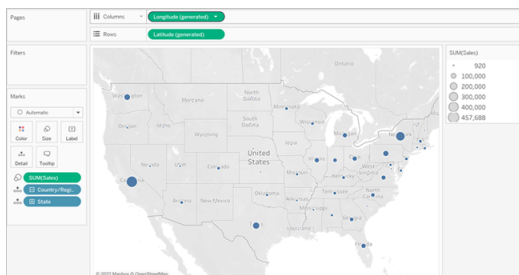

Filled Map with Pie Charts

Build a Simple Map

You can build several different types of maps for your geographic analysis in Tableau. If you're new to maps, or simply want to take advantage of the built in mapping capabilities that Tableau provides, you can create a simple point or filled (polygon) map similar to the examples below.

Prerequisites: To build a simple map, your data source must contain location data (for example, location names or latitude and longitude coordinates). If your data source doesn't contain location data, see the [Map Data](#) section for ways you can connect to location data.

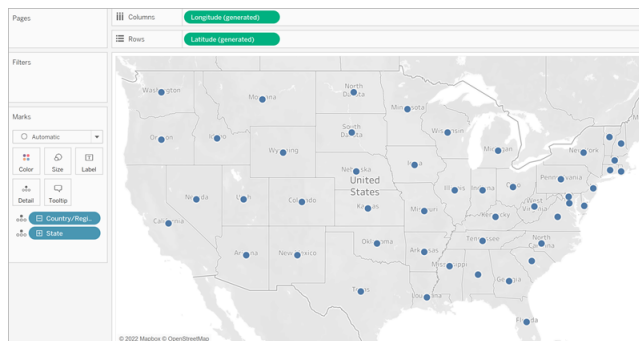

This topic illustrates how to create a simple map using an example. To follow along with the example below, open Tableau Desktop and connect to the **Sample-Superstore** data source, which comes with Tableau.

Build a simple point map

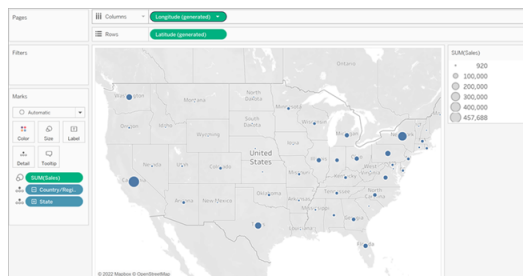

1. Navigate to a worksheet.
2. In the **Data** pane, open the Location folder and double-click on **State**.

A map view is automatically created because the State field is a geographic field. To learn more about geographic fields and how to create them, see [Assign a geographic role to a field on page 1718](#).

3. From the Orders table in the **Data** pane, drag **Sales** to **Size** on the Marks card.

The data points on the map update to show the amount of sales proportionally.

4. Select **Maps > Background Layers**.
5. In the Background pane, click on the **Style** drop-down and select **Normal**.

- Under **Background Map Layers**, clear **Country/Region Names**. The background map updates with the new settings.

Build a simple filled (polygon) map

- Navigate to a new worksheet.
- In the **Data** pane, open the Location folder and double-click on **State**.

A map view is automatically created.

- On the **Marks** card, click on the Mark Type drop-down and select **Map**.

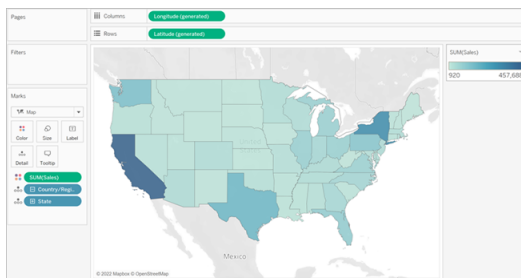

The map view updates to a filled (polygon) map.

4. From the Orders table in the **Data** pane, drag **Sales** to **Colour** on the Marks card.

The polygons on the map update to show the amount of sales using colour.

Build a heatmap (density map)

Heatmaps, also known as Density Maps, help you identify locations with greater or fewer numbers of data points. Heatmaps are most effective when working with a data set containing many data points where there is substantial overlap between the marks on the map.

To learn more about Heatmaps and find out how to create and customize them, see [Create Heatmaps that Show Trends or Density in Tableau on page 1790](#).

To follow along with this example, download the [heatmap_taxi_howto example workbook](#). (Click Download in the upper right-hand corner) and open it in Tableau Desktop.

1. Navigate to a new worksheet.
2. From the **Data** pane, drag both Pickup Latitude and Pickup Longitude onto the canvas.

A map view is automatically created.

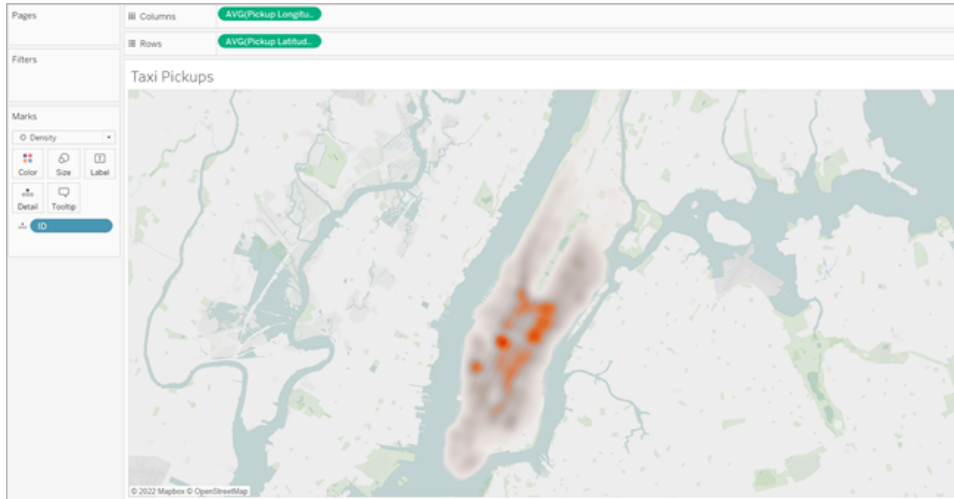

Note: Because Tableau is averaging the latitude and longitude of the data, there is only one mark on the canvas. This will update when you add a measure.

3. Drag a measure field, such as ID, to **Detail** on the Marks card.
4. On the Marks card, click the Mark Type drop-down and select **Density**.

The marks update on the map to show the concentration of taxi pickups per location. The darker colours indicate locations with more pickups, and the lighter colours indicate locations with fewer pickups.

[Mapping Concepts in Tableau](#) on page 1661

[Build Maps in Tableau](#) on page 1725

[Customise How Your Map Looks](#) on page 1845

Create Tableau Maps from Spatial Files

In Tableau Desktop, you can connect to the following spatial file types: Shapefiles, MapInfo tables, KML (Keyhole Markup Language) files, GeoJSON files, TopoJSON files and Esri File Geodatabases. You can then create point, line or polygon maps using the data in those files.

With a Creator licence in Tableau Cloud or Tableau Server, you can upload spatial file formats that only require one file (KML, GeoJSON, TopoJSON, Esri shapefiles packaged in a `.zip` and Esri File Geodatabases with the extension `.gdb.zip`) in the Files tab when you create a new workbook and connect to data.

Note: In current versions of Tableau, you can only connect to point geometries, linear geometries or polygons. You cannot connect to mixed geometry types.

Where to find spatial files

If you do not already have spatial files, you can find them at many open data portals. You can also find them on websites for your city or for a particular organisation, if they provide them.

Here are some examples:

- [LONDON DATASTORE](#)
- [EGIS South Africa](#)
- [U.S. Energy Information Administration](#)
- [USGS Water Resources](#)
- [Geospatial Information Authority of Japan](#)
- [Data.gov](#)
- [Census.gov](#)

Connect to spatial files

1. In Tableau Desktop: click the New Data Source icon and select **Spatial file**.
In Tableau Cloud or Tableau Server (Creator role): Select **Create > Workbook**. Select the **Files** tab.
2. Navigate to the folder that contains your spatial data, select the spatial file you want to connect to, and then click **Open**.

Note: To connect to spatial files, you must include all of the following files in the same directory:

- For Esri shapefiles: The folder must contain `.shp`, `.shx`, `.dbf`, and `.prj` files as well as `.zip` files. When connecting to Esri shapefiles in Tableau Cloud or Tableau Server, the file must be packaged in a `.zip`.

For Esri File Geodatabases: The folder must contain the File Geodatabase's `.gdb` or the `.zip` of the File Geodatabases's `.gdb`. When connecting to Esri shapefiles in Tableau Cloud or Tableau Server, the Esri File Geodatabase must be packaged with the extension `.gdb.zip`.

- **For MapInfo tables** (Tableau Desktop only): The folder must contain `.TAB`, `.DAT`, `.MAP`, and `.ID` or `.MID` and `.MIF` files.
- For KML files: The folder must contain the `.kml` file. (No other files are required.)
- For GeoJSON files: The folder must contain the `.geojson` file. (No other files are required.)
- For TopoJSON files: The folder must contain the `.json` or `.topojson` file. (No other files are required.)

How Tableau interprets your spatial data

As soon as you connect to your spatial data, Tableau reads the spatial reference information of the data set and transforms the data into latitude and longitude coordinates. All data, regardless of the spatial reference system, is transformed to **WGS84 (EPSG:4326)**.

Note: If your data does not display diacritics (accent marks on characters) properly, check to make sure the file is **UTF-8** encoded.

The Geometry field

When you connect to spatial data, Tableau creates a Geometry field for your point geometries or your polygons. You use the Geometry field to create a map with your spatial data.

The values in this field display the geometry primitive – for example, **Point** for point geometries, **Linestring** or **Multilinestring** for linear geometries, and **Polygon** or **Multipolygon** for polygons. But this is simply an alias for the underlying spatial data.

For more information on how to build a map with the Geometry field, see the [Build a map view from spatial data below](#) section.

Join spatial data

Sometimes your spatial data includes only the geometry information, and does not include any demographic or other information. In this case, you can join a spatial data source with another data source type, or even another spatial file that includes the additional data you need for your analysis, as long as the files have a column (or field) in common.

For example, you can join a KML file that contains custom geographies for school districts in Oregon, U.S. with an Excel spreadsheet that contains demographic information about those school districts.

For more information on the different ways to join spatial data, see [Join Spatial Files in Tableau on page 1692](#).

Build a map view from spatial data

1. Open a new worksheet.
2. In the Data pane, under Measures, double-click the **Geometry** field.

The Geometry field is added to Detail on the Marks card, and the Latitude (generated) and Longitude (generated) fields are added to the Columns and Rows shelves. A map view is created.

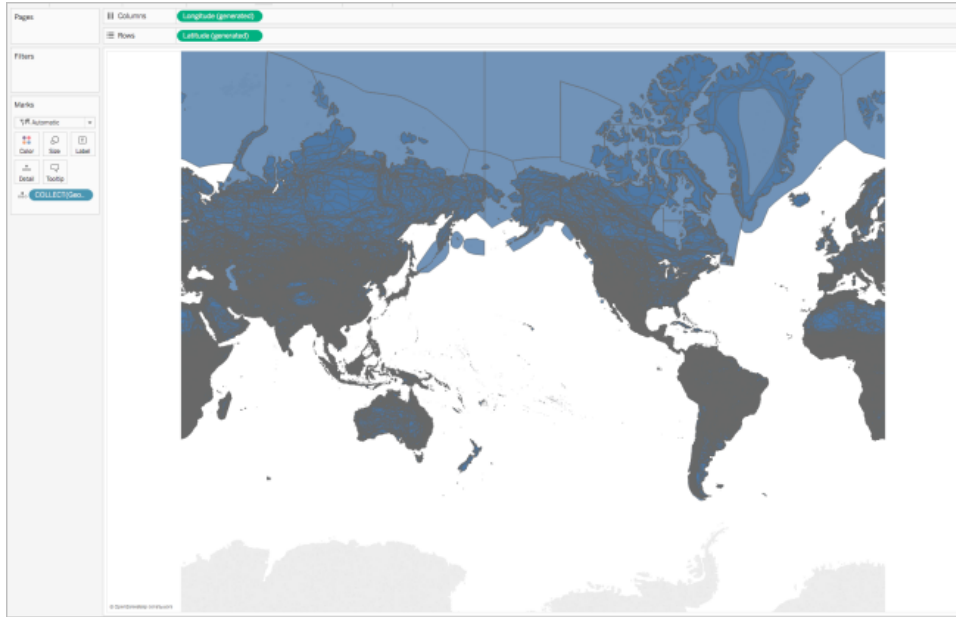

Filter geometries to improve view performance

When working with large spatial data sets, your view might take a long time to render. If this is the case, you can filter the number of geometries being added to the view using another dimension in your data source. For more information about filtering data, see [Filter Data from Your Views](#) on page 1315.

For example, in the image below, the view has been filtered down to a small subset of polygons using a dimension (Family Nam). The data source, from the [IUCN List of Threatened Species](#), contains data on endangered mammals around the world. Therefore, the dimension Family Nam contains a list of mammal family names. This view has been narrowed down to one family name: rhinoceroses. Polygons for only rhinoceroses are shown in the view.

Without the filter, the polygons for every mammal in the data source are shown around the world, and the view takes a long time to render every time you perform an action, such as select a mark in the view.

Add levels of detail to the view

The Geometry field is a measure, and by default, is aggregated into a single mark using the COLLECT aggregation when it is added to the view. All of your polygons or marks will be in the view, but they will operate as a single mark. You therefore need to :

- Add additional levels of detail to the view to break it up into separate marks (based on the level of detail you specify)
- or
- Dissaggregate the data all together so every single mark (polygon or data point) is separate.

To add additional levels of detail to the view:

- From Dimensions, drag one or more fields to **Detail** on the Marks card.

To disaggregate the data:

- Click **Analysis**, and then clear **Aggregate Measures**.

Customise the appearance of geometries

You can customise the appearance of points, polygons and lines by adding colour, hiding polygon lines, specifying which polygons or data points appear on top, and adjusting the size of your data points.

Add colour

To add colour to your data points or polygons, drag a dimension or measure to **Colour** on the Marks card.

For example, in the images above, the dimension (Presence), is placed on Colour to represent the presence of an animal in a particular area.

Hide polygon lines

By default, polygon lines are shown when you create a polygon map from spatial data. If you want a cleaner view, you can remove them.

Take the following images, for example. The first image shows polygon lines. The second image does not show polygon lines.

Polygon lines shown by default.

Polygon lines removed.

To hide polygon lines:

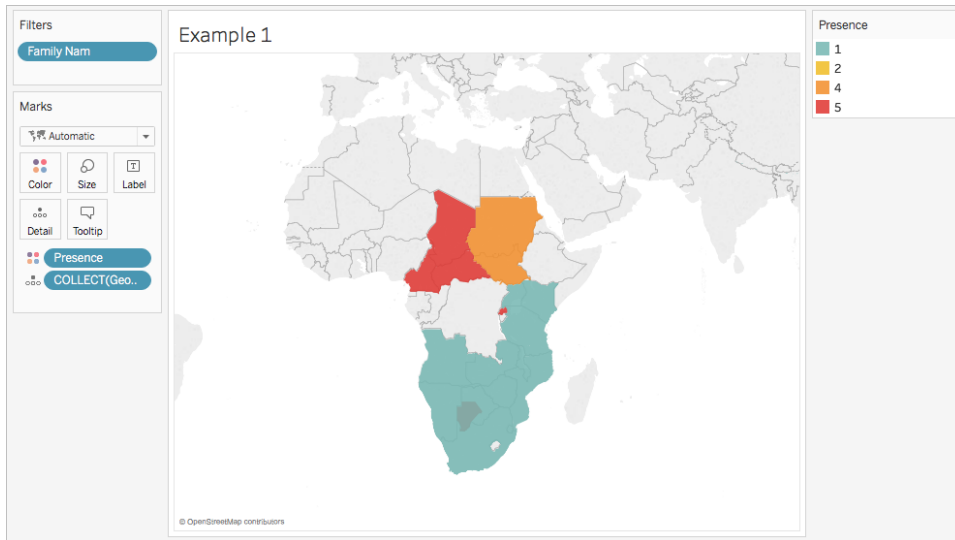

1. On the Marks card, click **Colour**.
2. Under Effects, select the **Border** drop-down, and then click **None**.

Specify which polygons or data points appear on top

Your polygons or data points might overlap or cover each other. You can specify which polygons or data points appear on top if you have a colour or size legend in the view.

For example, in the image below, notice that there is a smaller polygon hidden behind the larger teal polygon in southern Africa.

You can rearrange the items in your legend to control which data points or polygons appear on top. To do so, in the legend, select the item you want to be on top, and then drag it to the top of the list.

Adjust the size of data points

If you're using point geometries, you can adjust the size of the points on the map view. This is useful if you want to proportion your data points by quantitative values, such as by average

sales, or profit.

To adjust the size of your data points:

1. From the **Data** pane, drag a measure to **Size** on the Marks card.
2. On the Marks card, click the Mark Type drop-down and select **Circle**.
3. Optional: From the **Data** pane, drag one or more dimensions to **Detail** on the Marks card to add more data points to your view.

Note: The level of detail determines which data points are sized. Add additional dimensions to Detail on the Marks card to add levels of detail (more data points), otherwise you might end up with one large data point.

For more information about how to add levels of detail to the view, see the [Add levels of detail to the view on page 1739](#) section.

Build a dual-axis map from spatial data

If you join a spatial file either with another spatial file, or a different file type, you can create a dual-axis map using the geographic data from those files. This enables you to create more than one layer of your data on a map.

For example, the following is a dual-axis map view that was created using two spatial files. It contains two maps; one map shows the boroughs of New York City as polygons, and the other

shows data points for subway entrances around the city. The subway entrance data is layered over top of the city boroughs polygons.

1. In Tableau Desktop, open a new worksheet.
2. Connect to your data sources.
3. Create the first map view.

See [Build a map view from spatial data on page 1737](#) above for how to build a map view from spatial files.

4. On the Columns shelf, control-drag (command-drag on a Mac) the **Longitude** field to copy it, and place it to the right of the first **Longitude** field.

Important: This example uses the Latitude (generated) and Longitude (generated) fields that Tableau creates when you connect to spatial data. If your data source contains its own Latitude and Longitude fields, you can use them instead of the Tableau generated fields, or in combination with the Tableau generated fields. For

more information, see [Create Dual-Axis \(Layered\) Maps in Tableau](#) on page 1812.

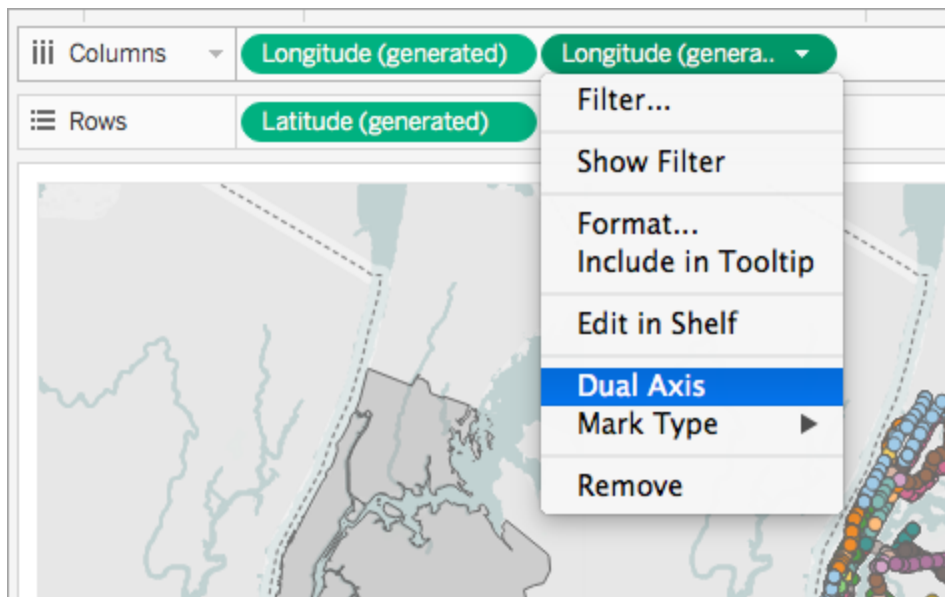

You now have two identical map views. There are now three tabs on the Marks card: one for each map view, and one for both views (All). You can use these to control the visual detail of the map views. The top Longitude tab corresponds to the map on the left of the view, and the bottom Longitude tab corresponds to the map on the right of the view.

5. On the Marks card, click one of the **Longitude** tabs, and then remove all fields on that tab. One of your map views is now blank.
6. Create the second map view by dragging the appropriate fields from the Data pane to the blank **Longitude** tab on the Marks card.

7. When your two map views are finished, on the Columns shelf, right-click the **Longitude** field on the right and select **Dual Axis**.

Your map data is now layered on one map view.

To change which data appears on top, on the Columns shelf, drag the **Longitude** field on the right, and place it in front of the **Longitude** field on the left.

[Join Spatial Files in Tableau](#) on page 1692

[Mapping Concepts in Tableau](#) on page 1661

[Create Dual-Axis \(Layered\) Maps in Tableau](#) on page 1812

Create Geographic Layers for Maps

When you need to add multiple layers of geographic data to a map, use marks layers in the Marks card. Marks layers act like transparent overlays. Each layer functions independently and can have its own mark type, captions and colour.

Note:

- Marks layers can be used only with geographic data.
- Fields can be shared between marks layers, but any filters that you apply to a field will apply to all marks layers

Build a view using marks layers

As you build a map, options for creating marks layers become available when you add more geographic fields to the view.

Add a marks layer

1. Build your first map in the view. Think of this as the base layer.
2. Drag a geographic field into the view. Notice the Add a Marks Layer control becomes available in the top-left corner of the view.
3. Drop the geographic field on the Add a Marks Layer control. A new marks layer is added to

the Marks card and the layer is displayed in the view.

Example: Working with mark layers

The following walk through uses the sample workbook [Marks Layers Example](#).

1. Open the Marks Layers Example workbook. It uses a connection to a geographic data source.
2. Drag the Neighbourhood Geometry field to the view. This creates a map in the view.
3. Drag the Neighbourhood Names field to Colour on Marks card.
4. Drag the Building Geometry field to the view. The Add a Marks Layer drop target displays in the top-left corner of the view.

Notice that the Marks card now includes two layers labelled Boston_Buildings.Building Geometry and Boston_Neighbourhoods.Neighbourhood Geometry.

5. Add another layer of data to the view. Drag Community Centres Geometry to the view.
Note: As a shortcut, you can right-click on a geographic field and click Add to New Layer in the drop-down menu.

6. In the sample workbook, click the new layer to open its Marks options, and then drag the Community Centres Name field to Colour.
7. To change the mark type, click on the mark type drop-down arrow, and then select Shape. Click on the Shape field on the Marks card for this layer, and then select the heavy 'X'.

Each layer's mark type, colour and formatting can be configured independently. To change the look of any layer, click on that layer to expand its Marks card, and then drag a geographic field to one of the Marks card properties such as Colour.

Control mark selection in layers

After you add layers to the view, you may want to control how the user interacts with the layers. With one layer, it is easy to select a single mark to get extra information, such as a caption or text label. However, with multiple layers, it might not be the best user experience to allow your audience to select all marks on all layers. You can control how your users interact with layers in the marks layers settings.

There are two ways to control how a user selects layers in the view.

Disable mark selection

In the Marks card, click on the drop-down arrow for a layer, and then select Disable Selection. This prevents users from selecting marks from that layer in the view.

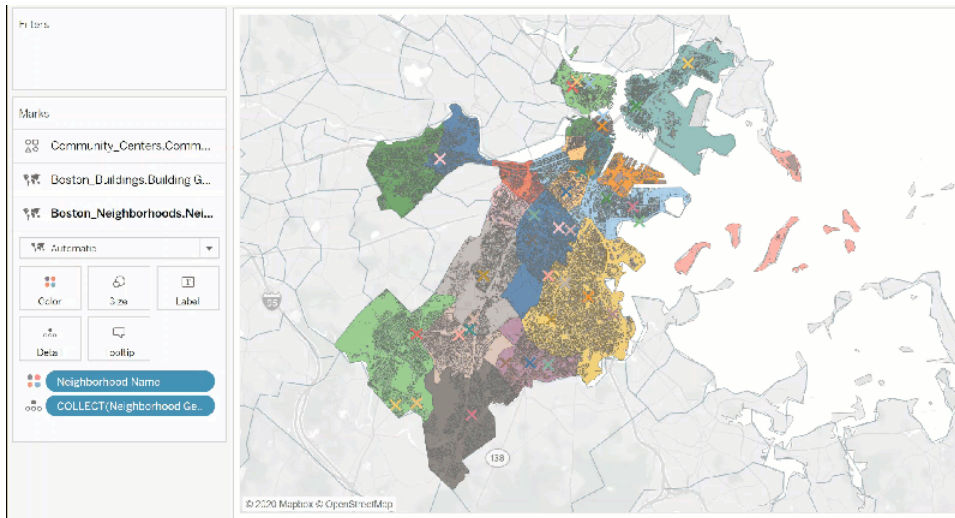

Hide a layer

To hide all marks on a layer

1. In the Marks card, click on the Control Layer Visibility icon to the left of the layer name.

The icon becomes visible when you select the layer in the Marks card, and stays visible when layer visibility is disabled.

2. To show a layer, click on the icon again.

Change layer settings

After you create a map with multiple layers, you can change layer order, rename layers, remove layers or hide layers.

Change layer order

Tableau renders the layers based on their order in the Marks card. Marks in layers at the top of the list will be displayed over marks in layers that are lower in the list. To change the layer order

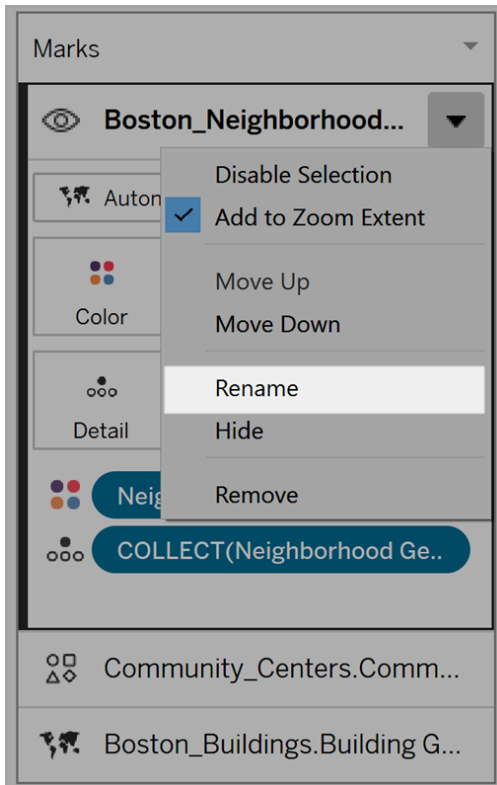

1. In the Marks card, click on a layer name and drag it until the orange indicator arrow appears. Orange indicates where the layer can be moved to.
2. Drop the layer in the new order location. Note: To cancel the move while you are dragging the layer, drop the layer in a different part of the view (wherever the orange indicator arrow isn't displayed).

Rename layers

When a new layer is created, Tableau assigns a name automatically based on the table name and field name. With large data sources, it can become difficult to manage many different layers. You can make this easier by renaming the layers and giving each layer a distinct name. To rename a layer

1. In the Marks card, click on a layer, and then click on the drop-down arrow to the right of the layer name.
2. Select Rename, type the new name and then press Enter.

Remove layers

If a layer is not useful anymore, you can remove it.

To remove a layer:

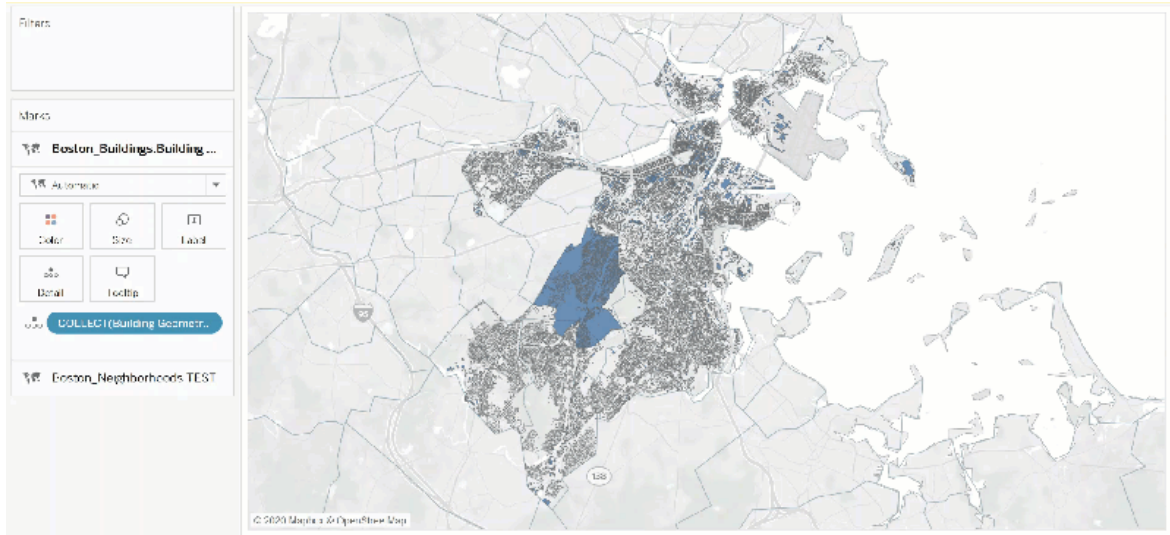

1. In the Marks card, click on a layer.
2. Click on the drop-down arrow to the right of the layer name, and then select Remove.

Add to Zoom Extent

By default, when you add a new layer to a map, Tableau will include all marks in the view. If there is a large difference between the scale of marks – for example, one layer showing all streetlights in a neighbourhood and the other layers showing the whole country's electrical grid – the desired detail can be lost.

To resolve this, we can disable this feature on a per-layer basis by selecting the drop-down arrow on the layer name, then unselect Add to Zoom Extent.

Let users customise views with the Layer Control

With the advent of Geographic Layers for Maps, you have the ability to create dense and information-rich views. However, these views may become difficult to navigate as the number of layers and marks increases.

The Layer Control is a panel that expands in the view when selected, displaying all the geographic data layers, and giving you quick access to each marks layer.

By using the Layer Control, you can hide or disable interactions on each layer, as well as save that selection as a custom view if you are working with a published workbook.

Enable the Layer Control

As the author, you can enable the Layer Control prior to publishing the workbook.

- Select **Maps > Map Options** > Tick or Untick “**Layer Control**”

By default, Layer Control is ticked, so when a workbook is published, users will be able to access the panel and hide or show mark layers.

Using the Layer Control

If the Layer Control is enabled, the Layer Control icon will appear in the Map Controls on the upper left-hand side of the view. Clicking on the icon will expand a panel where we can see all of the mark layers in the view.

Marks Layers Example

The Layer Control can be dragged around the view freely, but the position will reset each time the view is reloaded.

Each layer in the panel has a pair of icons next to it: the Interaction icon and the Visibility toggle. Any changes you make using the Control will be reflected in the Marks Layers. Hiding a layer using the Control functions is exactly the same as hiding a layer in the Marks Layers card.

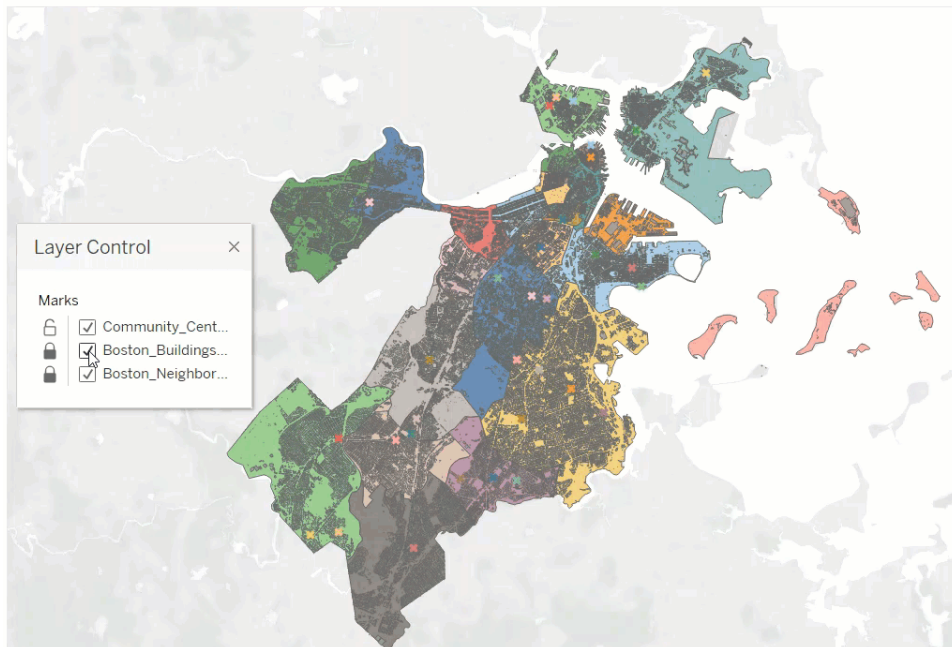

Selecting the Interaction icon will turn off the ability to select or interact with marks on that layer. This can be very useful for keeping background elements from being selected when doing a lasso selection, for example.

Marks Layers Example

Toggling Visibility off will hide all the marks on a layer, while toggling it on will show all the marks in the layer. Note that marks that are hidden are also removed from any selections.

Marks Layers Example

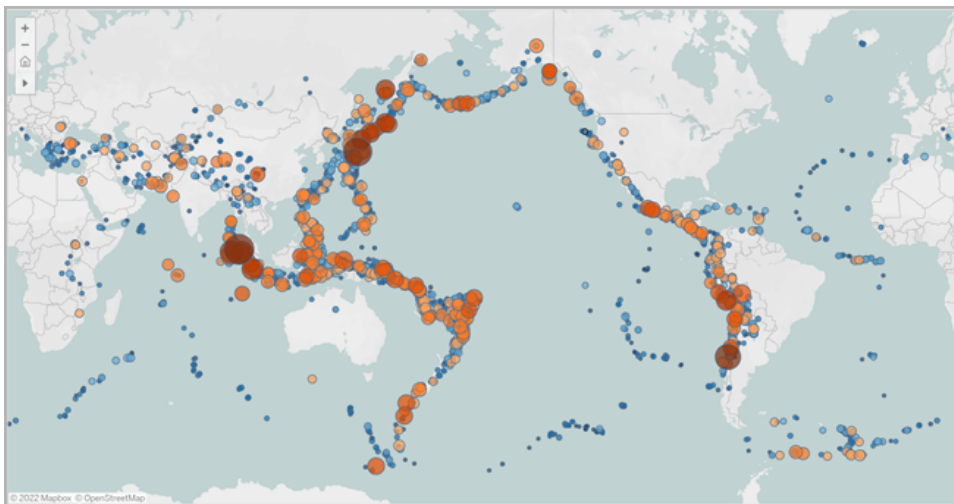

Custom views with the Layer Control

When you publish a view with the Layer Control enabled, any changes a user makes to the layers with the Layer Control won't be retained. However, the user can [Use Custom Views on page 3323](#) to keep their changes intact.

Create Maps that Show Quantitative Values in Tableau

You can create maps in Tableau Desktop that show quantitative values. These types of maps are called proportional symbol maps.

Proportional symbol maps are great for showing quantitative values for individual locations. They can show one or two quantitative values per location (one value encoded with size, and, if necessary, another encoded with colour). For example, you can plot earthquakes recorded between 1981 to 2014 around the world, and size them by magnitude. You can also colour the data points by magnitude for additional visual detail.

This topic illustrates how to create a proportional symbol map using an example. Follow the example to learn how to set up your data source and build the view for a proportional symbol map.

Your data source

To create a proportional symbol map, your data source should include the following types of information:

- Quantitative values
- Latitude and Longitude coordinates or location names (if recognised by Tableau)

It's also recommended that your data contain a large variation of values; otherwise, your symbols will appear approximately the same size in the view.

The following table is a snippet of the Earthquake data source, which is included in the [Create Proportional Symbol Maps in Tableau Example Workbook](#) on Tableau Public. It contains columns for earthquake magnitude and magnitude to the power of ten, and columns for latitude and longitude values. It also contains a column for the date and earthquake ID for added clarity and organisation.

| Earth-quake Date Time | ID | Mag-nitude | Mag-nitude^10 | Latitude | Lon-gitude |
|-----------------------|--------------------------|------------|----------------|----------|------------|
| 1/1/73 | centennial19730101114235 | 6.00000 | 17,488,747.0-4 | -35.570 | -15.427 |
| 02/01/1973 | pde1973010200532030-0_66 | 5.50000 | 25,329,516.2-1 | -9.854 | 117.427 |
| 03/01/1973 | pde1973010302294280-0_33 | 4.80000 | 6,492,506.21 | 1.548 | 126.305 |
| 04/01/1973 | pde1973010400314200-0_33 | 4.50000 | 3,405,062.89 | 41.305 | -29.272 |
| 05/01/1973 | pde1973010500394820-0_36 | 4.70000 | 5,259,913.22 | 0.683 | -80.018 |
| 06/01/1973 | pde1973010606185230-0_83 | 4.90000 | 7,979,226.63 | -22.354 | -69.310 |

Basic map building blocks:

| | |
|-----------------------|---|
| Columns shelf: | <i>Longitude</i> (continuous measure, longitude geographic role assigned) |
| Rows shelf: | <i>Latitude</i> (continuous measure, latitude geographic role assigned) |
| Detail: | One or more dimension fields |
| Size: | A measure field (aggregated) |
| Mark type: | <i>Automatic</i> |

Build the map view

To follow along with this example, download the [Create Proportional Symbol Maps in Tableau Example Workbook](#) from Tableau Public, and open it in Tableau Desktop.

1. Open a new worksheet.
2. In the Data pane, double-click **Latitude** and **Longitude**.

Latitude is added to the Rows shelf, and Longitude is added to the Columns shelf. A map view with one data point is created.

3. From the Data pane, drag **ID** to **Detail** on the Marks card. If a warning dialog appears, click **Add all members**.

A lower level of detail is added to the view.

4. From the Data pane, drag **Magnitude¹⁰** to **Size** on the Marks card.

Note that the **Magnitude¹⁰** field is used to encode size instead of the **Magnitude** field. This is because **Magnitude¹⁰** contains a wider range of values, so the differences between values can be seen visually.

You now have a proportional symbol map. The larger data points represent earthquakes with larger magnitudes, and the smaller data points represent earthquakes with smaller magnitudes.

In most cases, this is as far as you need to go to show quantitative values for single locations. However, in this case, since there are so many data points in the view, more visual detail is needed to help you differentiate between the earthquake magnitudes and to help you spot any trends.

5. From the Data pane, drag **Magnitude** to **Colour** on the Marks card.
6. On the Marks card, click **Colour** > **Edit Colours**.
7. In the Edit Colours dialog box, do the following:
 - Click the colour drop-down and select the **Orange-Blue Diverging** palette from the list.
 - Select **Stepped Colour**, and then enter **8**.
This creates eight colours: four shades of orange, and four shades of blue.
 - Select **Reversed**.
This reverses the palette so that orange represents a higher magnitude than blue.
 - Click **Advanced**, select **Centre**, and then enter **7**.

This shifts the colour palette and ensures that any earthquake over 7.0 magnitude will appear orange in colour, and any earthquake under 7.0 magnitude will appear blue in colour.

- Click **OK**.
8. On the Marks card, click **Colour** again, and then do the following:
- For **Opacity**, enter **70%**.
 - Under Effects, click the **Border** drop-down menu and select a dark blue border colour.

The map view updates with new colours. The dark orange data points represent earthquakes with higher magnitudes, while the dark blue data points represent earthquakes with lower magnitudes. The opacity of the marks is at 70% so you can see where the data points overlap.

9. On the Marks card, right-click the **ID** field and select **Sort**.
10. In the Sort dialog box, do the following:
- For Sort By, select **Field**, and then click the drop-down and select **Magnitude**.
 - For Sort Order, select **Descending**.
 - Click **OK**.

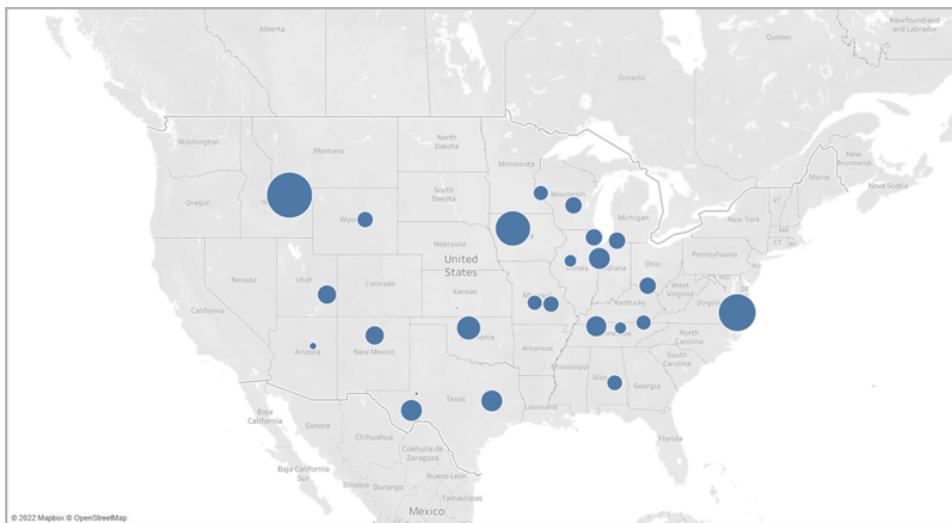

This sorts the data points in the view so that the larger magnitudes appear on top.

Your proportional symbol map is now complete.

Point location and attribute meaning

It's important to note that symbols on a map can sometimes be misinterpreted as representing actual ground area. For example, if you have a map view that plots earth impact craters across North America, and sizes each symbol by the diameter (in kilometres) of the impact area, you might get a map view that looks like this:

In this particular case, it could be very easy to interpret the size of these data points as representing the actual ground area of the craters. Your audience might assume that most of southwestern Montana, a state in the US, was destroyed by a crater, which is not accurate. In reality, the crater in Montana was simply one of the larger craters in the data source and has been sized accordingly.

To avoid misinterpretations, it might be helpful to include annotations or explanations of what the size actually represents. Even if it seems obvious.

[Assign Geographic Roles on page 1717](#)

Create Maps that Highlight Visual Clusters of Data in Tableau

You can create maps in Tableau Desktop that help you spot visual clusters, similar to the example below. These types of maps are called point distribution maps.

Point distribution maps are great for showing the how locations of your data points are distributed.

This topic illustrates how to create a point distribution map using an example. Follow the example in this topic to learn how to set up your data source, and build the view for a point distribution map.

Your data source

To create a point distribution map, your data source should include the following types of information:

- Latitude and longitude coordinates for all of your locations

For example, the following table is a snippet of the Hail data source, which is included in the [Create Point Distribution Maps in Tableau Example Workbook](#) on Tableau Public. It contains columns for the latitude and longitude coordinates of hail storms across the United States from 1955 to the 2013.

| Latitude | Longitude |
|----------|-----------|
| 32.2000 | -101.5000 |
| 38.5800 | -92.5800 |
| 41.2000 | -89.6800 |
| 39.2800 | -87.4000 |
| 41.7800 | -87.7800 |
| 39.5000 | -90.0800 |

Basic map building blocks

| | |
|-----------------------|---|
| Columns shelf: | <i>Longitude</i> (continuous dimension, longitude geographic role assigned) |
| Rows shelf: | <i>Latitude</i> (continuous dimension, latitude geographic role assigned) |
| Mark type: | <i>Automatic</i> |

Build the map view

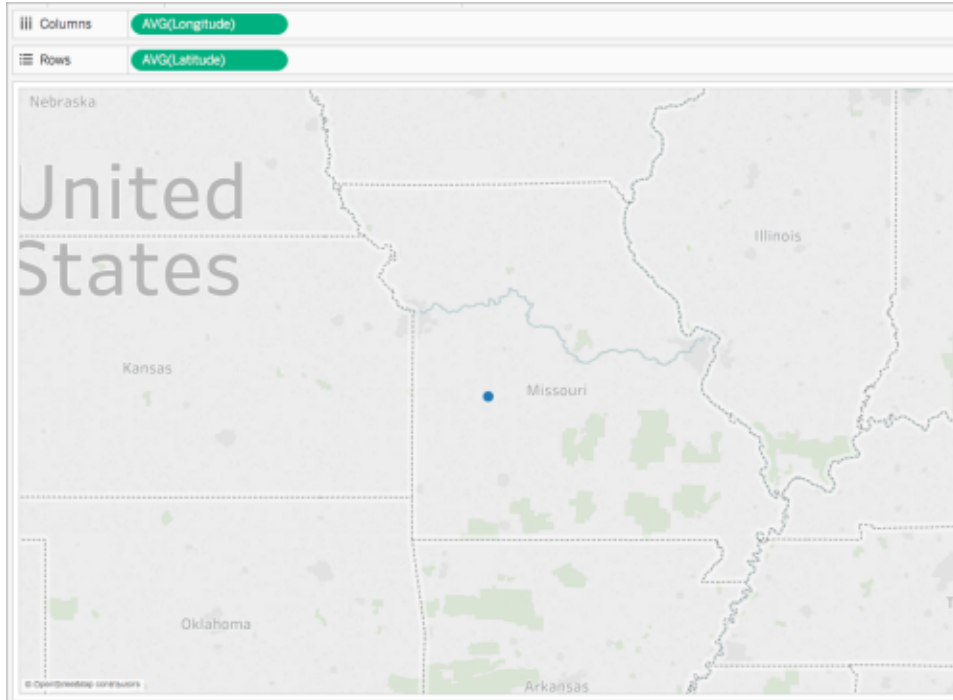

To follow along with this example, download the [Create Point Distribution Maps in Tableau Example Workbook](#) from Tableau Public, and open it in Tableau Desktop.

1. Open a new worksheet.
2. Ensure that the **Latitude** geographic role is assigned to your latitude field, and the **Longitude** geographic role is assigned to your longitude field.

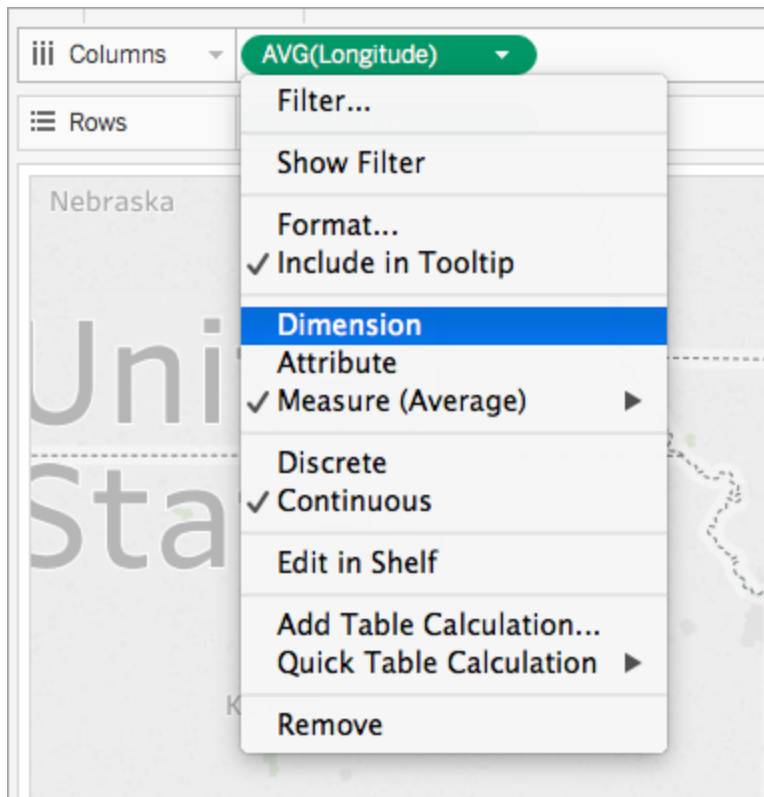

For more information, see [Assign a geographic role to a field](#) on page 1718.

3. In the Data pane, double-click **Latitude** and **Longitude** to add them to the view.

The Latitude and Longitude fields are added to the Columns and Rows shelves, and a map view with one data point is created.

4. On the Columns shelf, right-click **Longitude** and select **Dimension**.

5. On the Rows shelf, right-click **Latitude** and select **Dimension**.

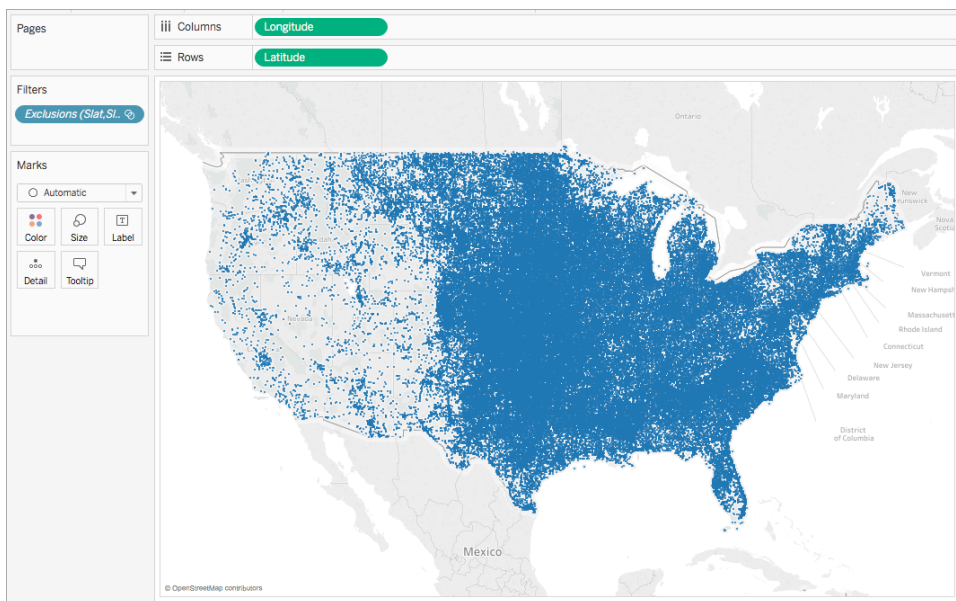

The map view updates with every location in your data source.

Note: You might need to filter some data points from the view.

6. On the Marks card, click **Size**, and then move the slider to the left.

Your point distribution map is now complete. A data point for every location in your data source is now plotted on the map (minus any you filtered from the view). You can now see that a majority of hailstorms occur in the eastern half of the United States.

[Mapping Concepts in Tableau](#) on page 1661

[Create Maps that Show Quantitative Values in Tableau](#) on page 1763

Create Maps that Show Ratio or Aggregated Data in Tableau

You can create maps in Tableau Desktop that show ratio or aggregated data, similar to the example below. These types of maps are called choropleth maps, or filled maps.

Choropleth maps are best for showing ratio or aggregated data for polygons. These polygons can be counties, regions, states, or any area or region that can be geocoded in Tableau. They can even be custom territories created in Tableau. For more information, see [Create Territories on a Map on page 1861](#).

Note: When using aggregated data, be careful when using counts. Counts are often related to size or population for regions. For example, you are likely to have a higher count for sales in regions with a higher count of people.

This topic illustrates how to create a choropleth map using an example. Follow the example in this topic to learn how to set up your data source and build the view for a choropleth map.

Your data source

To create a choropleth map, your data source should include the following types of information:

- Quantitative or qualitative values.
- Location names (if recognised by Tableau), or custom polygons. For more information, see [Create Tableau Maps from Spatial Files on page 1735](#).

The following table is a snippet of the countyObesity + (Obesity_State_County) data source, which is included in the [Create Choropleth Maps in Tableau Example Workbook](#) on Tableau Public. It contains columns for State, County, and Obesity Percent - 2012.

| State | County | Obesity Percent - 2012 |
|---------|----------------|------------------------|
| Alabama | Autauga County | 30.9000 |
| Alabama | Baldwin County | 26.7000 |
| Alabama | Barbour County | 40.8000 |
| Alabama | Bibb County | 40.1000 |
| Alabama | Blount County | 32.4000 |
| Alabama | Bullock County | 44.5000 |

Basic map building blocks:

| | |
|-----------------------|---|
| Columns shelf: | <i>Longitude</i> (continuous measure, longitude geographic role assigned) |
| Rows shelf: | <i>Latitude</i> (continuous measure, latitude geographic role assigned) |
| Detail: | One or more <i>geographic units</i> (dimensions with geographic roles assigned) |
| Colour: | <i>Measure or dimension</i> |
| Mark type: | <i>Automatic or Map</i> |

Build the map view

To follow along with this example, download the [Create Choropleth Maps in Tableau Example Workbook](#) from Tableau Public, and open it in Tableau Desktop.

1. Open a new worksheet.
2. In the **Data** pane, under the **State, County** folder, double-click **State**.

State is added to Detail on the Marks card and Longitude and Latitude are added to the Columns and Rows shelves. A map view is created with a data point for each state in your data source.

3. In the map view, select the **Alaska** and **Hawaii** data points, and then click **Exclude** on the tooltip that appears.

- On the Marks card, click the plus icon on the **State** field to drill down to the County level of detail.

There is now a data point for every county in your data source.

- From the Data pane, under the countyObesity\$ folder, drag **Percent-2012** to **Colour** on the Marks card.

The map view changes to a filled map mark type and the polygons are coloured green. Note that the default aggregation for the Percent-2012 measure is SUM by default.

- On the Marks card, right-click the **Percent-2012** field and select **Attribute**.

Since the data in this field is already a percentage, it does not make sense to aggregate it as a sum.

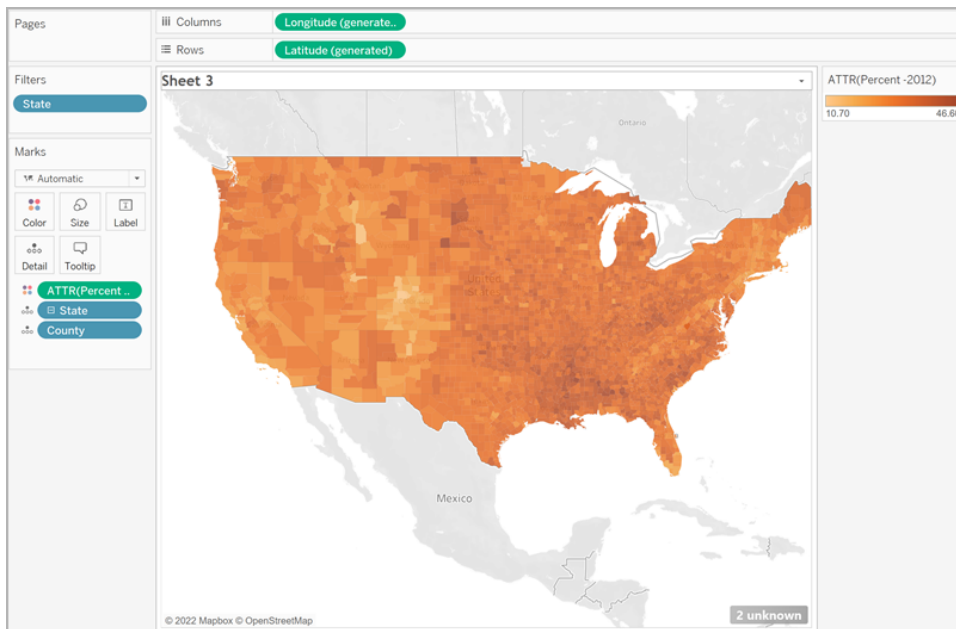

7. On the Marks card, click **Colour** and select **Edit Colours**.

8. In the Edit Colour dialog box, click the colour drop-down, select **Orange**, and then click **OK**.
9. On the Marks card, click **Colour** and then, under Effects, click the **Border** drop-down and select **None**.

Your choropleth map is now complete. There is an obesity percentage for each polygon (county) on the map view.

Add additional spatial context

You can add additional spatial context, such as state boundaries, by adding another layer to your map.

1. From the Data pane, drag **State** to the worksheet and drop it on to **Add a Marks Layer**.

Now you can see two layers on your Marks card: State and Country.

2. From the State layer on your Marks card, set the mark type to **Map**.

3. Click **Colour**, and then drag the opacity percentage from 80% to 0%.

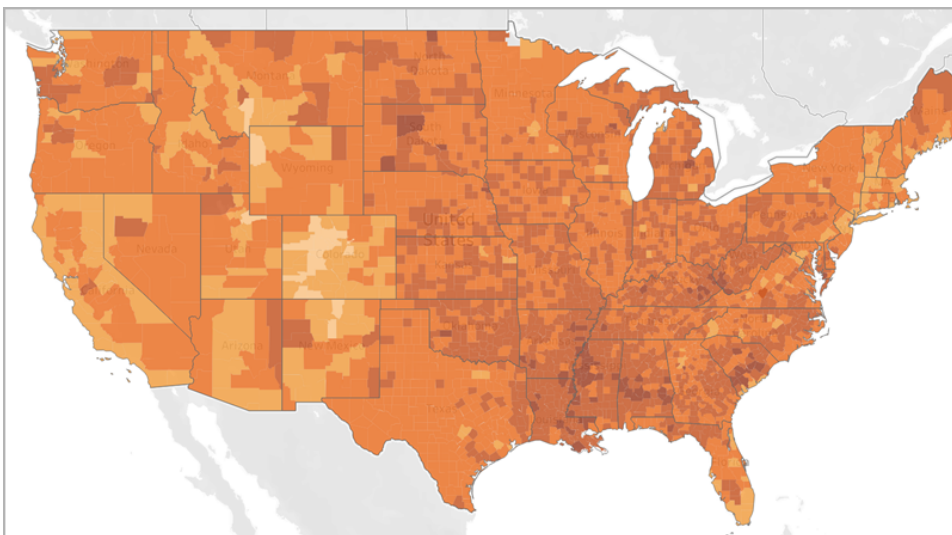

Your map updates to show state boundaries for additional context over the county data.

Note about colour distribution

The distribution you specify for the colour of the polygons highly affects how people interpret your data. For example, the map you created in the [Build the map view on page 1775](#) section used the Tableau default colour distribution. Colour was distributed evenly across all values.

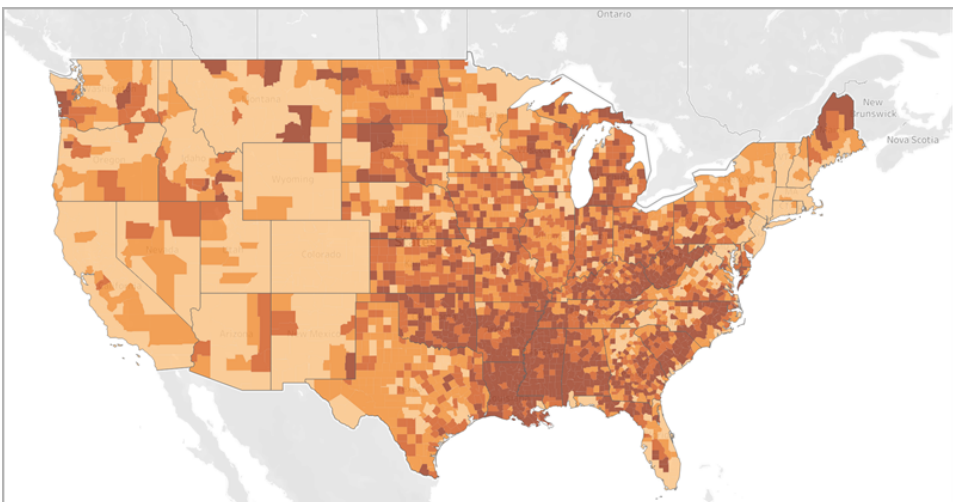

The map view looked like this:

However, if you decide to distribute the values across five colours (stepped colour, in Tableau), the map view might look like this:

Or maybe you want to see quartiles. If you use percentiles in your data and then use stepped colours for four steps, each step will have 25% of the data and might look like this:

Notice how the high obesity rates in the South are more visible when you use quartiles?

The colour distribution you choose depends on the information you're trying to show.

For example, if you wanted to show that obesity rates are higher in the South, you might choose the quartile example. However, if you want to show that obesity rates are high in the United States in general, you might choose the first example, which distributed colour evenly. Neither map is right or wrong; they just tell different stories.

Note about level of detail

The level of detail you specify in a choropleth map determines the patterns you want to see in the data. If you want to see a simplified pattern, consider aggregating up to a higher level of detail. If you want to dig in to find smaller trends, consider aggregating down to a lower level of detail.

For example, the map view you created in the [Build the map view on page 1775](#) section was aggregated at the County level of detail. The county level of detail was the lowest level of detail in the data source. If it's appropriate for your dataset, you could aggregate to a higher level of detail, such as state.

[Mapping Concepts in Tableau on page 1661](#)

[Assign Geographic Roles on page 1717](#)

[Create Maps that Show Quantitative Values in Tableau on page 1763](#)

[Create Territories on a Map on page 1861](#)

Create Maps that Show a Path Over Time in Tableau

You can create maps in Tableau Desktop that show a path over time, as in the example below. These types of maps are called flow maps, or path maps.

Flow maps are great for when you want to show where something went over time, such as the path of a storm.

This topic illustrates how to create a flow map using an example. Follow the example below to learn how to set up your data source, and build the view for a flow map.

Your data source

Note: Starting in Tableau version 10.4, you can connect to spatial files that contain linear geometries. If you have spatial data with linear geometries, you may not need to perform the steps below. To learn how to create a map using spatial data with linear geometries, see [Create Tableau Maps from Spatial Files](#) on page 1735

To create a flow map, your data source should include the following types of information:

- Latitude and longitude coordinates for each data point in a path
- A column to define the order to connect the points (this can be date information, or manually applied numbers, such as 1, 2, 3, 4, 5)
- A unique ID for each path
- Enough data points to shape each path into a line

For example, the following table is a snippet of the Storm data source, which is included in the [Create Flow Maps in Tableau Example Workbook](#) on Tableau Public. It contains data on the paths of storms, and has columns for **Latitude** and **Longitude**, **Date**, and **Storm Name**. In this example, the Date column is used as an order to connect the data points, and the Storm Name column is used as a unique ID for each path.

Though only a few data points for the storm PAKHAR are shown in this example, the actual data source has enough entries to provide a detailed path for every storm recorded in 2012.

Note that the table also includes two optional columns: Basin and Wind Speed. These fields can be used to quickly filter and add visual detail to the view. You'll see how in the section, [Build the map view](#) below.

| Storm Name | Date | Latitude | Longitude | Basin | Wind Speed (kt) |
|------------|---------------------|----------|-----------|--------------|-----------------|
| PAKHAR | 3/26/12 12:00:00 | 9.5000 | 115.700 | West Pacific | 0 |
| PAKHAR | 3/26/12 06:00:00 | 9.5000 | 115.400 | West Pacific | 0 |
| PAKHAR | 3/26/12 12:00:00 | 9.5000 | 115.100 | West Pacific | 0 |
| PAKHAR | 3/26/12 18:00:00 | 9.4000 | 114.800 | West Pacific | 0 |
| PAKHAR | 3/27/12 12:00:00 | 9.4000 | 114.500 | West Pacific | 0 |
| PAKHAR | 3/27/12 06:00:00 | 9.4000 | 114.300 | West Pacific | 35 |

Basic map building blocks:

| | |
|-----------------------|--|
| Columns shelf: | <i>Longitude</i> (continuous measure, longitude geographic role assigned) |
| Rows shelf: | <i>Latitude</i> (continuous measure, latitude geographic role assigned) |
| Detail: | <i>Dimension</i> (unique ID for each path) |
| Path: | <i>Date field</i> or <i>order field</i> to define order to connect the data points |
| Mark type: | <i>Line</i> |

Build the map view

To follow along with this example, download the [Create Flow Maps in Tableau Example Workbook](#) from Tableau Public, and open it in Tableau Desktop.

1. Open a new worksheet.

2. In the **Data** pane, under Measures, double-click **Latitude** and **Longitude**.

The Latitude and Longitude fields are added to the Columns and Rows shelves, and a map view with one data point is created.

3. From Dimensions, drag **Storm Name** to **Detail** on the Marks card.

The map view updates with a data point for every storm in the data source. In the next steps, you will narrow the storms down to only those that occurred in the western Pacific Ocean in 2012.

4. From Dimensions, drag **Date** to the **Filters** shelf.

5. In the Filter Field [Date] dialog box that appears, select **Years**, and then click **Next**.

6. In the Filter [Year of Date] dialog box that appears, click **2012**, and then click **OK**.

The map view updates to show only the storms that occurred in 2012.

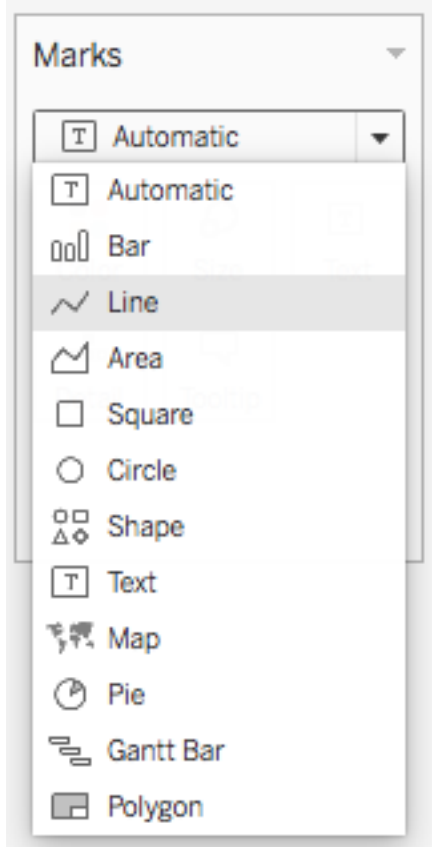

7. From Dimensions, drag **Basin** to the **Filters** shelf.

8. In the Filter Field [Basin] dialog box that appears, select **West Pacific**, and then click **OK**.

The map view updates to show only storms that occurred in the western part of the Pacific Ocean.

9. On the Marks card, click the mark-type drop-down and select **Line**.

A Path button appears on the Marks card, and the map view updates with a line connecting every data point.

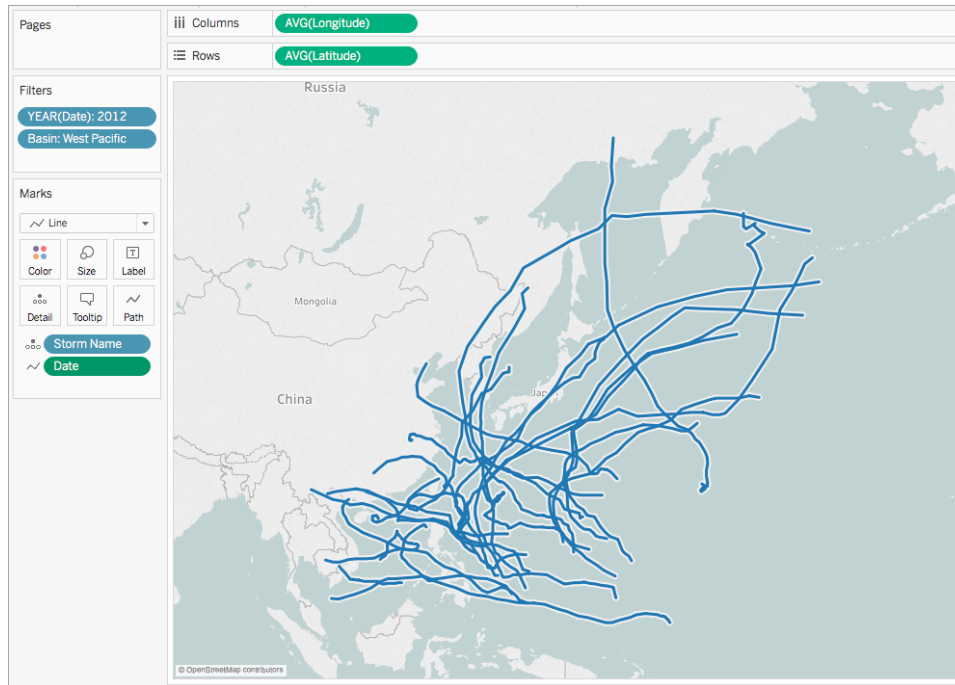

10. From Dimensions, drag **Date** to **Path** on the Marks card.

The line disappears. This is because the Date field is set to discrete years. Since the date field in the Storm data source includes day, month, year, and time, this is not the correct level of detail for this field.

11. On the Marks card, right-click the **YEAR(Date)** field and select **Exact Date**.

Now the map view updates with a data point for every recorded date and time. You can now see the individual paths of each storm.

12. From Measures, drag **Wind Speed** to **Size** on the Marks card.

The map view updates to show the varying wind speeds along each storm path.

13. On the Marks card, right-click the **SUM(Wind Speed)** field and select **Measure > Average**.

14. From Dimensions, drag **Storm Name** to **Colour** on the Marks card.

Each storm path is assigned a colour and the flow map is now complete.

You can now see the paths for every recorded storm that occurred in the West Pacific basin in 2012. You can also see at what point in their path their wind speeds were strongest.

Tableau Community post: [Origin-Destination Maps \(or Flow Maps\)](#)

Create Heatmaps that Show Trends or Density in Tableau

You can create maps in Tableau that reveal patterns or relative concentrations that might otherwise be hidden due to overlapping marks on a map. One common map type for this is a density map, also called a heatmap. Tableau creates density maps by grouping overlaying marks and colour-coding them based on the number of marks in the group.

Density maps help you identify locations with greater or fewer numbers of data points. They are most effective when working with a data set containing many data points where there's substantial overlap between the marks on the map.

Your data source

To create a density map, your data source should contain point geometry, latitude and longitude coordinates, or location names (if recognised as location names by Tableau).

Tableau can recognise location names and create a density map using the point locations assigned to Tableau geocoding locations, but density maps are most effective when the location data is very precise, such as location coordinates in a limited space. Density marks work best where the specific locations change continuously and smoothly across space, rather than values constrained to discrete locations such as borough or neighbourhood.

Basic map building blocks:

| | |
|-----------------------|---|
| Columns shelf: | <i>Longitude</i> (continuous dimension, longitude geographic role assigned) |
| Rows shelf: | <i>Latitude</i> (continuous dimension, latitude geographic role assigned) |
| Detail: | One or more fields with many underlying data points |
| Mark type: | <i>Density</i> |

Build the map view

You can choose **Density** from the mark type drop-down and Tableau will compute a density surface on your view. The density surface recomputes as you zoom or filter data on the remaining marks. When using Pages or a small multiples view, the Density is computed across the full domain of the data for comparative analysis.

To follow along with this example, download the [Create Heatmaps in Tableau Example Workbook](#) (click Download in the upper right hand corner), and open it in Tableau Desktop.

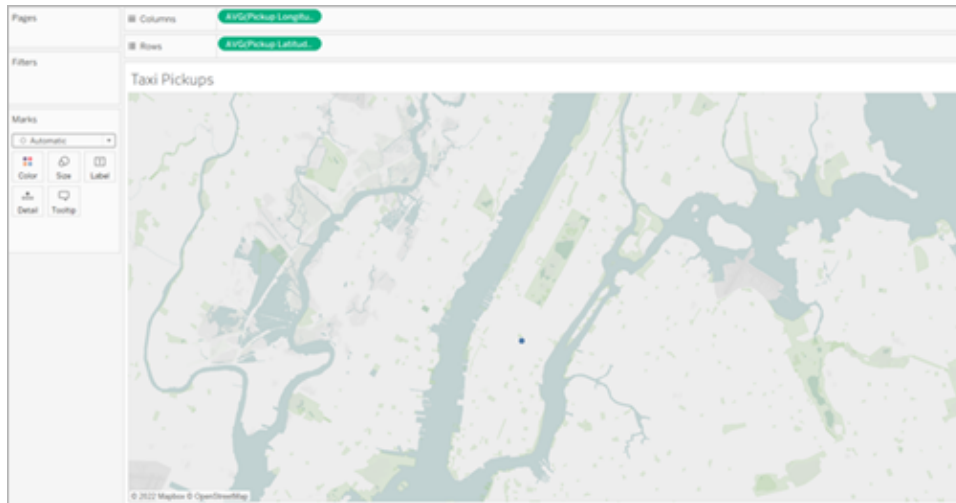

1. Open a new worksheet and connect to your data source.

In the data source used in this example, the fields are named Pickup Latitude and Pickup Longitude. Ensure that the Pickup Latitude geographic role is assigned to your latitude field, and the Pickup Longitude geographic role is assigned to your longitude field.

For more information, see [Assign a geographic role to a field](#).

2. In the Data pane, select both Pickup Latitude and Pickup Longitude and drag them onto the canvas.

The Latitude and Longitude fields are added to the Columns and Rows shelves, and a map view with one data point is created.

- Next, add distinct marks to the view. Right-click (Control-click on Mac) ID and drag it onto **Detail** on the Marks card. Because each pickup has its own ID, this action breaks up the marks and distinguishes one pickup from another on our map.

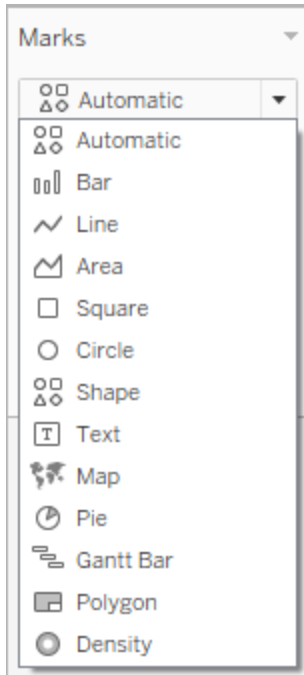

There will be a warning letting you know that the field added may contain more than the recommended maximum of 1000. Select **Add all members**.

The map view updates to show marks for every pickup location in your data source. Since every location is within Manhattan, the map will zoom to focus on Manhattan in New York City.

Note: You might need to filter some data points from your view to create the level of zoom desired.

4. On the Marks card, change the mark type to density by selecting the drop-down menu to the right of Automatic and select **Density**.

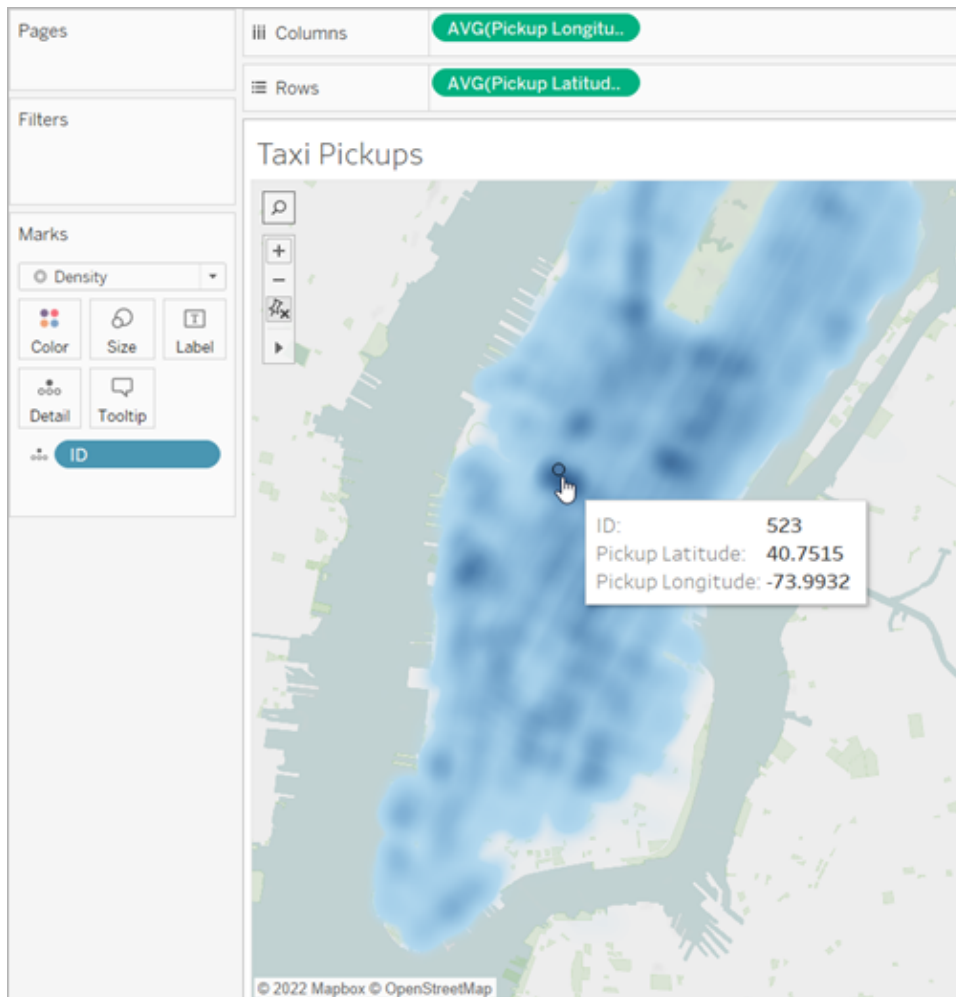

5. Your basic density map is created.

You can see that midtown is the most popular area for taxi pickups, and you can adjust the

focus further by using the zoom tool. Density will recompute as you zoom in or out.

You can select an individual data point from anywhere in your density map. These marks have size (10 pixels) and colour (blue) applied by default. Size and colour are not adjustable for underlying marks.

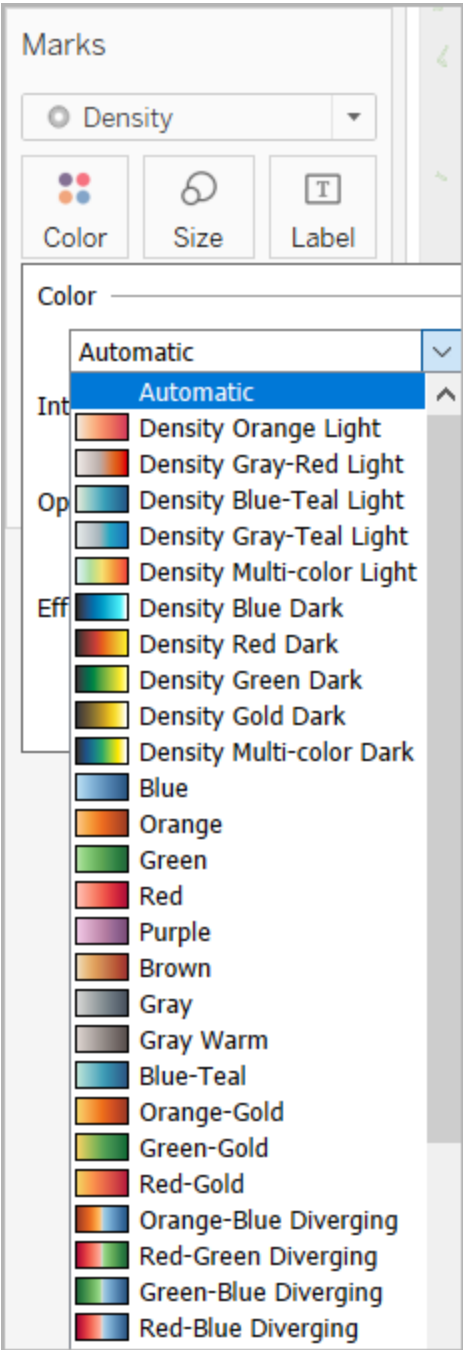

Zoom around the map to analyse your data. Selection, tooltips, labels, and hovering all work based on the marks in the zoom of the view. Density maps have no fixed or constant display and will always recompute as you zoom.

Adjust the appearance

You can adjust the colour, intensity and size of your marks to help you analyse the data on your density map.

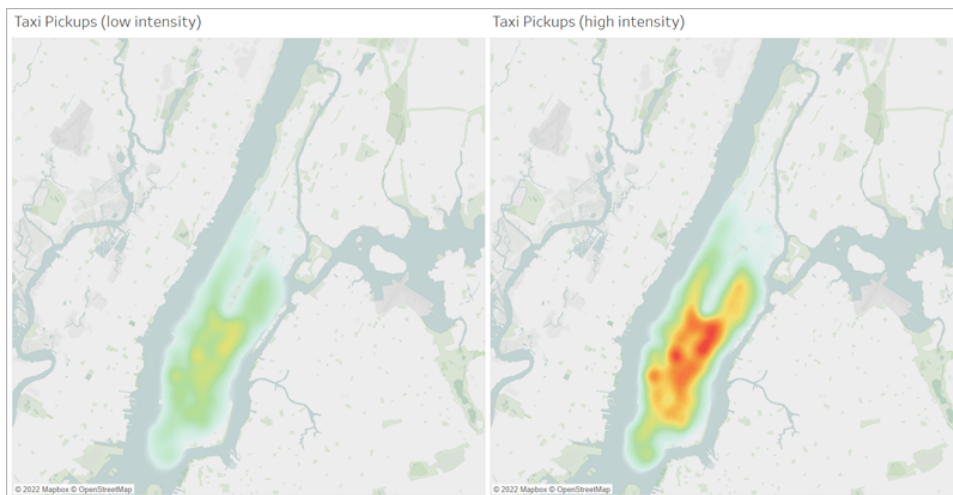

Colour: Adjust the colours of your density map by selecting **Colour** from the Marks card. Choose from ten density colour palettes or any of the existing colour palettes. The density colour palettes are tailored for working on either light or dark base maps.

Note: If your data source contains negative values, those values will also appear when a measure field is added to **Colour**. Use a diverging colour palette to make a clear distinction between positive and negative values.

Intensity: In the Colour menu, use the **Intensity** slider to increase or decrease the vividness of your map. For example, increasing density lowers the "max heat" spots in your data, so that more appear.

In the following image, the low intensity map is set at 50%, and the high intensity map is set at 75%.

Size: You can use the **Size** shelf to adjust the size of the density marks. Click the **Size** to show the size slider. Adjust the slider to increase or decrease the size of the marks group that makes your density map.

Create Maps that Show Paths Between Origins and Destinations in Tableau

You can create maps in Tableau Desktop that show paths between origins and destinations. These types of maps are called spider maps, or origin-destination maps.

Spider maps are great for when you're working with hubs that connect to many surrounding points. They are an excellent way to show the path between an origin and one or more destination locations.

There are several ways to create spider maps in Tableau. This topic illustrates how to create a spider map using two examples. Follow the examples in this topic to learn how to set up your data source and build the view for two different spider maps.

For other examples that might fit closer to your data, see the following workbooks on Tableau Public:

- [Puget Sound Radio Tower Bandwidth](#)
- [Recruitment Strategies in the English Premier League](#)
- [2014 U.S. Flight Departure Delays](#)

Note: In the following examples, the data source has points that each have a unique path ID and are each on a different row. If your origin and destination data are on the same row, you can use the MAKELINE function to generate a line mark between two spatial points. See [Create a visualisation using MAKELINE on page 2175](#).

Example 1: Metro station traffic in Paris, France

Learn how to build it

Set up your data source

To create this type of spider map in Tableau, your data source should include the following information:

- A path ID for every unique path. See [The Line Group \(Path ID\) column on the next page](#) below for more information.
- Numbers to define the drawing order of each data point (location). See [The Order of Points column on the next page](#) below for more information.
- Latitude and longitude coordinates for every location. See the example table below.
- A column with your location names (recommended, but not required).

The following table is a snippet of the Transports data source, which is included in the [Create Spider Maps in Tableau Example 1 Workbook](#) on Tableau Public. It contains metro traffic data for all metro lines in Paris, France. The first three metro stations for two metro lines are included in this example, and it contains the required columns **Line Group (Path ID)**, **Order of Points**, **Latitude** and **Longitude**. It also contains the additional columns **Line**, **Station** and **Traffic** for added clarity and organisation, but they're not required to build the map view.

| Line | Line Group (Path ID) | Order of Points | Station | Latitude | Longitude | Traffic |
|-----------|----------------------|-----------------|---------------------------|-----------|-----------|------------|
| 1 | 1 | 1 | La Défense (Grande Arche) | 48.891934 | 2.237883 | 14,275,382 |
| 1 | 1 | 2 | Esplanade de la Défense | 48.887843 | 2.250442 | 9,843,051 |
| 1 | 1 | 3 | Pont de Neuilly | 48.884509 | 2.259892 | 6,902,931 |
| 10 BOUCLE | 10 | 1 | Boulogne-Jean-Jaurès | 48.842222 | 2.238836 | 3,847,782 |
| 10 BOUCLE | 10 | 2 | Porte d'Auteuil | 48.848074 | 2.258648 | 687,237 |
| 10 BOUCLE | 10 | 3 | Michel-Ange-Auteuil | 48.847740 | 2.264297 | 2,222,709 |

The Line Group (Path ID) column

For each path, there is a unique key or string, which is added to every location in that path.

In this example, the Line Group (Path ID) column is used to identify each unique path. You will use this column to create your spider map.

For example, in the table above, there are two metro lines (1 and 10 Boucle), and each of those metro lines have a unique path ID listed in the **Line Group (Path ID)** column. For metro line 1, the Line Group is 1. For metro line 10 Boucle, the Line Group is 10. Every location in line one contains the line group 1, and every location in line 10 Boucle contains the line group 10.

The Order of Points column

This column defines the point order and the direction in which the line is drawn from the first data point to the last data point on your map, which, in this example is the start and end of the metro

line. This field is very important if you have more than two locations in a path, because it draws your paths in the desired order (you can think of it like connecting the dots).

In the example table above, there are three stations on line 1. They are listed in order from La Défense (Grande Arche) to Pont de Neuilly using the numbers **1** through **3** in the **Order of Points** column. The same is true for line 10 Boucle.

Basic map building blocks:

| | |
|-----------------------|---|
| Columns shelf: | <i>Longitude</i> (continuous measure, longitude geographic role assigned) |
| Rows shelf: | <i>Latitude</i> (continuous measure, latitude geographic role assigned) |
| Detail: | <i>Path ID field</i> (discrete dimension) |
| Path: | <i>Order field</i> (continuous dimension) |
| Mark type: | <i>Line</i> |

Build the map view

To follow along with this example, download the [Create Spider Maps in Tableau Example 1 Workbook](#) from Tableau Public, and open it in Tableau Desktop.

1. In the **Create Spider Maps in Tableau Example Workbook**, click the New Worksheet icon.
2. In the new worksheet, from Measures, drag **Longitude** to the **Columns** shelf, and **Latitude** to the **Rows** shelf.
3. From the Data pane, drag **Line Group (Path ID)** to **Detail** on the Marks card.
4. On the Marks card, click the Mark Type drop-down and select **Line**.

The map view updates with a line connecting all of the points. The Path button should appear on the Marks card.

5. From the Data pane, drag **Point Order** to **Path** on the Marks card.
Point Order is aggregated as a sum.
6. On the Marks card, right-click the **SUM(Point Order)** field and select **Dimension**.
The map view updates with a line for every metro line.

7. From the Data pane, drag **Line Group (Path ID)** to **Colour** on the Marks card.
Each line now has its own colour associated with it, and a colour legend is added to the view.

8. From the Data pane, drag **Longitude** to the **Columns** shelf and place it to the right of the first Longitude field.

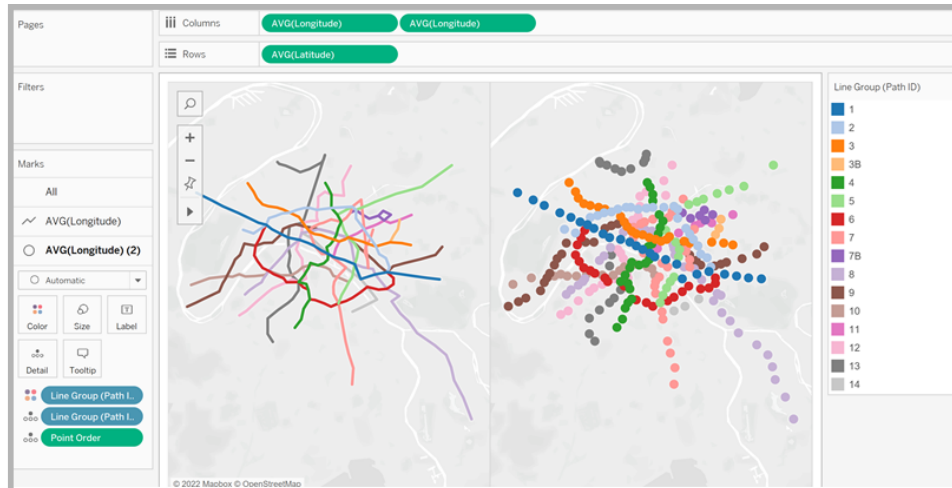

There are now two Longitude fields on the columns shelf. The view updates with two identical maps. The Marks card updates with two tabs: one for the map on the left, and one for the map on the right. You can customise each of these tabs to change the visual detail of each map view. There is an All tab to control the visual detail in both maps at the same time.

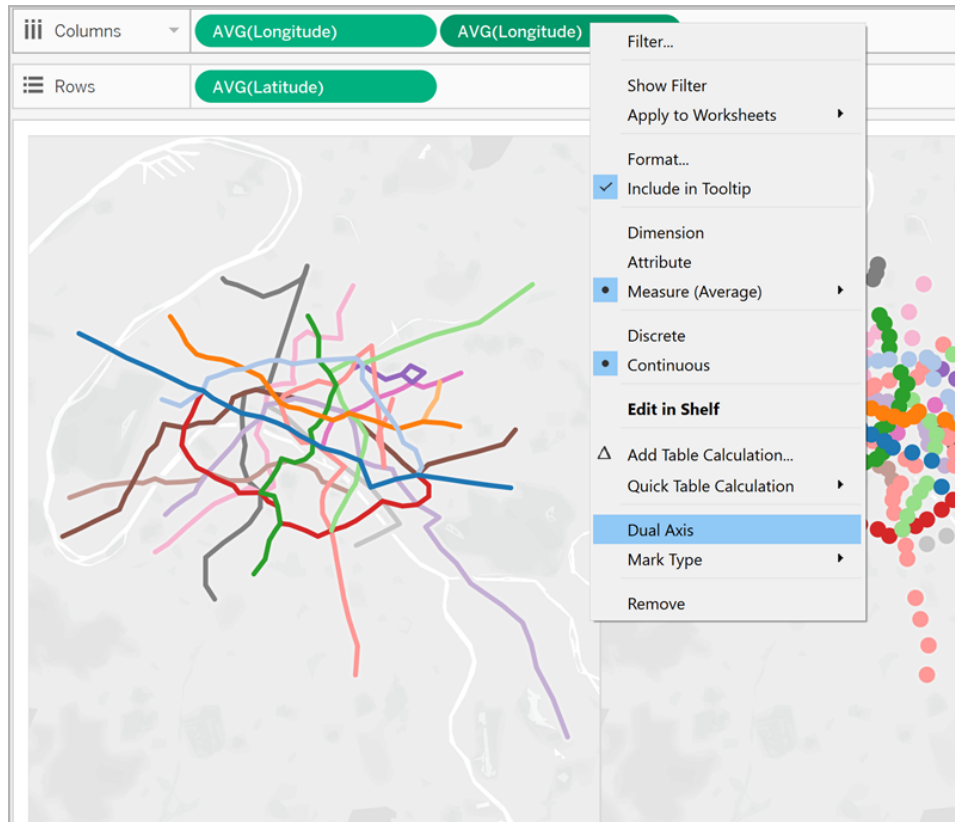

9. On the Marks card, click the bottom **AVG (Longitude) (2)** tab.

10. On the Marks card, under the bottom AVG (Longitude) tab, click the Mark type drop-down and select **Automatic**.

The map view on the right updates to a point map.

11. On the Columns shelf, right-click the second **AVG (Longitude)** field (on the right), and select **Dual Axis**.

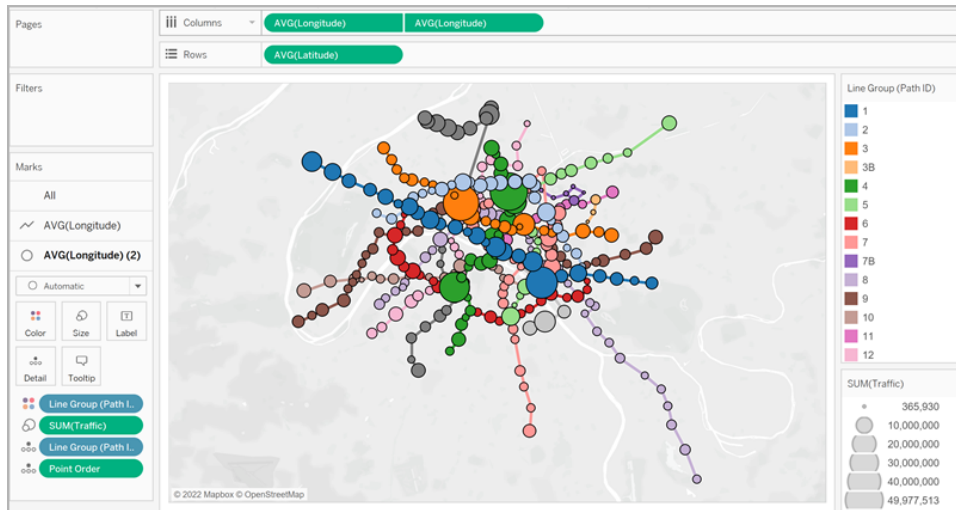

Your map views are now layered on top of one another.

12. From the Data pane, drag **Traffic** to **Size** on the bottom AVG (Longitude) Marks card.

The size of the data points update to show the amount of traffic per station.

13. On the Marks card, click **Size** and move the slider to the right.
14. On the Marks card, click **Colour**, and then, under Effects, click the **Border** drop-down and select a colour.

The view is now complete. You can quickly find the stations on each metro line with the most traffic.

Filter the amount of information in the view

If you want to filter the amount of lines you see in the view:

- From the Data pane, drag **Line Group** to the Filters shelf.

You can also right-click the **Line Group** field and select **Show Filter** to show a filter card in the view.

Example 2: Bike share data in Seattle, Washington

Learn how to build it

Set up your data source

Similar to the first example, for this type of spider map, your data source should contain the following information:

- A Path ID for every unique path. See [The Path ID column on the next page](#) below for more information.
- Latitude and longitude coordinates for every location. See the example table below.
- Two rows in your data source for each path. You should have one row for your origin location data and one row for your destination location data, repeated for every path. This is a crucial step that enables Tableau to draw your paths correctly. See [Origin-destination rows on the next page](#) below for more information.
- A column with your location names (recommended, but not required).

This example is a snippet of the Seattle bike share data source, which is included in the [Create Spider Maps in Tableau Example 2 Workbook](#). It has a column for **Origin-Destination**, **Station**, **Path ID**, **Latitude** and **Longitude**. Only the last three columns in this data source are required to create a spider map, but the Origin-Destination and Location Name columns provide further clarity and organisation.

| Origin-Destination | Station | Path ID | Latitude | Longitude |
|--------------------|---------|-------------|----------|------------|
| Origin | BT-01 | BT-01_BT-01 | 47.61841 | -122.35101 |
| Destination | BT-01 | BT-01_BT-01 | 47.61841 | -122.35101 |
| Origin | BT-01 | BT-01_BT-03 | 47.61841 | -122.35101 |
| Destination | BT-03 | BT-01_BT-03 | 47.61576 | -122.34843 |
| Origin | BT-01 | BT-01_BT-04 | 47.61841 | -122.35101 |
| Destination | BT-04 | BT-01_BT-04 | 47.61613 | -122.34108 |
| Origin | BT-01 | BT-01_BT-05 | 47.61841 | -122.35101 |

| | | | | |
|-------------|-------|-------------|----------|------------|
| Destination | BT-05 | BT-01_BT-05 | 47.61303 | -122.34410 |
|-------------|-------|-------------|----------|------------|

Origin-destination rows

For each unique path you want to create, you need a row for your origin location, and a row for your destination location in your data source. This means your origin location will be paired with every destination location.

For example, when showing the path between an origin bike share location and several destination locations in a city, you need a row for the origin location, and a row for the destination location for *every single path*.

In the example above, the origin station BT-01 is paired with several different destination locations (BT-01, BT-03, BT-04, BT-05) to show that bikes were checked out of the BT-01 location and returned either to the same location or to a different location. Each origin-destination pair is colour-coded to show that they make up one path. There is a column for Origin-Destination to further illustrate this concept, but this column is not required.

The Path ID column

The Path ID column is used to identify each unique origin-to-destination path. You will use this column to create your spider map.

For each origin and destination location, there is a unique key or string that identifies them as a pair.

In the example below, for the first origin-destination path, the Path ID is BT-01_BT-01. For the second origin-destination path, the Path ID is BT-01_BT-03. Each path ID is listed twice, once for the origin location, and once for the destination location. Again, each pair is colour-coded to indicate that they make up one path.

| Origin-Destination | Location Name | Path ID | Latitude | Longitude |
|--------------------|---------------|-------------|----------|------------|
| Origin | BT-01 | BT-01_BT-01 | 47.61841 | -122.35101 |
| Destination | BT-01 | BT-01_BT-01 | 47.61841 | -122.35101 |
| Origin | BT-01 | BT-01_BT-03 | 47.61841 | -122.35101 |
| Destination | BT-03 | BT-01_BT-03 | 47.61576 | -122.34843 |

Note: Your path ID can be anything you want. However, if you want to create complex calculated fields to help filter the locations later on, it helps if your path IDs are consistent across all paths. A great way to do this is to create Path IDs that are a combination of your origin and destination location names, separated by a delimiter. For example, the Path ID for the origin location BT-01 and the destination location BT-03 is BT-01_BT-03. For an example of why you might want to do this, see the [Option 2: Create a dynamic filter: on page 1810](#) section.

Basic map building blocks:

| | |
|-----------------------|---|
| Columns shelf: | <i>Longitude</i> (continuous dimension, longitude geographic role assigned) |
| Rows shelf: | <i>Latitude</i> (continuous dimension, latitude geographic role assigned) |
| Detail: | <i>Path ID field</i> (discrete dimension) |
| Mark type: | <i>Line</i> |

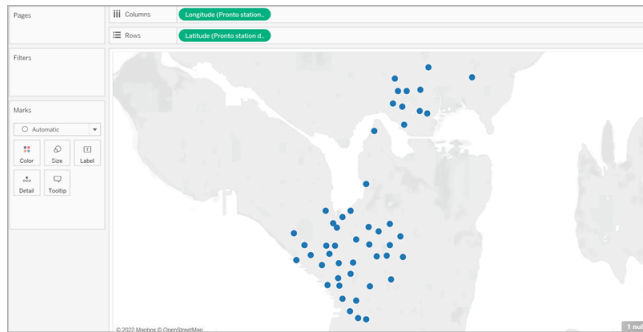

Build the map view

After you set up your data source, you can connect to it in Tableau Desktop and build a spider map. To follow along with this example, download the [Create Spider Maps in Tableau Example 2 Workbook](#) from Tableau Public.

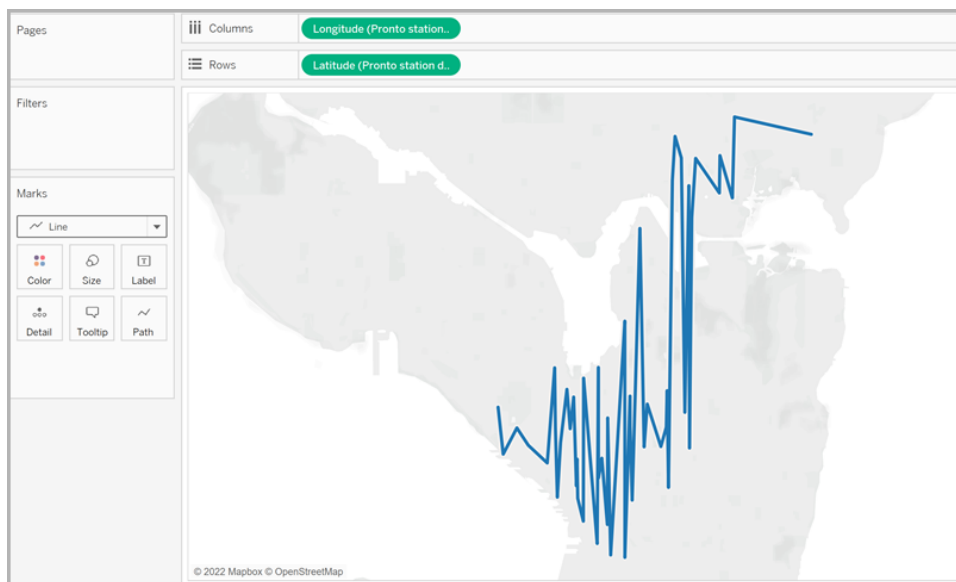

1. From the Data pane, drag **Longitude** to the **Columns** shelf and **Latitude** to the **Rows** shelf.
2. On the Columns shelf, right-click the **Longitude** field and select **Dimension**. Do the same for the **Latitude** field on the **Rows** shelf.

This will ensure Tableau does not aggregate your origin and destination locations.

You should see all the locations in the data source as data points on your map. In this example, there is a data point for every bike share location in the data source.

3. On the Marks card, click the Marks Type drop-down, and select **Line**. The view updates to show a line connecting each data point, and the Marks card updates with a Path button.

4. From the Data pane, drag **Path ID** to **Detail** on the Marks card.

If you have only a few origin-destination pairs, your view might look something like the following:

However, if you have many origin-destination pairs, your view might look more like this:

This is very common, and can be fixed by filtering a large portion of your paths from the view. Continue to the following section to learn a couple of ways to do so.

Filter the amount of information in the view

If your data source contains a lot of origin-destination pairs, you can filter most of them from the view.

Option 1: Create a simple filter:

1. From the Data pane, drag **Path ID** to the Filters shelf.
2. In the Filter dialog box that opens, do the following:
 - Under the **General** tab, select **None**.
 - Click the **Wildcard** tab.
 - Under the **Wildcard** tab, for **Match Value**, enter **BT-01**, and then click **Starts With**.
 - Click **OK**.

This filters the view down to only the paths that start with BT-01.

Option 2: Create a dynamic filter:

You can also create a calculated field and combine it with a parameter so you can switch between the paths you want to see right in the view. Follow the steps below to learn how.

Step 1: Create the parameter

1. On the Data pane, click the Data pane drop-down and select **Create Parameter**.
2. In the Create Parameter dialog box, do the following:
 - Name the parameter **StationSelected**.
 - For **Data type**, select **String**
 - For **Allowable values**, click **List**, select **Add from field**, and then select the **Location Names** field.
 - Click **OK**.

Step 2: Create the calculated field

1. Select **Analysis > Create Calculated Field**.
2. In the calculation editor, name the calculated field, **Select by Origin-Destination**, and then enter the following formula:

```
IF

LEFT([Path ID], FIND([Path ID], "_" ) -1) =

[StationSelected] THEN "Origin"

ELSEIF
```

```
RIGHT([Path ID], LEN([Path ID]) - FIND([Path ID], "_")) =  
[StationSelected] THEN "Destination"  
  
ELSE  
  
"Unselected stations"  
END
```

In the [table above](#), each Path ID (for example BT-01_BT-03) contains an underscore (_) as a delimiter to separate the origin location name (BT-01) from the destination location name (BT-03). This delimiter is used in the formula to tell Tableau which locations (selected in the parameter you created in step 1 of this procedure) are origin locations, and which are destination locations. The parameter you created above is also used in the formula (StationSelected).

3. Check that the calculation is valid, and then click **OK**.

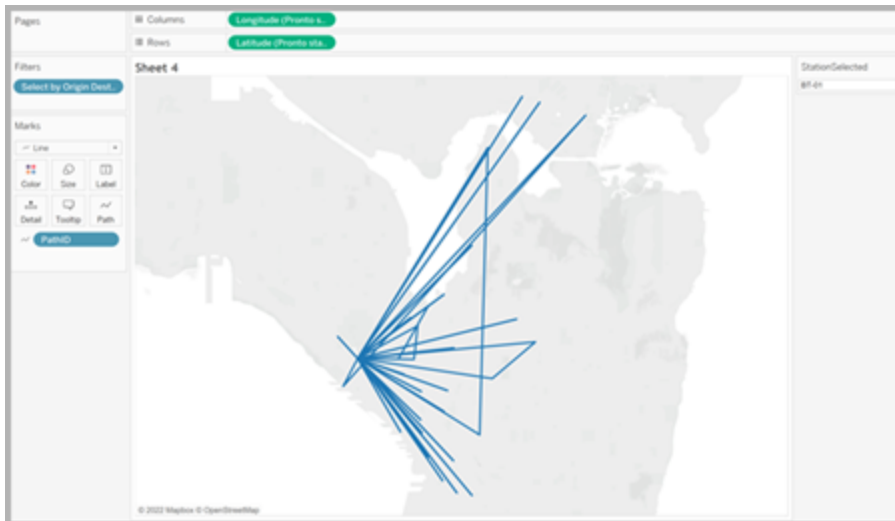

Step 3: Add the calculated field to the Filters shelf

1. From the Data pane, drag the calculated field to the **Filters** shelf.
2. In the Filter dialog box, select **Origin**, and then click **OK**.

Step 4: Show the parameter control

In the Data pane, right-click the parameter you created and select **Show Parameter Control**.

You can now select an origin from the parameter control in the view, and the marks on your map view will update.

Create Dual-Axis (Layered) Maps in Tableau

This article demonstrates how to create dual axis (layered) maps in Tableau using several examples. A dual-axis map is a map with two sets of geographic data overlaid on top of one another. For example, a filled map of US states with data points for each city layered on top.

There are three ways to create a dual-axis map in Tableau:

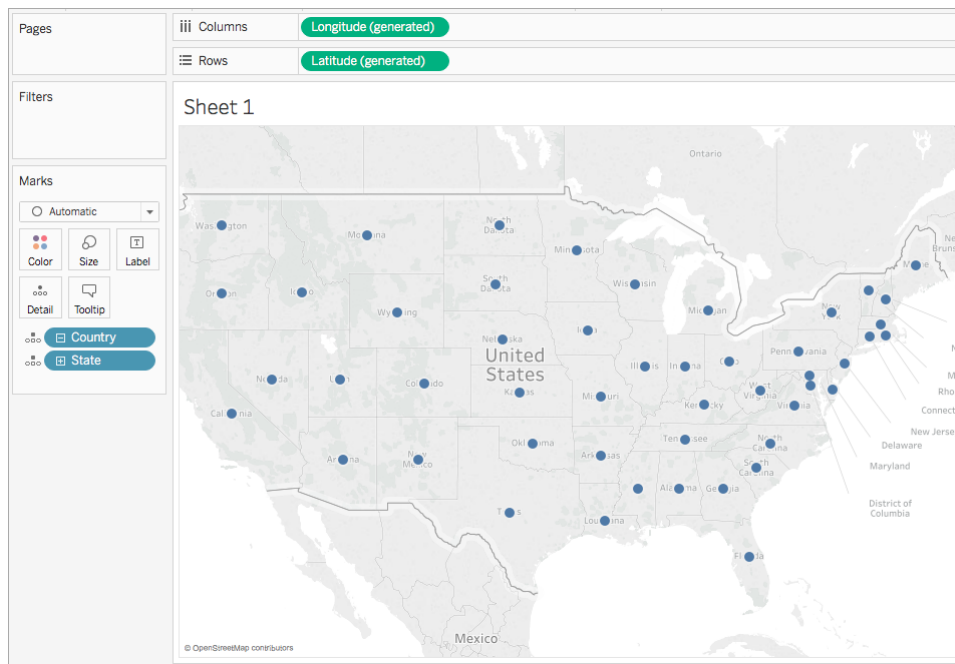

- [By using Tableau Latitude \(generated\) and Longitude \(generated\) fields](#)
- [By using custom latitude and longitude fields](#)
- [By using a combination of Tableau Latitude \(generated\) and Longitude \(generated\) fields, and custom latitude and longitude fields](#)

Follow the steps below to learn how to create a dual-axis map using each of these methods.

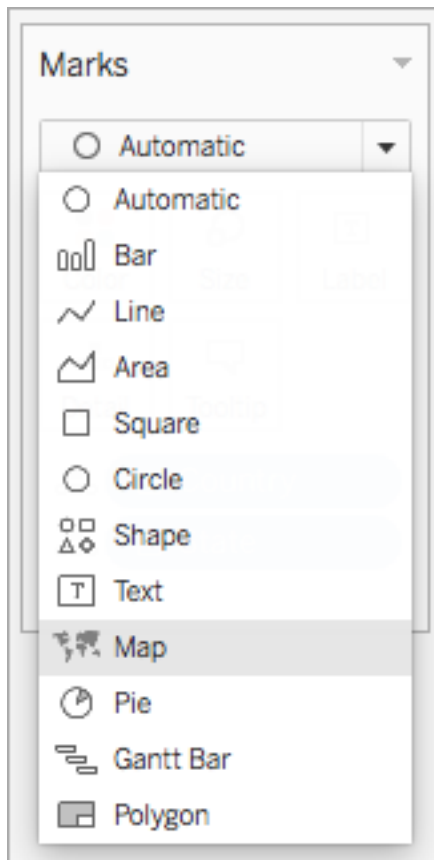

Create a dual-axis map from Tableau Latitude (generated) and Longitude (generated) fields

1. Open Tableau Desktop.
2. In the Connect pane, under Saved Data Sources, connect to the **Sample-Superstore** data source.
3. In the **Data** pane, under Dimensions, double-click **State**.

A map view is created.

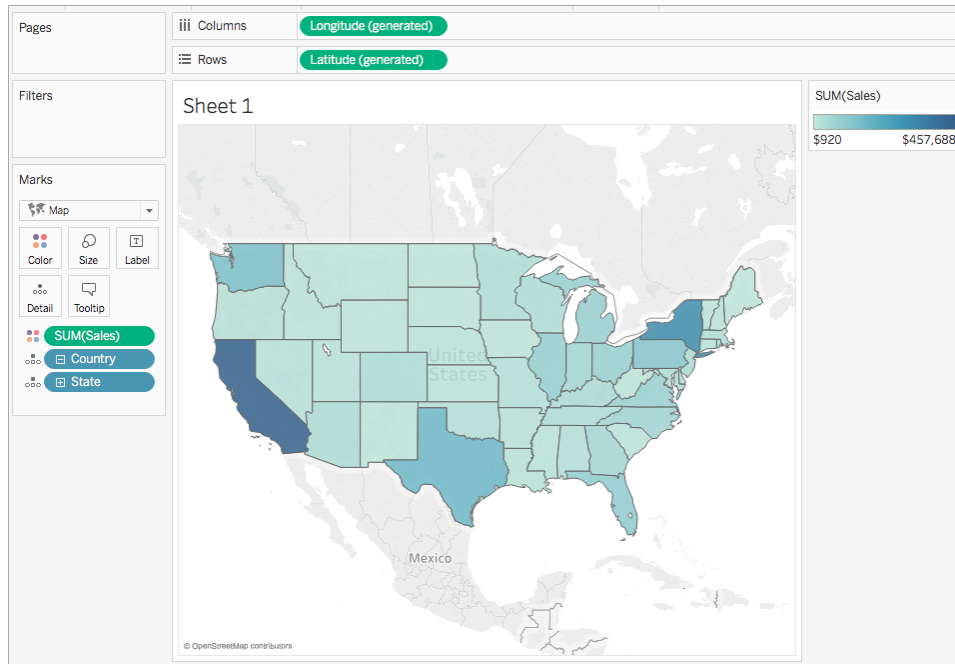

4. On the Marks card, click the Mark Type drop-down and select **Map**.

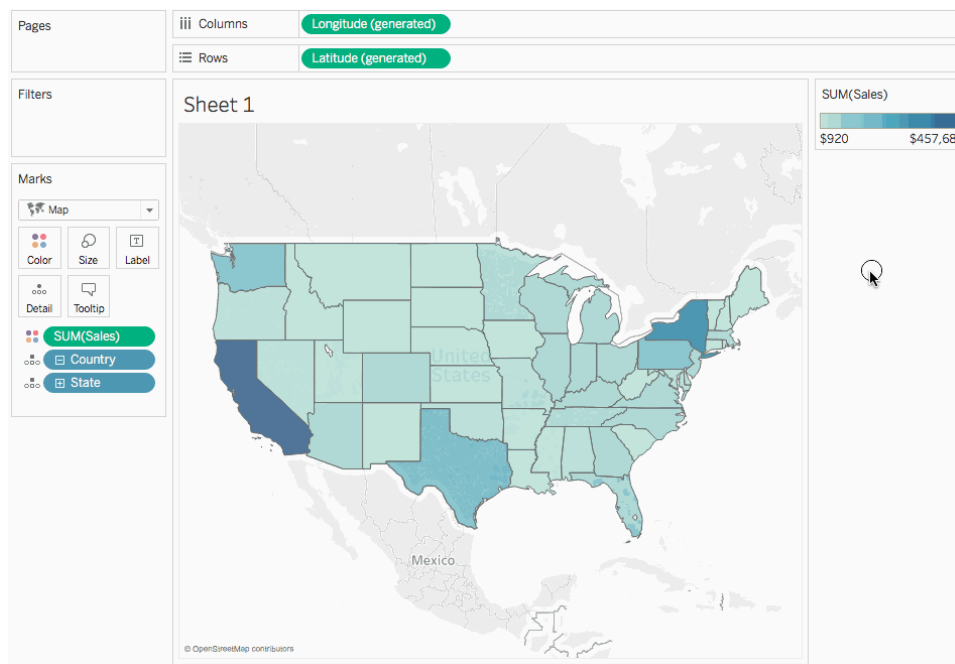

5. From the **Data** pane, under Measures, drag **Sales** to **Colour** on the Marks card.

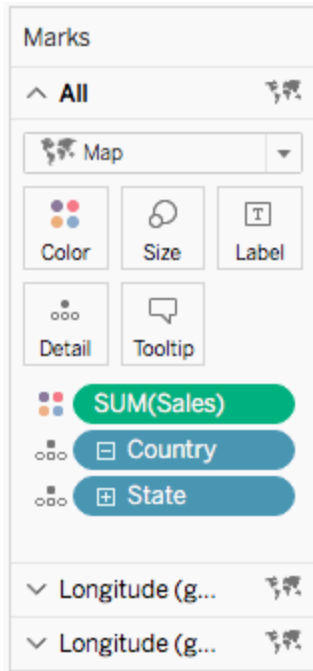

The map updates to show the sum of sales by state. The states with higher sales are darker blue, and the states with fewer sales are lighter blue.

- On the **Columns** shelf, control-drag (command-drag on a Mac) the **Longitude (generated)** field to copy it, and place it to the right of the first Longitude field.

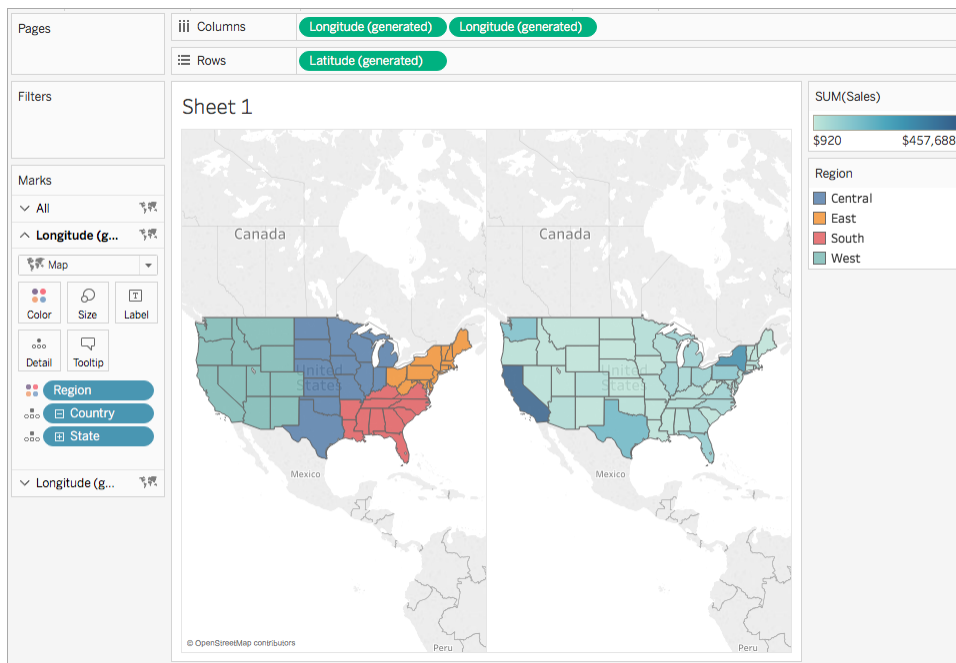

- On the Marks card, select the top **Longitude (generated)** tab.

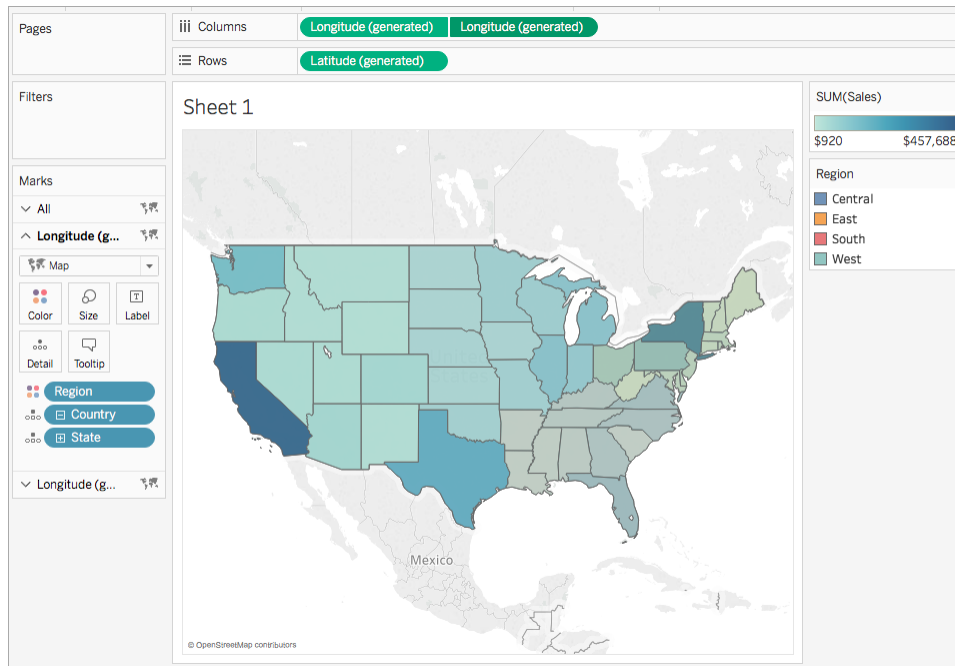

8. From the **Data** pane, under Dimensions, drag **Region** to **Colour** on the Marks card.

The map view on the left updates.

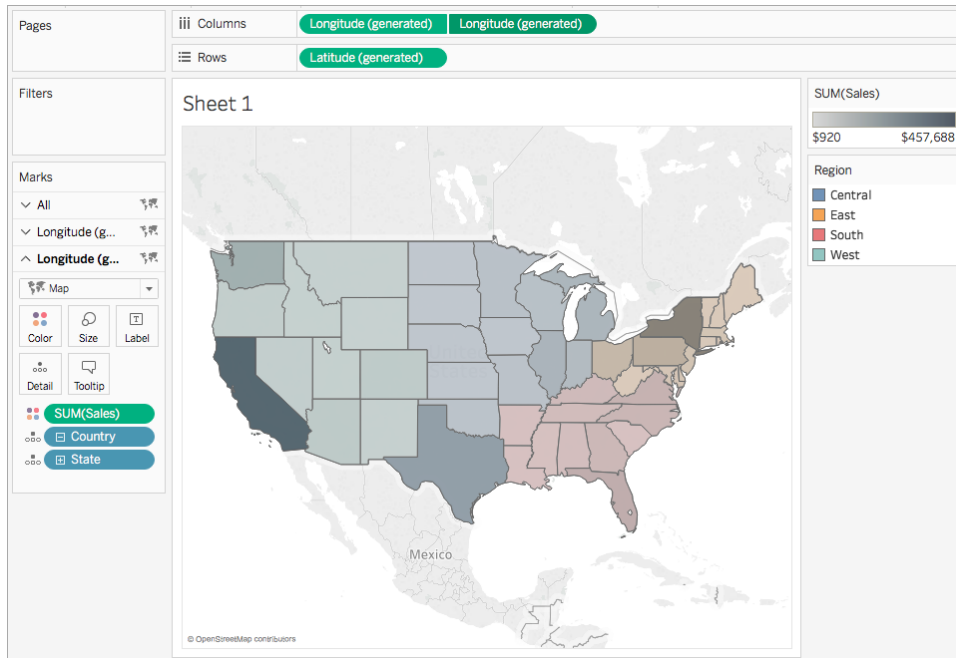

9. On the Columns shelf, right-click the **Longitude (generated)** field on the right and select **Dual Axis**.

The map views are now overlapping each other. You might not be able to see the map on the bottom layer.

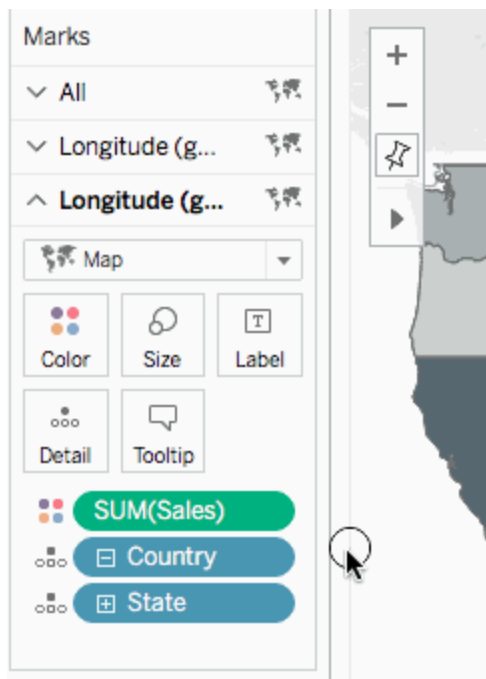

10. On the Marks card, ensure that the bottom Longitude (generated) tab is selected, and then click **Colour > Edit Colours**.
11. In the Edit Colours dialog box that opens, click the Palette drop-down, select **Grey**, and then click **OK**.

Notice that the colours of the map update.

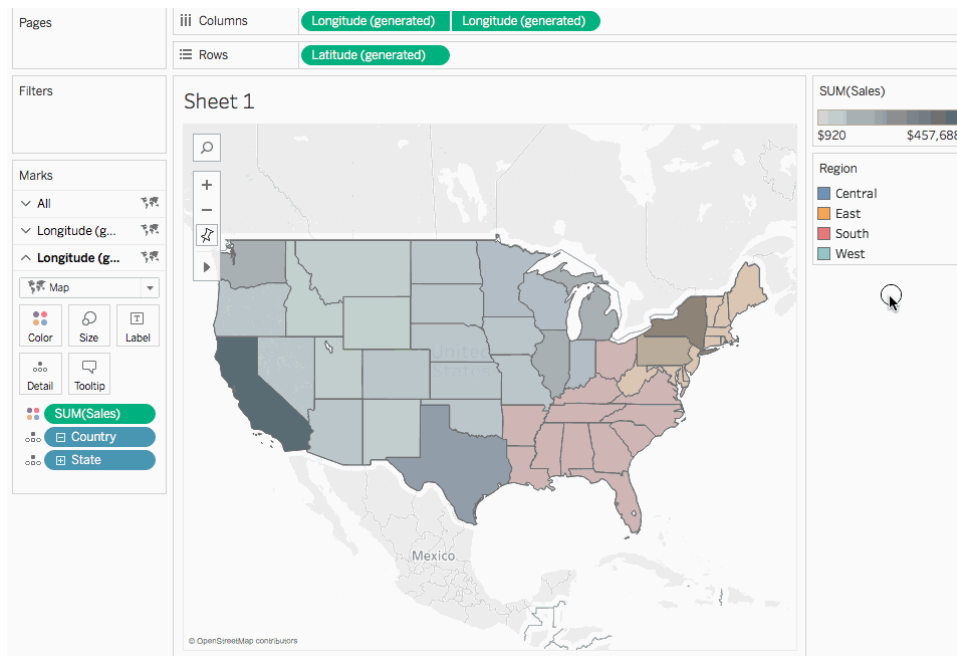

12. On the Marks card, click **Colour** again.
13. In the Colour pop-up dialog box, under Opacity, move the slider to approximately 75%.

The dual axis (layered) map is now complete. For each region, you can now see which states has the most sales.

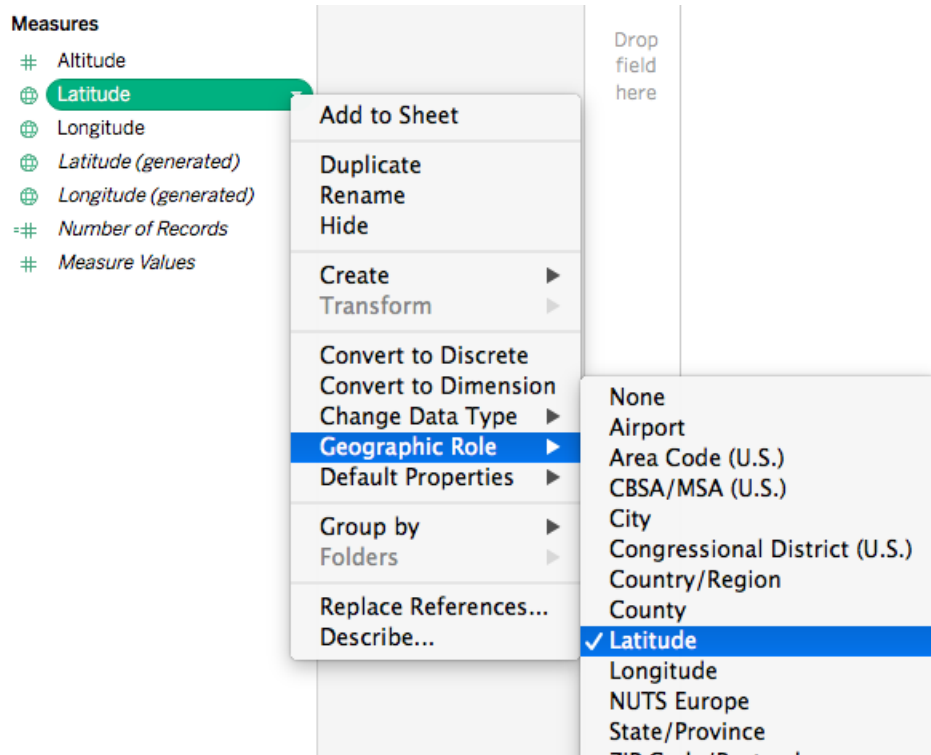

Tip: To change which map is on top, rearrange the Longitude (generated) fields on the Columns shelf.

Create a dual-axis map from custom latitude and longitude fields

If your data source contains custom latitude and longitude fields, you can use them instead of the Tableau Latitude (generated) and Longitude (generated) fields to create a dual-axis map. Follow the steps below to learn how.

1. Open Tableau and connect to a data source with custom latitude and longitude values.
2. Navigate to a new worksheet.
3. In the **Data** pane, right-click the custom latitude field and select **Geographic Role > Latitude**.

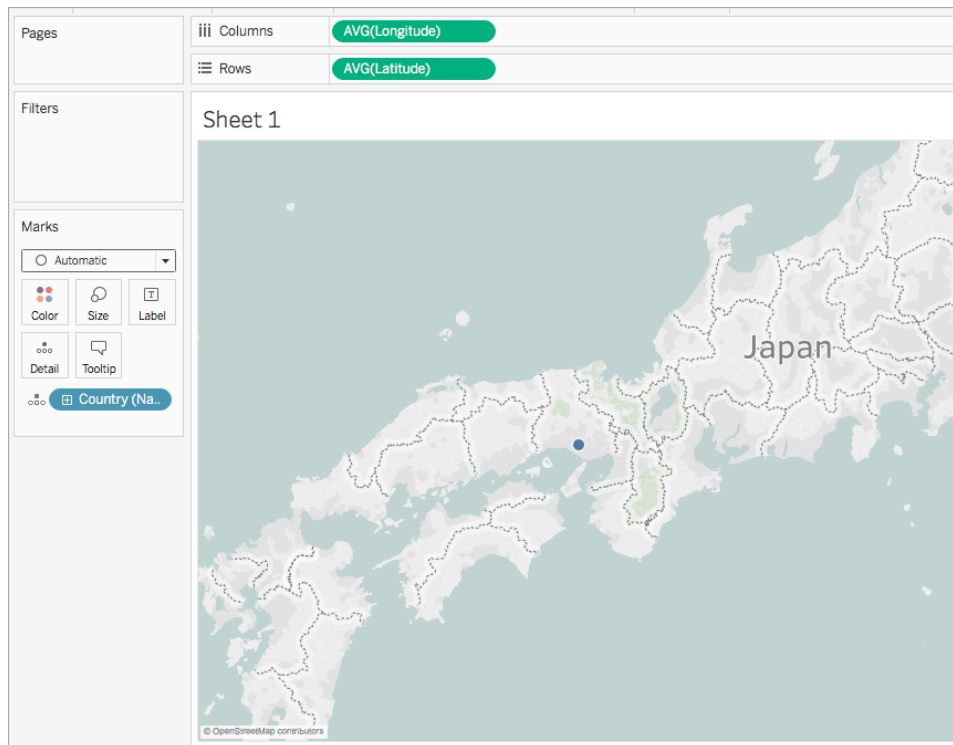

Note that the Latitude geographic role may already be assigned to the field.

4. In the **Data** pane, right-click the custom longitude field and select **Geographic Role > Longitude**.

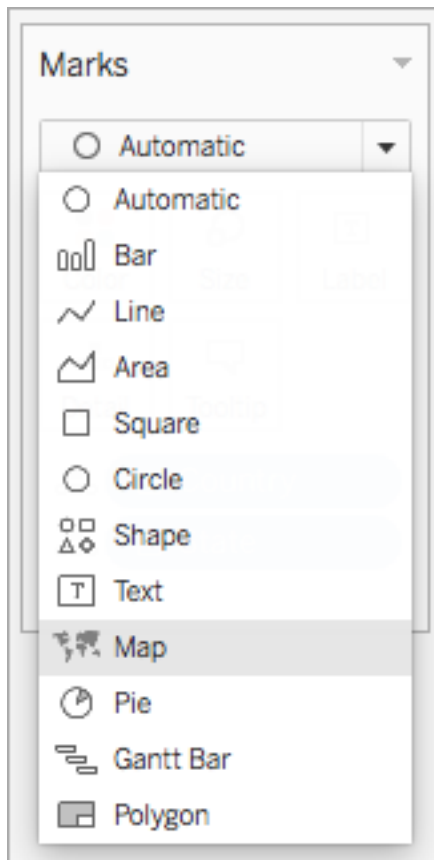

Note that the Longitude geographic role may already be assigned to the field.

5. From the **Data** pane, drag the custom latitude field to the **Rows** shelf.
6. From the **Data** pane, drag the custom longitude field to the **Columns** shelf.
7. From the **Data** pane, under Dimensions, drag a geographic field to **Detail** on the Marks card.

In this example, the geographic field, Country (Name), is used.

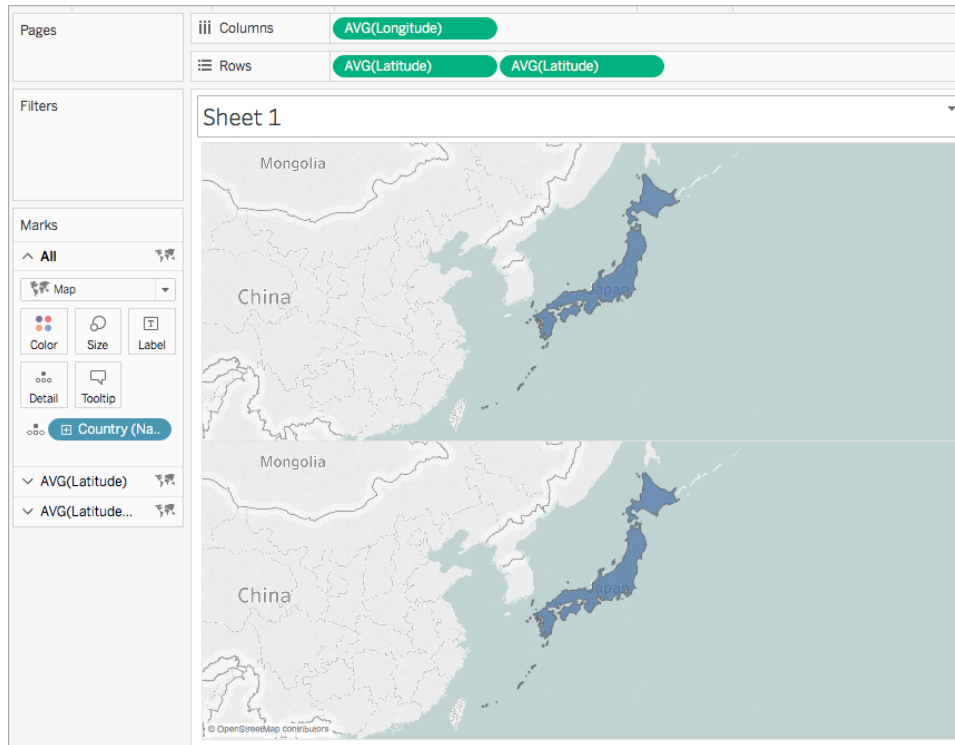

8. On the Marks card, click the Mark Type drop-down and select **Map**.

The map updates to a filled map.

9. On the Rows shelf, Ctrl-click (Command-click on a Mac) and drag the custom latitude field to the right. This copies the field.

A second, identical map is created and the Marks card updates to include three tabs. The middle tab is for the top map, and the bottom tab is for the bottom map.

10. On the Marks card, click on the bottom tab and remove the geographic field by dragging it off.
11. From the **Data** pane, drag a new geographic field to **Detail** on the Marks card.
In this example, Airport (City) is used.

12. On the Marks card, click **Colour** and select a colour for the marks. In this example, the colour orange is used.
 13. On the Rows shelf, right-click the custom latitude field on the right and select **Dual Axis**.
- The two maps are now combined.

Create a dual-axis map from a combination of generated and custom latitude and longitude fields

Follow the steps in each scenario to learn how to create a dual-axis map from generated and custom latitude and longitude fields.

Best practices for creating dual-axis maps with two sets of latitude and longitude fields:

- The Latitude(generated) and Longitude(generated) fields must be placed on the Columns and Rows shelves.
- The custom latitude and longitude fields must be placed on Detail on the Marks card, and then converted to dimensions. For more information, see [steps 11 and 12](#) in Scenario 1.
- The custom latitude and longitude fields must be assigned the Latitude and Longitude geographic roles. For more information, see [Assign Geographic Roles](#) on page 1717.
- When joining data sources, use a Full Outer join. For more information, see [Join Your Data](#) on page 796.

Scenario 1: Use generated and custom latitude and longitude fields from a single data source

1. Open Tableau Desktop and connect to a data source.

In this example, an excel spreadsheet that contains country and city names, as well as custom latitude and longitude columns for airport locations around the world, is used.

| Airports Airport (IATA) | Airports Airport (Name) | Airports Airport (City) | Airports Country (Name) | Airports Latitude | Airports Longitude |
|----------------------------|----------------------------|----------------------------|----------------------------|----------------------|-----------------------|
| GKA | GOROKA | GOROKA | PAPUA NEW GUINEA | -6.0817 | 145.392 |
| LAE | <i>null</i> | LAE | PAPUA NEW GUINEA | 0.0000 | 0.000 |
| MAG | MADANG | MADANG | PAPUA NEW GUINEA | -5.2069 | 145.789 |
| HGU | MOUNT HAGEN | MOUNT HAGEN | PAPUA NEW GUINEA | -5.8261 | 144.296 |
| LAE | NADZAB | NADZAB | PAPUA NEW GUINEA | -6.5697 | 146.726 |
| POM | PORT MORESBY JAC... | PORT MORESBY | PAPUA NEW GUINEA | -9.4433 | 147.220 |
| RAB | <i>null</i> | RABAU | PAPUA NEW GUINEA | 0.0000 | 0.000 |

2. Navigate to a new worksheet.

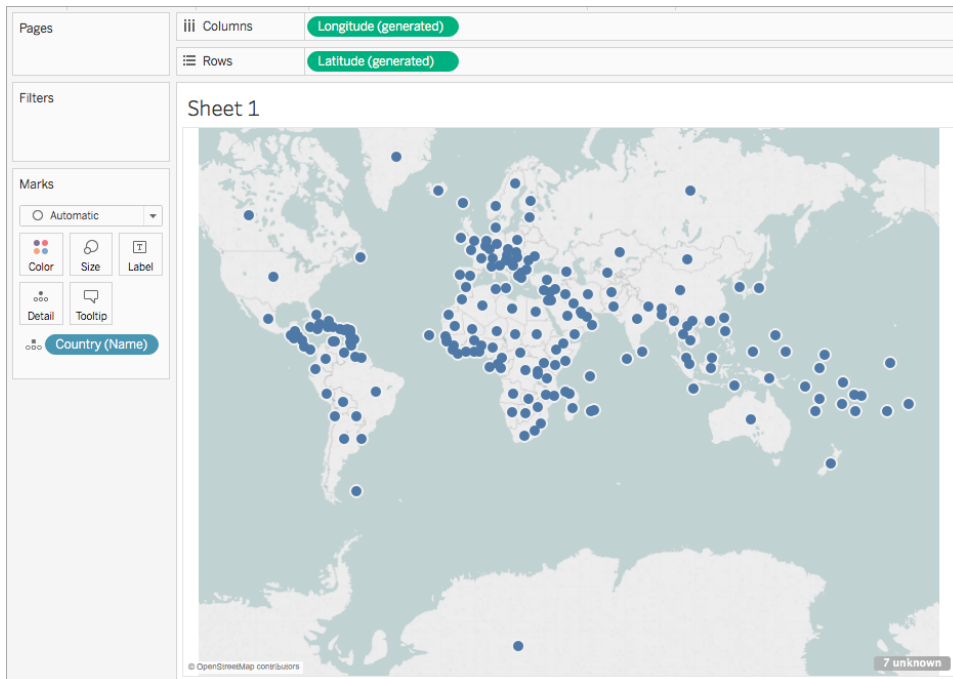

Notice that, in the Data pane, under Measures, there are two sets of latitude and longitude fields: the custom latitude and longitude fields from the data source, and the generated latitude and longitude fields that Tableau creates from your geographic fields.

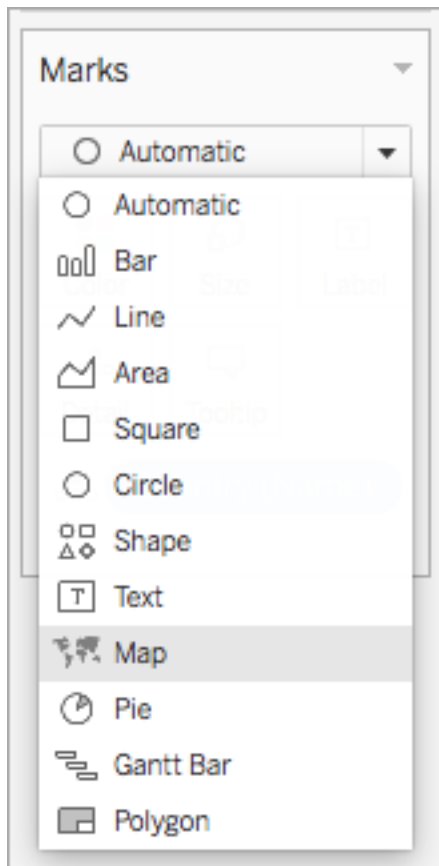

3. From the **Data** pane, under Measures, drag **Longitude(generated)** to the **Columns** shelf.
4. From the **Data** pane, under Measures, drag **Latitude(generated)** to the **Rows** shelf.

5. From the **Data** pane, under Dimensions, drag a geographic location to **Detail** on the Marks card.

In this example, **Country (Name)** is used. A map view with a data point for every country in the data source is created.

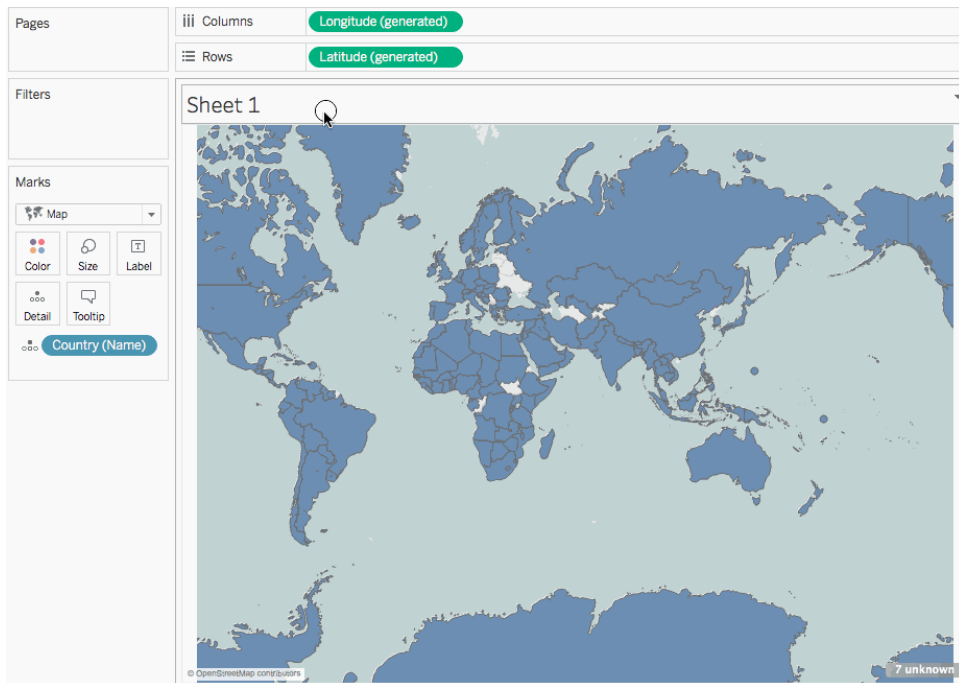

6. On the Marks card, click the Mark type drop-down and select **Map**.

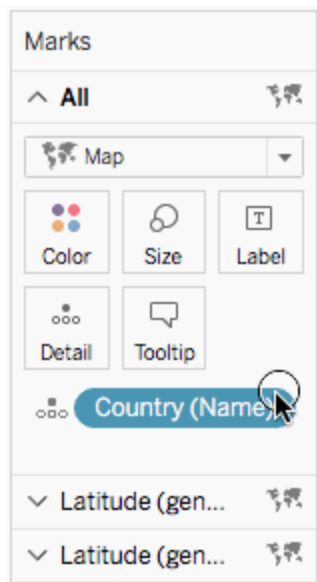

7. On the Rows shelf, Ctrl-click (Command-click on Mac) and drag the **Latitude(generated)** field to the right. This copies the field.

A second, identical map is created and the Marks card updates to include two tabs labelled Latitude(generated). The top tab is for the top map, and the bottom tab is for the bottom map.

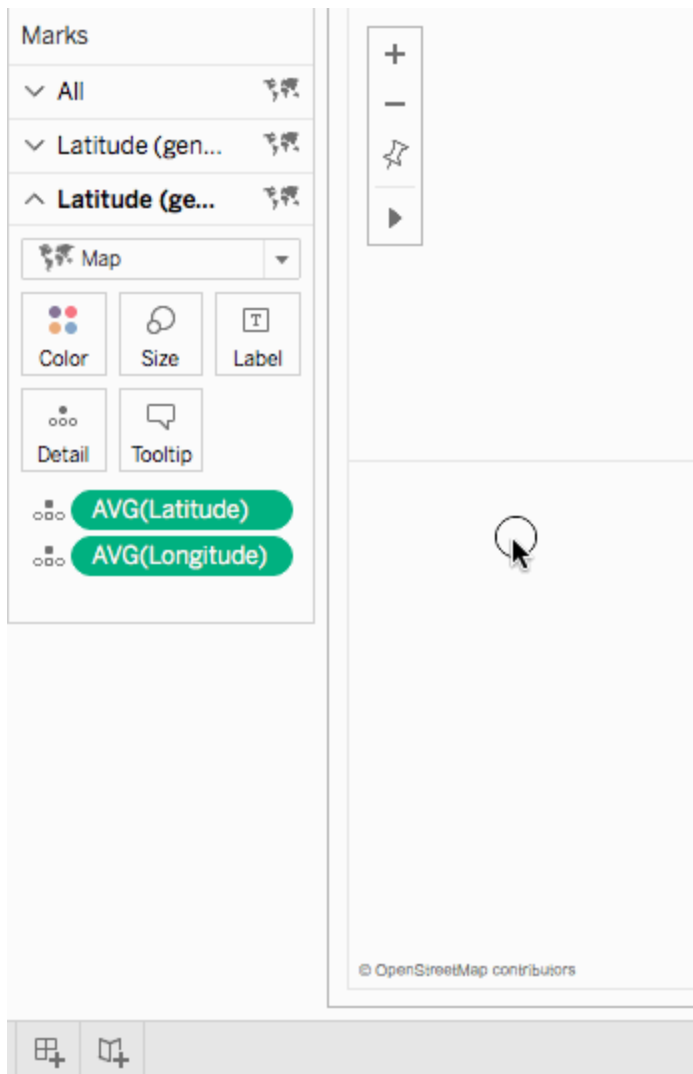

- On the Marks card, click the bottom **Latitude (generated)** tab and remove **Country (name)**.

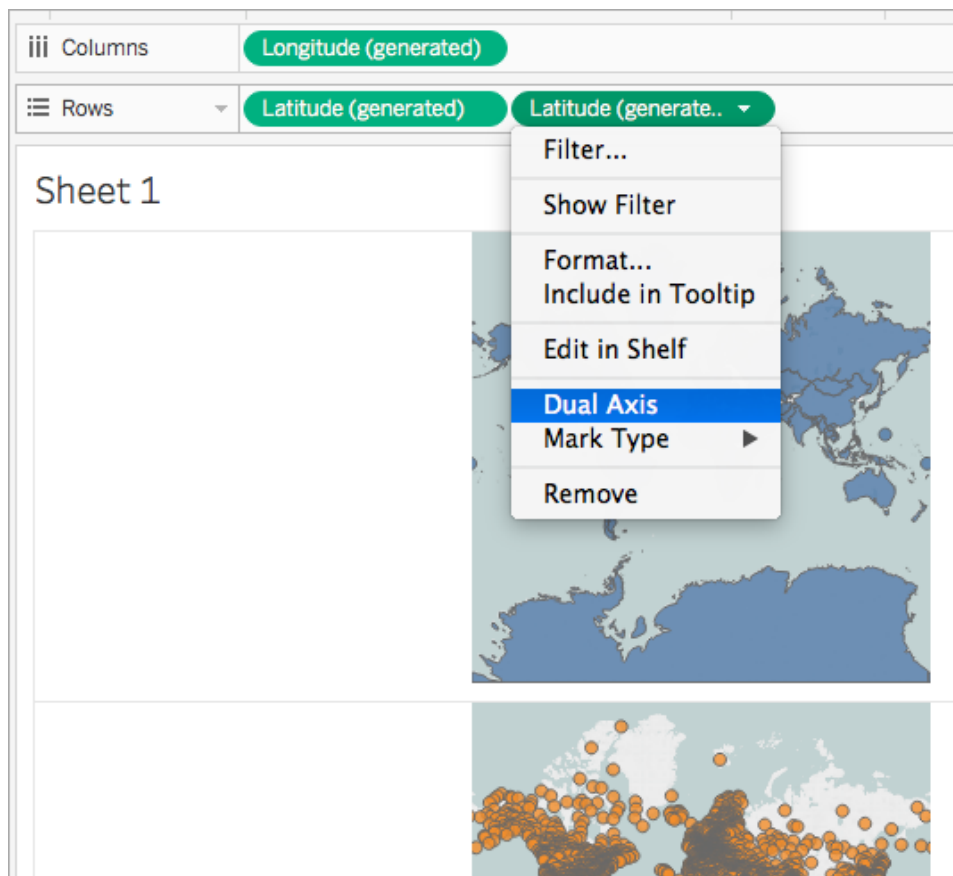

- From the Data pane, under Measures, drag the custom **Latitude** field to **Detail** on the Marks card.

10. From the Data pane, under Measures, drag the custom **Longitude** field to **Detail** on the Marks card.
11. On the Marks card, right-click the custom **Latitude** field and select **Dimension**.
12. Repeat step 11 for the custom **Longitude** field.

13. On the Marks card, click **Colour** and then select a new colour.
In this example, the colour orange is used.
14. On the Rows shelf, right-click the **Latitude(generated)** field on the right and select **Dual Axis**.

The two maps are now combined. You can filter the view as needed or zoom in to a particular area.

Data Source | Sheet 1

Scenario 2: Join spatial data with an independent data source and plot the data from both on the same map

1. Open Tableau Desktop and connect to spatial data. For more information, see [Connect to spatial files on page 1736](#).

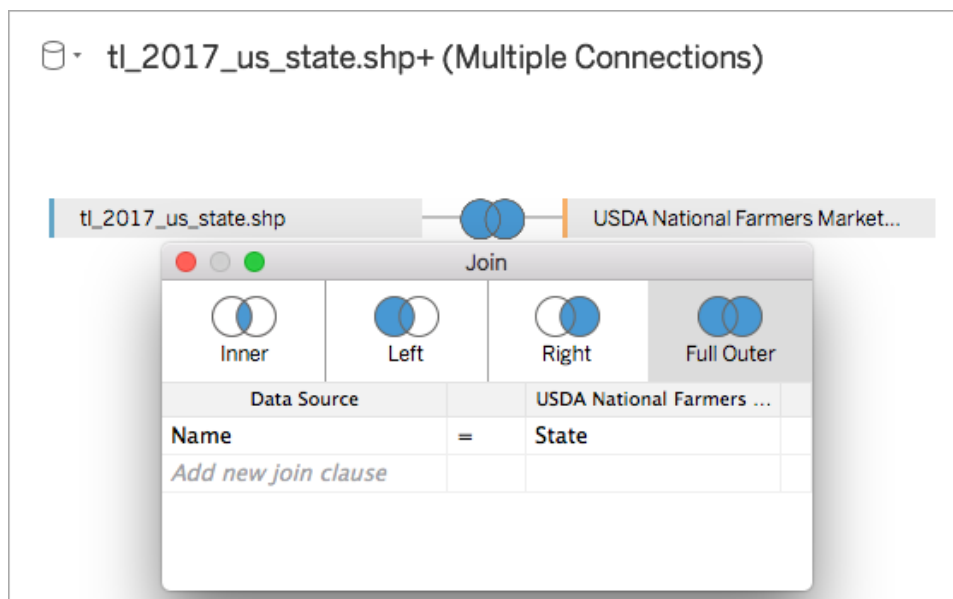

In this example, a shape file with polygon data for US states is used.

2. On the Data Source page, in the Connections pane, click **Add**.
3. Connect to another data source.

In this example, an excel spreadsheet with custom latitude and longitude columns is used.

4. Join the new data source to the spatial data using a Full Outer join. For more information on how to join data, see [Join Your Data on page 796](#).

In this example, the excel spreadsheet is joined to the shape file using columns that contain state names from each data source.

5. Navigate to a new worksheet.

Notice that, in the Data pane, there are two sets of Dimensions and two sets of Measures: one for each of your data sources.

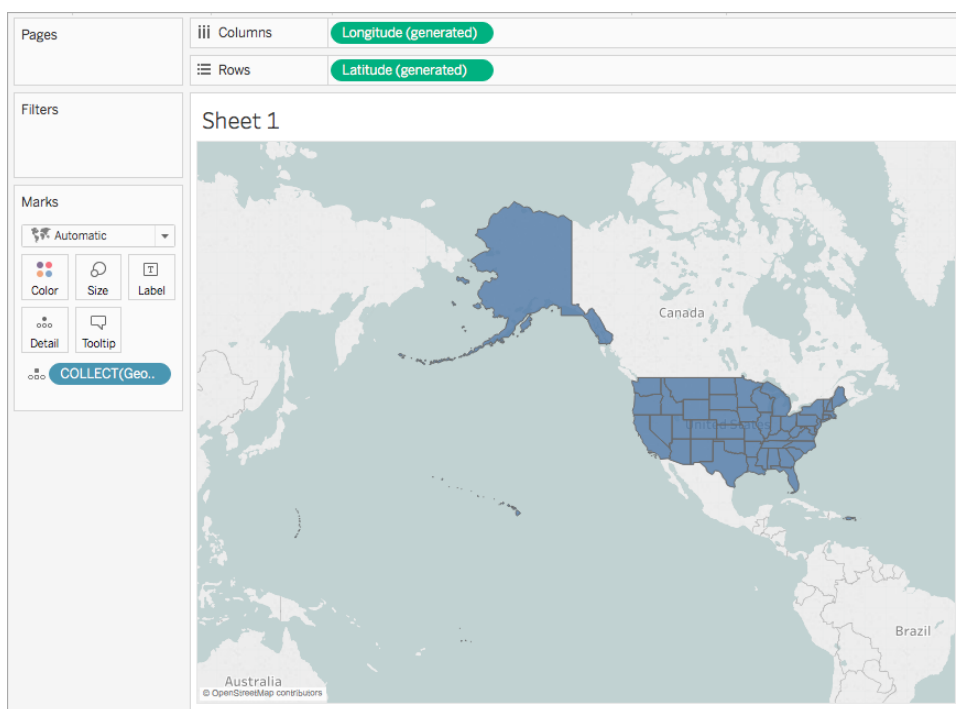

6. From the **Data** pane, under Measures, drag **Latitude(generated)** to the **Rows** shelf.
7. From the **Data** pane, under Measures, drag **Longitude(generated)** to the **Columns** shelf.

A blank map is created.

8. From the **Data** pane, drag either the Geometry field from your spatial data source, or a geographic field from your excel data source, to **Detail** on the Marks card.

The field you choose is for your bottom layer of data. For example, if you have polygon data in your spatial file, use the Geometry field so that the bottom layer will be filled polygons. If you have linear geometries in your spatial file, use a geographic field from your excel data source and format the map to be a filled or point map.

In this example, the **Geometry** field from the shape file is used. The map updates to a filled map of the United States.

9. On the Rows shelf, Ctrl-click (Command-click on a Mac) and drag the **Latitude (generated)** field to the right. This copies the field.

A second, identical map is created and the Marks card updates to include two tabs labelled Latitude(generated). The top tab is for the top map, and the bottom tab is for the bottom map.

10. On the Marks card, click the bottom **Latitude (generated) tab** and remove the geographic field.

In this example, COLLECT (Geometry) is removed.

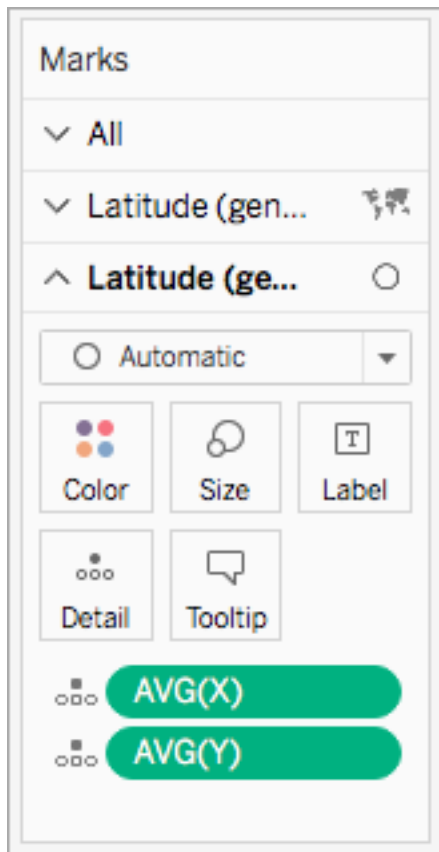

11. In the **Data** pane, under Measures, right-click the custom latitude field and select **Geographic Role > Latitude**. For more information, see [Assign Geographic Roles on page 1717](#).
12. In the **Data** pane, under Measures, right-click the custom longitude field and select **Geographic Role > Longitude**.
13. From the **Data** pane, under Measures, drag the custom latitude field to **Detail** on the Marks card.

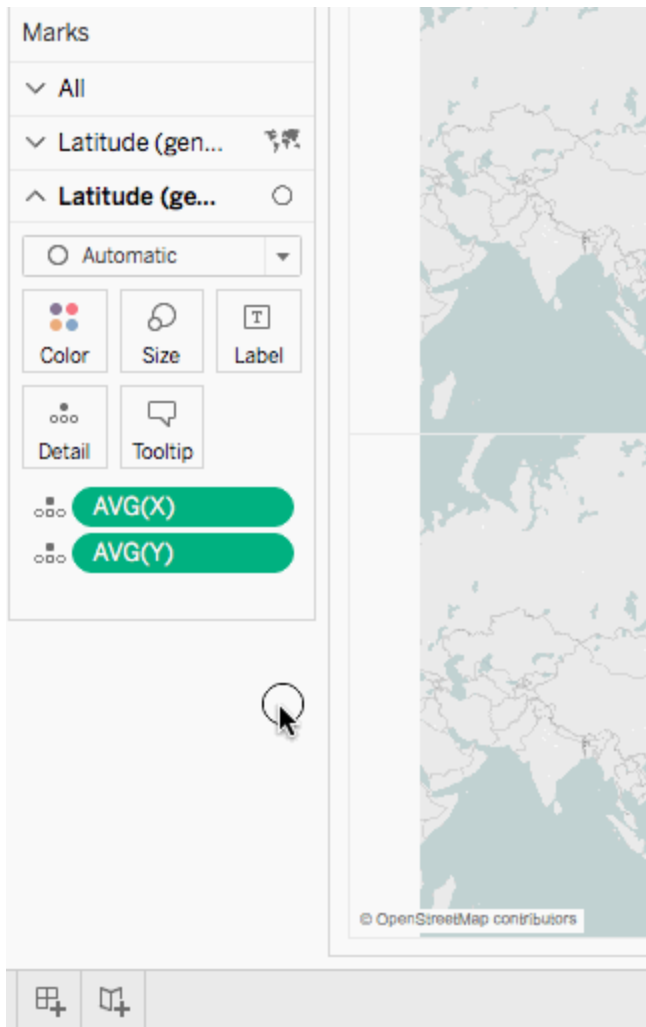

In this example, the custom latitude field is named Y.

14. From the **Data** pane, under Measures, drag the custom longitude field to **Detail** on the Marks card.

In this example, the custom longitude field is named X.

15. On the Marks card, right-click the custom latitude field and select **Dimension**.
16. Repeat step 13 for the custom longitude field.

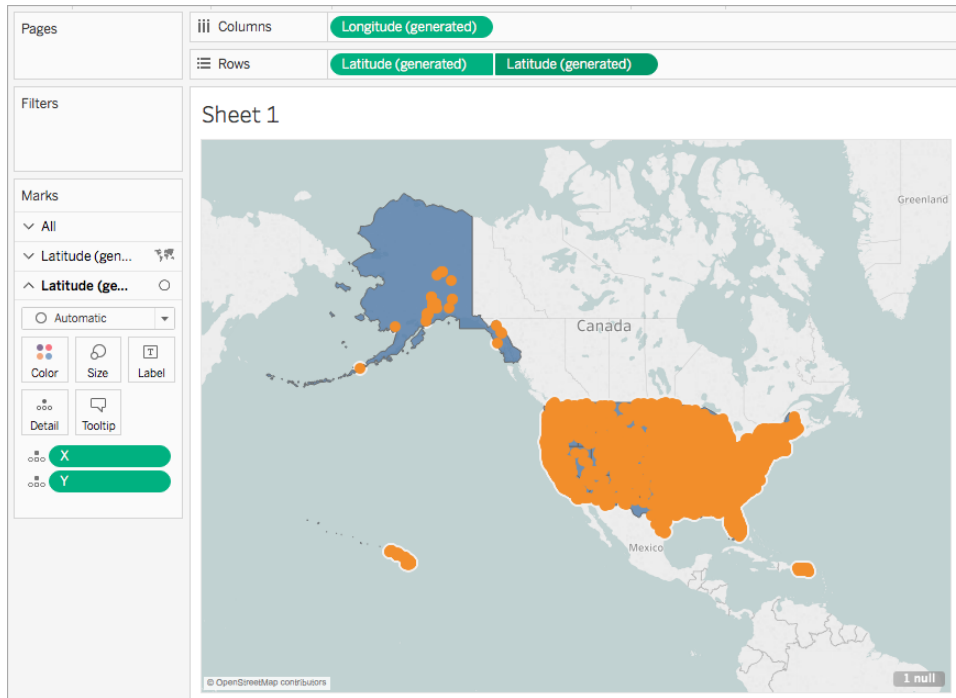

17. On the Marks card, click **Colour** and then select a new colour.

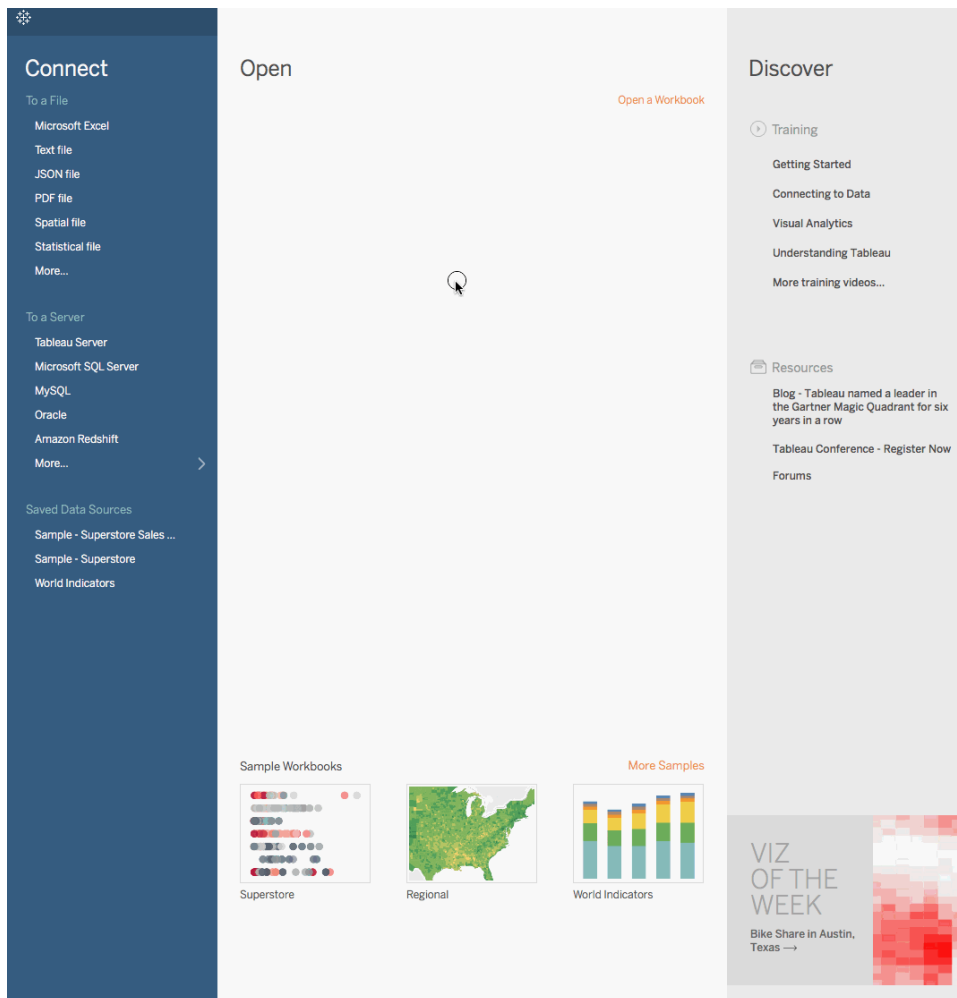

In this example, the colour orange is used.

18. On the Rows shelf, right-click the **Latitude(generated)** field on the right and select **Dual Axis**.

The two maps are now combined. You can filter the view as needed or zoom in to a particular area.

Check your work! Watch steps 1- 18 below:

Create Filled Maps with Pie Charts in Tableau

The pie mark type can be useful to show simple proportions to a relative whole. For example, pie marks might be effective when you want to show the percentage of profit for a product by

geographic location.

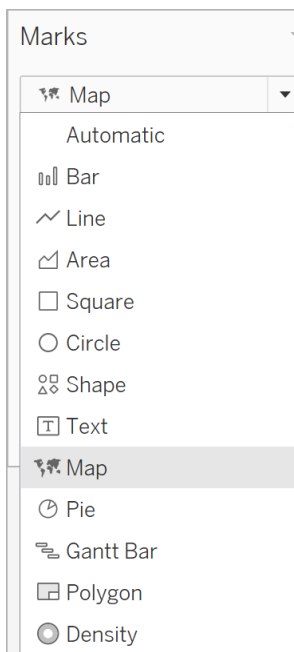

In this example, the pie mark type is used with the filled maps mark type to show the percentage of profit for office supplies, furniture and technology, relative to the total profits by state. It uses the Sample-Superstore data source that comes with Tableau Desktop.

Build the map view using layers

1. In Tableau, open a new workbook and connect to the Sample-Superstore data source.
2. On the Data Source page, click **Sheet 1** to go to a new worksheet.
3. In the Data pane, under the Orders table, open the Location folder and double-click **State**.

Tableau creates a symbol map with a data point for each state in the Sample-Superstore data source.

4. On the Marks card, click the Mark type drop-down and select the **Map** mark type.

5. From the Data pane, drag **Profit** to **Colour** on the Marks card.
6. From the Data pane, under the Orders table, open the Location folder and drag **State** to the map. When the field is over the map, you'll see an option to **Add a Marks Layer**. Drop **State** here to make a new layer.

You now have a map with two layers: filled state polygons showing Profit and point locations in the middle of each state. We'll turn these points into pie charts in the next steps.

7. If you'd like to organise and name your layers, click the drop-down arrow to the right of the layer name, select **Rename** and rename the layer to a name that reflects its content, for example, "Pie Chart".
8. On the Pie Chart layer, click the Mark type drop-down and select the **Pie** mark type.

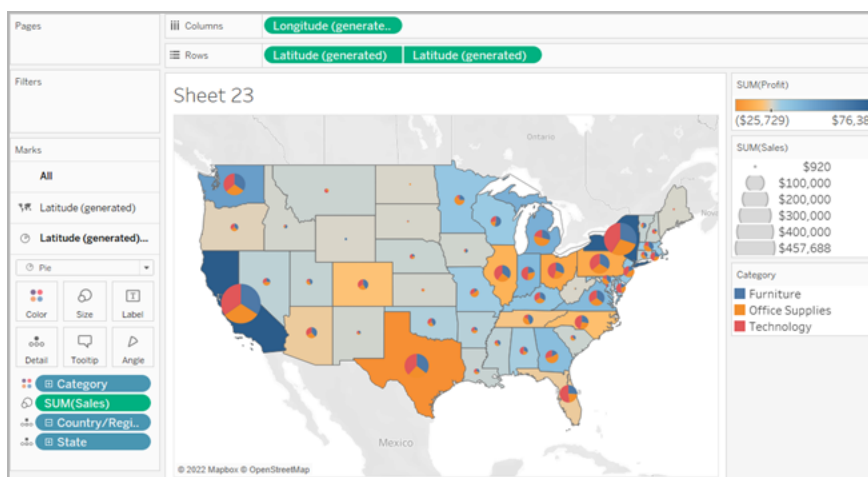

9. From the Orders table in the Data pane, drag **Sales** to **Size** on the Marks card on the Pie Chart layer.

The sum of sales for each state is shown in a proportionally sized circle.

10. Under the Orders table in the Data pane, open the Product folder and drag **Category** to **Colour** on the Marks card.

Tip: If pie charts are too small, click **Size** on the Marks card and adjust the size.

The map updates to show the sum of profit and the sum of sales for each category and state.

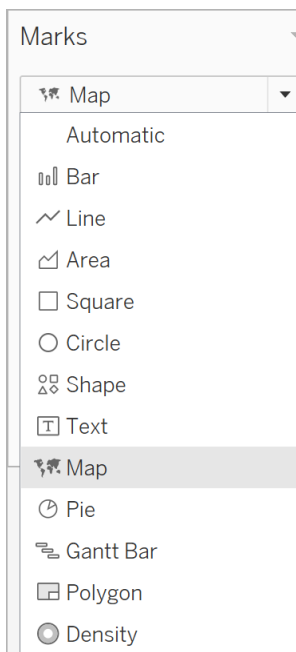

Build the map view using a dual axis

1. In Tableau, open a new workbook and connect to the Sample-Superstore data source.
2. On the Data Source page, click **Sheet 1** to go to a new worksheet.
3. In the Data pane, under the Orders table, open the Location folder and double-click **State**.

Tableau creates a symbol map with a data point for each state in the Sample-Superstore data source.

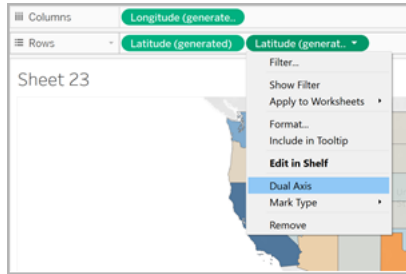

4. On the Marks card, click the Mark type drop-down and select the **Map** mark type.

5. From the Data pane, drag **Profit** to **Colour** on the Marks card.
6. From the Data pane, drag **Latitude (generated)** to the **Rows** shelf, and place it to the right of the other Latitude field.

You now have two identical map views.

7. On the Rows shelf, right-click the second **Latitude** field and select **Dual Axis**.

The second map is now layered on top of the first map. There are now three drop-downs on the Marks card: one for each map view and one for both views (All). These are three separate marks cards that you can use to control the visual detail for each of the map views.

8. On the Marks card, click one of the **Latitude (generated)** tabs, and then click the Mark type drop-down and select the **Pie** mark type.
9. From the Orders table in the Data pane, drag **Sales** to **Size** on the Latitude (generated) Marks card you selected.

The sum of sales for each state is shown in a proportionally sized circle.

10. Under the Orders table, open the Product folder and drag **Category** to **Colour** on the same Marks card.

Tip: If the pie charts are too small, click **Size** on the Marks card to adjust the size.

The map view now shows the sum of profit, as well as the sum of sales for each category, for each state.

[Get Started Mapping with Tableau](#) on page 1635

Customise Maps

Customise How Your Map Looks

This article describes how you can customise the appearance of a map view in Tableau.

Note: Many of the tasks in this article make use of the **Map Layers** pane. To open this pane, select **Map > Map Layers**. In older versions of Tableau, select **Map > Map Options**.

Select a Tableau background map style

When you are connected to the Tableau background map, you can choose between six built-in background map styles: Normal, Light, Dark, Streets, Outdoors and Satellite. You can see these styles below:

Normal

Light

Dark

Streets

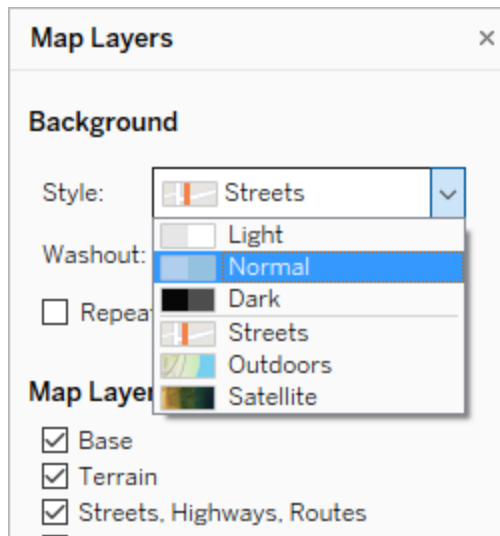

Outdoors

Satellite

To select a Tableau background map style:

1. Select **Map > Map Layers**.
2. In the Map Layers pane on the left-hand side of the workspace, under Background, click the **Style** drop-down menu, and then select a background map style.

For more information about the built-in Tableau background maps, see [Select Background Maps](#) on page 1871.

Import your own background map

If the built-in Tableau background map styles don't meet your needs, you can import your own background map from a Web Map Service (WMS) server or a Mapbox map.

To import your own background map:

1. Select **Map > Background Maps > Map Services**.
2. In the Map Services dialog box, click **Add**, and then select to add WMS servers or Mapbox maps.
3. Follow the prompts to connect Tableau to the map service of your choice.

For more information, see [Use Web Map Service \(WMS\) Servers](#) on page 1876 or [Use Mapbox Maps](#) on page 1873.

4. When finished, click **Close**.
5. Select **Map > Background Maps**, and then select the background map you want to use.

The map updates to include the background map you choose.

Add a static background image

In addition to importing your own background map, you can add a static background image to your workbook and plot your data on it. For example, you can take a Google Map image and plot your data on it.

For more information, see the following topics:

- [Use Background Images in Your Views](#) on page 1891
- [Add Images of Google Maps and OpenStreetMap as Background Images in Tableau](#) on page 1901
- [Find Background Image Coordinates](#) on page 1903

Show or hide map layers

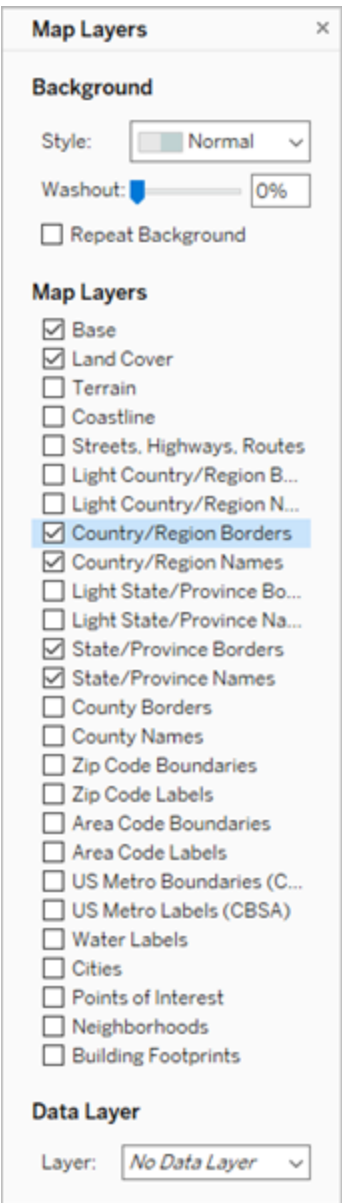

If you are using the Tableau background map, or a WMS map or Mapbox map that contains custom layers, you can show or hide layers on your background map to customise the background elements that frame your geospatial data. For example, you can overlay Streets and Highways/Motorways or county boundaries on the map to give your data context.

To add or subtract map layers:

1. Select **Map > Map Layers**.
2. In the Map Layers pane, under the Map Layers section, select one or multiple map layers.

Note: Some map layers are only visible at specific zoom levels. If a map layer is unavailable at your current level of zoom, it will appear greyed out.

To use layers that are not available, zoom further in to the view.

Some map layers are built to work with certain styles. What follows is a description of the different map layers available. Some of these layers are only available when using certain map styles.

| Layer Name | Description | present in map style |
|------------|--|----------------------|
| Base | Shows the base map including water and land areas. | All |

| Layer Name | Description | present in map style |
|--------------------------------------|---|-----------------------------|
| Land Cover | Shades wilderness areas and parks to give the map more depth. | All except Satellite |
| Terrain | Displays a relief of vertical elevation changes. | All except Satellite |
| Coastlines | Displays coastlines. | Light, Dark, Normal |
| Streets, High-ways/Motorways, Routes | Marks dual-carriageways and motorways as well as small city streets. This layer includes the motorway and street names as well. | All |
| Light Country/Region Borders | Shows a light grey outline of country/region borders and names. | Light, Dark, Normal |
| Light Country/Region Names | Shows country and region names in a light grey. | Light, Dark, Normal |
| Country/Region Borders | Highlights country and region borders in a darker grey. | All |
| Country/Region Names | Highlights country and region names in a darker grey. | All |
| Light State/Province Borders | Shows a light grey outline of state borders and names. | Light, Dark, Normal |
| Light State/Province Names | Shows state and province names in a light grey. | Light, Dark, Normal |
| State/Province Borders | Highlights state and province borders in a darker grey. | All |
| State/Province Names | Highlights state and province names in a darker grey. | All |

| Layer Name | Description | present in map style |
|----------------------------|--|-----------------------------|
| County Borders | Highlights second-level administration borders and US county borders. | Light, Dark, Normal |
| County Names | Highlights second-level administration names and US county names. | Light, Dark, Normal |
| Postcode Boundaries | Marks zip code and postcodes boundaries for US and select countries. You must zoom in to see this layer. | Light, Dark, Normal |
| Postcode Labels | Shows labels of zip code and postcodes boundaries for US and select countries. You must zoom in to see this layer. | Light, Dark, Normal |
| Area Code Boundaries | Marks US area code boundaries. You must zoom in to see this layer. | Light, Dark, Normal |
| Area Code Labels | Shows labels for the US area codes. You must zoom in to see this layer. | Light, Dark, Normal |
| US Metro Boundaries (CBSA) | Marks US Metropolitan Statistical Areas and Micropolitan area boundaries. | Light, Dark, Normal |
| US Metro Labels (CBSA) | Shows labels for the US Metropolitan Statistical Areas and Micropolitan areas. | Light, Dark, Normal |
| Water Labels | Shows labels for bodies of water. | All |
| Cities | Shows labels for cities. | All |
| Points of Interest | Displays labels for points of interest such as schools, parks, cemeteries, businesses and important build- | All |

| Layer Name | Description | present in map style |
|---------------------------------------|--|------------------------------|
| | ings. This layer is dependent on the zoom level. | |
| Neighbourhoods | Shows labels for neighbourhoods in cities. You must zoom in to see this layer. | All |
| Subway/Underground and Train Stations | Displays the names of subway/underground and train stations. You must zoom in to see this layer. | All except Satellite |
| Building Footprints | Shows the outline of buildings, where available. You must zoom in to see this layer. | Satellite, Streets, Outdoors |
| House Numbers | Displays the house numbers of buildings, with and without building footprints. You must zoom in to see this layer. | Streets, Outdoors |
| Contour Lines | Displays lines indicating vertical elevation change in metres. This layer is dependent on zoom level. | Outdoors |

Add layers for US demographic data

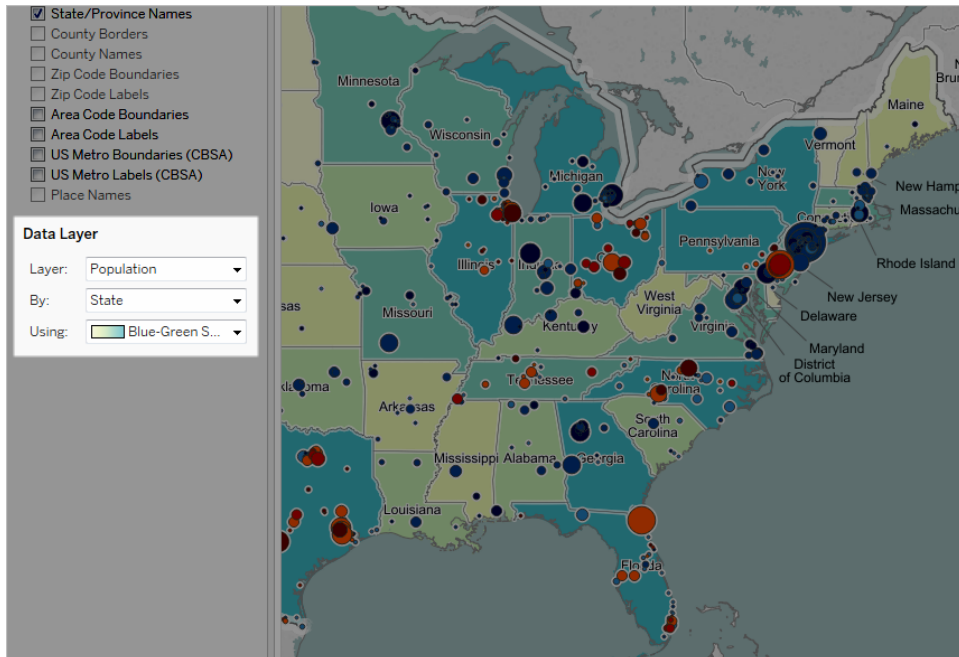

If you are using the Tableau background map, you can turn on a variety of predefined data layers that show US census information. The data in these layers is for demographic data collected from the US ACS Census.

Note: Map data layers are only available for locations in the US.

To add data layers for locations outside the US you can connect to a WMS server that contains the desired demographic information. For more information, see [Use Web Map Service \(WMS\) Servers](#) on page 1876.

To add a US data layer to your map view:

1. Select **Map > Map Layers**
2. In the **Map Layers** pane, under **Data Layer**, do the following:
 - Click the **Layer** drop-down menu and select a data layer.
 - Click the **By** drop-down menu, and then select to layer the data by **State**, **County**, **Zip Code** or **Block Group**.
 - Click the **Using** drop-down menu to select a colour scheme.

Once you select a data layer, it is added as shading to the map and a legend is shown to explain the colours of the layers. To hide or show this legend at any time, select **Map > Map Legend**.

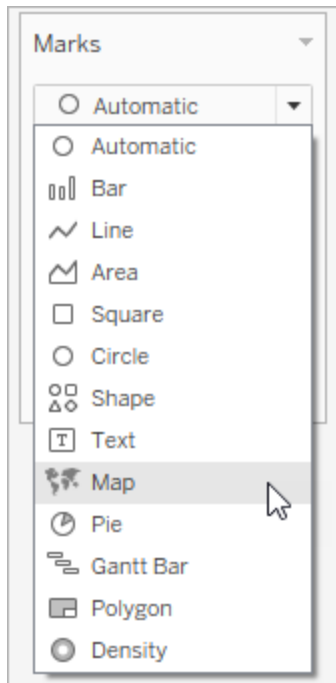

Change the mark type

By default, when you add a geographic field to the view, Tableau creates a point map. You can change this to a polygon (filled) map, a line map or a density map (heatmap).

Note: Filled maps are not available at the city or postcode level.

To change a point map to a filled or line map:

- On the Marks card, click the Mark Type drop-down and select **Map**.

To change a point map to a heatmap (density map):

- On the Marks card, click the Mark Type drop-down and select **Density**.

Add levels of detail

With maps, for each level of detail you add, the more granular your data becomes. For example, you might look at obesity rates at the state level, or you could drill down into the county level, like the examples below. Adding or subtracting levels of detail changes the make up of your map.

To add levels of detail to the view:

- From Dimensions, drag a geographic field to **Detail** on the Marks card.

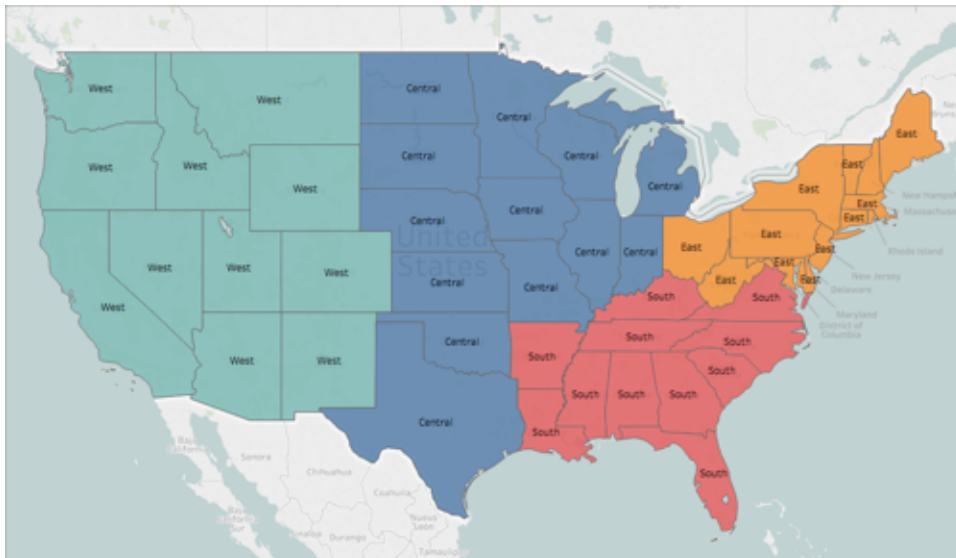

Add colour

There are two ways you can add colour to your map view: You can colour locations categorically, or you can colour locations quantitatively.

To colour locations on your map categorically:

- From the **Data** pane, drag a dimension to **colour** on the Marks card.

The image below shows each state in the US coloured by region: West, Central, South and East. The dimension, Region, is on colour on the Marks card.

**To colour each location on your map quantitatively:**

- From the **Data** pane, drag a measure to **colour** on the Marks card.

The image below shows each state in the US coloured by the amount of sales they

achieved. The measure, Sales, is on colour on the Marks card.

For more information about colour, see [Colour Palettes and Effects](#) on page 1300.

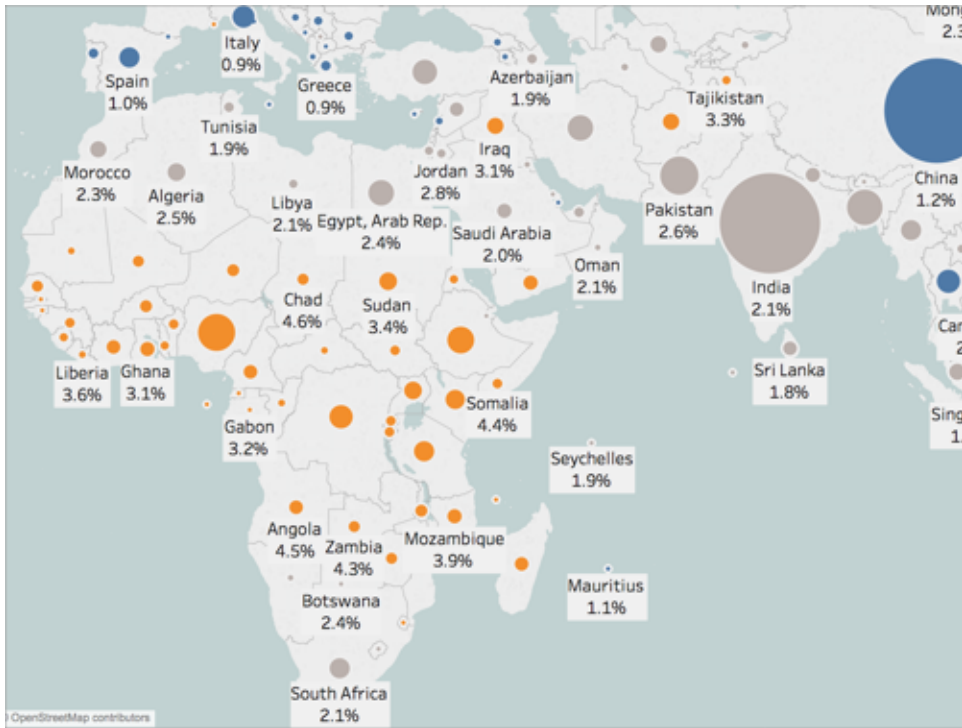

Add labels

You can add labels to your locations to provide extra context. For example, you can add labels for location name and sales.

To add labels to your data, from the **Data** pane, drag a dimension or measure to **Label** on the Marks card.

A label appears in the centre of your location (if a polygon), or to the side of your location (if a data point).

You can add multiple labels.

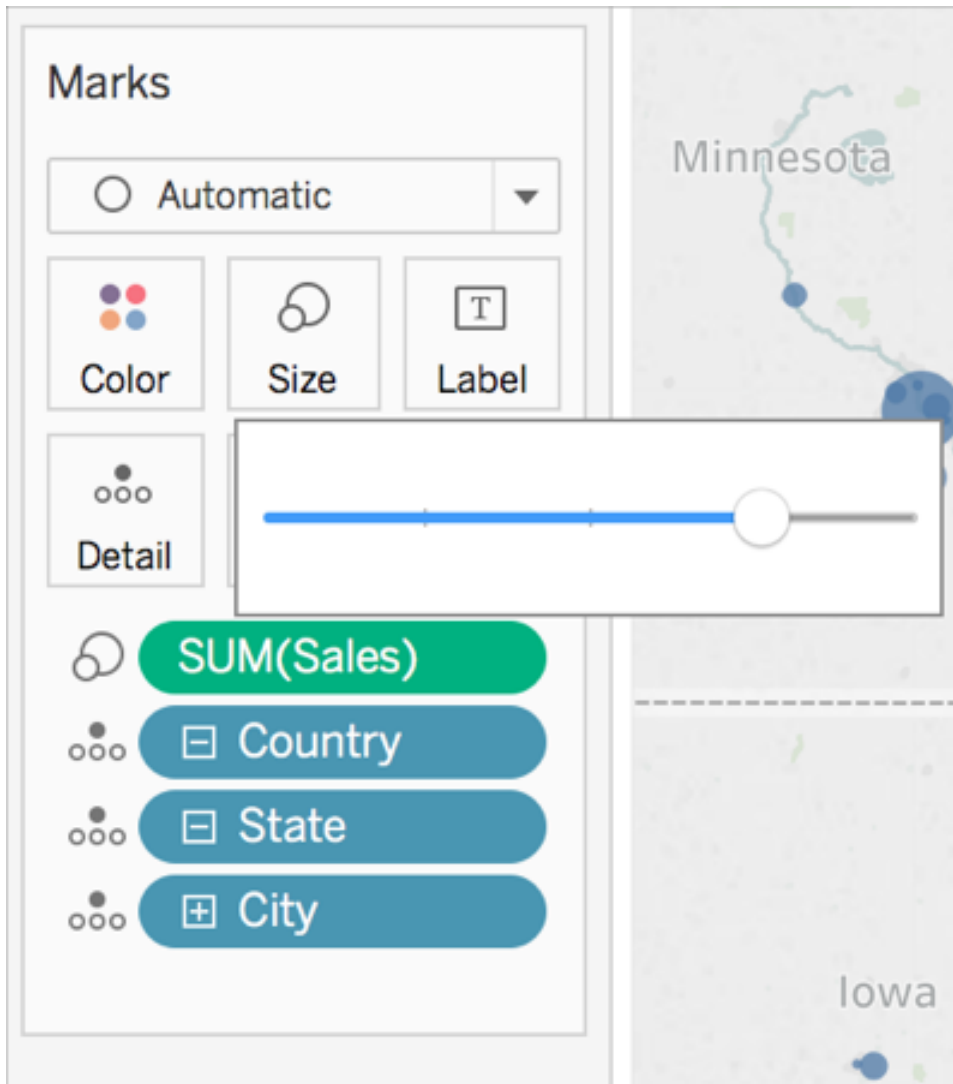

Adjust the size of your data points

You can adjust the size of your data points to compare and contrast them, or make smaller data points easier to see.

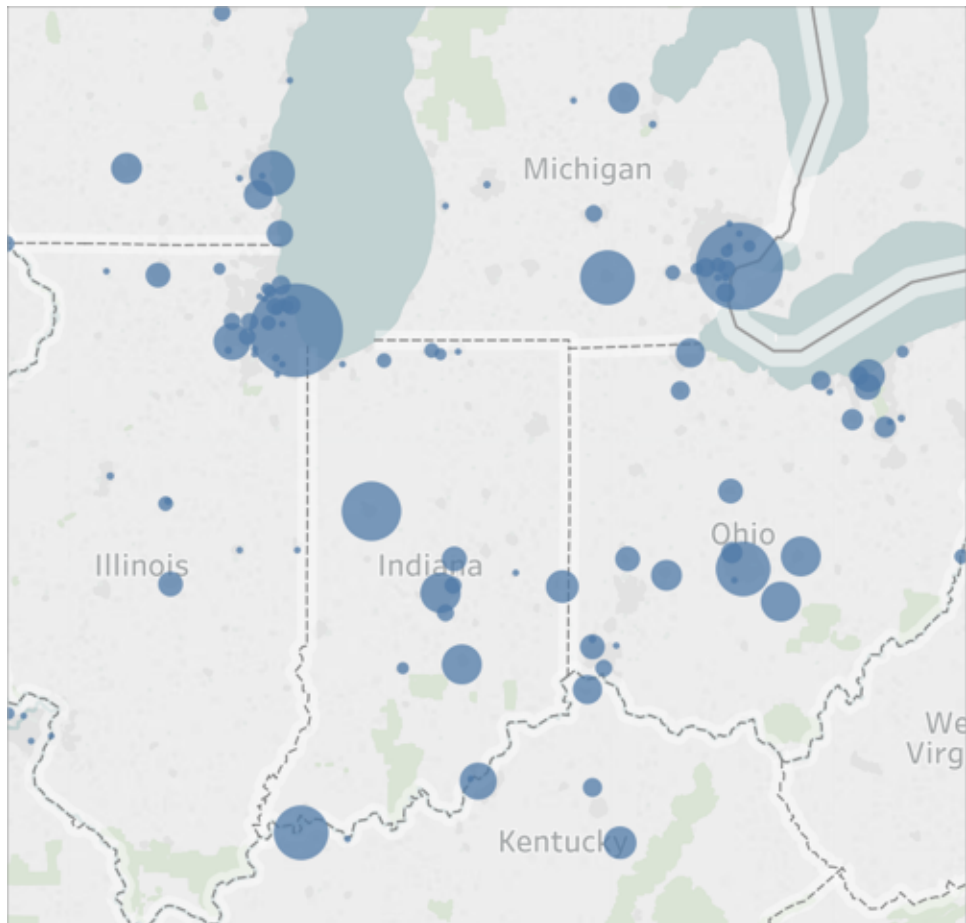

To uniformly adjust the size of your data points:

- On the Marks card, click **Size**, and then adjust the slider to the left or right.

To size your data points quantitatively:

- From Measures, drag a field to **Size** on the Marks card.

Create custom tooltips

You can create custom tooltips to show additional information about your locations when your audience hovers or clicks on them. You can type in your own information to appear for all marks, or add a field that will update with information specific to each mark.

To add a field to a tooltip:

- From the Data pane, drag the field to **Tooltip** on the Marks card.

To edit a tooltip:

1. On the Marks card, click **Tooltip**.
2. In the Edit Tooltip dialog box, format the tooltip how you would like it to appear.

For more information about customising tooltips, see [Format tooltips on page 2985](#) and [Add tooltips to marks on page 1278](#).

[Select Background Maps on page 1871](#)

Create Territories on a Map

When you're analysing data on a map view, you might want to group *existing* locations together to create your own territories or regions, such as sales territories for your organisation.

In Tableau, there are several ways to create territories:

- [Option 1: Select and group locations on a map on the next page](#)
- [Option 2: Create a territory from a geographic field on page 1865](#)

- **Option 3: Geocode a territory field using another geographic field** on page 1865

Option 1: Select and group locations on a map

If you have created a map view, you can select and group locations (marks) on the map to create your territories.

For example, the following map view shows the total sales by postcode for a company with sales across Australia.

The first thing you might be thinking is: That's a lot of postcodes! In fact, there is a mark in this map view for every single 4-digit postcode in Australia, and each of those marks has an aggregation for SUM of Sales. If you're looking for sales information for every single postcode in Australia, then this is the view for you.

However, you might not want to analyse every individual location in your map view. Instead you might have your own areas, regions or territories that you want to analyse as a whole. For example, maybe your organisation splits Australia into five different sales territories, and you want to analyse the total sales for each of them.

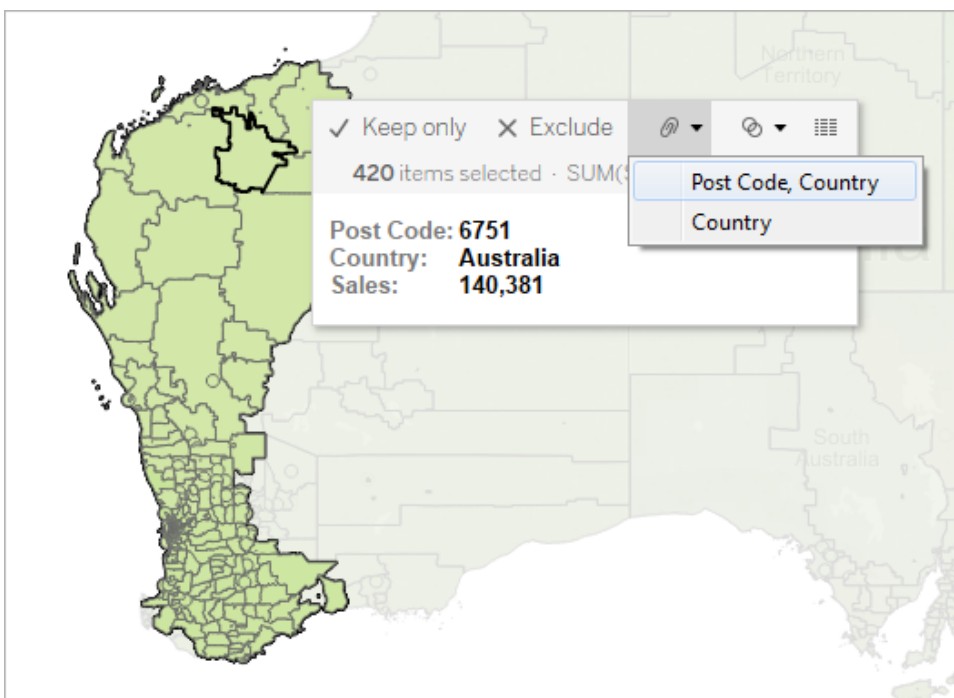

In this case, because you've already created a map view, you can select locations directly on the map and group them to create your own territories. Follow the steps below to learn how.

Step 1: Select locations on the map to group into a territory

On the map view, select the locations (marks) that you want to group into your own territory. For more information about how to select marks, see [Select marks on page 1985](#).

Step 2: Create the first group (your first territory)

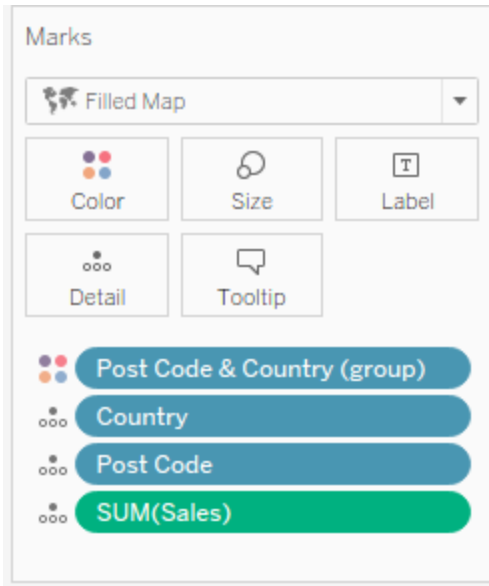

When you select marks in the view, or hover over a selection, a tooltip appears. On that tooltip, click the Group icon, and then select the level of detail you want to group the locations by.

A new group field is added in the **Data** pane with a group icon next to it. To change the locations within the group at any time, right-click the group field in the **Data** pane and select **Edit group**.

The new field is also added to **Colour** on the **Marks** card.

Notice that the marks you selected are now all the same colour.

Step 3: Continue grouping data to add territories

Repeat steps 1 and 2 to create additional territories. Each territory is added as a group within the group field you created in step 2. You can create as many territories as you want.

Step 4: Add the group field to the view

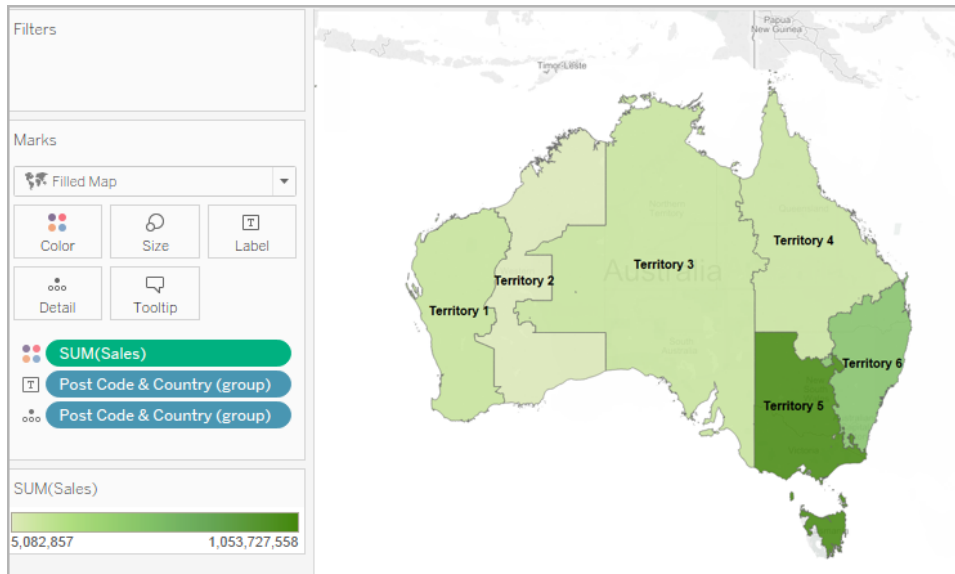

From the **Data** pane, drag the newly created group field to **Detail** on the **Marks** card. Next, to make each territory appear as a single mark, you must also remove the related geographic field (s) from the view.

For example, if you grouped postcodes at the **Postcode, Country** level, you must remove the **Postcode** and **Country** fields from the view.

In the image below, notice that the **Postcode** and **Country** fields are no longer on **Detail** on the **Marks** card because they have been replaced by the **Postcode & Country (group)** field.

In this example, there are five groups within the Postcode & Country (group) field, so five territories appear on the map. Aggregations, such as SUM(Sales), are computed at the level of the territory, rather than separately for each location within the territory.

You can now see the SUM(Sales) for each territory by colour. Territory 5 has the most sales.

Option 2: Create a territory from a geographic field

You can also create territories by creating groups in the **Data** pane.

1. In the **Data** pane, right-click a geographic field (such as City or County) and select **Create > Group**.
2. In the Create Group dialog box, select the locations you want in your first territory and click **Group**. Each group you create represents a territory.
3. Repeat step 2 until you've created all of your territories, and then click **OK**.

The new group field is added to the **Data** pane.

4. From the **Data** pane, drag the newly created group field to **Detail** on the **Marks** card.

You can also drag the field to **Colour** or **Label** on the **Marks** card to help differentiate between each territory.

Change locations in your territory groups

If you want to change the locations in your territory groups at any time, right-click the group field in the **Data** pane and select **Edit group**.

Option 3: Geocode a territory field using another geographic field

If your data source already contains a custom territory field, you can quickly geocode it to make a map in Tableau using an existing geographic field in your data source.

For example, the following data source contains a custom territory field for geographic areas called **Geographic Zone**. It contains the values, **North**, **Central** and **South**.

If you were to bring this field into Tableau by itself, Tableau would not be able to recognise it as geographic data.

However, this data source also contains three geographic fields that Tableau *does* recognise: **Country**, **Region** and **City**.

Each row in this data source contains a value for country, region, city and geographic zone. Therefore, each location is assigned a value from the custom territory field.

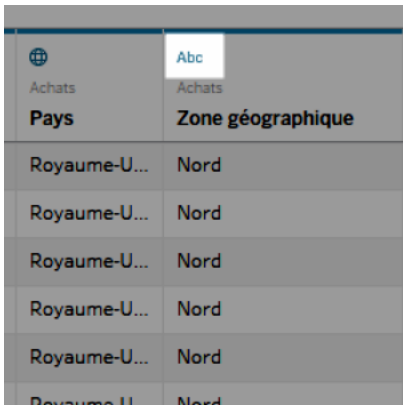

|  Achats Ville |  Achats Région |  Achats Pays |  Achats Zone géographique |
|--|---|---|--|
| Leeds | Angleterre | Royaume-U... | Nord |
| Leeds | Angleterre | Royaume-U... | Nord |
| West Bromwich | Angleterre | Royaume-U... | Nord |
| West Bromwich | Angleterre | Royaume-U... | Nord |
| West Bromwich | Angleterre | Royaume-U... | Nord |
| Le Bouscat | Aquitaine | France | Centre |
| Le Bouscat | Aquitaine | France | Centre |
| Le Bouscat | Aquitaine | France | Centre |

Because the geographic zone field is included in the workbook with other geographic fields that contain locations that Tableau recognises, you can geocode it at the level of detail of one of those fields.

Follow the steps below to geocode a territory field using another geographic field:

Step 1: Assign a geographic role to the territory field

On the data source page, click the data type icon for the custom territory field and select **Geographic Role > Create from**, and then select a level of detail to aggregate the field.

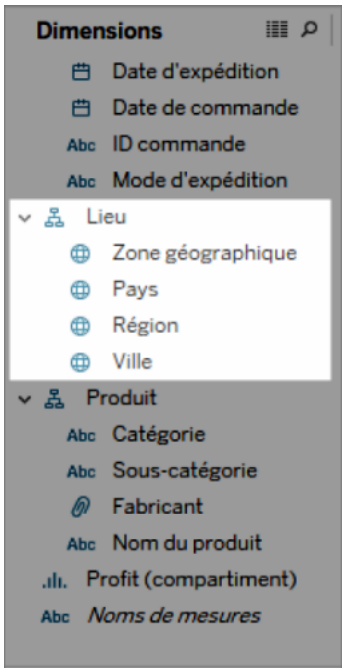

A screenshot of the 'Zone géographique' dropdown menu in Tableau. The menu is open, showing a list of geographic fields. The first two options are 'Royaume-Uni' and 'Nord', both preceded by a globe icon. The rest of the list is truncated with ellipses. The menu is titled 'Zone géographique' and has a search bar at the top.

| Zone géographique |
|-------------------|
| Royaume-Uni |
| Nord |
| Royaume-Uni |
| Nord |
| Royaume-Uni |
| Nord |
| Royaume-Uni |
| Nord |
| Royaume-Uni |
| Nord |

The options you see are based on the available geographic fields in your data source. Choose the level of aggregation you want in the view. If you're unsure how they will affect your view, try several different levels of detail. You can always undo and try again.

After you assign a geographic role to the territory field, it's added to its respective place in the location hierarchy. You can see it in the **Data** pane when you go to any worksheet.

Note: You can also click the data type icon next to the field in the **Data** pane to geocode a territory field using the above procedure.

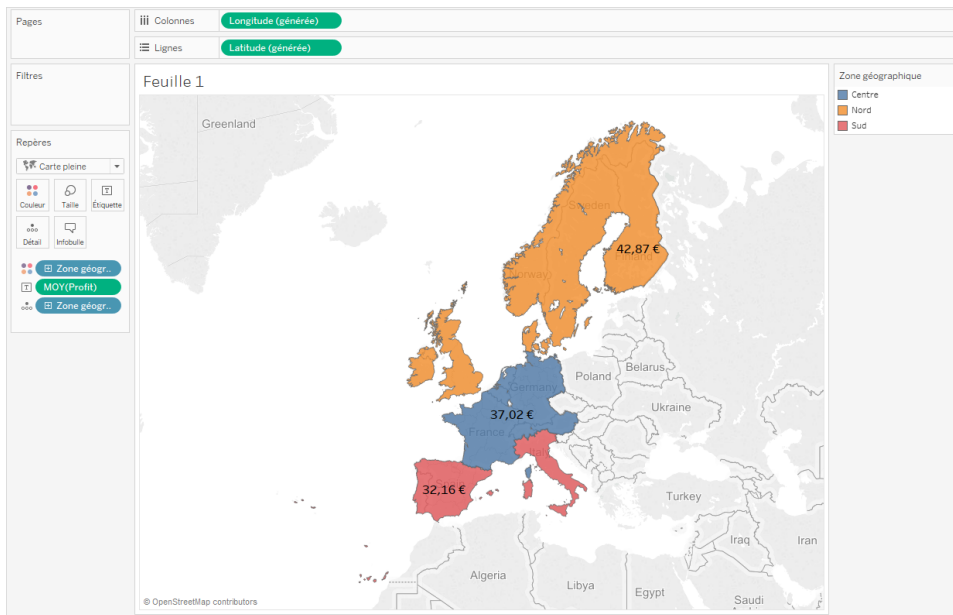

Step 2: Add the territory field to the view

Create a map view and add the newly geocoded territory field to the **Marks** card. You can place it on **Detail**, **Colour**, **Label** or **Tooltip**. Note that fields on **Detail** determine the level of aggregation in the view.

The custom territory field functions similar to your other geographic fields.

In the example below, the custom territory field (Zone géographique) is on **Detail** and **Colour** on the **Marks** card. The average profit is shown for each territory (since the lowest level of detail is the territory field).

If you add another geographic field to **Detail** on the **Marks** card, such as the country field (Pays), the aggregation will update to show information for that level of detail.

Blend custom territory data

If your data source does not contain a territory field, you can blend a territory field with another geographic field in your data source. For more information, see [Blend Geographic Data on page 1709](#). After you have blended your custom territory field with another field, follow the procedure in [Step 1: Assign a geographic role to the custom territory field](#) to geocode your territory field.

Customise How People Interact with your Map

When you create a map view, there are several default ways you can explore and interact with the view. You can zoom in and out of the view, pan, select marks and even search for locations worldwide with map search.

However, sometimes you want to limit some of the ways your audience can interact with your map.

You can customise how your audience interacts with your view in the following ways using the **Map Options** dialog box.

Show a map scale

You can display a scale on your map so that your audience can understand distances between your data points. This scale appears in the bottom-right corner of the view and updates as you zoom in and out of the map.

Note: A map scale will not display on non-Web Mercator projections, such as a WMS using Plate Carrée.

To show a map scale on your map:

1. Select **Map > Map Options**.
2. In the Map Options dialog box that appears in the view, select **Show Map Scale**.
3. Under Units, click the drop-down and select the units of measurement you want.
 - If you want the scale to show measurements in metres and kilometres, select **Metric**.
 - If you want the scale to show measurements in feet and miles, select **US**
 - If you want the units of measurement to be determined by your workbook locale, select **Automatic**.

Note: This setting also determines the units that the Radial tool uses to measure distances. For more information, see [Change the units of measurement on page 1890](#) in the Measure Distances between Data Points and Locations on a Map View topic.

Hide map search

You can hide the map search icon so your audience cannot search for locations in your map view.

To hide the map search icon:

1. Select **Map > Map Options**.
2. In the Map Options dialog box that appears in the view, clear **Show Map Search**.

Note: When you hide the map search icon, you also hide the locate me button for views published on the web. For more information about the locate me button, see [Explore Data in Maps on page 1883](#).

Hide the view toolbar

You can hide the view toolbar in a map view so your audience cannot lock the map in place or zoom the map to all of your data.

To hide the view toolbar:

1. Select **Map > Map Options**.
2. In the Map Options dialog box that appears in the view, clear **Show View Toolbar**.

Note: When you hide the view toolbar, you can still use keyboard shortcuts to zoom in and out of the view, pan and select marks. For more information, see [Shortcuts for selecting and navigating marks on page 3457](#).

Turn off pan and zoom

You can turn off pan and zoom in your map view, as well as in background images, so your audience cannot pan or zoom in or out of the view.

To turn off pan and zoom:

1. Select **Map > Map Options**.
2. In the Map Options dialog box that appears in the view, clear **Allow Pan and Zoom**.

When you turn off pan and zoom, the pan tool and all zoom controls are removed from the view toolbar, and the rectangular tool becomes the default tool. Keyboard shortcuts for zooming in

and out of the view, or panning, no longer work. If the map search icon is not hidden, you can still navigate the view by searching for locations with the map search box.

[Search for Locations in Your Map](#) on page 1885

[Zoom and Pan Views and Select Marks](#) on page 1982

Select Background Maps

Tableau comes installed with a set of background maps that you can access to create map views.

By default, Tableau maps appear with a **Light** background layer provided by Mapbox maps.

The eight background maps that come installed with Tableau are described in this table.

| Background Map | Description |
|------------------|--|
| Light | A subtle map that puts the emphasis on the marks while providing geographic context. All areas without data appear in white or light grey. |
| Normal | A general-purpose map similar to Light. Land areas without data appear in white or light grey, and bodies of water appear in light blue. |
| Dark | A subtle map that puts the emphasis on marks while providing geographic context. The inverse of the Light map; areas without data appear in black or dark grey. |
| Streets | A general-purpose map that includes major road and transport networks. |
| Outdoors | A general-purpose map that includes terrain and natural features, including bodies of water and parks. |
| Satellite | A stylised map with global satellite imagery. |
| Offline | A map that you can use while not connected to the internet. This background map stores the images that make up the map in a cache on your machine for improved performance and offline access. For more information, see the offline maps section. |
| None | A visualisation that displays data between latitude and longitude on a viz type other than a map. |

Change your background map:

In Tableau select **Map > Background Maps** and then select the background map you want to use.

Change your default background map in Tableau Desktop (feature deprecated)

Note: Changing your default background map is a legacy feature that only works with WMS maps on Tableau Desktop. We don't recommend using this feature.

You can choose to set your default background map to a Web Map Service (WMS) or offline map. To learn more about using a WMS map, see [Use Web Map Services \(WMS\) Servers](#).

To specify a default background map:

1. In Tableau Desktop, select **Map > Background Maps > Add WMP Map...** or **Offline**.
2. Select **Map > Background Maps > Set as Default** to set the selected background map to the default.

The background map is automatically saved as a Tableau Map Source (.tmsd) file and placed in the Mapsources folder of your My Tableau

Repository. It's now the default background map for all new worksheets.

Use the Offline background map

You can create and inspect data in a map view offline using the offline background map that comes with Tableau Desktop.

To use the offline background map:

- In Tableau, select **Map > Background Maps > Offline**

Note: The offline background map uses map images stored on your machine. You can find these images in the following locations:

- **On Windows:** `C:\Program Files\Tableau\<Tableau Version>\Local\Maps`
- **On Mac:** `//Applications/<Tableau Version>.app/Contents/install/local/maps`

There are several actions, however, that require Tableau to retrieve a map image that may not be stored. If the new map image isn't stored on your machine, you won't be able to load the map until you reconnect to the online map that comes with Tableau.

You may need to reconnect to the online map if you would like to do one or more of the following:

- **Turn layers on or off** – if you decide to turn on a layer that isn't stored in the cache, Tableau needs to connect to retrieve the necessary information.
- **Zoom in or out** - zooming in or out on a map requires different map images. If the images at the specified zoom level don't exist in the cache, Tableau needs to retrieve the updated maps.
- **Pan** - panning sometimes requires new map images. If you're working offline and don't have the necessary map images and legends stored in the cache, the new images and legends won't load.

To reconnect to the Tableau map:

- On Tableau Desktop, select **Map > Background Maps > Tableau**

Note: If you set a map to Offline and then publish the workbook, the published workbook will still use the Offline stored maps, with all of the functionality and limitations of Offline maps noted earlier.

Use Mapbox Maps

If you have access to Mapbox maps, you can add them to your workbooks or use them to create map views in Tableau Desktop. For a list of country-specific data available, see [Supported Map Data](#).

When you publish a view that uses Mapbox maps to Tableau Server, Tableau Cloud or Tableau Public, your audience can view your data and your Mapbox map without having a Mapbox account.

Starting in Tableau Desktop 2019.2, Mapbox styles Streets, Outdoors and Satellite are available by default in Tableau in the Map Layers pane. For more information on map styles and map layers, see [Customise How Your Map Looks](#) on page 1845.

Add a Mapbox map to your workbook

In Tableau Desktop, you can add a Mapbox map to your workbook and use it as a background map.

After you add a Mapbox map to your workbook, the map is saved with the workbook and available to anyone with whom you share the workbook. You can also save a Mapbox map as a Tableau Map Source (.tms) file that you can share with others so that they can quickly connect to

it and use it in their own workbooks. For more information, see [Save a Map Source on page 1881](#). To add a Mapbox map:

1. In Tableau Desktop, select **Map > Background Maps > Add Mapbox Map**.
2. In the Add Mapbox Map dialog box, add:
 - **Style name:** Enter a name for the Mapbox map. This name can be anything you want, and will appear in the Background maps menu after you add the map.
 - **URL:** Enter a style URL for the Mapbox map you want to add.

This URL contains the style ID for your Mapbox map, your access token, and your username. It might look similar to the following:

```
https://api.mapbox.com/styles/v1/<username>/<styleid>?access_token=<access token>
```

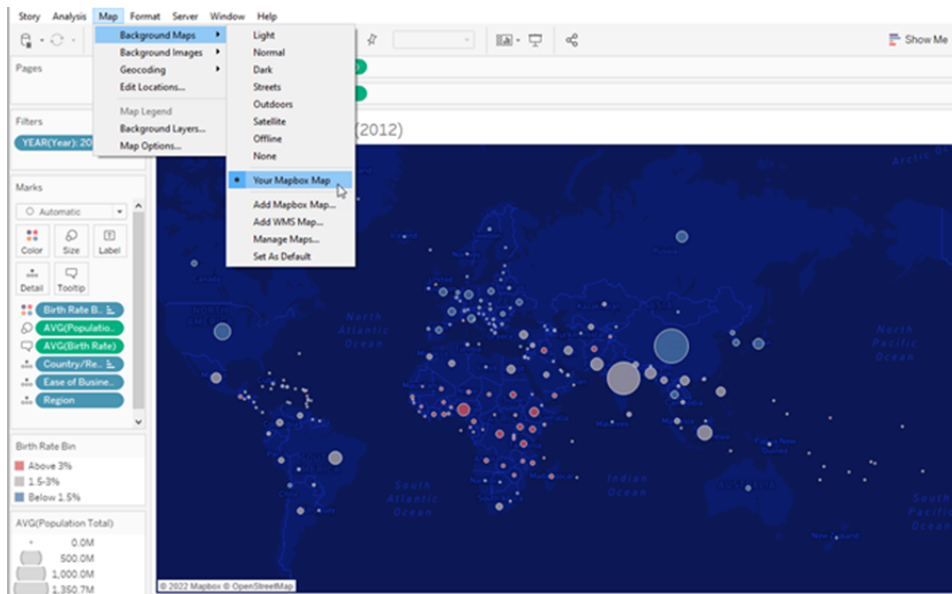

The screenshot shows a dialog box titled "Add Mapbox Map" with a close button (X) in the top right corner. Inside the dialog, there are two text input fields. The first field is labeled "Style Name" and contains the placeholder text "Style Name". The second field is labeled "URL" and contains the placeholder text "URL". Below the "URL" field, there is a link that says "Learn More". At the bottom of the dialog, there are two buttons: "Cancel" and "OK".

For more information about any of the above items, see the [Access Tokens](#), [Maps](#), and [Styles](#) sections of the Mapbox API Help.

3. When finished, click **OK** to exit the Add Mapbox Map dialog box, and then click **Close** to return to the view.

Create a map view using a Mapbox map

To create a map view using a Mapbox map, select **Map > Background Maps**, and then select the Mapbox map you want to use. Next, build the map view. For more information, see [Mapping Concepts in Tableau on page 1661](#).

Add or subtract map layers from the view

When you add a Mapbox Studio map to Tableau, all the map's layers are added, too. Layer groups and single layers in Mapbox Studio will display as individual layers in the Map Layers Pane in Tableau, and will retain the layer configuration set in Mapbox Studio.

If a layer group in Mapbox Studio includes sublayers that are turned off, those sublayers will also be turned off when the map is added to Tableau, and the layer group will appear as a single layer in the Map Layers pane. If the layer group is turned off in Tableau, then back on, all of that layer group's sublayers will be turned on.

Map layers are different from data layers in Tableau. In Tableau, Data Layers are pre-built tiles that include demographic information by various levels, like State and County. Data layers and Mapbox are independent of one another in Tableau. For more information about how data layers work, see [Customise How Your Map Looks](#) on page 1845.

Note: When you add a custom map from Mapbox Studio, Tableau imports the data for every layer, even if the layer is turned off. Your map's performance could be affected if it includes many layers and sublayers. To improve performance, add or remove layers and sublayers in Mapbox Studio before adding your map to Tableau.

[Use Web Map Service \(WMS\) Servers](#) on the next page

[Save a Map Source](#) on page 1881

[Import a Map Source](#) on page 1882

[Select Background Maps](#) on page 1871

[Customise How Your Map Looks](#) on page 1845

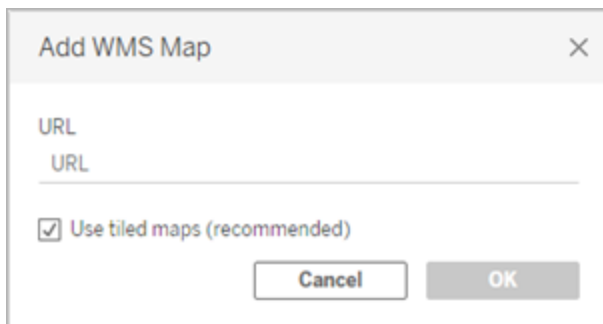

Use Web Map Service (WMS) Servers

In Tableau Desktop, you can connect to map servers with the Web Map Service (WMS) protocol. WMS is a standard protocol for requesting and receiving geographically referenced imagery.

You can connect to any WMS server that supports the WMS 1.0.0, 1.1.0 or 1.1.1 standards.

Connect to a WMS server

1. In Tableau Desktop, select **Map > Background Maps > WMS Servers**.
2. In the Add WMS Servers dialog box, type the URL for the server you want to connect to in Tableau, and then click **OK**.

You can add as many map servers as you want to a workbook. Each WMS server you add appears as a background map in the **Background Maps** menu.

Save a WMS server as a Tableau map source

After you add a WMS server to your workbook, it is saved with the workbook and available to anyone you share the workbook with. You can also save a WMS server as a Tableau Map Source (.tms) file, which you can share with others so they can quickly connect to it and use it in their own workbooks.

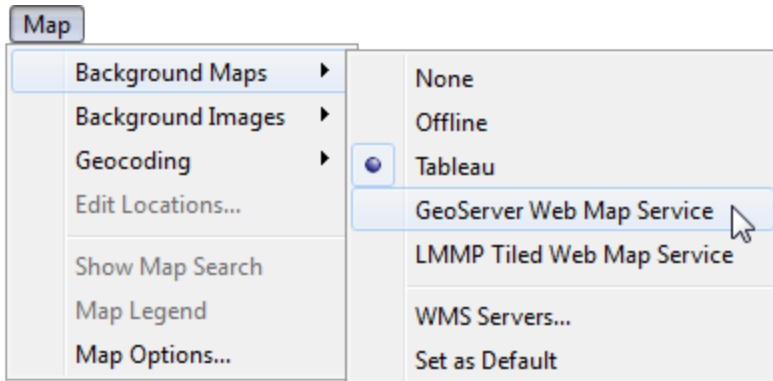

For more information about how to save a map as a Tableau map source, see [Save a Map Source](#) on page 1881.

Use a WMS background map

After you connect to a WMS server, you can create a map view using the WMS background map that Tableau creates.

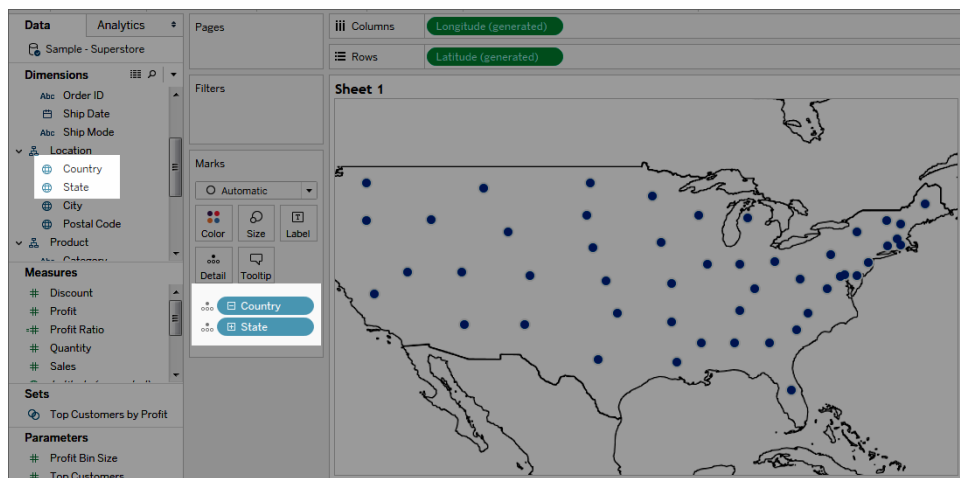

To create a map view using a WMS server:

1. In Tableau Desktop, select **Map > Background Maps**, and then select a WMS background map to use in the view.

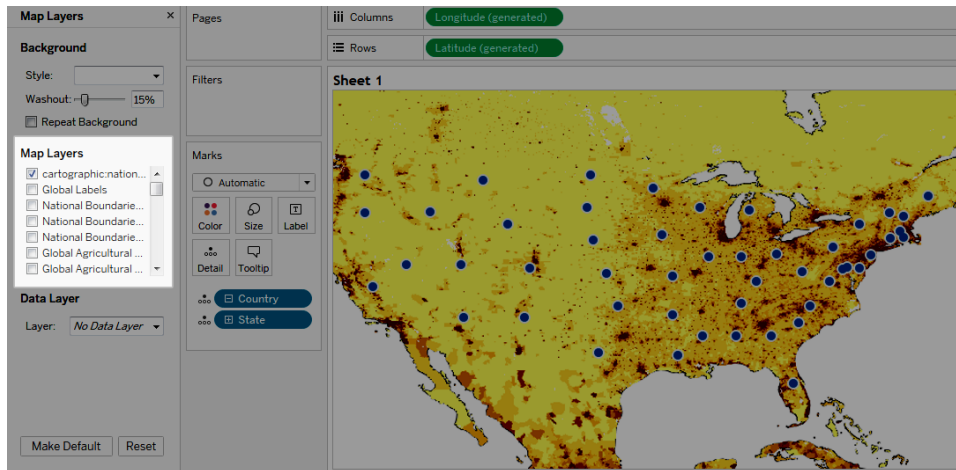

2. Add a geographic field to the view.

For more information, see [Mapping Concepts in Tableau](#) on page 1661.

3. Select **Map > Map Layers**, and then select the map layers you want to show in the view.

For more information, see [Customise How Your Map Looks](#) on page 1845.

Performance considerations

The content, speed, and performance of a WMS server is reliant on the network and WMS provider. If your Internet connection is interrupted or if you're working behind a restrictive firewall, you can use the Offline background map that comes installed with Tableau Desktop to avoid any performance issues while you build your map view. You can switch back to your WMS server at any time.

Note: With the offline background map, you might only be able to access up to four levels of zoom. For more information, see [Select Background Maps](#) on page 1871.

Supported Spatial Reference Systems

Tableau automatically supports the following list of Spatial Reference Systems (SRS) / European Petroleum Survey Group (EPSG) codes. WMS servers must support at least one of the following spatial reference systems to be compatible with Tableau mapping features.

Supported SRS/EPSS Codes in Tableau:

3857 - WGS 84 / Pseudo-Mercator [DEFAULT]

4326 - WGS 84

4269 - NAD83

3824 - TWD97

3889 - IGRS

4019 - Unknown datum based on the GRS 80 ellipsoid

4023 - MOLDREF99

4030 - Unknown datum based upon the WGS 84 ellipsoid

4031 - Unknown datum based upon the GEM 10C ellipsoid

4046 - RGRDC 2005

4075 - SREF98

4081 - REGCAN95

4126 - LKS94 (ETRS89)

4130 - Moznet

4140 - NAD83(CSRS98)

4148 - Hartebeesthoek94

4151 - CHTRF95

4152 - NAD83(HARN)

4163 - Yemen NGN96

4166 - Korean 1995

4167 - NZGD2000

4170 - SIRGAS 1995

4171 - RGF93

4172 - POSGAR

4173 - IRENET95

4176 - Australian Antarctic

4180 - EST97

4189 - REGVEN

4190 - POSGAR 98

[Import a Map Source](#) on the next page

[Select Background Maps](#) on page 1871

[Customise How Your Map Looks](#) on page 1845

Save a Map Source

After you add a Mapbox map or WMS server to your workbook, you can save it as a Tableau map source (.tms).

Saving a Mapbox map or WMS server as a Tableau Map Source allows you to share your map with others so they can quickly import it into their own workbooks and use it to create new map views. For more information about importing a Tableau Map Source into a workbook, see [Import a Map Source](#) on the next page.

1. Select **Map > Background Maps > Map Services**. This opens the Map Services dialog box.
2. Select the map that you want to save as a Tableau map source, and then click **Export**. This opens the Export Connection dialog box.
3. Type a name for the file, choose a location, and then click **Save**.

The Tableau map source includes any default map layer settings you have specified in the workbook. For example, the map source will include any custom set of map layers you have specified to show by default. For more information, see [Customise How Your Map Looks](#) on page 1845 in the Set Map Layers topic.

Note: If you change the default settings for the map layer options, you should export the map again to include the new settings in the Tableau map source file.

See also:

[Select Background Maps](#) on page 1871

Import a Map Source

You can import a Tableau Map Source (.tms) that someone has shared with you into a workbook, and then use it to create custom map views.

1. Select **Map > Background Maps > Manage Maps...**

The Manage Maps dialog box appears.

2. Click **Import**.

The Import Connection dialog box opens.

3. Navigate to the saved Tableau map source file (.tms) that you want to import, select it, and then click **Open**. This closes the Import Connection dialog box and adds the Tableau map source to the list of maps in the Map Services dialog box.

If you want to edit the newly added Tableau map source, select it from the list, and then click **Edit**. Otherwise, click **Close** to return to the view.

You can import as many Tableau map sources as you want into a workbook. Each Tableau map source you add appears as a background map in the **Background Maps** menu and is automatically selected as the default background map until another Tableau map source is imported, until you connect to a WMS server or Mapbox map or until you select to use a different background map.

Note: When you create a new map view, the background map that is selected in the **Background Maps** menu is used to create the map for that view.

[Save a Map Source](#) on the previous page

[Select Background Maps](#) on page 1871

Explore Data in Maps

Tableau maps can help you quickly find locations and analyse data worldwide. There are many ways you can explore and interact with map views. You can zoom in and out, pan and select marks with the view toolbar, and even search for locations worldwide with map search.

If you don't see the view toolbar or the map search icon, or if you can't pan or zoom, it's probably because the workbook author has chosen to customise how others can interact with the view.

The workbook author can choose to hide the view toolbar and the map search icon so they do not appear in the view. Similarly, the workbook author can choose to turn off pan and zoom to control how you interact with the view.

For more information, see [Customise How People Interact with your Map](#).

Select marks, pan and zoom

You can use the view toolbar in the upper left corner of the view to select marks, pan and zoom in and out of a map view. For more information, see [Zoom and Pan Views and Select Marks on page 1982](#).

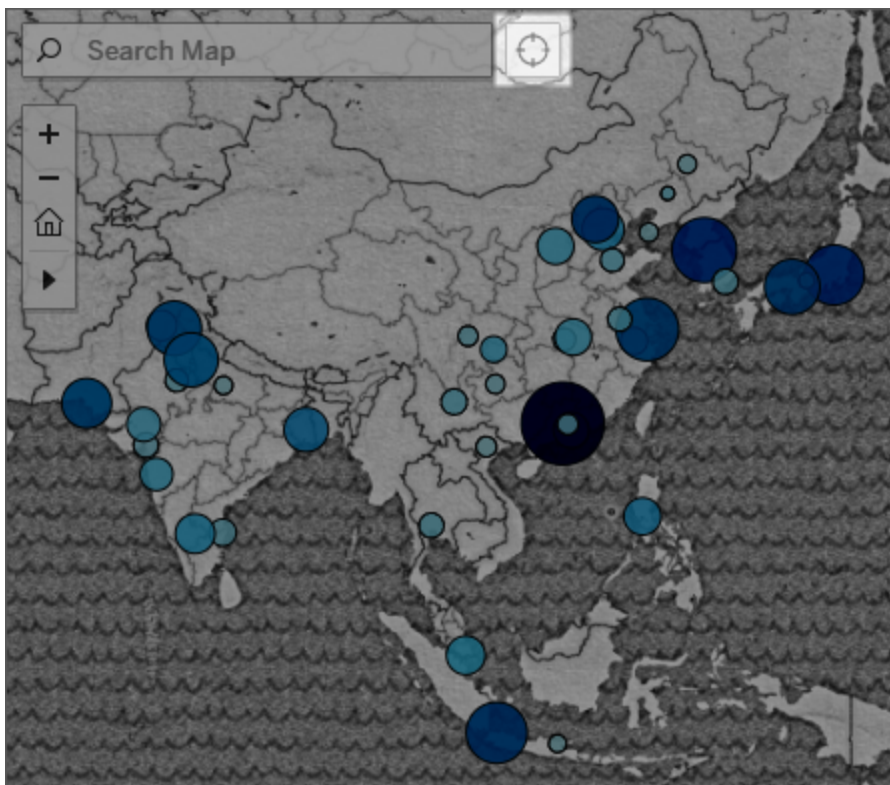

Search for locations

You can use the map search icon  to search for locations in your map view. For more information, see [Set Map Search Options](#).

Find your current location

If you're exploring a map view on Tableau Server or Tableau Cloud, you can use the locate me button to quickly pan and zoom to your current location. To do so, click the map search icon in the top-left corner of the view, and then, next to the search box that appears, click the locate me button.

Note: Finding your current location is not supported on Tableau Desktop.

Note: When you click the locate me button, you might be prompted by your web browser to allow Tableau access to find your current location. If you block access, Tableau will be unable to zoom to your current location.

Return to the initial view

After zooming in and out of the view, or panning to a new location, you can return to the initial view of your map. To do so:

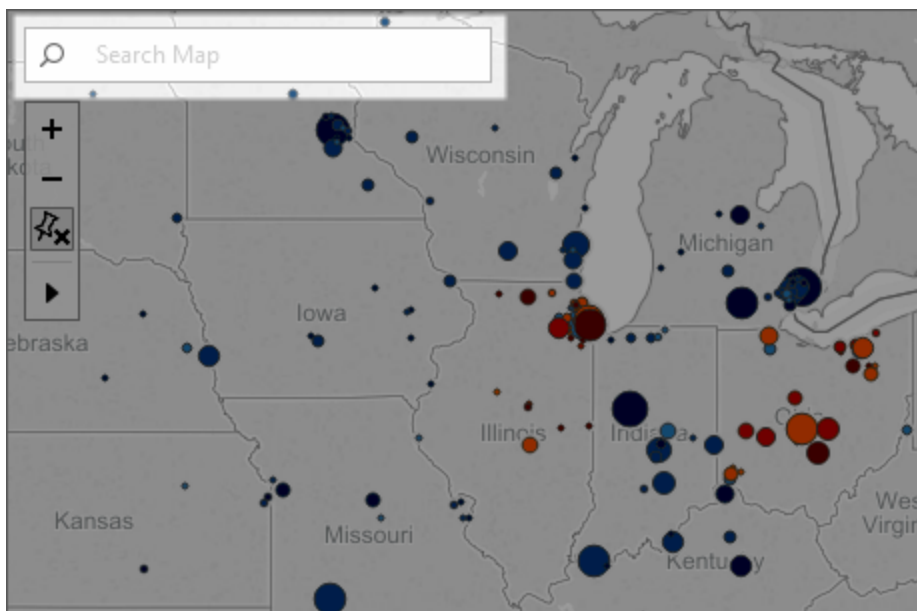

On Tableau Desktop, click the reset axes button  on the view toolbar.

On Tableau Server or Tableau Cloud, click the zoom home button  on the view toolbar.

Search for Locations in Your Map

Map search helps you find locations in a map view so you can quickly explore and inspect data.

The map search icon appears in the top left corner of the view. When you click the search  icon, a search box appears.

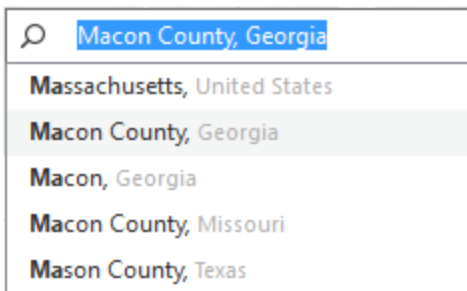

When you begin to type in the search box, map search suggests possible locations that are in your map view. The suggestions are based on location names and text in your data source.

You can search for the following location types:

- Continent
- Country
- State or province
- County
- City
- Post code

Select a location from the list of suggestions to pan and zoom to that location on the map.

Hide Map Search

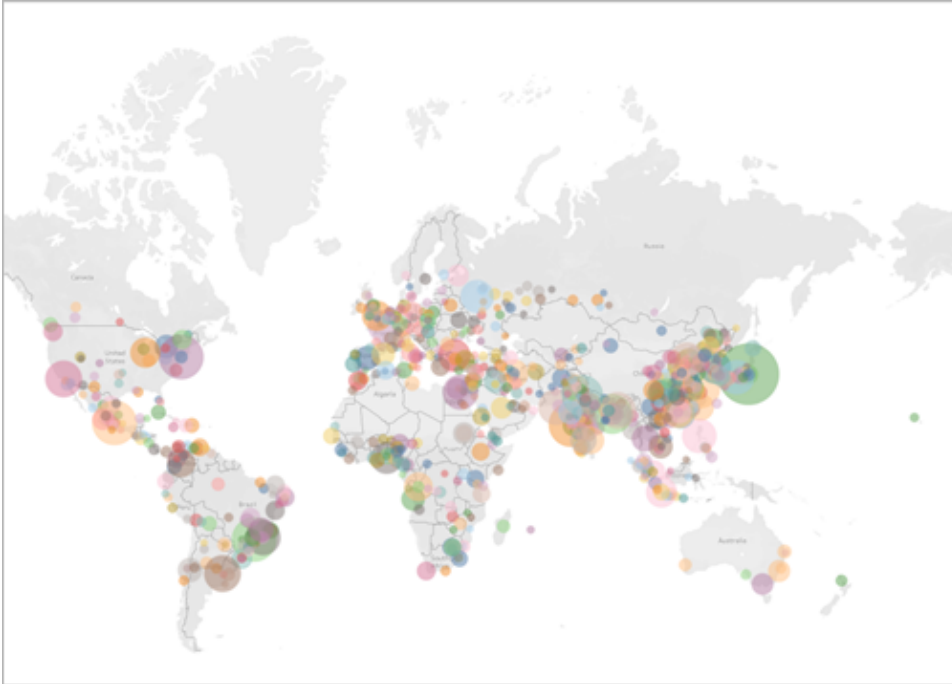

By default, the map search icon appears in the top left corner of the view. When you publish a view to Tableau Server or Tableau Cloud, or share the view through Tableau Reader, the map search icon remains in the view. If you do not want viewers to search for locations in your map view, you can hide the map search icon.

For more information about showing and hiding map search, see [Customise How People Interact with your Map](#) on page 1869.

Measure Distances Between Data Points and Locations on a Map

While exploring data in a map view, you might have questions about how that data relates to its surrounding geography, locations, or landmarks. To answer these types of questions, you can use the Radial tool to measure approximate distances in your map view.

The following view shows the number of earthquakes of magnitude 6.0 and higher that have occurred around the world between January, 1994 and February, 2014.

At a global scale, this view is very powerful, but you or your audience might want to zoom in and explore certain areas more closely. For example, maybe you want to see how many earthquakes have occurred in Indonesia in the past 10 years, specifically within 100 miles of its capital, Jakarta.

To do this, you can use the Radial tool to find all the earthquakes within approximately 100 miles of the capital city.

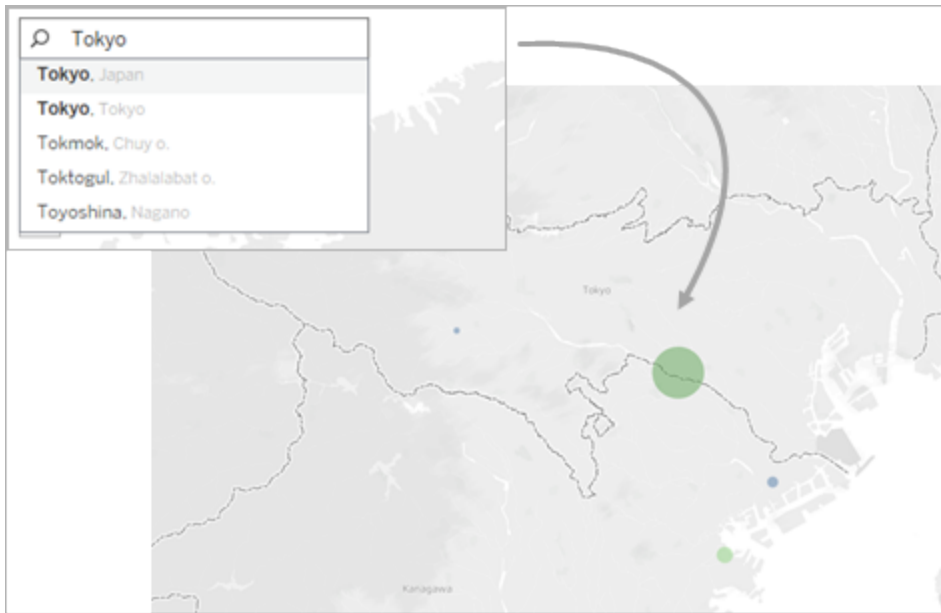

Follow the steps below to learn how to measure distance with the Radial tool.

Step 1: Zoom in to an area or location

The first step to measuring distance in maps with the Radial tool is to zoom in to an area or location in the map view. For more information about how to zoom in and out of the view, see [Zoom and Pan Views and Select Marks on page 1882](#).

You can also use map search to quickly navigate to a location in your map. For more information about how to use map search, see [Search for Locations in Your Map on page 1885](#).

Note: You must zoom in to the map several times before you can measure distance with the Radial tool. The measured distance will not appear if you are zoomed too far out of the map. For more information, see the [Measurement accuracy on page 1890](#) section.

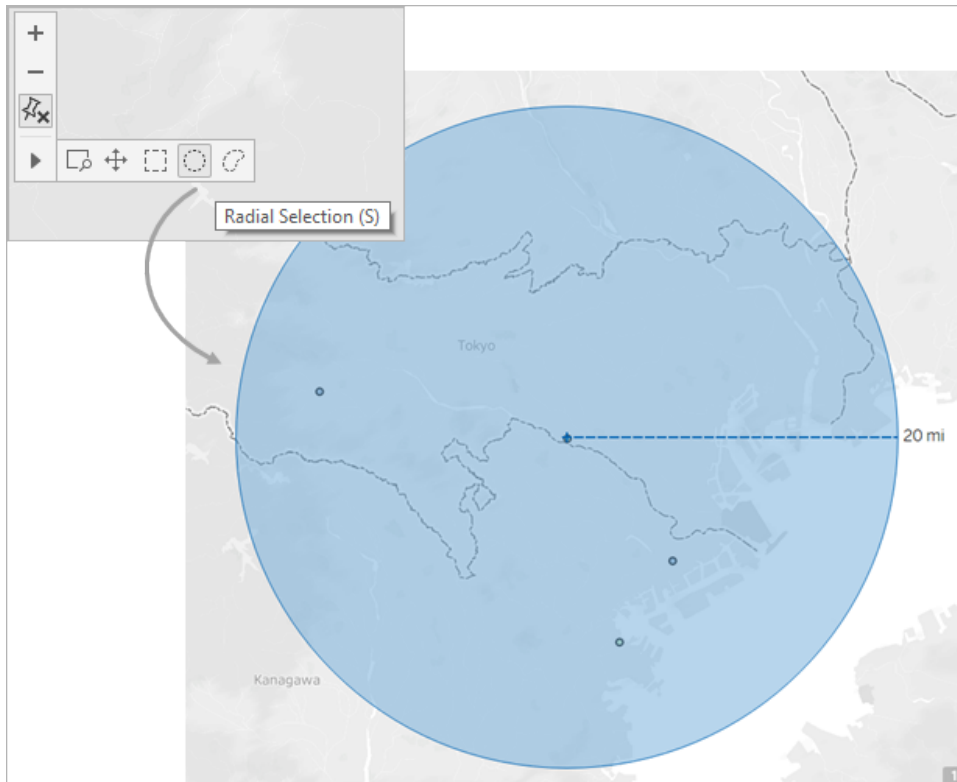

Step 2: Select the Radial tool

After you have zoomed in to a particular area or location in your view, select the Radial tool on the view toolbar, and then click and drag across the view. The measured distance appears to the right of the circle that appears when you drag across the view.

For more information about how to use the Radial tool, see [Select marks on page 1985](#).

Note: If you do not see a measured distance, you must zoom in further to a location or area in the view.

Note: If the view toolbar is hidden, press **S** on your keyboard to use the Radial tool.

As you drag, the Radial tool selects marks that are located within the radius of the circle. In this example, the radius is 100 miles, and it is centred over Jakarta. This means that, according to this data, all of the selected earthquakes (25) have occurred within approximately 100 miles of Jakarta in the past 10 years.

Measurement accuracy

By default, Radial tool measurements have a small margin of error because, in the map projection, distances become exaggerated and stretch as you move away from the equator. This means that the Radial tool can only measure approximate distances.

The Radial tool can measure distance more accurately the closer you are to the equator, and the further you zoom in to the view.

Note: By design, the Radial tool does not display a measured distance when you are zoomed too far out of the view, because the measurement might be inaccurate.

Change the units of measurement

By default, your workbook locale determines which units the Radial tool uses to measure distance. If your workbook locale is set to a country that uses the Imperial system, the Radial tool measures distance in feet and miles. If your workbook locale is set to a country that uses the Metric system, the Radial tool measures distance in metres and kilometres.

You can change the units the Radial tool uses to measure distance for any map view in your workbook.

To do so, select **Map > Map Options**. Next, under **Units**, click the drop-down menu and choose from the following:

- If you want to measure distances in metres and kilometres, select **Metric**.
- If you want to measure distances in feet and miles, select **U.S.**
- If you want the units of measurement to be determined by your workbook locale, select **Automatic**.

The units you choose will be saved with the workbook and will remain if you publish the map view to Tableau Server, Tableau Cloud or Tableau Public.

See also:

[Show a map scale on page 1869](#)

Map Storing

When you create map views using the online map provider, Tableau stores the images that make up the map in a cache. That way, as you continue your analysis you don't have to wait for the maps to be retrieved. In addition, by storing the maps, you can do a certain amount of work when you are offline. For more information, see [Select Background Maps on page 1871](#).

The cache for the maps are stored with your temporary internet files and can be cleared at any time by deleting the temporary files from your browser.

Stored map images and legends remain valid for about thirty days. After that time, Tableau will not use the stored image; instead, it will require you to reconnect and fetch an updated map. This is to prevent the map images from becoming outdated.

Use Background Images in Your Views

Background images are images that you display underneath your data in order to add more context to the marks in the view. A common use of background images is adding custom map images that correspond to a coordinate system in your data.

For example, you might have data that corresponds to several floors in a building. You can use background images to overlay that data on the actual floor plan of the building to give more

context. Other examples of using background images include showing a model of the sea floor, images of web pages for analysing web logs, and even levels from video games to visualize player statistics.

While Tableau allows you to load dynamic maps from the online and offline provider, background images allow you to use your own custom images whether they are special maps or any other image that corresponds to your data.

Add background images to your workbook

When you add a background image to the view, you need to specify a coordinate system by mapping both the X and Y axes to the values of fields in your database. If you are adding a map, the X and Y axes should be longitude and latitude expressed as a decimal. However, you can map the axes to any relevant fields based on your own coordinate system.

To add a background image:

1. Select **Map > Background Images** and then select a data source.

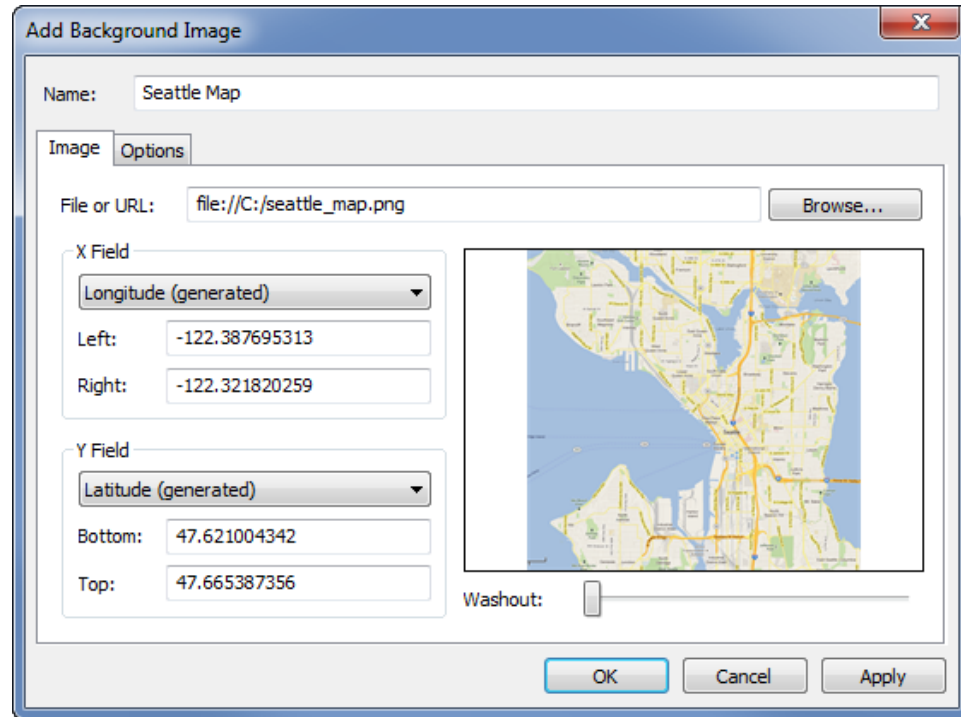

2. In the Background Images dialog box, click **Add Image**.

3. In the Add Background Image dialog box do the following:
- Type a name for the image into the **Name** text box.
 - Click **Browse** to navigate to and select the image you want to add to the background. You can also type a URL to link to an image hosted online.
 - Select the field to map to the x-axis of the image and specify the left and right values. When adding a map, the longitude values should be mapped to the x-axis using decimal values (instead of degrees/minutes/seconds or N/S/E/W).
 - Select the field to map to the y-axis of the image and specify the top and bottom values. When adding a map, the latitude values should be mapped to the y-axis using decimal values (instead of degrees/minutes/seconds or N/S/E/W).
 - You can adjust the intensity of the image using the Washout slider. The farther the

slider moves to the right, the more faded the image will appear behind your data.

4. You can specify the following options using the **Options** tab:

- **Lock Aspect Ratio** - select this option to maintain the original dimensions of the image for any manipulations of the axes. Deselecting this option allows the image's shape to be distorted.
- **Always Show Entire Image** - select this option to avoid cropping the image when the data encompasses only a portion of the image. If you lock both the axis in a view, this option may be negated.
- Add conditions for when to show the image. Refer to [Filter Data from Your Views](#)

on [page 1315](#) to learn more about defining conditions.

5. Click **OK**.

When you add the x and y fields to the Rows and Columns shelf in the view, the background image displays behind the data. If the background image does not display, make sure that you are using the disaggregated measures for the x and y fields. To disaggregate all measures, select **Analysis > Aggregate Measures**. To change each measure individually, right-click the field on the shelf and select **Dimension**. Finally, if you've used the generated Latitude and Longitude fields for the x and y fields, you'll need to disable the built in maps before your background image will display. Select **Map > Background Maps > None** to disable the built-in maps.

In order to make the marks in a view more visible when placed on top of a background image, each mark is surrounded by a solid contrasting colour called a halo. You can turn mark halos off by selecting **Format > Show Mark Halos**.

Build a view with a background image

After you add a background image, you need to build the view in a way that matches the x and y mappings you specified for the image. That is, the fields you specified as x and y must be on the

proper shelves. Follow the steps below to set up the view correctly:

1. Place the field mapped to the x-axis on the **Columns** shelf.

If you are working with maps, the longitude field should be on the columns shelf. It may seem backward at first, however, the fields on the columns shelf determine the values distributed across the x-axis.

2. Place the field mapped to the y-axis on the **Rows** shelf.

If you are working with maps, the latitude field should be on the rows shelf. It may seem backward at first, however, the fields on the rows shelf determine the values distributed across the y-axis.

Edit a background image

After adding a background image, you can always go back and edit the x and y field mappings as well as any of the options on the Options tab.

To edit an image:

1. Select **Map > Background Images**.
2. In the Background Images dialog box, select the image you want to edit and click **Edit** (you can also just double-click the image name).

3. In the Edit Background Image dialog box, make the changes to the image and click **OK**.

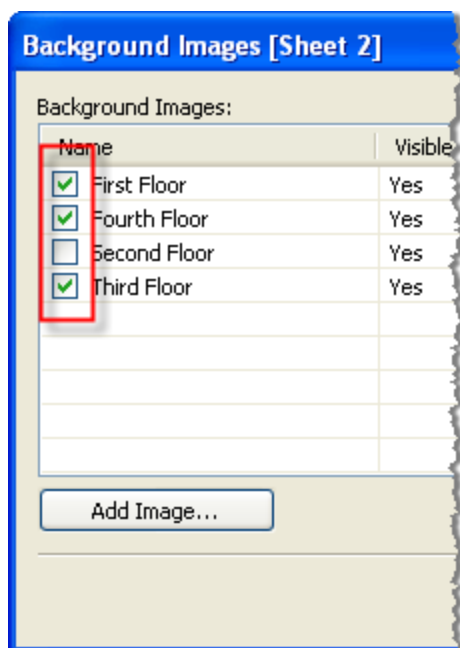

Enable or disable background images

Although you can add multiple images to a workbook, you may want to only use a subset of the images for a particular set of worksheets. For example, you may want to show a map of the entire United States of America on one view, and maps of individual states in other views.

Use the check boxes in the Background Images dialog box to enable and disable the images for the current worksheet. You can show several images by enabling multiple images on a single worksheet. For example, you may have several images that you want to tile in the background to make a larger background image.

To enable or disable a background image:

1. Select **Map > Background Images**.
2. In the Background Images dialog box, select the check boxes next to the images you want enabled.

3. Click **OK**.

Add show and hide conditions to background images

When you add a background image and enable it, the image will be shown automatically on any worksheet that has the required fields used in the view. To avoid showing an image on all the worksheets, you can specify show/hide conditions. Show/Hide conditions are conditional statements that you define to specify when to show the image. For example, you may have a floor

plan image for a multi-story building. While each image is associated with the same coordinates (the corners of the building), you do not want to show the first floor map when looking at the third floor information. In this case, you can specify a condition to only show the first floor image when the Floor field is equal to one.

To specify show/hide conditions:

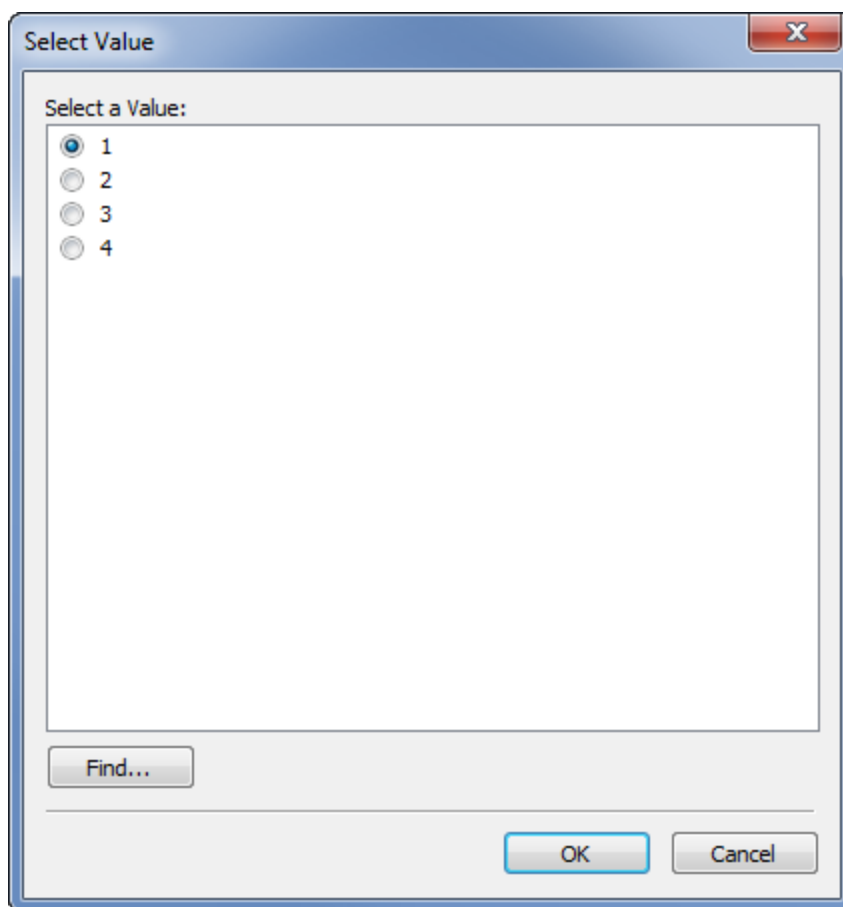

1. Select **Map > Background Images** and then select a data source.
2. In the Background Images dialog box, select the image you want to add a condition to and click **Edit**.
3. In the subsequent dialog box, select the **Options** tab.
4. Click the **Add** button at the bottom of the dialog box.

5. Select a field to base the condition on. In the example described above, the field is Floor.

6. Specify when you want to show the image by selecting a value of the field. For this example, one is selected.

7. Click **OK**.

A condition statement is added to the image. In the building floor plan example, the condition statement is Only show the image when Floor is equal to One.

8. Click **OK** twice to close the Background Image dialog boxes and apply the changes.

When you add multiple conditions, the background image will only show when all conditions are met. For example, if a background image has two conditions on Property Name and Floor, it will only show when Property is Greenwood Estates and Floor is 3.

Remove a background image

When you no longer want to use a background image you can either disable it or remove it, making it unavailable to all worksheets.

To remove an image:

1. Select **Map > Background Images**.
2. In the Background Images dialog box, select the image you want to remove and click **Remove**.

3. Click **OK**.

- [Maps and Geographic Data Analysis in Tableau](#) on page 1635

Add Images of Google Maps and OpenStreetMap as Background Images in Tableau

You can add images of Google Maps or OpenStreetMap as static background images in Tableau, and then plot data points onto them. To plot data points onto a background image of GoogleMaps or OpenStreetMap, you need both latitude and longitude coordinates of your data.

This topic describes how to obtain latitude and longitude coordinates for Google Maps and OpenStreetMap, as well as how to plot them on a background image in Tableau.

Step 1: Find your map coordinates

Follow the steps below to find map coordinates for Google Maps or OpenStreetMaps.

Option 1: Map data points onto Google Maps

1. Go to <http://www.gorissen.info/Pierre/maps/googleMapLocation.php> and locate the geographic area that you want to plot data points.
2. Once you have located the area you want, hover over the easternmost side of the area and write down the longitude coordinate (displayed in the bottom right corner of the map). Do the same for the westernmost side of the area.
3. Hover over the northernmost part of the area and write down latitude coordinate. Do the same for the southernmost part of the area.

You should now have two latitude coordinates (one top and one bottom) and two longitude coordinates (one east and one west).

You will use these coordinates to define the scale of your background image in Tableau, and to ensure that you can plot data points onto the image using latitude and longitude coordinates.

4. Take a screenshot of your map and save it to your computer.
5. Follow the steps in "[Step 2: Add your map image as a background image below](#)" to add the image as a background image in Tableau.

Option 2: Map data points onto a map in OpenStreetMap

1. Go to <http://www.openstreetmap.org> and zoom in on the geographic area you want to plot data points.
2. On the top menu bar, click **Export**.

The Export pane provides the latitude and longitude coordinates of the area in the view. You can edit these coordinates to select a different area.
3. Write down the coordinates displayed in the box.
4. On the right side of the page, click the share icon, and then click the **Download** button.
5. Follow the steps listed in "[Step 2: Add your map image as a background image below](#)" to add the image as a background image in Tableau.

Step 2: Add your map image as a background image

1. Open Tableau Desktop and connect to the data you want to plot on the map image.
2. Select **Maps > Background Images**, and select the data source you want to use to plot data on your background image.
3. In the Background Images dialog box, click **Add Image**.
4. In the Add Background Image dialog box, click **Browse**, and then navigate to the location of the map image you created earlier in Step 1: Find your map coordinates.
5. In the Add Background Image dialog box, do the following:
 - For the **X Field** drop-down list, select **Longitude (generated)**.
 - In the **Left** box, type the easternmost longitude in your map image.
 - In the **Right** box, type the westernmost longitude in your map image.
 - For the **Y Field** drop-down list, select **Latitude (generated)**.
 - In the **Bottom** box, type the southernmost latitude in your map image.
 - In the **Top** box, type the northernmost latitude in your map image.

6. When finished, click **OK** in both the Add Background Image and Background Images dialog boxes.
7. Select **Maps>Background Maps>None**.

The background image shows up only if there is no background map.
8. From the Measures pane, drag **Latitude (generated)** to the **Rowss**shelf and **Longitude (generated)** to the **Columnss**shelf.

Your background image should appear in the view. If it does not, or if it appears at the wrong scale, complete the following steps to fix your axes.
9. In the view, double-click the Y axis.
10. In the Edit Axis dialog box, under Range, select **Fixed**.
11. In the **Fixed start** text box, enter the bottom most longitude in your map image.
12. In the **Fixed end** text box, enter the top most longitude in your map image.
13. Click **OK**.
14. Repeat steps 9 - 13 for the other axis.

To learn how to plot your data on the background image, see steps 1, 2, and 4 in [Find Background Image Coordinates](#) below.

[Select Background Maps](#) on page 1871

Find Background Image Coordinates

In many scenarios, you might want to map your data onto a background image instead of on a Tableau map. This article explains how to plot data points on a background image.

There are several steps in this process:

1. Create a table in your data source for X and Y coordinates.
2. Connect to your data source in Tableau Desktop and join the coordinate table with the rest of your data.
3. Import your background image and build the view.
4. Annotate points on the background image.
5. Add coordinates to the coordinates table in your data source.
6. Refresh your data source in Tableau.

Step 1: Create the coordinate table

Create a table in your data source that contains columns to identify a unique mark. In this example, there are three columns:

- The first column holds the unique identifier for each mark.
- The other two columns are for the X and Y coordinates.

After you create your columns, you join the new coordinate table to the original data source. The join is based on the unique identifier used in both the original data source and the coordinate table (the identifier that represents a single mark).

1. Select a scale that is appropriate for your background image. If the image is wider than it is tall, use X: 0-100 and Y: 0-50.
2. For this example, open the Sample Superstore Excel file from your Tableau repository in Excel and select a new sheet tab.
3. On the new tab, put a single row in a table that contains one of the unique identifiers and the X and Y end points you selected for your two scales.

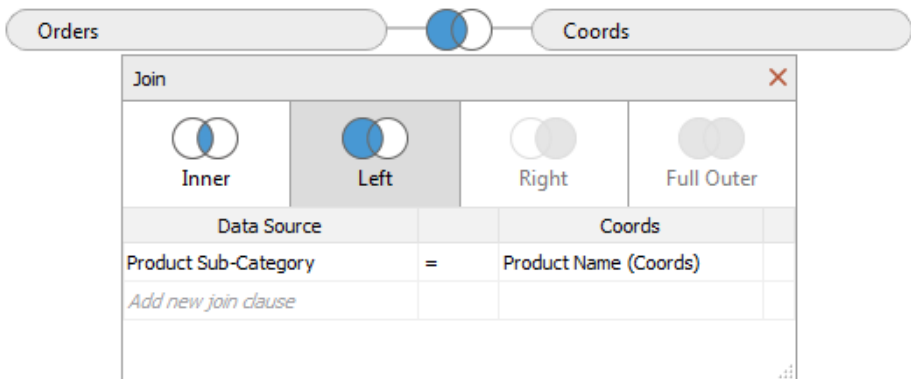

In this case, **Product Sub-category** is a column in Sample Superstore, and one of its members is **Tables**. The **X** endpoint is **100**, and the **Y** endpoint is **50** because that is the scale for the background image.

| | A | B | C | D |
|---|----------------------|-----|----|---|
| 1 | Product Sub-category | X | Y | |
| 2 | Tables | 100 | 50 | |
| 3 | | | | |
| 4 | | | | |
| 5 | | | | |

4. Change the tab name to **Coords** and save the file.

Step 2: Connect to the coordinate table

1. In a new Tableau workbook, select **Connect to Data**.
2. In the **Connect to Data** dialog box, select **Microsoft Excel** and then click **Next**.
3. On the data source page, do the following:
 - Drag the Orders sheet to the Join area.
 - Drag the Coords sheet to the Join area.
 - Click the join icon to modify the existing join.
 - In the Join dialog box that opens, select **Left**, and then select **Product Sub-Category** for the **Data Source** column, and **Product Name (Coords)** for the **Coords** column.

4. Close the Join dialog box, and then select the sheet tab to go to a worksheet.

Step 3: Import the background image

1. In the new worksheet, select **Maps > Background Images, Sample - Superstore**. This opens the Background Images dialog box.

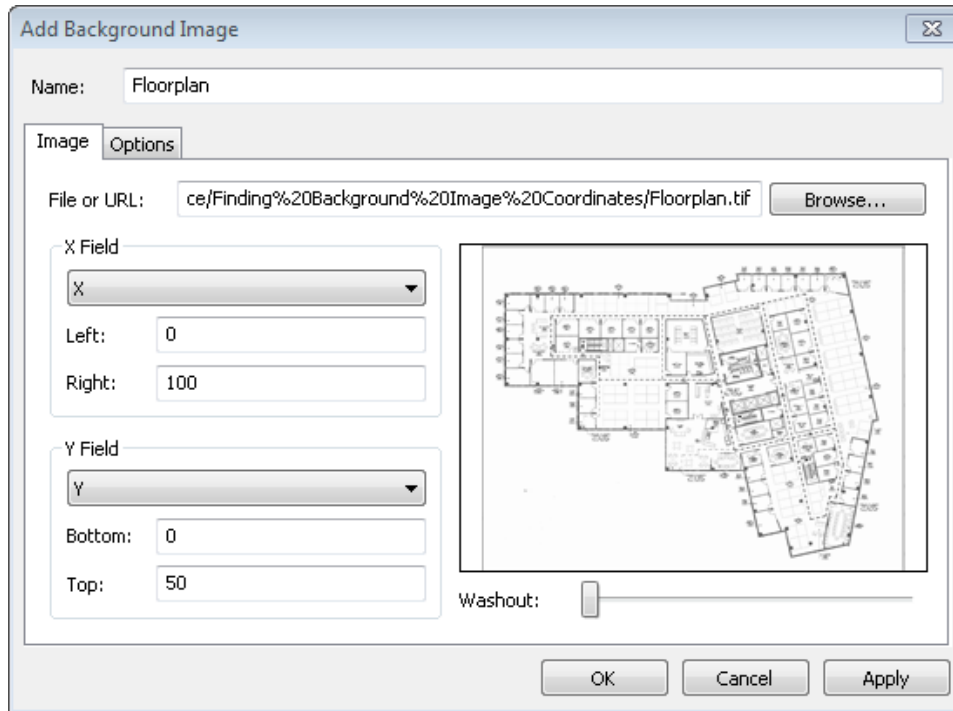

2. In the **Background Images** dialog box, click **Add Image**.
3. In the **Add Background Image** dialog box, browse to and select the file.
4. For **X Field**, select **X** in the list.

Note: If you do not see the X field in the list, it means that you need to change the X field to be a continuous number.

To change the field to be a number, right-click the **X** field in the Data pane, and select **Change Data Type > Number (Whole)**. To convert the field to be continuous, right-click the **X** field in the Data pane, and select **Convert to Continuous**.

Repeat these steps for the **Y** field.

5. In the **Right** text box, type **100** (100 is the number you used in the coordinate table).
6. For **Y Field**, select **Y** in the list.
7. In the **Top** text box, type **50** (50 is the number you used in the coordinate table). Be sure to type in the correct text box.

8. Click **OK**, and then click **OK** in the **Background Images** dialog box. (Disregard the **Valid** setting of **No** in the **Background Images** dialog box.)

Step 4: Find the coordinates

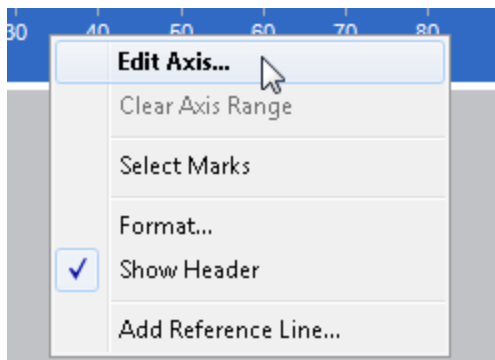

1. From the Data pane, drag **X** to the **Columns** shelf and **Y** to the **Rows** shelf.
2. On the **Columns** shelf, right-click **X** and select **Dimension**.
3. On the **Rows** shelf, right-click **Y** and select **Dimension**.

Note: This step is only necessary if the X and Y fields were brought in to Tableau as Measures.

The background image appears in the view.

4. Right-click the X axis and select **Edit Axis**.

5. In the **Edit Axis** dialog box, select **Fixed**, and then in the **Start** text box, type **0** and in the **End** text box, type **100**.
6. Click **OK**.
7. Right-click the Y axis and select **Edit Axis**.

8. In the **Edit Axis** dialog box, select **Fixed**, and then in the **Start** text box, type **0** and in the **End** text box, type **50**.
9. Click **OK**.

Now the axes start at zero.

10. Right-click anywhere on the image where you want to find the coordinates, and select **Annotate > Point**.

For more information about annotating marks or points in the view, see the [Add Annotations on page 1369](#) topic in the Tableau Help.

11. In the **Edit Annotation** dialog box, click **OK**.
12. Repeat steps 10 and 11 for each point you want to annotate.

The coordinates appear on the background image as a callout. You can move a callout to a location where it shows up better; just click and drag it. You can also resize the callout by dragging one of the size handles. You can move a coordinate point to a new location by clicking and dragging the arrowhead; the coordinates in the callout change to reflect the new location.

- 1911

| | A | B | C | D |
|---|----------------------|-------|-------|---|
| 1 | Product Sub-category | X | Y | |
| 2 | Tables | 100 | 50 | |
| 3 | Labels | 17.16 | 41.42 | |
| 4 | Paper | 9.00 | 29.81 | |
| 5 | Bookcases | 23.95 | 23.21 | |
| 6 | Office machines | 32.27 | 22.77 | |
| 7 | | | | |
| 8 | | | | |

14. In Tableau, select **Data > Sample - Superstore > Refresh**.

The refreshed view displays marks at the coordinate locations.

If you don't want to continue to display the callouts, you can select and remove them on the background image.

Add Viz Extensions to Your Worksheet

Viz Extensions are web applications that can extend the native visual capabilities of Tableau. Viz Extensions give users the ability to interact with custom viz types on their worksheets.

Tableau Extensions expand worksheet functionality with the help of web applications created by Tableau, Tableau Partners and third-party developers in our community. If you're a developer and want to create your own extensions, see the [Tableau Extensions API](#) documentation on GitHub.

A Viz Extension is similar to a [dashboard extension](#) in that it's a web application that is hosted on the [Tableau Exchange](#). It's different from a dashboard extension in that you add it to a worksheet while building the viz, rather than adding it to a dashboard as an object.

Add a Viz Extension to a worksheet

There are two ways to add a Viz Extension to your worksheet via the Marks card. If you've already downloaded it through the Tableau Exchange, you can add it as a local file. Or you can download it from the Tableau Exchange in the flow of authoring your Viz.

Add a Viz Extension as a local file

If you've already selected and downloaded a Viz Extension from the Tableau Exchange, it will be saved on your computer as a .trex file.

1. Open a Tableau workbook and connect to your data source.
2. In a worksheet, on the Marks card, expand the Mark type drop-down menu.
3. Under Viz Extensions, select **Add Extension**.

4. In the Add an Extension dialog box that appears, select **Access Local Viz Extensions**.

5. Navigate to and open the saved .trex file.
6. If prompted, allow or deny the Viz Extension access to data in the workbook.

The Viz Extension loads in the view, and the mark type changes to the name of the Viz Extension.

Add a Viz Extension while authoring your viz

If you haven't already selected and downloaded a Viz Extension, you can do so in the flow of authoring a viz.

1. Open a Tableau workbook and connect to your data source.
2. In a worksheet, on the Marks card, expand the Mark type drop-down menu.
3. Under Viz Extensions, select **Add Extension**.

4. In the Add an Extension dialog box that appears, select the Viz Extension that you'd like to load onto your worksheet. In this example, we're loading a Sankey diagram built by Tableau.

5. If prompted, allow or deny the Viz Extension access to data in the workbook. For more information, see [Data security, Network-enabled and Sandboxed extensions](#).
6. Select **Open**.

The Viz Extension loads in the view, and the mark type changes to the name of the Viz Extension.

Use the Marks card to encode your marks

Drag fields onto the encoding boxes on the Marks card to build the viz. The Mark encoding boxes and formatting options are determined by the developer. Check the extension description on the Tableau Exchange for information on the Viz Extension you're loading.

To follow along with the Sankey extension, follow these encoding instructions:

The Sankey extension is built to use extension-specific encoding for **Levels** and **Links**. These can be used with the built-in Marks encoding boxes Tooltip and Details to build the Sankey on the worksheet.

- **Level** - Sankey levels represent the categorical dimensions that are related by the Sankey. In this extension, you can include up to 5 discrete dimensions as Levels.
- **Link** - Sankey links connect the categories across the Sankey. This encoding will size the width of each link based on a numeric measure.

Ensure that extensions are allowed on Tableau Cloud

If you're not able to add a Viz Extension, check to see if extensions have been allowed on your site. A Tableau administrator must allow extensions to run on a site and add Network-enabled extensions to an allow list. Administrators should only allow extensions that you have tested and trust.

To learn more about adding Network-enabled extensions to an allow list, see [Tableau Help: Change the default settings for a site](#).

Data security, Network-enabled and Sandboxed extensions

Extensions are web applications that come in two forms:

- *Network-enabled extensions* run on web servers located outside of your local network.
- *Sandboxed extensions* run in a protected environment without access to any other resource or service on the web.

Before adding a Network-enabled extension, be certain that you trust the website that hosts it. By default, extensions use the HTTPS protocol, which guarantees an encrypted channel for sending and receiving data, and ensures some privacy and security.

For more information about data security when using extensions, see [Extension Security - Best Practices for Deployment](#).

Allow or deny data access to a Network-enabled extension

Depending on how an extension is designed, it can access either visible data in a view, or full underlying data, table and field names from data sources, and information about data source connections. When you add an extension, you're given an opportunity to allow or deny the extension to run and access this data.

Reset data access for your extension

If you need to reset the data access permissions for your extension, you can simply reload the extension by selecting Add Extension on the Marks card and then re-adding the extension to the worksheet. These steps kick off the process to allow or deny access to the extension.

Ensure that JavaScript is enabled in Tableau Desktop

Viz extensions interact with data using the Tableau Extensions API library, a JavaScript library. If you want to use extensions, be sure that JavaScript is enabled in the security settings:

Choose **Help > Settings and Performance > Set Dashboard Web View Security > Enable JavaScript**.

Get support for Viz Extensions

To get help for an extension, you'll need to contact the developer or company who created it through the Tableau Exchange.

Note: Tableau doesn't provide support for extensions or for other programs that interface with the Extensions API. However, you can submit questions and ask for help in the [Tableau developer community](#).

Analyse Data

This section describes the various ways you can perform more advanced analysis in Tableau. Read the following articles for information on how to create calculated fields, find clusters in data, calculate percentages and use various tools to explore and inspect data.

Discover Insights Faster with Explain Data

Explain Data in the Data Guide helps you to inspect, uncover and dig deeper into the marks in a viz as you explore your data. You can use Explain Data to analyse dashboards, sheets or selected marks for possible outliers and correlations in the underlying data. Explain Data builds statistical models and proposes possible explanations for individual marks in a viz, including potentially related data from the data source that isn't used in the current view.

For information on running Explain Data and exploring explanations, see [Get Started with Explain Data](#) on the next page.

Note: This topic describes how Explain Data works in Tableau 2021.2 and later versions. If you have a previous version of Tableau, read this topic in [version 2021.1 of Explain Data help](#).

As you build different views, use Explain Data as a jumping-off point to help you explore your data more deeply and ask better questions. For more information, see [How Explain Data helps to augment your analysis](#) on the next page. For information on what characteristics make a data source more interesting for use with Explain Data, see [Requirements and Considerations for Using Explain Data](#) on page 1949.

Access to Explain Data

Explain Data is enabled by default at the site level. Server administrators (Tableau Server) and site administrators (Tableau Cloud) can control whether Explain Data is available for a site. For more information, see [Disable or Enable Explain Data for a Site](#) on page 1968.

Authors who can edit workbooks and have the Run Explain Data permission capability for a workbook can run Explain Data in editing mode. All users with the Run Explain Data capability can run Explain Data in viewing mode in Tableau Cloud and Tableau Server.

When allowed by site administrators, explanations can be shared in viewing mode via email or Slack with other Tableau Cloud and Tableau Server users. For more information, see [Configure Tableau to allow users to share explanations via email and Slack on page 1956](#).

Authors can use Explain Data Settings to control which explanation types are displayed in the Data Guide pane.

For information on controlling access to Explain Data, explanation types and fields, see [Control Access to Explain Data on page 1951](#).

How Explain Data helps to augment your analysis

Explain Data is a tool that uncovers and describes relationships in your data. It can't tell you what is causing the relationships or how to interpret the data. **You are the expert on your data.** Your domain knowledge and intuition are key in helping you decide what characteristics might be interesting to explore further using different views. For related information, see [How Explain Data Works on page 1957](#) and [Requirements and Considerations for Using Explain Data on page 1949](#).

For more information on how Explain Data works and how to use Explain Data to augment your analysis, see these Tableau Conference presentations:

- [From Analyst to Statistician: Explain Data in Practice \(1 hour\)](#)
- [Leveraging Explain Data \(45 minutes\)](#)

Get Started with Explain Data

Use Explain Data in your flow of analysis as you are exploring the marks in a viz. Explain Data runs automatically when the Data Guide pane is open and updates based on the current selection (dashboard, sheet or mark).

Use Explain Data

- [Run Explain Data on a dashboard, sheet or mark on the facing page](#)
- [Drill into explanations on page 1924](#)
- [View analysed fields on page 1924](#)

Author Workbooks and Control Access

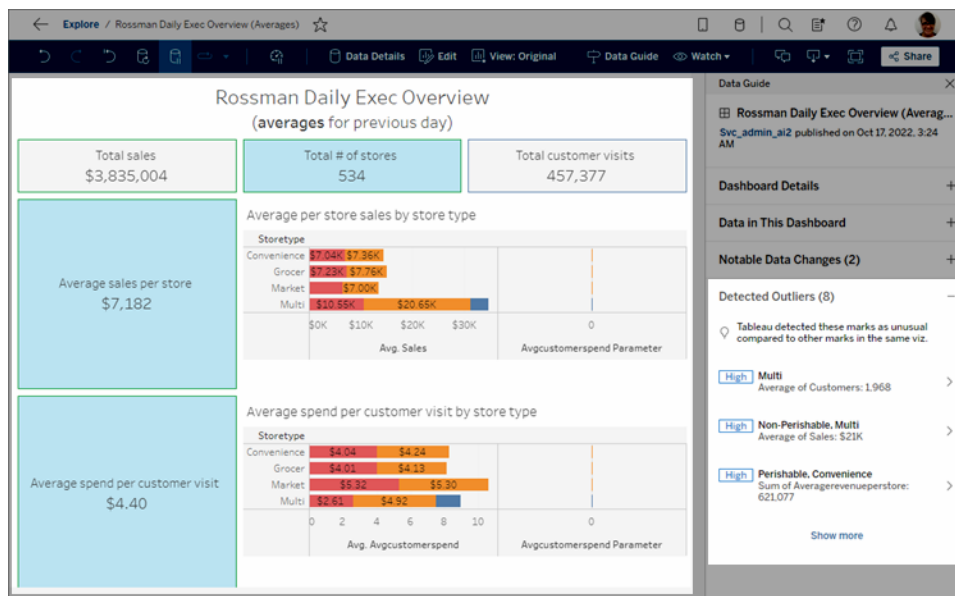

- [Requirements and Considerations for Using Explain Data](#)
- [Change Explain Data Settings \(Authors-only\)](#)

- [Terms and concepts in explanations](#) on page 1926
- [Explanation Types](#)
- [Control Access to Explain Data](#) on page 1951
- [Disable or Enable Explain Data for a Site](#) on page 1968
- [How Explain Data Works](#) on page 1957

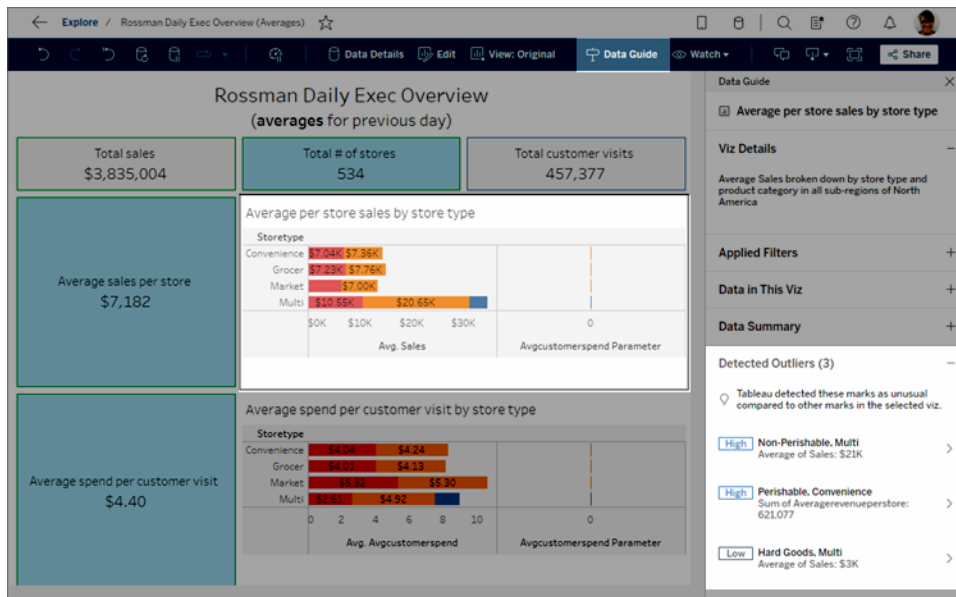

Run Explain Data on a dashboard, sheet or mark

These are the basic steps to run Explain Data in Tableau Desktop, Tableau Cloud and Tableau Server:

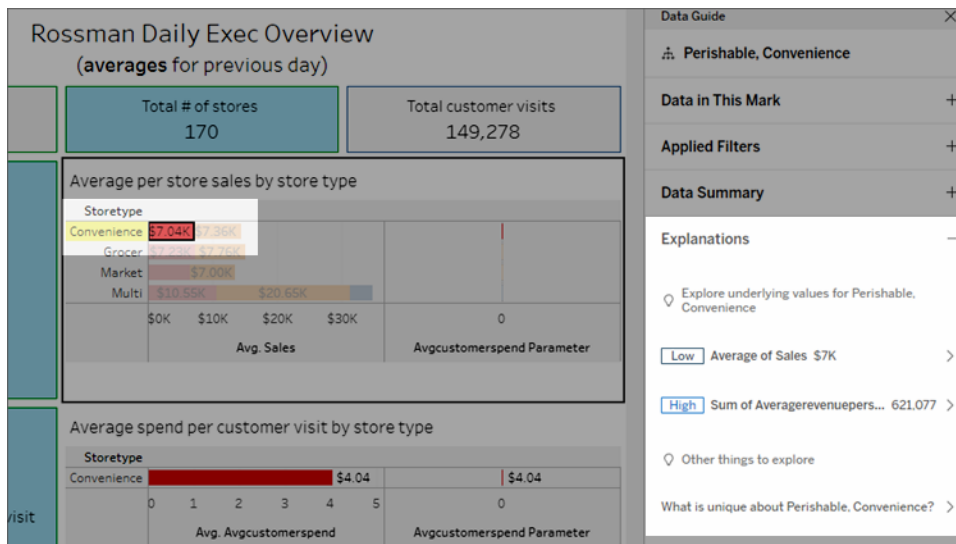

1. Open a dashboard or sheet in a workbook.
2. In the view toolbar, select **Data Guide** to open the Data Guide pane.
3. If you open a dashboard, Explain Data will analyse it for outliers.

If you select a sheet in the dashboard, Explain Data analyses the marks in that sheet for outliers.

If you select a mark in the dashboard, Explain Data specifically analyses that mark for explanations.

The marks that are being explained are highlighted in the viz as you select corresponding explanations.

Optionally, you can select a mark in a viz, hover the cursor over the mark. In the tooltip menu, select **Data Guide**.

In Tableau Public, select the lightbulb in the tooltip menu to run Explain Data.

Possible explanations for the value of the analysed mark are displayed in the Data Guide pane. Select different explanation names to expand the details and start exploring.

Explain Data permissions required for seeing explanations

If you see Detected Outliers with a note to contact the owner of the viz, it is because you need permission to see these types of explanations. Select the owner name to go to their Tableau content page with their email address. Contact the owner to ask them to give you Explain Data permissions for the workbook or view.

If you are the owner of the workbook, for more information on setting permissions, see [Control who can use Explain Data and what they can see on page 1952](#).

Tips for using Explain Data

- Multiple marks can't be selected for comparison with each other.
- The view must contain marks that are aggregated using SUM, AVG, COUNT, COUNTD or AGG (a calculated field).
- When Explain Data cannot analyse the type of mark selected, a message is displayed to indicate why. For more information, see [Situations where Explain Data is not available](#).

- The data you analyse must be drawn from a single, primary data source. Explain Data does not work with blended or cube data sources.
- For information on what characteristics make a data source more interesting for use with Explain Data, see [Requirements and Considerations for Using Explain Data on page 1949](#).

Drill into explanations

1. In the Data Guide pane, select an explanation name to see more details.
Select an explanation to expand or contract its details.
2. Scroll to see more explanation details.
3. Hover over charts in the explanations to see details on different data points. Select the **Open**  icon to see a larger version of the visualisation.

Creators or Explorers who open the view for editing can select the **Open**  icon to open the visualization as a new worksheet and explore the data further.

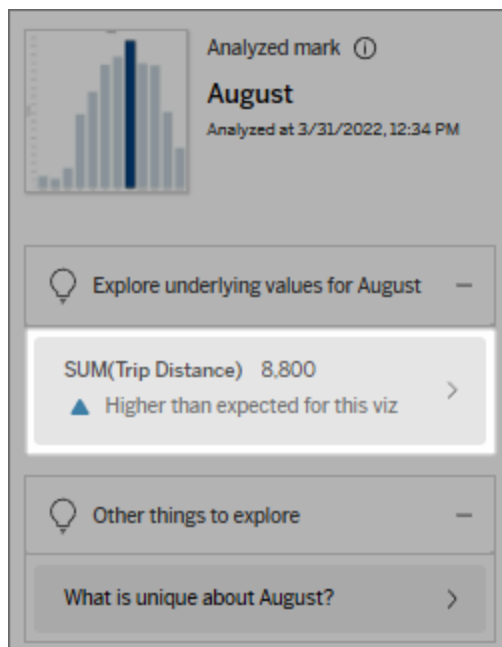

Note: Creators and Explorers who have editing permissions can also control Explain Data Settings. For more information, see [Control Access to Explain Data on page 1951](#).

4. Hover over a Help icon  to see tooltip help for an explanation. Select the Help icon  to keep the tooltip open. Select a **Learn More** link to open the related help topic.

View analysed fields

1. [Run Explain Data on a dashboard, sheet or mark on page 1921](#).

2. In the Data Guide pane, under **Explore underlying values for**, select a target measure name.

3. Select the *number-of-fields* link at the bottom of the pane.

Authors have the option to open Explain Data Settings to control which fields are included in the analysis. For more information, see [Change fields used for statistical analysis](#).

Terms and concepts in explanations

The following terms and concepts appear frequently in explanations. You may find it helpful to become acquainted with their meaning in the context of using Explain Data.

What is a mark?

A mark is a selectable data point that summarises some underlying record values in your data. A mark can be made of a single record or multiple records aggregated together. Marks in Tableau can be displayed in many different ways such as lines, shapes, bars and cell text.

Tableau gets the records that make up the mark based on the intersection of the fields in the view.

The **analysed mark** refers to a mark in a dashboard or sheet that was analysed by Explain Data.

For more information on marks, see [Marks](#).

What does expected mean?

The expected value for a mark is the median value in the expected range of values in the underlying data in your viz. The expected range is the range of values between the 15th and 85th percentile that the statistical model predicts for the analysed mark. Tableau determines the expected range each time it runs a statistical analysis on a selected mark.

If an expected value summary says the mark is *lower than expected* or *higher than expected*, it means the aggregated mark value is outside the range of values that a statistical model is predicting for the mark. If an expected value summary says the mark is *slightly lower* or *slightly higher* than expected or *within the range of natural variation*, it means the aggregated mark value is within the range of predicted mark values, but is lower or higher than the median.

For more information, see [What is an expected range?](#)

What are dimensions and measures?

Each column name in a database is a field. For example, Product Name and Sales are both fields. In Tableau, fields like Product Name that categorise data are called dimensions; fields with quantifiable data like Sales are called measures. Tableau aggregates measures by default when you drag them into a view.

Some explanations describe how the underlying record values and the aggregations of those values may be contributing to the value of the analysed mark. Other explanations may mention the distribution of values across a dimension for the analysed mark.

When you run Explain Data on mark, the analysis considers dimensions and measures in the data source that aren't represented in the view. These fields are referred to as unvisualised dimensions and unvisualised measures.

For more information on dimensions and measures, see [Dimensions and Measures](#).

What is an aggregate or aggregation?

An aggregate is a value that is a summary or total. Tableau automatically applies aggregations such as SUM or AVG whenever you drag a measure onto Rows, Columns, a Marks card option or the view. For example, measures are displayed as SUM(Sales) or AVG(Sales) to indicate how the measure is being aggregated.

To use Explain Data, your visualisation must use a measure that is aggregated with SUM, AVG, COUNT, COUNTD or AGG.

For more information about aggregation, see [Data Aggregation in Tableau](#).

What is a record value?

A record is a row in a database table. A row contains values that correspond to each field. In this example, Category, Product Name and Sales are fields (or columns). Furniture, Floor Lamp and \$96 are the values.

| Category | Product Name | Sales |
|-----------|--------------|---------|
| Furniture | Floor Lamp | \$96.00 |

What is a distribution?

A distribution is a list of all the possible values (or intervals) of the data. It also indicates how often each value occurs (frequency of occurrence).

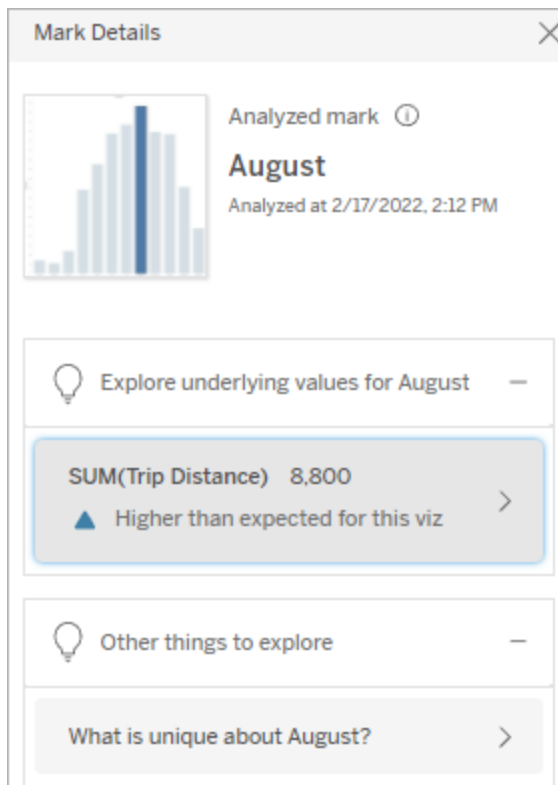

Explanation Types in Explain Data

Each time you select a new mark in a viz or dashboard and run Explain Data, Tableau runs a new statistical analysis considering that mark and the underlying data in the workbook. Possible explanations are displayed in expandable sections for the Data Guide pane. For information about how Explain Data analyses and evaluates explanations, see [How Explain Data Works on page 1957](#).

Explore underlying values

This section lists explanations for each measure that can be explained (referred to as *target measures*). Each explanation listed here describes a relationship with the values of the target measure that are tested on the analysed mark. Use your real-world, practical understanding of

the data to determine if the relationships found by Explain Data are meaningful and worth exploring.

In this example, Trip Distance is the target measure

Underlying Characteristics

These explanations describe how underlying records of the marks in the view may be contributing to the aggregated value of the measure being explained. Mark attributes can include **Extreme Values**, **Null Values**, **Number of Records** or the **Average Value** of the mark.

Note: For definitions of common terms used in explanations, see [Terms and concepts in explanations](#) on page 1926.

Extreme Values

This explanation type indicates if one or more records have values that are significantly higher or lower than most records. If the explanation is supported by a model, it indicates the extreme value is affecting the target measure of the analysed mark.

When a mark has extreme values, it doesn't automatically mean it has outliers or that you should exclude those records from the view. That choice is up to you depending on your analysis. The explanation is simply pointing out an extreme value in the mark. For example, it could reveal a mistyped value in a record where a banana cost 10 pounds instead of 10 pence. Or, it could reveal that a particular sales person had a great quarter.

Note: This explanation must be enabled by the author to be visible in viewing mode for a published workbook. For more information, see [Control Access to Explain Data on page 1951](#).

This explanation shows:

- The number of underlying records in the analysed mark.
- The extreme value or values contributing to the value of the target measure.
- The distribution of values in the mark.
- The record details that correspond to each distribution value.

In this example, a single extreme value of 463 hours rented is contributing to the higher-than-expected sum of Total Time Rented of 613 hours.

A likely reason for this high value could be that someone forgot to

Exploration options:

- Hover over a circle in the chart to see its corresponding value.
 - Select the left or right arrow below the details list to scroll through record details.
 - If available, select **View Full Data**, and then select the **Full Data** tab to see all records in a table.
 - Select the **Open**  icon to see a larger version of the visualisation.
- dock the bike when they returned it. In this case, the author might want to exclude this value for future analysis.

Next steps for analysis:

- If the number of records is low, examine these values

compared to the extreme value.

- If the extreme value is significantly higher or lower than the other record values, exclude it and consider how it changes the value of the analysed mark.
- When considering the data with and without the extreme value, use this as an opportunity to apply your practical knowledge about the data.

Visualise the Difference

This section shows:

- How the analysed mark value changes when the extreme value is excluded.

Exploration options:

- Select the **Open**  icon to see a larger version of the visualisation.
- Explore the difference with and without the

extreme value (or values).

- Authors can open the view as a new sheet and apply a filter to exclude the extreme value.

Next steps for analysis:

- If the extreme value is significantly higher or lower than the other record values, exclude it and see how it changes the value of the analysed mark.
- When considering the data with and without the extreme value, use

In this example, when the extreme value of 483 is excluded, the analysed mark is no longer high compared to other marks in the view. Other marks now stand out. The author might want to explore the other marks to consider why these other locations have higher hours for bike rentals.

this as an
opportunity
to apply your
practical
knowledge
about the
data.

Null Values

The Null Values explanation type calls out situations where there is a higher-than-expected amount of missing data in a mark. It indicates the fraction of target measure values that are null and how the null values might be contributing to the aggregate value of that measure.

This explanation shows:

- The percentage of values that are null in the target measure for the analysed mark (blue circle).

In this example, the percentage of null values in the target measure is shown as a blue circle.

Exploration options:

- Hover over each circle in the scatter plot to see its details.
- Scroll to see more of the chart.
- Select the

Open  icon
to see a larger
version of the
visualisation.

**Next steps for
analysis:**

- Optionally
exclude null
values in the
mark for fur-
ther analysis.

Number of Records

This explanation type describes when the count of the underlying records is correlated to the sum. The analysis found a relationship between the number of records that are being aggregated in a mark and the mark's actual value.

While this might seem obvious, this explanation type helps you explore whether the mark's value is being affected by the magnitude of the values in its records or simply because of the number of records in the analysed mark.

This explanation shows:

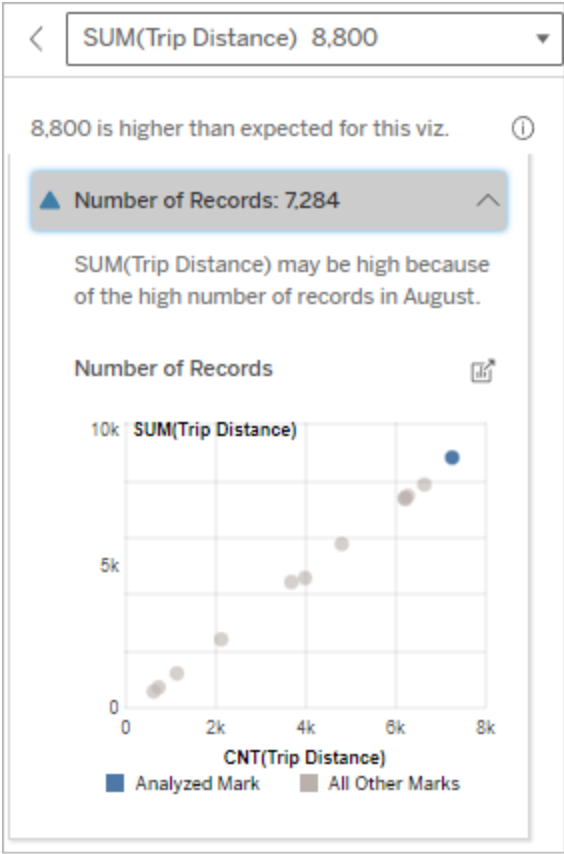

- The number of records in the target measure for the analysed mark (dark blue bar).
- The number of records in the target measure for other marks in the source visualisation (light blue bar).

Exploration options:

- Hover over each bar to see its details.
- Scroll to see more of the chart.
- Select the **Open**  icon to see a larger version of the visualisation.

Next steps for analysis:

- Compare

In this example, the number of records for Trip Distance is listed for each value of Ride Month, which is a dimension in the original visualisation. August has the highest total trip distance value.

You might explore whether August has the highest value for trip distance because more rides occurred in August, or if it has the highest trip distance because some rides were longer.

whether the individual values of records are low or high, or the number of records in the analysed mark is low or high.

- Authors, if you are surprised by a high number of records, you might need to normalise the data.

Average Value of Mark

This explanation type describes when the average of a measure is correlated to the sum. Compare whether the average value is low or high, or the number of records is low or high.

This explanation shows:

- The average of the target measure for each value of a dimension used in the source visualisation.

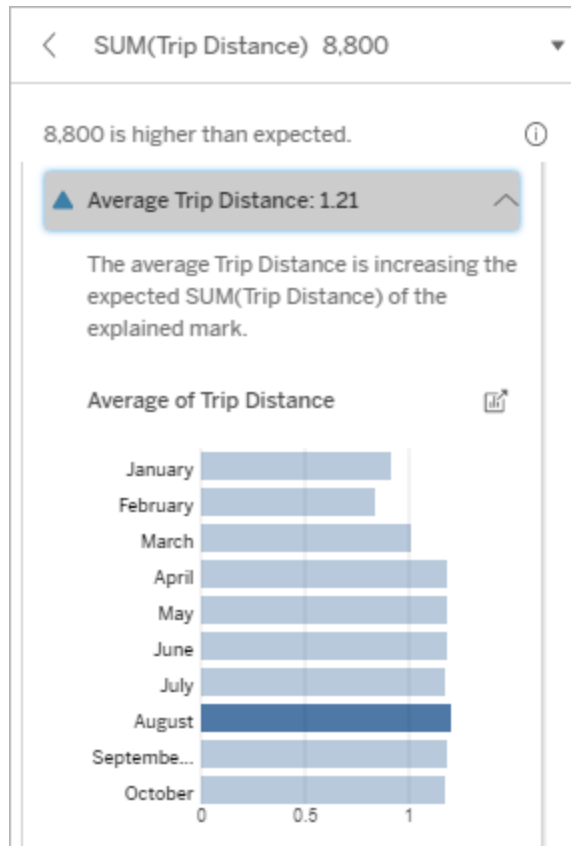

Exploration options:

- Hover over each bar to see its details.
- Scroll to see more of the chart.
- Select the

Open  icon to see a larger version of the visualisation.

Next steps for analysis:

- Compare whether the average value is low or high, or the number of records is low or high. For example,

In this example, the average trip distance for August is not significantly higher or lower than most months. This suggests that trip distance is higher for August because there were more rides in August, rather than from people taking longer rides.

- are profits high
because you
sold a lot of
items or
because you
sold expensive
items?
- Try to figure
out why the
analysed mark
has a sig-
nificantly
higher or lower
average value.

Contributing Single Value

Use this explanation to understand the composition of the record values that make up the analysed mark.

This explanation type identifies when a single value in an unvisualised dimension may be contributing to the aggregate value of the analysed mark. An unvisualised dimension is a dimension that exists in the data source but isn't currently being used in the view.

This explanation indicates when every underlying record of a dimension has the same value, or when a dimension value stands out because either many or few of the records have the same single value for the analysed mark.

Note: For definitions of common terms used in explanations, see [Terms and concepts in explanations](#) on page 1926.

This explanation shows:

- The percentage of the number of records for a single value of a dimension for the analysed mark (blue bar) versus all marks (grey bar) in the source visualisation.
- The percentage of the number of records for all other values of a dimension for the analysed mark (blue bar) versus all marks (grey bar) in the source visualisation.
- The average of the target measure for the single value of a

In this example, the statistical analysis has exposed that many of the rides come from the station neighbourhood of Back Bay. Note that Station Neighbourhood is an unvisualised dimension that has some relationship to Trip Distance in the underlying data for the source visualisation.

dimension in the analysed mark (blue bar) versus all marks (grey bar).

- The average of the target measure for all other values of a dimension for the analysed mark (blue bar) versus all marks (grey bar) in the source visualisation.

Exploration

options:

- Hover over each bar to see its details.
- Select the

Open  icon to see a larger version of the visualisation.

Next steps for analysis:

- Use this explanation to

- understand the composition of the record values that make up the analysed mark.
- Authors might want to create a new visualisation to explore any unvisualised dimension surfaced in this explanation.

Top Contributors

Use this explanation to see the values that make up the largest fraction of the analysed mark.

For a COUNT aggregation, the top contributors show dimension values with the most records. For SUM, this explanation shows dimension values with the largest partial sum.

Contributing Dimensions

Use this explanation to understand the composition of the record values that make up the analysed mark.

This explanation type shows that the distribution of an unvisualised dimension may be contributing to the aggregate value of the analysed mark. This type of explanation is used for target measure sums, counts and averages. An unvisualised dimension is a dimension that exists in the data source but isn't currently being used in the view.

Note: For definitions of common terms used in explanations, see [Terms and concepts in explanations](#) on page 1926.

This explanation shows:

- The percentage of the number of records for all values of a dimension for the analysed mark (blue bar) versus all values of a dimension for all marks (grey bar) in the source visualisation.
- The average of the target measure for all values of a dimension for the analysed mark (blue bar) all values of a dimension for all marks (grey bar).

Exploration options:

- Hover over each bar to see its details.
- Scroll to see more of the

In this example, the statistical analysis has exposed that more rides were taken from South Station and MIT and fewer rides were taken from Charles Circle and Kendall, compared to rides taken for marks overall.

Note that Station Name is an unvisualised dimension that has some relationship to Trip Distance in the underlying data for the source visualisation.

chart.

- Select the

Open  icon

to see a larger
version of the
visualisation.

Next steps for analysis:

- Use this
explanation to
understand the
composition of
the record val-
ues that make
up the ana-
lysed mark.
- Authors might
want to create
a new visu-
alisation to
explore any
unvisualised
dimensions
surfaced in this
explanation.

Contributing Measures

This explanation type shows that the average of an unvisualised measure may be contributing to the aggregate value of the analysed mark. An unvisualised measure is a measure that exists in the data source but isn't currently being used in the view.

This explanation can reveal a linear or quadratic relationship between the unvisualised measure and the target measure.

Note: For definitions of common terms used in explanations, see [Terms and concepts in explanations](#) on page 1926.

This explanation shows:

- The relationship between the sum of the target measure and the average of an unvisualised measure for the analysed mark (blue circle) and all marks (grey circles) in the view.
- If the sum of the target measure is high or low because the average value of the unvisualised measure is high or low.

In this example, one possible reason why trip distance is high is because the average total time rented is also high.

Exploration options:

- Hover over each circle to

see its details.

- Select the

Open  icon

to see a larger
version of the
visualisation.

Next steps for analysis:

- Authors might
want to create
a new visu-
alisation to
explore any
unvisualised
measures sur-
faced in this
explanation.

Other things to explore

This section provides possible reasons why the analysed mark is unique or unusual. These explanations:

- Do not explain why the value of this mark is what it is.
- Are not related in any way to the value of the measures in the source visualisation.
- Do not take any target measures into account.

Other Dimensions of Interest

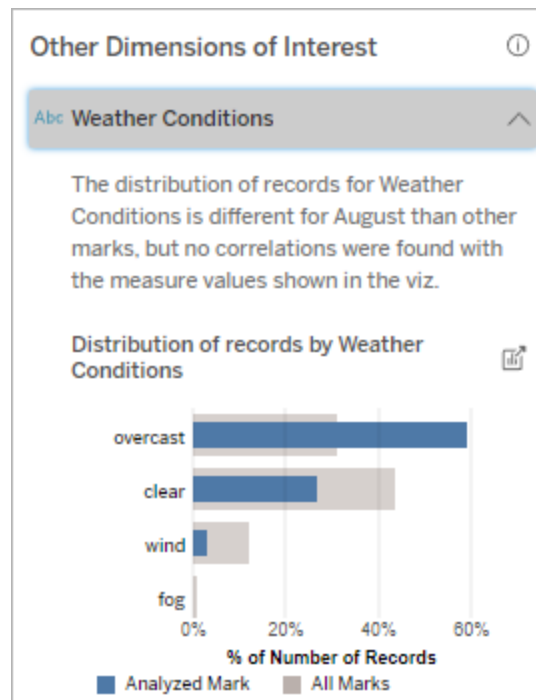

Use this explanation to understand the composition of the record values that make up the analysed mark.

The distribution of an unvisualised dimension in the analysed mark is unusual compared to the distribution of values for all other marks in the view. An unvisualised dimension is a dimension that exists in the data source but isn't currently being used in the view.

Note: For definitions of common terms used in explanations, see [Terms and concepts in explanations](#) on page 1926.

This explanation shows:

- The percentage of the number of records for all values of a dimension for the analysed mark (blue bar) versus all values of a dimension for all marks (grey bar) in the source visualisation.

Exploration options:

- Hover over each bar to see its details.
- Scroll to see more of the chart.
- Select the

Open  icon to see a larger version of the visualisation.

In this example, a high percentage of records are associated with overcast weather. Because the data is about bike rentals in Boston, and the analysed mark is Trip Distance for August, we can assume that the weather is typically warm and humid. People might have rented bikes more often on overcast days to avoid the heat. It's also possible there were more overcast days in August.

Next steps for analysis:

- Use this explanation to understand the composition of the record values that make up the analysed mark.
- Authors might want to create a new visualisation to explore any unvisualised dimensions surfaced in this explanation.

Requirements and Considerations for Using Explain Data

Explain Data is always available to authors in Tableau Desktop.

For Tableau Cloud and Tableau Server: When Explain Data is enabled for a site, Creators and Explorers with the appropriate permissions can run Explain Data when editing a workbook. All users with the appropriate permissions can run Explain Data in viewing mode in published workbooks. For more information, see [Control Access to Explain Data on page 1951](#).

What makes a viz a good candidate for Explain Data

Explain Data works best on visualisations that require deeper exploration and analysis, rather than infographic-style, descriptive vizzes that communicate summarised data.

- Row-level data is necessary for Explain Data to create models of your data and generate explanations. Vizzes with underlying, row-level data, where relationships might exist in unvisualised fields are good candidates for running Explain Data.

- Vizires based on pre-aggregated data without access to row-level data are not ideal for the statistical analysis performed by Explain Data.

What data works best for Explain Data

When you are using Explain Data in a worksheet, remember that Explain Data works with:

- **Single marks only** – Explain Data analyses single marks. Multiple mark analysis is not supported.
- **Aggregated data** – The view must contain one or more measures that are aggregated using SUM, AVG, COUNT or COUNTD. At least one dimension must also be present in the view.
- **Single data sources only** – The data must be drawn from a single, primary data source. Explain Data does not work with blended or cube data sources.

When preparing a data source for a workbook, keep the following considerations in mind if you plan to use Explain Data during analysis.

- Use a data source with underlying data that is sufficiently wide. An ideal data set has at least 10-20 columns in addition to one (or more) aggregated measures to be explained.
- Give columns (fields) names that are easy to understand.
- Eliminate redundant columns and data prep artifacts. For more information, see [Change fields used for statistical analysis on page 1964](#).
- Don't discard unvisualised columns in the data source. Explain Data considers fields in the underlying data when it analyses a mark.
- Low cardinality dimensions work better. The explanation of a categorical dimension is easier to interpret if its cardinality is not too high (< 20 categories). Dimensions with more than 500 unique values will not be considered for analysis.
- Don't pre-aggregate data as a general rule. But if the data source is massive, consider pre-aggregating the data to an appropriate level of detail.
- Use extracts over live data sources. Extracts run faster than live data sources. With live data sources, the process of creating explanations can create many queries (roughly one query per each candidate explanation), which can result in explanations taking longer to be generated.

Situations where Explain Data is not available

Sometimes Explain Data will not be available for a selected mark, depending on the characteristics of the data source or the view. If Explain Data cannot analyse the selected mark, the Explain Data icon and context menu command will not be available.

Explain Data can't be run in views that use:

- Map coordinate filters
- Blended data sources
- Data sources with parameters
- Data sources that don't support COUNTD or COUNT(DISTINCT ...) syntax, such as Access.
- Filters on aggregate measures
- Disaggregated measures

Explain Data can't be run if you select:

- Multiple marks
- Axis
- Legend
- Grand total
- Trend line or reference line
- A mark in a view that contains a very low number of marks

Explain Data can't be run when the measure to be used for an explanation:

- Isn't aggregated using SUM, AVG, COUNT, COUNTD
- Is a table calculation
- Is used in measure values

Explain Data can't offer explanations for a dimension when it is:

- A calculated field
- A parameter
- Used in Measure Names and Measure Values
- A field with more than 500 unique values. Dimensions with more than 500 unique values will not be considered for analysis.

Control Access to Explain Data

Your access to Explain Data will vary depending on your site role and content permissions. Explain Data is always available to authors in Tableau Desktop. Authors with appropriate permissions can run Explain Data in editing mode in Tableau Cloud and Tableau Server.

Authors can also control whether Explain Data is available in viewing mode in published workbooks and which explanation types are displayed.

Be aware that Explain Data can surface values from dimensions and measures in the data source that aren't represented in the view. As an author, you should run Explain Data and test the

resulting explanations to make sure that sensitive data isn't being exposed in your published workbooks.

Who can access Explain Data

Explain Data is enabled by default at the site level. Server administrators (Tableau Server) and site administrators (Tableau Cloud) can control whether Explain Data is available for a site. For more information, [Disable or Enable Explain Data for a Site on page 1968](#).

| Mode | Who Can Access |
|---------------------|---|
| Viewing mode | Tableau Viewers , Explorers and Creators who have the Run Explain Data permission capability can run and explore Explain Data explanations in viewing mode. |
| Editing mode | <p>Tableau Creators can run Explain Data when editing a view in Tableau Desktop, Tableau Cloud or Tableau Server. Explorers who have the Run Explain Data permission capability and editing permissions can run Explain Data when editing a workbook in Tableau Cloud or Tableau Server.</p> <p>Creators and Explorers who have editing permissions can open new worksheets for further analysis.</p> <p>They can also use Explain Data Settings to control who can use Explain Data and what they can see.</p> |

Control who can use Explain Data and what they can see

A combination of settings must be enabled to make Explain Data available in editing mode and viewing mode in Tableau Cloud and Tableau Server.

Editing mode

Requirements for authors to run Explain Data or edit Explain Data settings in editing mode:

- Site setting: **Availability of Explain Data** set to **Enable**. Enabled by default.
- Site role: Creator, Explorer (can publish)
- Permissions: **Run Explain Data** capability set to **Allowed**. Unspecified by default. If you open a workbook (Tableau version 2022.1 or earlier) that used this permission in Tableau version 2022.2 or later, you will need to reset the Run Explain Data capability to Allowed.

Note: The **Download Full Data** capability for a Creator or Explorer (can publish) controls whether they see the View Full Data option in Extreme Values explanations. Viewers are always denied the Download Full Data capability. However, all users can see record-level details when the Extreme Values explanation type is enabled in Explain Data settings.

Creators and Explorers with editing permissions and the Run Explain Data permission capability can access **Explain Data Settings**, which provide options for controlling:

- The **explanation types that are displayed** in the Data Guide pane.
- The **fields that are included in, or excluded from** statistical analysis.

These options are set for the entire workbook and can only be set in the Explain Data Settings dialog box.

Viewing mode

Requirements for all users to run Explain Data in viewing mode:

- Site setting: **Availability of Explain Data** set to **Enable**. Enabled by default.
- Site role: Creator, Explorer or Viewer
- Permissions: **Run Explain Data** capability set to **Allowed**. Unspecified by default. If you open a workbook (Tableau version 2022.1 or earlier) that used this permission in Tableau version 2022.2 or later, you will need to reset the Run Explain Data capability to Allowed.

Note: To see explanations of Detected Outliers in the Data Guide, users of a viz must have the Explain Data permission allowed for the workbook or view. The owner of the workbook will need to open the permissions settings for this workbook in Tableau Server or Tableau Cloud and allow the Explain Data permission to that user.

Open the Explain Data Settings dialog box

1. From the **Analysis** menu, choose **Explain Data Settings**. Or, in the Data Guide pane, click the settings icon (bottom right).

Include or exclude explanation types displayed by Explain Data

Creators and Explorers who have editing permissions can choose to exclude (or include) explanation types displayed for all workbook users.

1. In the **Explain Data Settings** dialog box, click on the **Explanation Types** tab.

2. In the list of explanation types, select or clear an explanation type.
3. Click **OK**.

Test the setting by saving and closing the published workbook and then opening a view from the workbook in viewing mode. Select a mark that typically has Extreme Value explanations, and then run Explain Data to check the explanation results.

Include or exclude fields used for statistical analysis

Creators or Explorers who have editing permissions can choose to exclude (or include) fields that are eligible for analysis.

1. In the Data Guide pane (bottom right), choose the settings icon. Or, choose the **Edit** button in the **Analysed Fields view**.

2. In the **Explain Data Settings** dialog box, click on the **Fields** tab.
3. In the list of fields under **Include**, click on the drop-down arrow and select **Automatic** to include an eligible field every time Explain Data runs for that workbook.

Note that fields must have less than 500 unique values to be included in the analysis.

Select **Never Include** to explicitly exclude the field.

Select **Include None** to run a statistical analysis on the data without considering fields.

Select **Reset** to return to the default settings.

4. Click **OK**.

Test the setting by saving the published workbook. Select a mark, and then run Explain Data to check the explanation results.

Configure Tableau to allow users to share explanations via email and Slack

Tableau administrators can control whether explanations can be shared in viewing mode via email or Slack to other Tableau users.

Follow these steps to allow notifications and sharing via email and Slack in Tableau Cloud or Tableau Server:

1. Click **Settings**.
2. On the General tab, scroll down to **Manage Notifications**.
3. For Collaboration, select **Share** for **On Tableau**, **Email** and **Slack**.

To share explanations via Slack, the Tableau app must be set up for your Slack workspace. Sharing explanations with Slack is enabled by default in Tableau Cloud.

In Tableau Server, an administrator will need to set up the Tableau app for Slack. For more information, see [Integrate Tableau with a Slack Workspace](#).

How Explain Data Works

Use Explain Data as an incremental, jumping-off point for further exploration of your data. The possible explanations that it generates help you to see the different values that make up or relate to an analysed mark in a view. It can tell you about the characteristics of the data points in the data source, and how the data might be related (correlations) using statistical modelling. These explanations give you another tool for inspecting your data and finding interesting clues about what to explore next.

Note: Explain Data is a tool that uncovers and describes relationships in your data. It can't tell you what is causing the relationships or how to interpret the data. **You are the expert on your data.** Your domain knowledge and intuition is key in helping you decide what characteristics might be interesting to explore further using different views.

For related information on how Explain Data works, and how to use Explain Data to augment your analysis, see these Tableau Conference presentations:

- [From Analyst to Statistician: Explain Data in Practice \(1 hour\)](#)
- [Leveraging Explain Data \(45 minutes\)](#)

What Explain Data is (and isn't)

Explain Data is:

- A tool and a workflow that leverages your domain expertise.
- A tool that surfaces relationships in your data and recommends where to look next.
- A tool and a workflow that helps expedite data analysis and make data analysis more accessible to a broader range of users.

Explain Data is not:

- A statistical testing tool.
- A tool to prove or disprove hypotheses.
- A tool that is giving you an answer or telling you anything about causality in your data.

When running Explain Data on marks, keep the following points in mind:

- **Consider the shape, size and cardinality of your data.** While Explain Data can be used with smaller data sets, it requires data that is sufficiently wide and contains enough marks (granularity) to be able to create a model.
- **Don't assume causality.** Correlation is not causation. Explanations are based on models of the data, but are not causal explanations.

A correlation means that a relationship exists between some data variables, say A and B. You can't tell just from seeing that relationship in the data that A is causing B, or B is causing A, or if something more complicated is actually going on. The data patterns are exactly the same in each of those cases and an algorithm can't tell the difference between each case. Just because two variables seem to change together doesn't necessarily mean that one causes the other to change. A third factor could be causing them both to change, or it may be a coincidence and there might not be any causal relationship at all.

However, you might have outside knowledge that is not in the data that helps you to identify what's going on. A common type of outside knowledge would be a situation where the data was gathered in an experiment. If you know that B was chosen by flipping a coin, any consistent pattern of difference in A (that isn't just random noise) must be caused by B. For a longer, more in-depth description of these concepts, see the article [Causal inference in economics and marketing](#) by Hal Varian.

How explanations are analysed and evaluated

Explain Data runs a statistical analysis on a dashboard or sheet to find marks that are outliers, or specifically on a mark you select. The analysis also considers possibly related data points from the data source that aren't represented in the current view.

Explain Data first predicts the value of a mark using only the data that is present in the visualisation. Next, data that is in the data source (but not in the current view) is considered and added to the model. The model determines the range of predicted mark values, which is within one standard deviation of the predicted value.

What is an expected range?

The expected value for a mark is the median value in the expected range of values in the underlying data in your viz. The expected range is the range of values between the 15th and 85th percentile that the statistical model predicts for the analysed mark. Tableau determines the expected range each time it runs a statistical analysis on a selected mark.

Possible explanations are evaluated on their explanatory power using statistical modelling. For each explanation, Tableau compares the expected value with the actual value.

| value | Description |
|---|--|
| Higher than expected/Lower than expected | If an expected value summary says the mark is <i>lower than expected</i> or <i>higher than expected</i> , it means the aggregated mark value is outside the range of values that a statistical model is predicting for the mark. If an expected value summary says the mark is <i>slightly lower</i> or <i>slightly higher</i> than expected, or <i>within the range of natural variation</i> , it means the aggregated mark value is within the range of predicted mark values, but is lower or higher than the median. |
| Expected Value | If a mark has an expected value, it means its value falls within the expected range of values that a statistical model is predicting for the mark. |
| Random Variation | When the analysed mark has a low number of records, there may not be enough data available for Explain Data to form a statistically significant explanation. If the mark's value is outside of the expected range, Explain Data can't determine whether this unexpected value is being caused by random variation or by a meaningful difference in the underlying records. |
| No Explanation | When the analysed mark value is outside of the expected range and it does not fit a statistical model used for Explain Data, no explanations are generated. |

Models used for analysis

Explain Data builds models of the data in a view to predict the value of a mark and then determines whether a mark is higher or lower than expected given the model. Next, it considers additional information, like adding additional columns from the data source to the view, or flagging record-level outliers, as potential explanations. For each potential explanation, Explain Data fits a new model and evaluates how unexpected the mark is given the new information. Explanations are scored by trading off complexity (how much information is added from the data source) against the amount of variability that needs to be explained. Better explanations are simpler than the variation they explain.

| Explanation type | Evaluation |
|----------------------------------|--|
| Extreme values | <p data-bbox="532 258 1344 422">Extreme values are aggregated marks that are outliers, based on a model of the visualised marks. The selected mark is considered to contain an extreme value if a record value is in the tails of the distribution of the expected values for the data.</p> <p data-bbox="532 449 1338 569">An extreme value is determined by comparing the aggregate mark with and without the extreme value. If the mark becomes less surprising by removing a value, then it receives a higher score.</p> <p data-bbox="532 596 1370 890">When a mark has extreme values, it doesn't automatically mean it has outliers, or that you should exclude those records from the view. That choice is up to you depending on your analysis. The explanation is simply pointing out an interesting extreme value in the mark. For example, it could reveal a mistyped value in a record where a banana cost 10 pounds instead of 10 pence. Or, it could reveal that a particular sales person had a great quarter.</p> |
| Number of records | <p data-bbox="532 926 1344 1092">The number of records explanation models the aggregate sum in terms of the aggregate count; average value of records models it in terms of the aggregate average. The better the model explains the sum, the higher the score.</p> <p data-bbox="532 1119 1344 1197">This explanation describes whether the sum is interesting because the count is high or low, or because the average is high or low.</p> |
| Average value of the mark | <p data-bbox="532 1232 1377 1398">This type of explanation is used for aggregate marks that are sums. It explains whether the mark is consistent with the other marks because in terms of its aggregate count or average, noting the relation $SUM(X) = COUNT(X) * AVG(X)$.</p> <p data-bbox="532 1425 1344 1503">This explanation describes whether the sum is interesting because the count is high or low, or because the average is high or low.</p> |
| Contributing Dimensions | <p data-bbox="532 1539 1357 1705">This explanation models the target measure of the analysed mark in terms of the breakdown among categories of the unvisualised dimension. The analysis balances the complexity of the model with how well the mark is explained.</p> <p data-bbox="532 1732 1305 1801">An <i>unvisualised dimension</i> is a dimension that exists in the data source but isn't currently being used in the view. This type of</p> |

| Explanation type | Evaluation |
|------------------------------|---|
| | <p>explanation is used for sums, counts and averages.</p> <p>The model for unvisualised dimensions is created by splitting out marks according to the categorical values of the explaining column, and then building a model with the value that includes all of the data points in the source visualisation. For each row, the model attempts to recover each of the individual components that made each mark. The analysis indicates whether the model predicts the mark better when components corresponding to the unvisualised dimension are modelled and then added up, versus using a model where the values of the unvisualised dimension are not known.</p> <p>Aggregate dimension explanations explore how well mark values can be explained without any conditioning. Then, the model conditions on values for each column that is a potential explanation. Conditioning on the distribution of an explanatory column should result in a better prediction.</p> |
| Contributing Measures | <p>This explanation models the mark in terms of this unvisualised measure, aggregated to its mean across the visualised dimensions. An <i>unvisualised measure</i> is a measure that exists in the data source but isn't currently being used in the view.</p> <p>A Contributing Measures explanation can reveal a linear or quadratic relationship between the unvisualised measure and the target measure.</p> |

Analysed Fields in Explain Data

Explain Data runs a statistical analysis on a dashboard or sheet to find marks that are outliers, or specifically on a mark you select. The analysis also considers possibly related data points from the data source that aren't represented in the current view.

Explain Data might not include every column from the data source in the analysis. In many cases, certain types of fields will be automatically excluded from the analysis. For more information, see [Fields excluded by default on page 1967](#).

Note: Dimensions with more than 500 unique values won't be considered for analysis (unless allowed by the author in Explain Data Settings).

All users can view information on which fields are included or excluded in the current analysis. Creators and Explorers who have editing permissions can edit the fields used by Explain Data for statistical analysis.

View fields analysed by Explain Data

When you expand an explanation for a measure that is contributing to the value of the mark, a link that indicates the number of fields considered in the analysis is displayed at the bottom of the Data Guide pane.

Click the link to see the list of fields included in or excluded from the current statistical analysis.

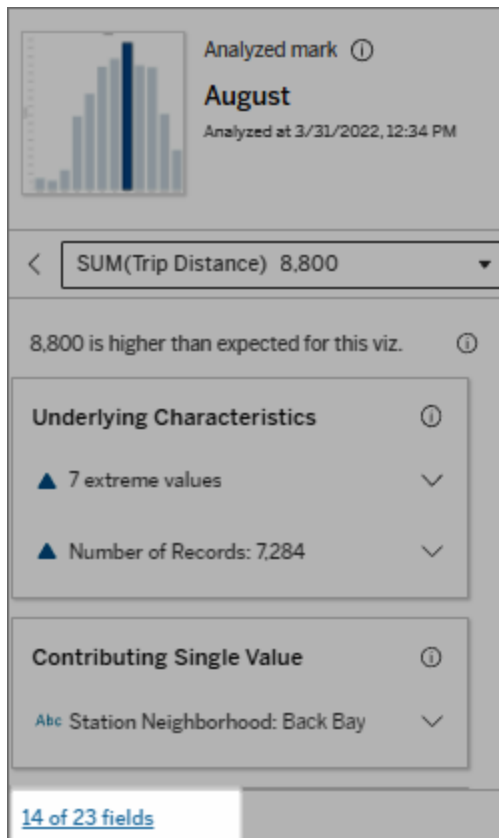

When a data source contains more than 1000 unvisualised dimensions or measures, you might see an alert asking if you want Explain Data to consider more fields. Click **Explain All** to run an analysis that includes more fields. The analysis may take longer to complete.

To view fields used by Explain Data for statistical analysis

1. Run Explain Data on dashboard, sheet or mark.
2. In the Data Guide pane, under **Contributing to the value of**, click a measure name.

3. Click on the *number-of-fields* link at the bottom of the pane.

Change fields used for statistical analysis

Creators and Explorers who have editing permissions can select fields to be included or excluded from the statistical analysis in the Fields tab of the Explain Data Settings dialog box.

When a data source contains dimensions with a large number of unique values (up to 500), those fields won't be considered for analysis.

To edit the fields used by Explain Data for statistical analysis

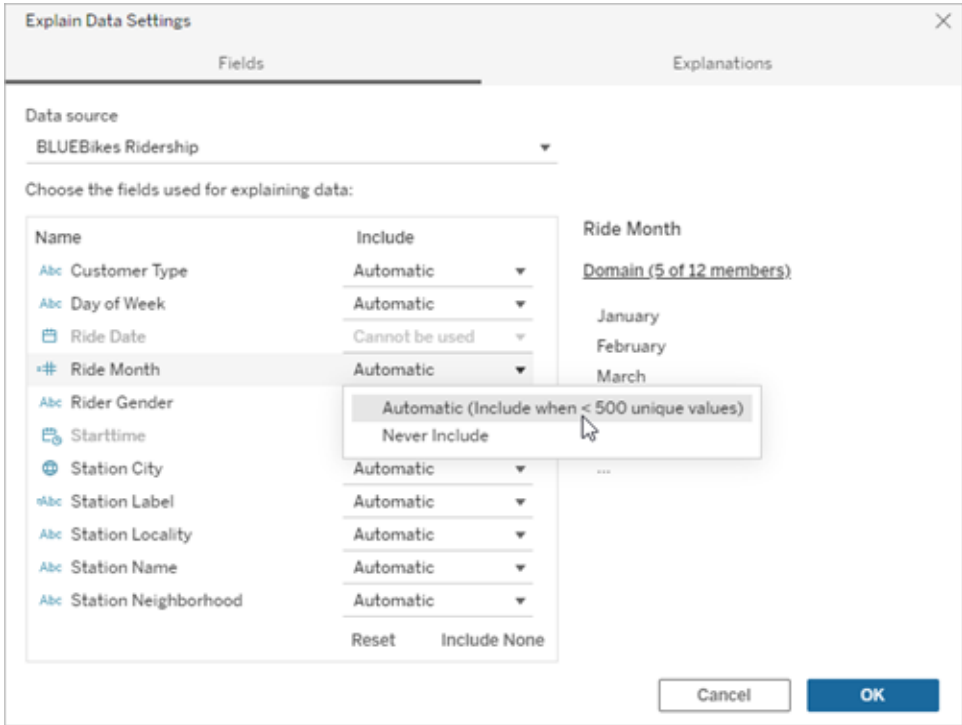

Settings for analysed fields are applied at the data source level.

1. Run Explain Data on a mark when editing a view.
2. In the Data Guide pane, click the settings icon at the bottom of the pane. Or, click the **Edit** button in the Analysed Fields view ([how to open analysed fields](#)).

3. In the Explain Data Settings dialog box, click on the **Fields** tab.
4. Click a drop-down arrow next to a field name, select **Automatic** or **Never Include**, and then click **OK**.

Note that fields must have less than 500 unique values to be included in the analysis.

Fields excluded by default

Fields excluded by default

All unvisualised measures when there are more than 1,000 measures in the data source.

All unvisualised dimensions when there are more than 1,000 dimensions in the data source.

Fields that use geometry, latitude or longitude

Reasons for exclusion

Computing explanations for more than 1000 unvisualised measures or dimensions can take longer to compute, sometimes several minutes. These fields are excluded by default for initial analysis, but you can choose to include them for further analysis.

In this situation, you might see an alert asking if you want Explain Data to consider more fields. Click the alert link to get more information. Click **Explain All** to run an analysis that includes more fields.

Geometry, latitude or longitude by themselves can never be explanations. It is highly likely that an explanation that calls out the latitude or the lon-

| Fields excluded by default | Reasons for exclusion |
|--|--|
| | gitude as an explanation is due to a spurious correlation and not a probable explanation. |
| Dimensions with high cardinality (dimensions with > 500 members) | High cardinality dimensions take longer to compute. Dimensions with more than 500 unique values will not be considered for analysis. |
| Groups, bins or sets | Not currently supported. |
| Table calculations | Table calculations cannot be analysed when table calculations are at a different level of detail than the view. |
| Unvisualised measures that can't be averaged | Unvisualised measures that can't be averaged include measures that are calculated fields where the calculation expression includes aggregations (display as AGG() fields when added to the sheet). |
| Discrete measures and continuous dimensions | Not currently supported. |
| Hidden fields | Not available. |
| Calculated fields with errors | No values present to analyse. |

Disable or Enable Explain Data for a Site

Explain Data is enabled for sites by default, but Tableau administrators may disable it.

1. Go to the **General** site settings.
2. (Tableau Server only) In the **Web Authoring** section, select **Let users edit workbooks in their browser**.
3. In the **Availability of Explain Data** section, select from these options:
 - **Enable** lets Creators and Explorers with the appropriate permissions run Explain Data in editing mode. Lets all users with appropriate permissions run Explain Data when it is enabled for viewing mode.
 - **Disable** prevents all users from running Explain Data or accessing Explain Data settings in workbooks.

4. In Tableau Cloud and Tableau Server 2023.3 or later, to use Explain Data:
 - In the **Availability of Data Guide** section, select **Show**. For more information about Data Guide, see [Explore Dashboards with Data Guide on page 2704](#).

Explore and Inspect Data in a View

When you are ready to explore and analyse your view, Tableau offers a selection of dynamic data inspection tools that help you isolate the data of interest. For example, if you have a dense data view, you can focus on a particular region, select a group of outliers, and view the underlying data source rows for each mark.

Select marks to highlight data points in the view

The simplest way to add highlighting to a view is to select the marks you want to highlight. When you manually select a mark in the view, all other marks are dimmed to draw attention to the selection. Your selection is saved with the workbook.

For more information on how to use selection tools, see [Select marks on page 1985](#). Also see [Legend Highlighting on page 1402](#), [Highlight Data Points in Context on page 1405](#), [Highlight Toolbar Button on page 1408](#), and [Highlight Actions on page 1401](#).

You can select multiple marks by holding down the Ctrl key on your keyboard (Command key on Mac) while you select each mark. You can also use one of the advanced selection tools to select marks within a specific shape.

You can also select marks and headers to filter what is being displayed in the view. For more details, see [Select to keep or exclude data points in your view on page 1316](#) and [Select headers to filter data on page 1317](#).

Analyse selected marks using tooltips

When you select one or multiple marks in a view, and then continue to hover in the same spot, several options for inspecting your data are available in the tooltip.

Tableau Desktop version

Web version

Tooltips provide additional information about the marks in your view, and provide the following data analysis options:

- Keep only the selected marks in the view. ✓ Keep Only
For more information, see [Select to keep or exclude data points in your view on page 1316](#).
- Exclude the selected marks from the view. ✗ Exclude
For more information, see [Select to keep or exclude data points in your view on page 1316](#).
- Create a group based on the selected marks. @ For more information, see [Correct Data Errors or Combine Dimension Members by Grouping Your Data on page 1099](#).
- Create a set that contains the selected marks (Tableau Desktop only). 🔗 For more information, see [Create Sets on page 1101](#).

- View the underlying data of the marks selected.  For more information, see [View Underlying Data](#) on page 1991.

For related information on Tooltips, see [Tooltips](#) on page 84.

For details on related analysis tools, see [Zoom and Pan Views and Select Marks](#) on page 1982, [Undo and Redo](#) on page 1988, and [Drop Lines](#) on page 2508.

Highlight data by category in tooltips

If you include discrete (categorical) dimensions or measures in your tooltip, you can use them to select marks in the view that have the same values. If Tooltip selection is turned on for your worksheet, then these fields show as underlined text when you mouse over them. Clicking on the tooltip selects all the marks in the view that have the same value.

In the example below, when you click on Bill Shonely (the value for Customer Name) in the tooltip, any mark in the view that also includes Bill Shonely as a customer is selected and all other marks are dimmed.

To turn this functionality off or on, select the **Allow selection by category** check box in the Edit Tooltips dialog box. For more information about setting tooltip properties, see [Add tooltips to marks](#) on page 1278.

Explore data in maps

Tableau maps can help you quickly find locations and analyse data worldwide. There are many ways you can explore and interact with map views. You can zoom in and out, pan and select marks with the view toolbar, and even search for locations worldwide with map search.

For more details, see [Explore Data in Maps](#) on page 1883, [Search for Locations in Your Map](#) on page 1885, and [Measure Distances Between Data Points and Locations on a Map](#) on page 1886.

Add analytics objects to the view (trend lines, forecasts, reference lines and bands)

Drag reference lines, box plots, trend lines forecasts and other items into your view from the **Analytics** pane, which appears on the left side of the workspace. Toggle between the **Data** pane and the **Analytics** pane by clicking the tabs at the top of the side bar. For more details, see [Apply Advanced Analysis to a View \(Analytics Pane\)](#) on page 48.

Tableau Desktop Analytics pane

In Tableau Desktop, options for adding Analytics objects to the view are available the **Analytics** pane or menu, or in context in the view. For example, reference lines and bands are available when you edit an axis, and trend lines and forecasts are available from the Analysis menu.

The **Analytics** pane provides drag-and-drop access for the various options.

On the web, most Analytics objects are available from the Analytics pane.

Compare marks data with recalculated lines

If there is an analytics object in your view, such as an average line, constant line, trend line, reference line or distribution line or band, selecting one or multiple marks in the view lets you instantly compare the analytical data for the selected marks to all data in the view.

For example, selecting marks in a view that contains a trend line creates a second, recalculated trend line, the value of which is determined by the selected marks only, so you can compare that trend to the overall trend.

Recalculated lines are displayed by default when you select marks in a view that already contains analytics objects. In Tableau Desktop, if you don't want recalculated lines to be created you can turn them off.

Turn off recalculated lines (Tableau Desktop only):

1. Select an analytics object in the view, such as a trend line, and click **Edit**.
2. In the **Edit** dialog box, clear **Show recalculated line for highlighted or selected data points**.

Alternatively, you can right-click (control-click on Mac) an analytics object in the view and clear **Show Recalculated Line**.

When you return to the view and select or highlight marks, recalculated lines will not appear. For more information, see [Highlight Actions on page 1401](#).

Recalculated lines and highlight actions

Recalculated lines also work with highlighting actions, both in worksheets and dashboards.

For example, if you create a highlight action in a dashboard, selecting marks in one sheet will highlight marks in the other sheets in the dashboard. If those other sheets have trend lines, reference lines, or other analytics objects, recalculated lines will appear as the views update.

Use Data Details to see visualisation information

Starting in 2019.3, Tableau Catalog is available as part of the Data Management offering for Tableau Server and Tableau Cloud. When the Tableau Catalogue is enabled in your environment, you can use the Data Details pane to see visualisation information. For more information about Tableau Catalog, see "About Tableau Catalog" in the [Tableau Server](#) or [Tableau Cloud](#) Help.

When you're looking at a published view and Tableau Catalogue is enabled in your environment, you can see information about the data used in the view by selecting **Data Details** in the toolbar above the view in workbooks and dashboards. Details include:

- A sparkline that shows the number of times a sheet or dashboard was viewed over the last 12 weeks.
- Information about the workbook (name, project, author, date modified, data quality warnings).
- The data sources used in the sheet or dashboard.
- A list of the fields in use. Select a field to see the field metadata, such as a description or calculation.

The links in the **Data Details** pane take you to that item, which opens in a separate window.

If there's a data quality warning in the lineage of any of the data used in a view, workbook or dashboard, the **Data Details** tab shows a blue circle with a white exclamation mark in it. Click the **Data Details** tab, then click the data quality warning to see the details of the warning.

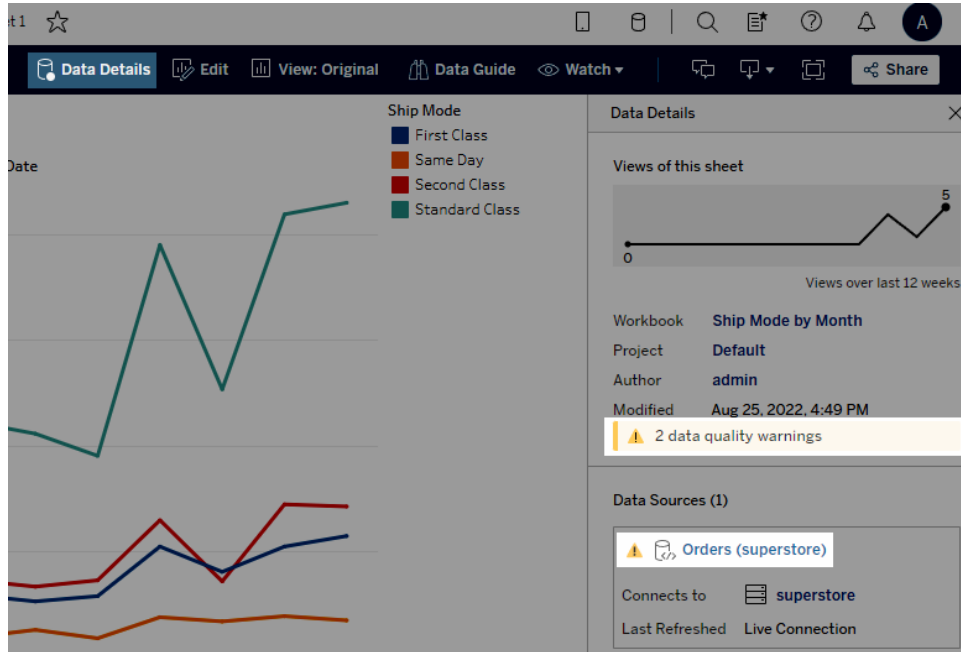

High visibility data quality warnings

When a data quality warning is tagged as important by, for example, the data item owner or an admin:

- A notification appears when anyone opens a published view that uses the affected data, with a link to the Data Details pane:

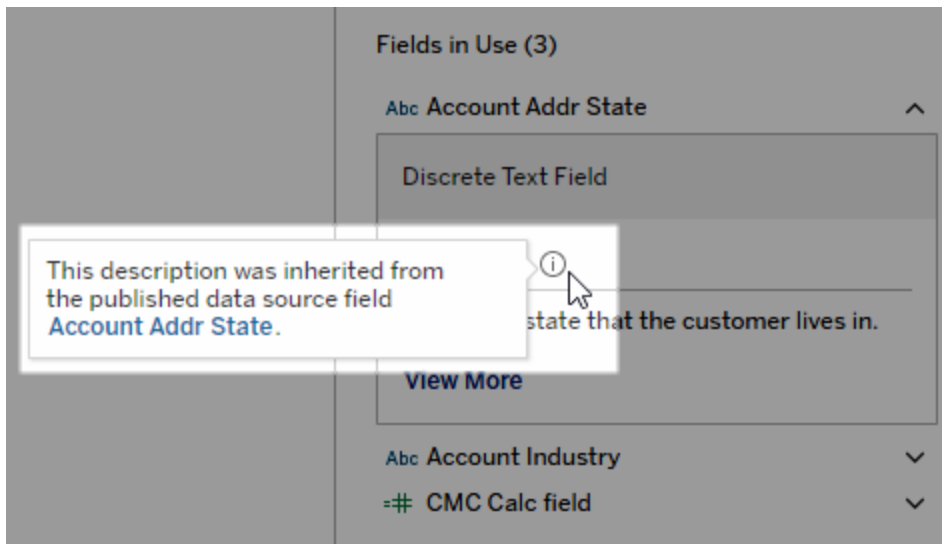

- On the Data Details pane (and elsewhere in Tableau), the warning's visibility is raised by using a yellow warning symbol:

Fields can show upstream descriptions

If a field used in a view doesn't have a description in the workbook, Catalogue can look up and display the description from the field or column upstream from it, if one exists. If a published data source is upstream and has a description for this field, the Data Details pane displays that field description. If not, this field shows the description from the column that the field references in the upstream table.

When a field gets its description from an upstream source, an information icon appears next to **Description**, telling where the description came from.

Some fields, such as a calculated field, group field or set field, don't support showing a description from an upstream source. Also, workbooks and data sources don't support displaying upstream field or column descriptions.

For information about adding descriptions, see "Add or edit descriptions" in [Manage Web Content](#) on page 3301.

Zoom and Pan Views and Select Marks

In the upper-left corner of a view, the view toolbar lets you zoom in and out, pan the view, and select data marks.

Show or hide the view toolbar

Tip: If you don't see the view toolbar in Tableau Cloud or Tableau Server, ask the content owner to show it using these instructions. Or [use keyboard shortcuts](#) to zoom, pan and select marks.

When you hover over a map view, the view toolbar appears by default, but you can change that behaviour. For more information, see [Customise How People Interact with your Map on page 1869](#). You can also show the toolbar in other types of views, such as scatter or box plots.

1. If you're working with a dashboard, select the zone on which you'd like to show or hide the toolbar.
2. From the top menu, select **Worksheet > Show View Toolbar**. Then select one of the following options:
 - **Automatic** shows the toolbar when you hover over a map view.
 - **Show on hover** shows the toolbar when you hover over any type of view.
 - **Hide** doesn't show the toolbar on the selected view. (To improve usability on mobile devices, however, the toolbar will appear when users interact with scrollable views or multiple selections.)

Tip: In Tableau Desktop, you can quickly toggle the toolbar on or off. Right-click anywhere in a view, and select **Show View Toolbar** or **Hide View Toolbar**.

Zoom and pan

The view toolbar provides zoom controls and a pan tool that lets you see a different areas of a zoomed view.

Zoom in and out

On the view toolbar, click the Zoom In button  to zoom in and the Zoom Out button  to zoom out.

If the view toolbar is hidden, double-click the view to zoom in; to zoom out, hold down Shift and then double-click the view.

Zoom to a specific area

To zoom in to a specific area of the view, click the Zoom Area tool button  on the view toolbar, and then drag in the view.

If the view toolbar is hidden, hold down Ctrl + Shift (Windows) or Command+ Shift (macOS) to use the Zoom Area tool.

Reset the view

After you zoom in or out, the axes in the view are fixed to a specific range. To quickly reset the axes so they automatically zoom the view to all of your data, do one of the following:

- In Tableau Desktop, click the Reset button  on the view toolbar.
- In Tableau Server or Tableau Cloud, click the Zoom Home button  on the view toolbar.

Pan a view

To pan, do one of the following:

- Hold down Shift, and then drag across the view.
- On the view toolbar, hover over the arrow, select the Pan tool , and then drag across the view.

Select marks

Select marks to see information about them in tooltips that appear. You can also quickly view underlying data or filter selected marks from a view. For more information, see [Tooltips on page 84](#).

When you select marks in the view, all other marks are dimmed to draw attention to the selection. Your selection is saved with the workbook.

Select individual or multiple marks

To select an individual mark, click it. To add more individual marks to a selection, hold down the Ctrl key (Windows) or the Command key (macOS).

To select multiple marks at once, drag across the view while using the Rectangular, Radial, and Lasso tools on the view toolbar.

Make rectangular selections

The Rectangular tool selects marks within a rectangular shape. To use the Rectangular tool,

hover over the arrow on the view toolbar, click the Rectangular tool button , and then drag across the view.

Note: The Rectangular tool is the default tool in most views and may not appear in the view toolbar. In this case, simply drag across the view to use the rectangular tool.

Make radial selections

The Radial tool selects marks within a circular area. To use the Radial tool, hover over the arrow

on the view toolbar, click the Radial tool button , and then drag across the view.

You can also measure distance in a map view with the Radial tool. For more information, see [Measure Distances Between Data Points and Locations on a Map](#) on page 1886.

Make lasso selections

With the Lasso tool, you can select multiple marks by drawing a freehand shape around them. This tool is useful when you want to include only certain marks, and exclude others around them.

To use the Lasso tool, hover over the arrow on the view toolbar, click the Lasso tool button , and then draw a freehand shape around the marks you want to select.

Undo and Redo

You can perform unlimited undo and redo of almost all actions in Tableau Desktop, as well as the content viewing and authoring modes of Tableau Cloud and Tableau Server. For example, you can quickly return to a sheet you were just viewing, or you can cycle through changes to a data source you're editing.

Tableau saves your undo and redo history across all worksheets until you exit; the history isn't saved between sessions.

Keyboard shortcuts

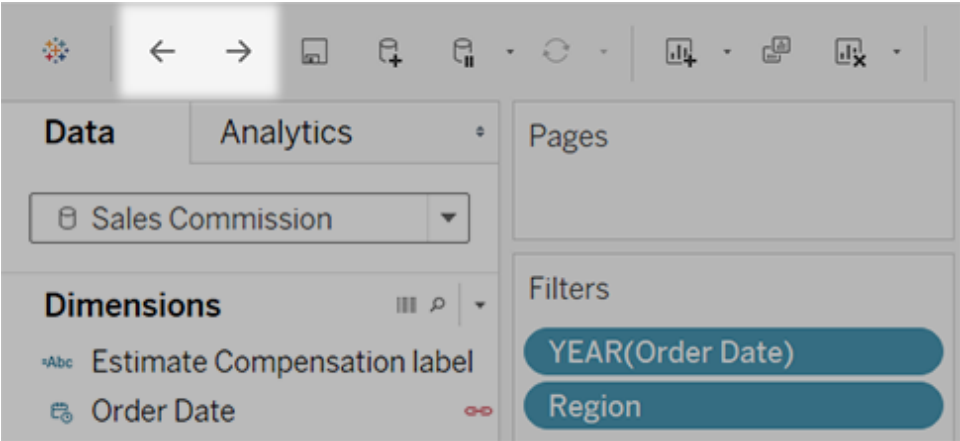

To quickly undo or redo changes, use these keyboard shortcuts:

- On Windows, press Ctrl+Z to undo and Ctrl+Y to redo.
- On macOS, press Command+Z to undo and Command+Shift+Z to redo.

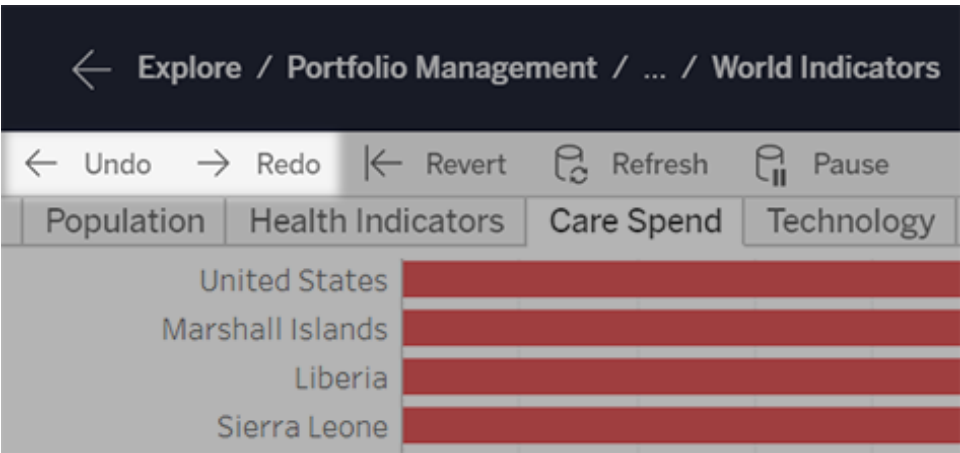

Undo and Redo buttons

In the upper-left corner of Tableau Desktop, Tableau Cloud and Tableau Server, you can click the Undo and Redo buttons.

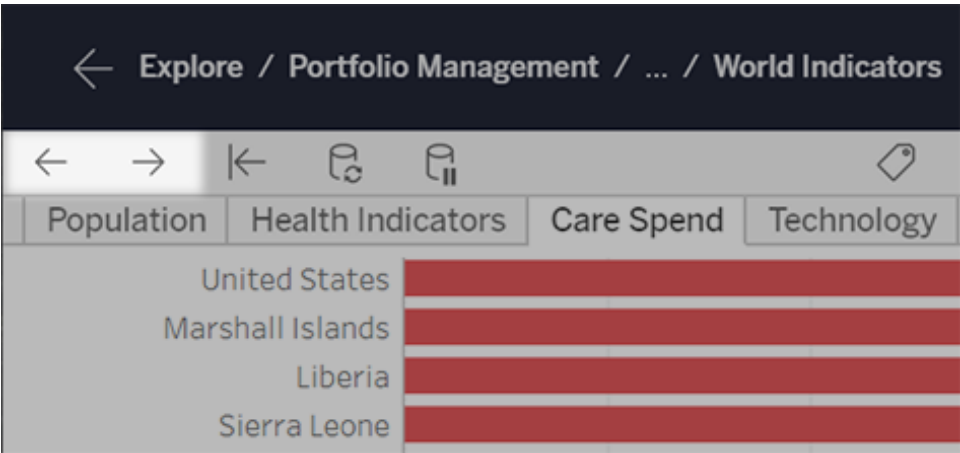

Here's how those buttons appear in Tableau Desktop:

And here's how they appear in Tableau Cloud and Tableau Server:

If your browser window is more narrow, the buttons appear like so:

I don't see the toolbar for these buttons

Well, you've got a few options. Either use the [keyboard shortcuts](#) above, or do the following:

- For Tableau Desktop, select **Window > Show Toolbar**.
- For an embedded view from Tableau Cloud or Tableau Server, ask the content owner to unhide the toolbar using the “toolbar” [URL parameter](#).

Now start making some wild changes in Tableau so you can undo and redo them to your heart's content!

Summary Card

The **Summary Card**, available on the **Show/Hide Cards** toolbar menu , provides a quick view of information about a selection or the entire data source.

When you select data in the view, the **Summary Card** updates to show you information only for the data within the selection:

By default, the **Summary Card** shows Sum, Average, Minimum, Maximum and Median values for the data in the view. The summary card values update to show these values for the current selection of data points. (Average is computed by summing all relevant values and then dividing by the total number of values. Median is computed by sorting values from lowest to highest and

then selecting the middle value.) The Count value at the top of the card indicates the number of marks in the view or selection.

You can use the drop-down menu for the **Summary Card** to show additional statistics:

- **Standard Deviation**

A measure of data spread around its average, measured in the same units as the data itself. The sample standard deviation is an unbiased estimate of the population standard deviation given a slight correction. This standard deviation includes the correction.

- **First Quartile**

A measure of location that is commonly used with other quartiles to provide a robust measure of spread. Robust in this case means not as sensitive to outliers as the standard deviation. The first quartile is the 25th percentile, typically the lower line in a boxplot.

- **Third Quartile**

A measure of location that is commonly used with other quartiles to provide a robust measure of spread. Robust in this case means not as sensitive to outliers as the standard deviation. The third quartile is the 75th percentile, typically the upper line in a boxplot.

- **Skewness**

A measure of the tendency of your data to have extreme values to one side. Positive skewness means the extreme values are to the right, while negative skewness means the extreme values are to the left.

- **Excess Kurtosis**

A measure of the tendency of your data to have more extreme or outlying values than a normal distribution. A normal distribution has a kurtosis of 3 so this value is kurtosis minus three.

View Underlying Data

When you see a Tableau visualisation, do you wonder what data makes up each mark or even the entire viz? A typical viz contains aggregated measures based on the structure of the dimensions in the view. Every mark you see in a viz has underlying column and row data. The View Data window displays this data in a tabular format, scoped to the current selection or the current view.

If you have the required permissions, you can view underlying data in a worksheet, sheets in a dashboard or in the Data Source page. In the worksheet, you can **customise** the View Data window and **download** that customised view in CSV format.

Note: Customised sort results aren't included in the downloaded data.

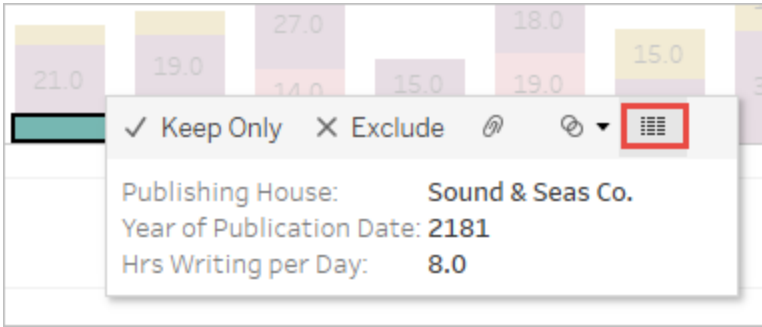

By default, the View Data window displays up to 10,000 rows of data in Tableau Desktop and up to 200 rows of data in Tableau Cloud and Tableau Server.

Note: Columns might be displayed differently in the View Data window, and the column order might be different when you export it to CSV format. In Tableau version 2022.1 and later, you can manually customise the column order before you export the data.

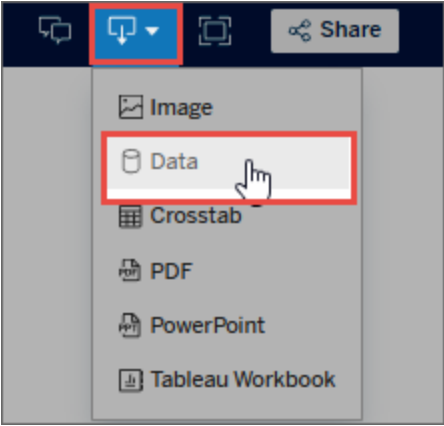

This change in how column order is handled in the View Data window is required to support relationships and logical tables. If you use scripts that depend on a customised column order, we recommend using the Tableau Extensions API for View Data to download underlying data to CSV format.

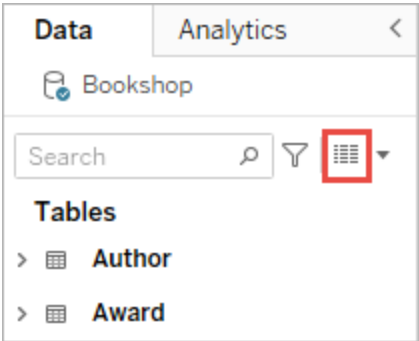

Where you can open the View Data window

The data you see in the View Data window varies depending on the context of where you open it.

| Context | Scope | How |
|--|--|---|
| Worksheet: Selected Mark or Marks | In a worksheet, selecting one or more marks and then selecting View Data from the tooltip menu displays underlying data scoped | Select one or more marks in the view, then select View Data from the tooltip menu. |

10,000 rows

The View Data window displays multiple tabs on the left side of the window. The number of tabs and types of tabs vary depending on the current scope.

- The **Summary** tab displays the dimensions that define the view and the aggregated measure or measures that make up the mark.

When more than one continuous date field is used in a view, the rows for field values won't be merged in the summary data. This behaviour applies to continuous dimensions in general, but most commonly will occur with date fields.

- A tab for each table that has a measure present in the view, showing all fields from that table. The **Full Data** tab is displayed for single table data sources.

To show all fields, select **(All)** under **Show Fields**. When **(All)** is selected, each tab shows all dimensions that define the view, regardless of which table they're from.

- Field names are shown as column headers. Hover near the top of a column to display the drop-down menu and Sort button. You can also click anywhere in a column header to display its drop-down menu.
- Some calculations used in the view might be displayed on tabs as well:
 - Calculations that don't belong with a table in the Data pane, such as aggregate calculations or calculations that span tables.
 - LOD calculations (**FIXED** or **INCLUDE** only), even if they reside in a table in the Data pane. Ad hoc LOD calculations aren't shown in View Data.

- All relevant fields used in the calculation are displayed, regardless of their original table, as well as the value of the calculation itself.

Open View Data in a viz for one or more marks

Click on a mark to display its tooltip. In the tooltip menu, click the View Data icon . You can also select multiple marks simultaneously and then click View Data in the tooltip menu see the combined View Data results.

Note: The **Include command buttons** option must be selected for tooltips in the viz for the View Data button to be available.

Open View Data for the entire view

Tableau Cloud and Tableau Server

To see the underlying data for the entire view, in viewing or editing mode, click the **Download** button on the toolbar and then select **Data**. Make sure no marks are selected in the view, otherwise, the data is scoped to your selection.

In a dashboard, underlying data can be viewed based on the selected worksheet. Select a sheet in the dashboard before you click the Download button to make the Data option available.

Tableau Desktop

To see the underlying data for the entire view, from the **Analysis** menu, select **View Data**. The View Data window is displayed with similar results for viewing data for a mark, but instead it displays all of the data in use in the view.

Open View Data for the Data pane

To see the underlying data for each field in the data source, listed by table, click on the View Data icon  in the top of the Data pane, next to the Search field.

You can open the View Data for the Data pane in Tableau Desktop only.

Open View Data in the Data Source page

The View Data window can be opened per table for the data source. Viewing data for the data source before or during analysis can be useful to give you a sense of the scope of each table, its fields and their values and general impressions about the data.

When you open View Data in the Data Source page, you can move and sort the field columns in the View Data window, but you can't download the data.

In the Data Source page, hover over a table or sheet in the left pane to display the View Data icon , then click on the icon.

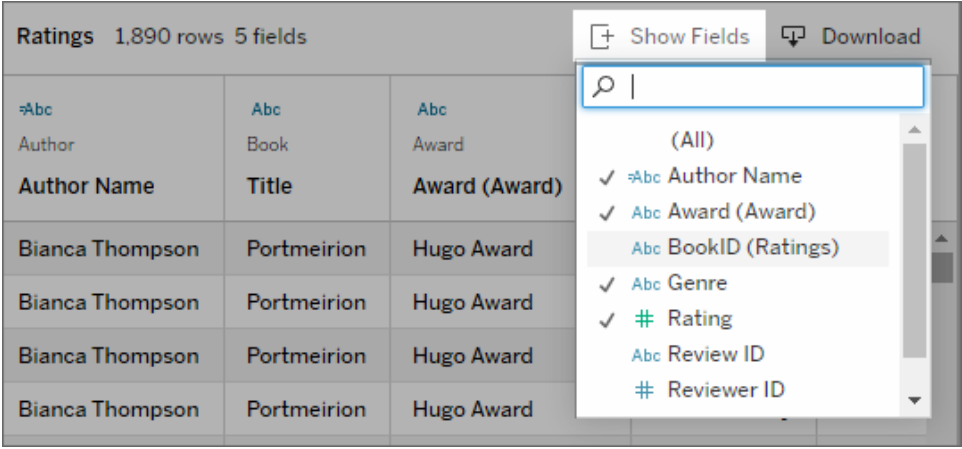

The View Data window displays the data for that table.

Customise the View Data window

All customisation options are available when you open View Data in a worksheet and are used for downloaded data.

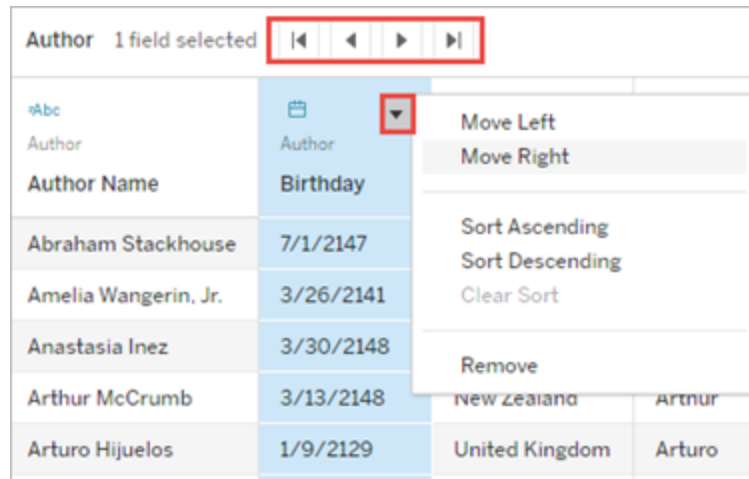

The customisations you make remain until you close the View Data window. Closing the View Data window discards all customisations.

Note: For the Data Source page, sorting and moving fields are the only options available for View Data.

| Option | How | Where |
|-----------------------------------|---|--|
| Show or hide field columns | Click Show Fields and tick or untick a field name. To show all fields, select (All) . Fields are added to the right of the currently displayed fields. |  |

| Option | How | Where |
|--------|-----|-------|
|--------|-----|-------|

| | | |
|---------------------------|--|--|
| Move field columns | Select one or more field columns and then click on the right or left arrows at the top of the window. Or, select the drop-down menu and click Move Right and Move Left . | |
|---------------------------|--|--|

Tip: To group non-adjacent columns together, press Ctrl while selecting the columns, and then move the selected columns to the left or right.

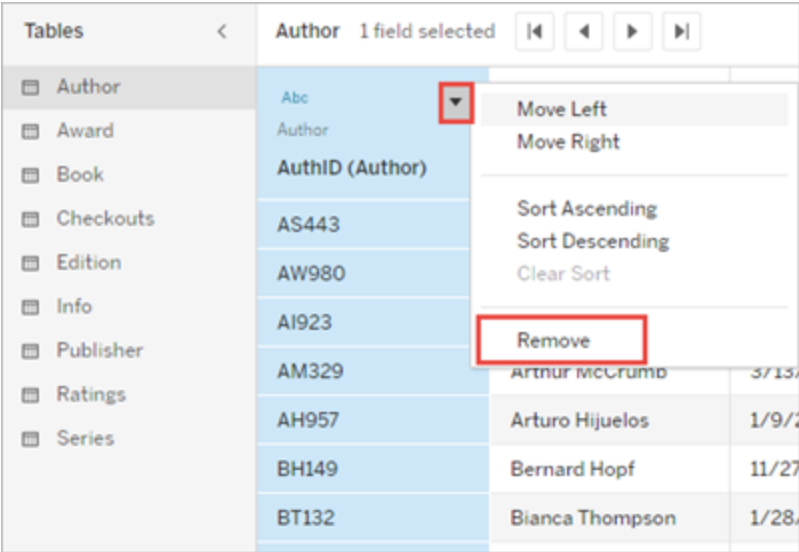

Option

How

Where

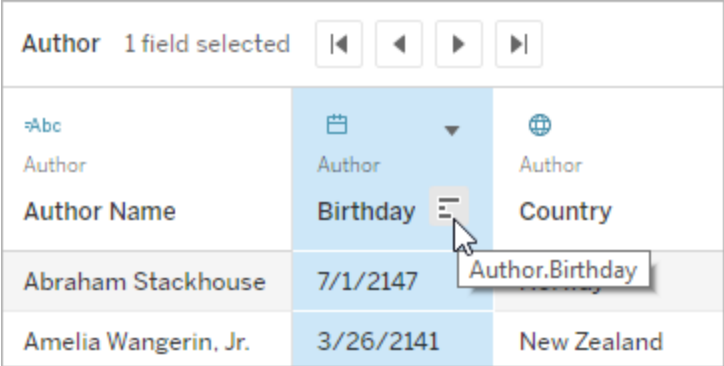

Remove field columns

Select a field column and then select **Remove** from the drop-down menu. Or, click **Show Fields** and untick the field to remove its column.

Sort data

Hover near the top of a column to display the Sort button. Click the Sort button to change the sort. Optionally, click the drop-down menu and select **Sort Ascending** or **Sort Descending**

Note:
Customis
ed sort
results

| Option | How | Where |
|--------|-----|-------|
|--------|-----|-------|

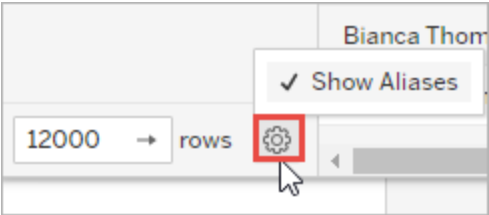

aren't included in downloaded data.

| | | |
|--|--|--|
| Edit the maximum number of rows displayed | | |
|--|--|--|

By default, the View Data window displays up to the first 10,000 rows of data in Tableau Desktop and up to the first 200 rows of data in Tableau Cloud and Tableau Server.

You can increase or decrease the maximum number of rows displayed in the View Data window. This setting has no effect on the number of rows exported when you click the **Download** button.

| Option | How | Where |
|---------------------|--|--|
| | Click in the number of rows field to edit it. Click the arrow button or press Enter on your keyboard to apply the change. | |
| Show aliases | Click the Settings button to show or hide aliases for all field names. |  |

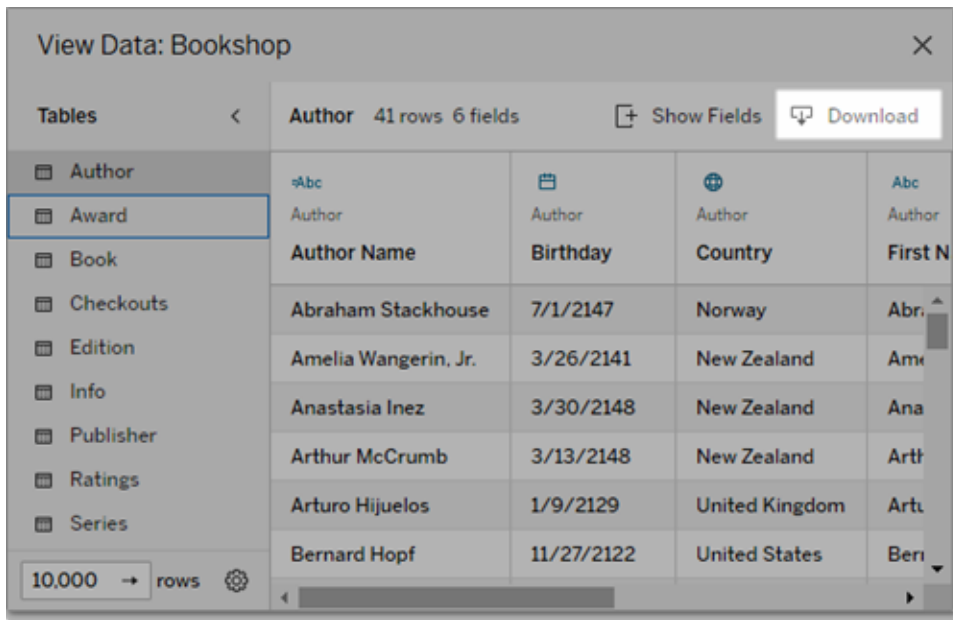

Download data from the View Data window

To export all of the data for the selected tab, click the **Download** button.

The data is exported to a CSV file using the current configuration as the View Data window and isn't limited to the number of rows currently displayed in the View Data window.

Note: Customised sort results aren't included in downloaded data.

Null values are downloaded as empty strings.

Note: If you are a workbook author and want to ensure your audience can't copy or download the underlying data, consider [turning off the command buttons in the tooltips](#) or denying workbook [permissions](#) to download the summary or full data.

Copy data from the View Data window

You can copy portions of the data from the View Data window for use in a spreadsheet or another Tableau workbook (really, anywhere you can paste text). Null values are copied as empty strings.

- Select cells of interest and press Ctrl+C (Windows) or Command+C (Mac), and then paste the data into a spreadsheet, another Tableau workbook or another destination of your choice.

Note: If you want to download all of the values in the underlying data, click the **Download** button. Selecting and copying a column copies only values that are currently loaded in the View Data window and might not include all of the values in the underlying data.

Why can't I see the View Data icon?

If you can't find the View Data icon for a mark, check that tooltips and tooltip menu command buttons are turned on. Specifically, the **Show tooltips** and **Include command buttons** options must be selected for tooltips in the viz for the View Data button to be available in a tooltip.

Alternatively, right-click on a mark and select **View Data** from the drop-down menu. This method works when tooltips or command buttons aren't enabled.

There are several reasons why the View Data icon for a mark might not be displayed in a published viz:

- Tooltips aren't enabled.
- Tooltip command buttons have been turned off.
- You might not have the necessary permissions to view data.

Get Details About Fields and Sheets in a Workbook

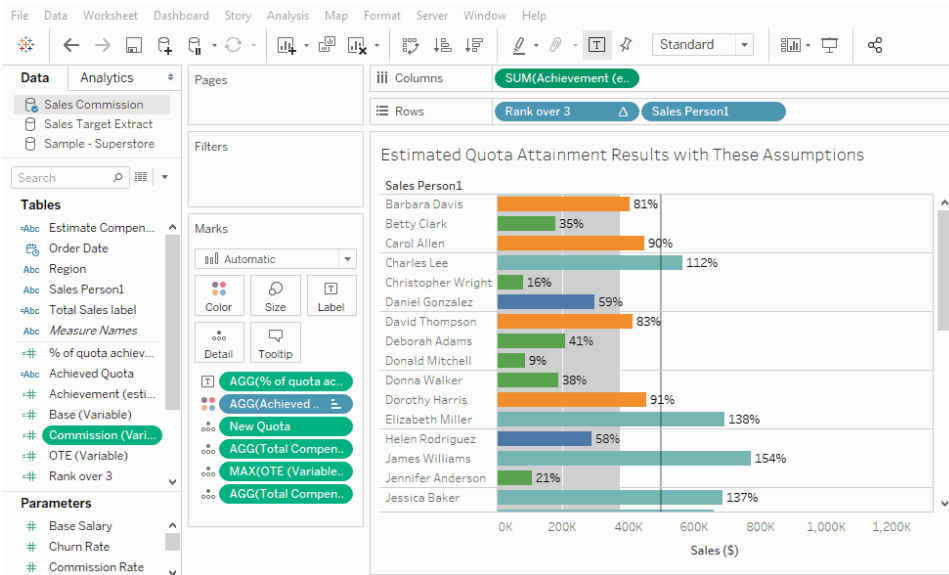

When you want to see details about the elements in use in a viz, select the **Worksheet** menu, and then click **Describe Sheet**.

For details about a field (such as data role, data type, domain, aggregation, calculation formula), click **Describe** in a field's context menu in the **Data** pane. You can then share those details with someone else by copying that summary text.

Note: For related information, see these blog posts from Tableau Visionaries Ryan Sleeper (PlayfairData) and Bridget Cogley (TableauFit): [3 Ways the Describe Feature Can Help You Use Tableau](#) and [10 Intro Tips to Tableau When You're Handed Someone Else's Workbooks](#).

Display sheet details

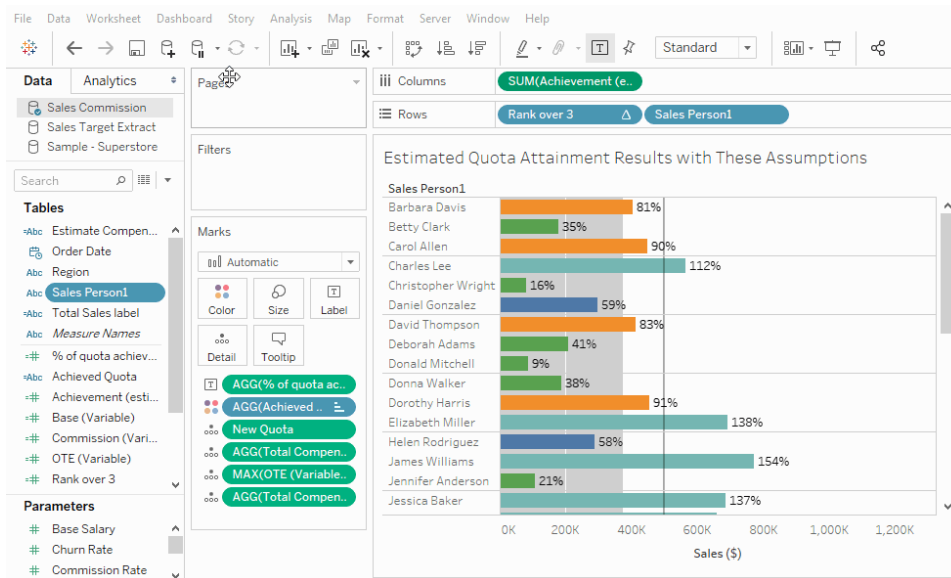

Click **Worksheet** > **Describe Sheet** when editing a viz to view a description of the workbook, data source, fields and layout of the current worksheet. This summary includes the Caption in the first line, but provides other important summary information. You can then copy and paste this information into other applications.

Note: If you have Trend Lines turned on, the Describe Sheet dialog box includes information about the trend line model. For more information, see [Assess Trend Line Significance](#) on page 2505. If you have Forecasting turned on, the Describe Sheet dialog box includes information about estimated data. For more information, see [Forecast Descriptions](#) on page 2552.

Display field details

When you click **Describe** in the context menu of a field in the Data pane, you can view a description of the workbook, data source, fields and layout of the current worksheet. This summary includes the Caption in the first line, but provides other important summary information. You can then copy and paste this information into other applications.

Create Custom Fields with Calculations

If your underlying data doesn't include all of the fields you need in order to answer your questions, you can create new fields in Tableau using calculations and then save them as part of your data source. These fields are called calculated fields.

This section provides all the documentation you need to get started with calculations in Tableau.

Get Started with Calculations in Tableau

This article describes how to create and use calculated fields in Tableau using an example.

You'll learn Tableau calculation concepts, as well as how to create and edit a calculated field. You will also learn how to work with the calculation editor, and use a calculated field in the view.

If you're new to Tableau calculations or to creating calculated fields in Tableau, this is a good place to start.

Why Use Calculated Fields

Calculated fields allow you to create new data from data that already exists in your data source. When you create a calculated field, you are essentially creating a new field (or column) in your data source, the values or members of which are determined by a calculation that you control. This new calculated field is saved to your data source in Tableau, and can be used to create more robust visualisations. But don't worry: your original data remains untouched.

You can use calculated fields for many, many reasons. Some examples might include:

- To segment data
- To convert the data type of a field, such as converting a string to a date.
- To aggregate data
- To filter results
- To calculate ratios

Types of calculations

You create calculated fields using calculations. There are three main types of calculations you can use to create calculated fields in Tableau:

- **Basic calculations** - Basic calculations allow you to transform values or members at the data source level of detail (a row-level calculation) or at the visualisation level of detail (an aggregate calculation).
- **Level of Detail (LOD) expressions** - Just like basic calculations, LOD calculations allow you to compute values at the data source level and the visualisation level. However, LOD calculations give you even more control on the level of granularity you want to compute. They can be performed at a more granular level (INCLUDE), a less granular level (EXCLUDE), or an entirely independent level (FIXED) with respect to the granularity of the visualisation.

For more information, see [Create Level of Detail Expressions in Tableau on page 2395](#).

- **Table calculations** - Table calculations allow you to transform values at the level of detail of the visualisation only. For more information, see [Transform Values with Table Calculations on page 2355](#).

The type of calculation you choose depends on the needs of your analysis and the question you want to answer.

Create a calculated field

Once you have determined the type of calculation you want to use, it's time to create a calculated field. This example uses a basic calculation.

Note: The example in this article uses the **Sample-Superstore** data source that comes with Tableau Desktop. To follow along with the steps in this article, connect to the **Sample-Superstore** saved data source and navigate to **Sheet 1**.

1. In Tableau, select **Analysis > Create Calculated Field**.
2. In the Calculation Editor that opens, do the following:
 - Enter a name for the calculated field. In this example, the field is called, **Discount Ratio**.
 - Enter a formula. This example uses the following formula:

```
IIF([Sales] !=0, [Discount]/[Sales],0)
```

This formula checks if sales is not equal to zero. If true, it returns the discount ratio (Discount/Sales); if false, it returns zero.

Tip: To see a list of available functions, click the triangle icon on the right-hand side of the Calculation Editor.

Each function includes syntax, a description, and an example for your reference. Double-click a function in the list to add it to the formula. For more tips, see [Tips for Working with Calculated Fields in Tableau on page 2458](#).

3. When finished, click **OK**. The new calculated field is added to Data pane as a measure because it returns a number. An equal sign (=) appears next to the data type icon. All calculated fields have equal signs (=) next to them in the **Data** pane.

Use a calculated field in the view

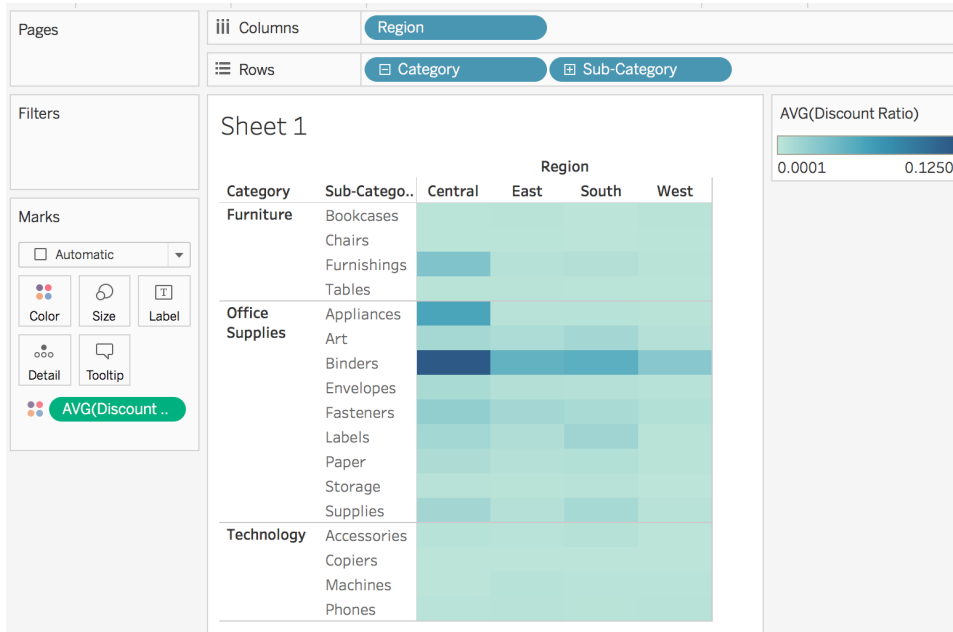

Step 1: Build the view

1. From the **Data** pane, drag **Region** to the **Columns** shelf.
2. From the **Data** pane, drag **Category** to the **Rows** shelf.
3. On the **Rows** shelf, click the plus icon (+) on the **Category** field to drill-down to Sub-category.

Step 2: Add the calculated field to the view

1. From the **Data** pane, drag **Discount Ratio** to **Colour** on the Marks card. The view updates to highlight table.

- Binders are heavily discounted in the Central region. Notice that Discount Ratio is automatically aggregated as a sum.
2. On the Rows shelf, right-click **SUM(Discount Ratio)** and select **Measure (Sum) > Average**. The view updates to show the average of discount ratio.

Edit a Calculated Field

If at any time you need to change a calculation, you can edit the calculated field and it will update across your entire workbook.

To edit a calculated field:

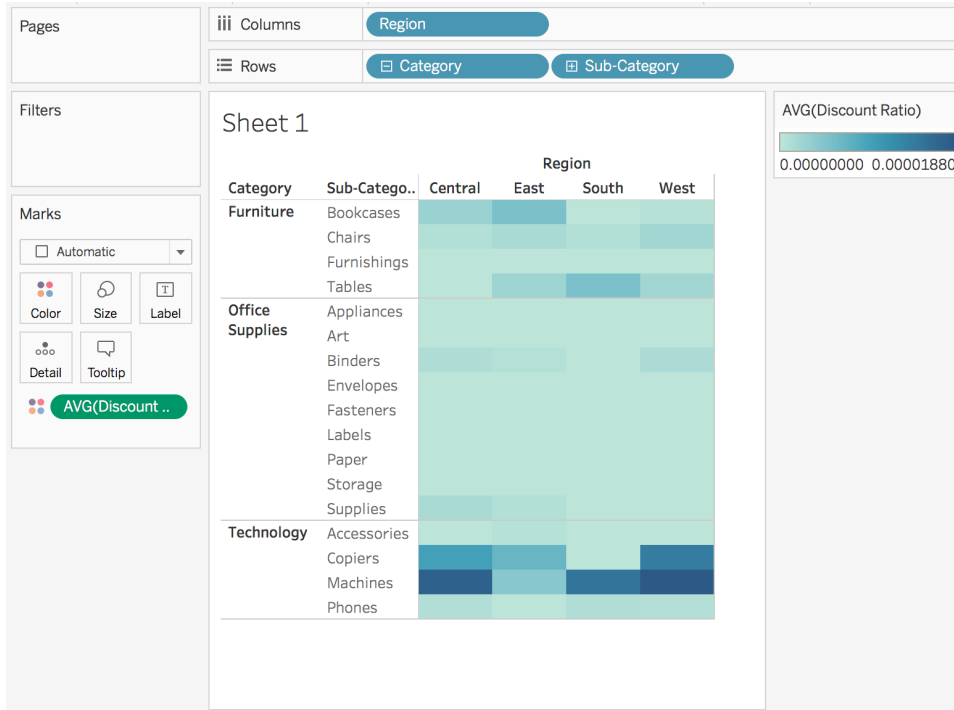

1. In the **Data** pane, right-click the calculated field and select **Edit**.
2. In the Calculation Editor that opens, you can do the following:
 - Edit the name of the calculated field.
 - Update the formula.

For this example, the formula is changed to return a discount ratio for orders over 2000 USD in sales:

```
IIF([Sales] > 2000, [Discount]/[Sales],0)
```

3. Click **OK**.

The view updates to reflect the changes automatically. You *do not* need to re-add the updated calculated field to the view.

Create a Simple Calculated Field

Sometimes your data source does not contain a field (or column) that you need for your analysis. For example, your data source might contain fields with values for Sales and Profit, but not for Profit Ratio. If this is the case, you can create a calculated field for Profit Ratio using data from the Sales and Profit fields.

This topic demonstrates how to create a simple calculated field using an example.

Step 1: Create the calculated field

1. In a worksheet in Tableau, select **Analysis > Create Calculated Field**.
2. In the Calculation Editor that opens, give the calculated field a name. In this example, the calculated field is called **Profit Ratio**.

Step 2: Enter a formula

1. In the Calculation Editor, enter the following formula:

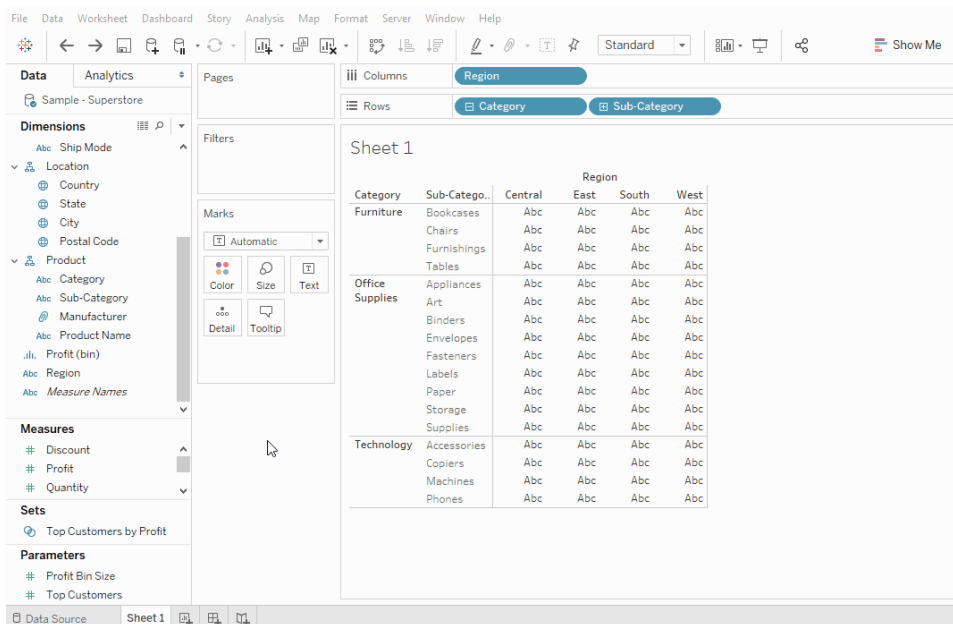

```
SUM([Profit])/SUM([Sales])
```

Formulas use a combination of functions, fields and operators. To learn more about creating formulas in Tableau, see [Formatting Calculations in Tableau on page 2439](#) and [Functions in Tableau on page 2039](#).

2. When finished, click **OK**. The new calculated field is added to the Data pane with an = in front of the data type icon to indicate it's a calculated field.

You are now ready to use the calculated field in the view.

Check your work! Watch how to create a simple calculated field in action:

Understanding Calculations in Tableau

This series introduces the basics of understanding calculations in Tableau. In this topic, you'll learn why and when to use calculations.

Why use calculations

Calculations allow you to create new data from data that already exists in your data source, as well as perform computations on your data. This allows you to perform complex analyses and add fields to your data source on your own and on the fly.

When to use calculations

The first hurdle to learning calculations in Tableau is to recognise when you actually need to use one. You can use calculations for many, many reasons. Some examples might include:

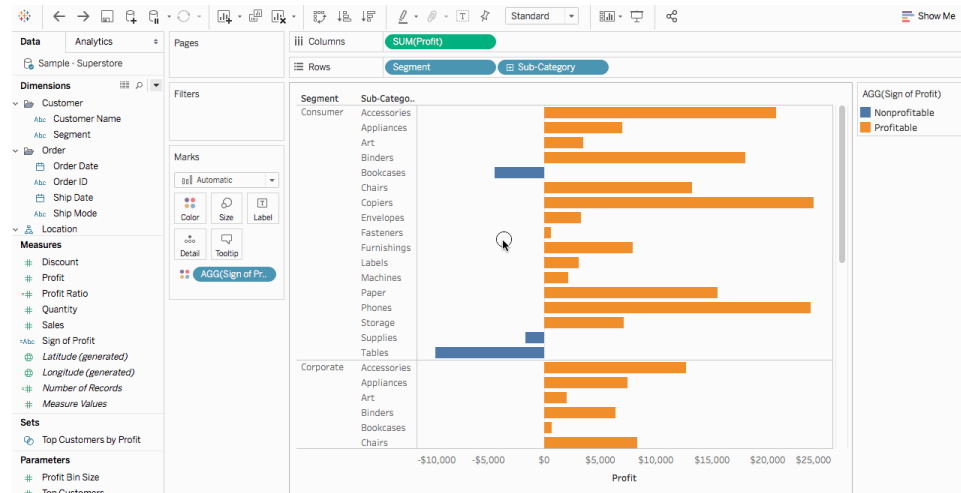

- To segment data
- To convert the data type of a field, such as converting a string to a date.
- To aggregate data
- To filter results
- To calculate ratios

Some common scenarios might include:

- **The data you need for your analysis is missing from your data source.**

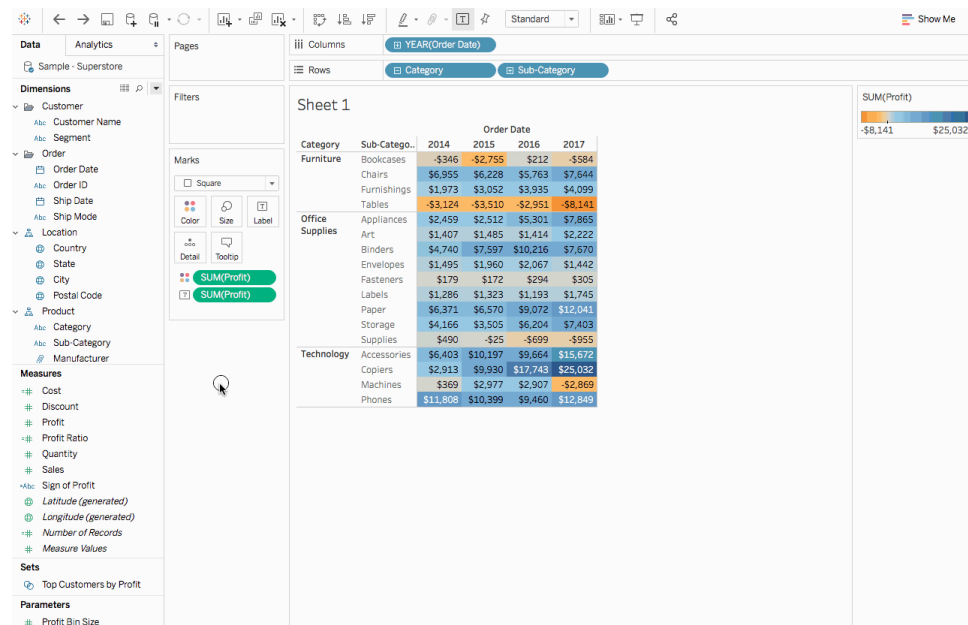

For example, if you have a Sales and Profit field in your data source, but you want to calculate cost, you can *create* a Cost field using a formula similar to the following.

```
[Sales] - [Profit]
```

- You want to transform values in your visualisation.

For example, you might want to calculate the difference in profit from one year to the other. You can use a quick table calculation to show the difference in profit in the visualisation.

- You want to quickly categorise data.

For example, you might want to quickly colour the data in your visualisation as profitable or non-profitable. You can create a calculated field using a calculation similar to the following and then add it to Colour on the Marks card.

```

IF SUM([Profit]) > 0
THEN "Profitable"
ELSE "Nonprofitable"
END

```

Types of Calculations in Tableau

This article explains the types of calculations you can use in Tableau. You'll learn the difference between each calculation and how they are computed.

There are three main types of calculations you can use to create calculated fields in Tableau:

- **Basic expressions**
- **Level of Detail (LOD) expressions**
- **Table calculations** on page 2024

Basic expressions

Basic expressions allow you to transform values or members at the data source level of detail (a row-level calculation) or at the visualisation level of detail (an aggregate calculation).

For example, consider the following sample table, which contains data on two fantasy authors and their books. Perhaps you want to create a column with only the author's last name and a column that displays how many books are in each series.

| Book ID | Book Name | Series | Year Released | Author |
|---------|--------------------------------------|--------------------------|---------------|-----------------------|
| 1 | The Lion, the Witch and the Wardrobe | The Chronicles of Narnia | 1950 | C.S. Lewis |
| 2 | Prince Caspian: The Return to Narnia | The Chronicles of Narnia | 1951 | C.S. Lewis |
| 3 | The Voyage of the Dawn Treader | The Chronicles of Narnia | 1952 | C.S. Lewis |
| 4 | The Silver Chair | The Chronicles of Narnia | 1953 | C.S. Lewis |
| 5 | The Horse and His Boy | The Chronicles of Narnia | 1954 | C.S. Lewis |
| 6 | The Magician's Nephew | The Chronicles of Narnia | 1955 | C.S. Lewis |
| 7 | The Last Battle | The Chronicles of Narnia | 1956 | C.S. Lewis |
| 8 | Daughter of the Forest | Sevenwaters | 1999 | Juliet Maril- lier |
| 9 | Son of the Shadows | Sevenwaters | 2000 | Juliet Maril- lier |
| 10 | Child of the Prophecy | Sevenwaters | 2001 | Juliet Maril- lier |
| 11 | Heir of Sevenwaters | Sevenwaters | 2008 | Juliet Maril- lier |
| 12 | Seer of Sevenwaters | Sevenwaters | 2010 | Juliet Maril- lier |
| 13 | Flame of Sevenwaters | Sevenwaters | 2012 | Juliet Maril- lier |

Row-level calculations

To create a column that displays the author's last name for every row in the data source, you can use the following row-level calculation that splits on a space:

```
SPLIT([Author], ' ', 2 )
```

The result can be seen below. The new column, titled **Author Last Name** is shown on the far right. The colours demonstrate the level of detail the calculation is performed at. In this case, the calculation is performed at the row-level of the data source, so each row is coloured separately.

| Book ID | Book Name | Series | Year Released | Author | Author Last Name |
|---------|--------------------------------------|--------------------------|---------------|---------------------|------------------|
| 1 | The Lion, the Witch and the Wardrobe | The Chronicles of Narnia | 1950 | C.S. Lewis | Lewis |
| 2 | Prince Caspian: The Return to Narnia | The Chronicles of Narnia | 1951 | C.S. Lewis | Lewis |
| 3 | The Voyage of the Dawn Treader | The Chronicles of Narnia | 1952 | C.S. Lewis | Lewis |
| 4 | The Silver Chair | The Chronicles of Narnia | 1953 | C.S. Lewis | Lewis |
| 5 | The Horse and His Boy | The Chronicles of Narnia | 1954 | C.S. Lewis | Lewis |
| 6 | The Magician's Nephew | The Chronicles of Narnia | 1955 | C.S. Lewis | Lewis |
| 7 | The Last Battle | The Chronicles of Narnia | 1956 | C.S. Lewis | Lewis |
| 8 | Daughter of the Forest | Sevenwaters | 1999 | Juliet Marillier | Marillier |
| 9 | Son of the Shadows | Sevenwaters | 2000 | Juliet Marillier | Marillier |

| | | | | | |
|----|-----------------------|-------------|------|------------------|-----------|
| 10 | Child of the Prophecy | Sevenwaters | 2001 | Juliet Marillier | Marillier |
| 11 | Heir of Sevenwaters | Sevenwaters | 2008 | Juliet Marillier | Marillier |
| 12 | Seer of Sevenwaters | Sevenwaters | 2010 | Juliet Marillier | Marillier |
| 13 | Flame of Sevenwaters | Sevenwaters | 2012 | Juliet Marillier | Marillier |

Aggregate calculations

To create a column that displays how many books are in each series, you can use the following aggregate calculation:

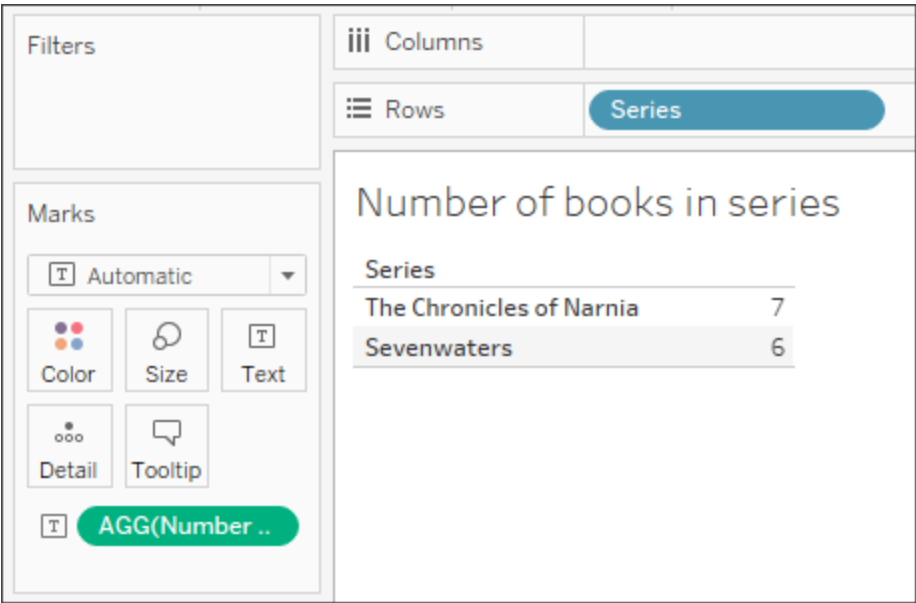

```
COUNT ([Series])
```

The result can be seen below. The new column, titled **Number of Books in Series – at Series level of detail** shows how that calculation would be performed at the Series level of detail in the view. The colours help demonstrate the level of detail in which the calculation is being performed.

| Series | Number of Books in Series – at Series level of detail |
|--------------------------|---|
| The Chronicles of Narnia | 7 |
| The Chronicles of Narnia | |
| The Chronicles of Narnia | |
| The Chronicles of Narnia | |
| The Chronicles of Narnia | |
| The Chronicles of Narnia | |
| The Chronicles of Narnia | |

| | |
|-------------|---|
| Sevenwaters | 6 |
| Sevenwaters | |
| Sevenwaters | |
| Sevenwaters | |
| Sevenwaters | |
| Sevenwaters | |

In Tableau, the data looks like this:

But if you drag in **Book Id**, (which is a more granular field), the calculation updates based on that new granularity since aggregate calculations are performed at the visualisation level of detail.

Level of Detail (LOD) expressions

Just like basic expressions, LOD expressions allow you to compute values at the data source level and the visualisation level. However, LOD expressions give you even more control on the level of granularity you want to compute. They can be performed at a more granular level (INCLUDE), a less granular level (EXCLUDE), or an entirely independent level (FIXED).

For more information, see [Create Level of Detail Expressions in Tableau](#) on page 2395.

For example, consider the same sample table as [above](#). If you wanted to compute when a book series was launched, you might use the following LOD expression:

```
{ FIXED [Series]:(MIN([Year Released])) }
```

The result can be seen below. The new column, titled **Series Launched**, displays the minimum year for each series. The colours help demonstrate the level of detail in which the calculation is being applied.

| Book ID | Book Name | Series | Year Released | Author | Series Launched |
|---------|---------------------|----------------|---------------|--------|-----------------|
| 1 | The Lion, the Witch | The Chronicles | 1950 | C.S. | 1950 |

| | | | | | |
|----|--------------------------------------|--------------------------|------|------------------|------|
| | and the Wardrobe | of Narnia | | Lewis | |
| 2 | Prince Caspian: The Return to Narnia | The Chronicles of Narnia | 1951 | C.S. Lewis | 1950 |
| 3 | The Voyage of the Dawn Treader | The Chronicles of Narnia | 1952 | C.S. Lewis | 1950 |
| 4 | The Silver Chair | The Chronicles of Narnia | 1953 | C.S. Lewis | 1950 |
| 5 | The Horse and His Boy | The Chronicles of Narnia | 1954 | C.S. Lewis | 1950 |
| 6 | The Magician's Nephew | The Chronicles of Narnia | 1955 | C.S. Lewis | 1950 |
| 7 | The Last Battle | The Chronicles of Narnia | 1956 | C.S. Lewis | 1950 |
| 8 | Daughter of the Forest | Sevenwaters | 1999 | Juliet Marillier | 1999 |
| 9 | Son of the Shadows | Sevenwaters | 2000 | Juliet Marillier | 1999 |
| 10 | Child of the Prophecy | Sevenwaters | 2001 | Juliet Marillier | 1999 |
| 11 | Heir of Sevenwaters | Sevenwaters | 2008 | Juliet Marillier | 1999 |
| 12 | Seer of Sevenwaters | Sevenwaters | 2010 | Juliet Marillier | 1999 |
| 13 | Flame of Sevenwaters | Sevenwaters | 2012 | Juliet Marillier | 1999 |

In Tableau, the calculation remains at the Series level of detail since it uses the FIXED function.

If you add another field to the view (which adds more granularity) the values for the calculation are not affected, unlike an aggregate calculation.

The screenshot shows the Tableau Desktop interface with the 'Columns' shelf containing 'Series', 'Book Name', and 'Year Released'. The 'Rows' shelf is empty. The 'Marks' shelf is set to 'Automatic'. The view displays a table titled 'Series Launched' with columns for 'Series', 'Book Name', and 'Year Released'. The data is grouped by 'Series'.

| Series | Book Name | Year Released |
|--------------------------|--------------------------------------|---------------|
| The Chronicles of Narnia | The Lion, the Witch and the Wardrobe | 1950 |
| | Prince Caspian: The Return to Narnia | 1951 |
| | The Voyage of the Dawn Treader | 1952 |
| | The Silver Chair | 1953 |
| | The Horse and His Boy | 1954 |
| | The Magician's Nephew | 1955 |
| | The Last Battle | 1956 |
| Sevenwaters | Daughter of the Forest | 1999 |
| | Son of the Shadows | 2000 |
| | Child of the Prophecy | 2001 |
| | Heir to Sevenwaters | 2008 |
| | Seer of Sevenwaters | 2010 |
| | Flame of Sevenwaters | 2012 |

Table calculations

Table calculations allow you to transform values at the level of detail of the visualisation only.

For more information, see [Transform Values with Table Calculations](#) on page 2355.

For example, consider the same sample table as [above](#). If you wanted to compute the number of years since the author released their last book, you might use the following table calculation:

```
ATTR([Year Released]) - LOOKUP(ATTR([Year Released]), -1)
```

The result is shown below. The new column, titled **Years Since Previous Book**, displays the number of years between the book released in that row and the book released in the previous row (on the far right-side of the column) and demonstrates how the table calculation is being computed (on the left-side of the column).

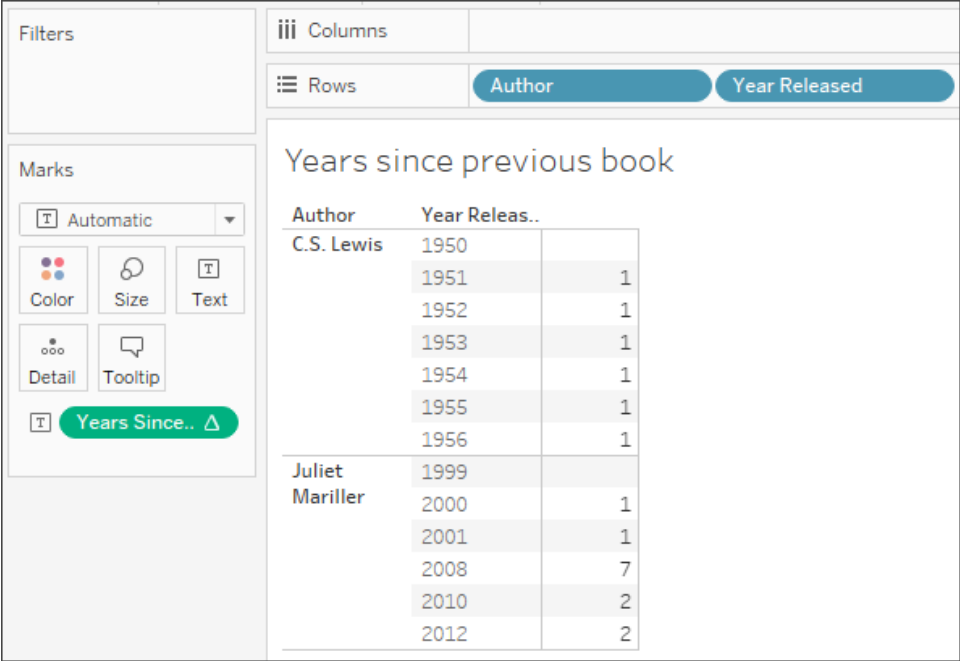

The colours help demonstrate how the table calculation is being computed. In this case, the table calculation is being computed down each pane.

Note: Depending on the table calculation and how it is being computed across the table, the results may vary. For more information, see [Transform Values with Table Calculations](#) on page 2355.

| Book ID | Book Name | Series | Year Released | Author | Years Since Previous Book | | |
|---------|--------------------------------------|--------------------------|---------------|------------|---------------------------|------|---|
| 1 | The Lion, the Witch and the Wardrobe | The Chronicles of Narnia | 1950 | C.S. Lewis | NULL | | |
| 2 | Prince Caspian: The Return to Narnia | The Chronicles of Narnia | 1951 | C.S. Lewis | 1951- | 1950 | 1 |
| 3 | The Voyage of the Dawn Treader | The Chronicles of Narnia | 1952 | C.S. Lewis | 1952- | 1951 | 1 |
| 4 | The Silver Chair | The Chronicles of Narnia | 1953 | C.S. Lewis | 1953- | 1952 | 1 |
| 5 | The Horse and His Boy | The Chronicles of Narnia | 1954 | C.S. Lewis | 1954- | 1953 | 1 |

| | | | | | | | |
|----|------------------------|--------------------------|------|------------------|-------|------|---|
| 6 | The Magician's Nephew | The Chronicles of Narnia | 1955 | C.S. Lewis | 1955- | 1954 | 1 |
| 7 | The Last Battle | The Chronicles of Narnia | 1956 | C.S. Lewis | 1956- | 1955 | 1 |
| 8 | Daughter of the Forest | Sevenwaters | 1999 | Juliet Marillier | NULL | | |
| 9 | Son of the Shadows | Sevenwaters | 2000 | Juliet Marillier | 2000- | 1999 | 1 |
| 10 | Child of the Prophecy | Sevenwaters | 2001 | Juliet Marillier | 2001- | 2000 | 1 |
| 11 | Heir of Sevenwaters | Sevenwaters | 2008 | Juliet Marillier | 2008- | 2001 | 7 |
| 12 | Seer of Sevenwaters | Sevenwaters | 2010 | Juliet Marillier | 2010- | 2008 | 2 |
| 13 | Flame of Sevenwaters | Sevenwaters | 2012 | Juliet Marillier | 2012- | 2010 | 2 |

In Tableau, the data looks like this:

However, if you change the visualisation in a way that affects the layout, such as removing a dimension from the view, the calculation values change.

For example, in the image below, **Author** is removed from the viz. Since the table calculation is computed by pane, removing Author changes the granularity and layout of the viz (instead of two panes there is now only one). The table calculation therefore calculates the time between 1956 and 1999.

Choosing the Right Calculation Type

The type of calculation you choose depends on the needs of your analysis, the question you want to answer, and the layout of your visualisation.

Which calculation is right for your analysis?

Choosing the type of calculation to use for your analysis is not always easy. When trying to decide, consider the following questions and examples.

Note: This content was originally published on the Tableau Blog. See [A Handy Guide to Choosing the Right Calculation for Your Question](#) to read it.

Basic expression or table calculation?

Question 1:

Do you already have all the data values you need on the visualisation?

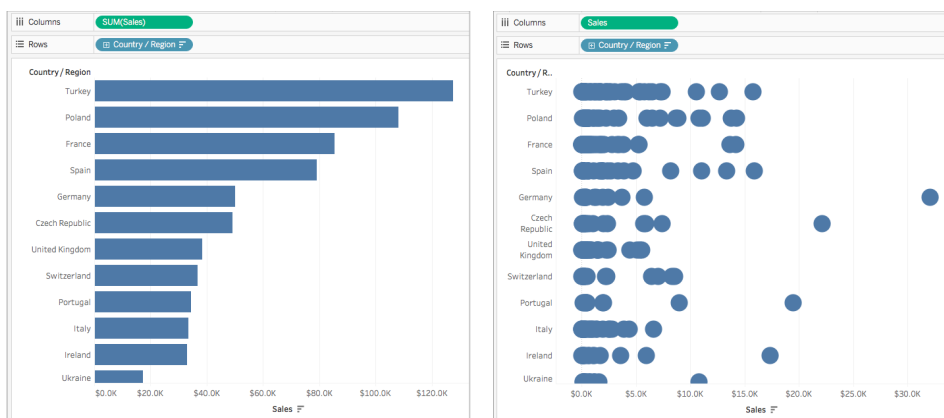

- If the answer is **yes**: You can use a table calculation.
- If the answer is **no**: Use a basic calculation.

Example:

Consider the following two visualisations. The visualisation on the left is a bar chart that shows the total sales per country/region. The visualisation on the right also shows sales per country/region, but sales has been disaggregated.

How could you calculate the 90th percentile of sales for each of these visualisations?

The bar chart on the left is aggregated by SUM. Therefore, there is not enough detail in this view to use a table calculation. You can use a basic aggregate expression to calculate the 90th percentile of sales for each country in this example using the following formula:

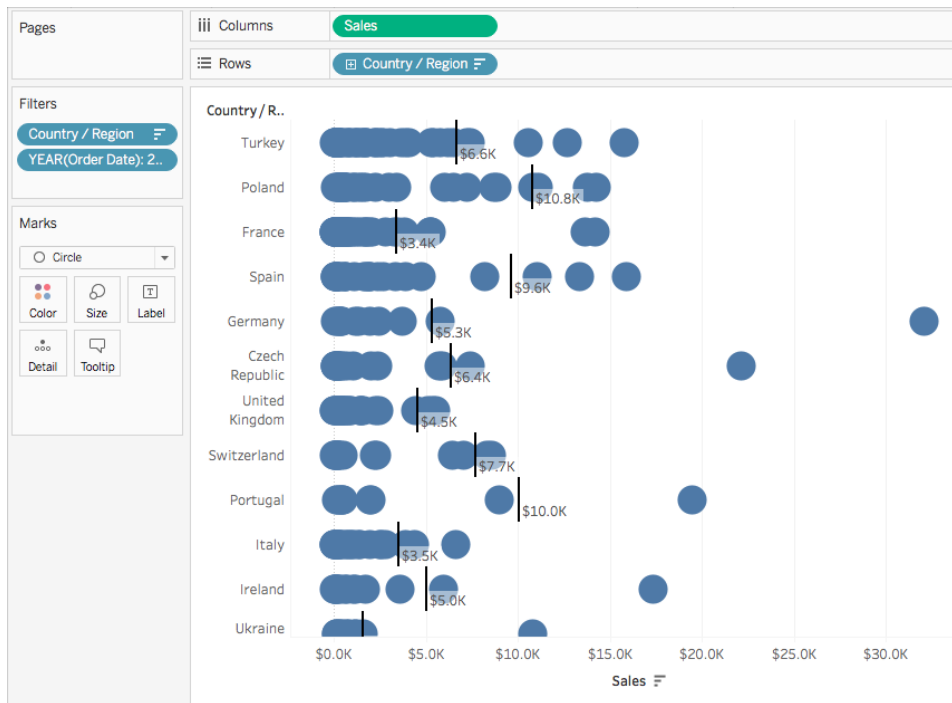

```
PERCENTILE ([Sales], .90)
```

This results in a value for 90th percentile per country as a label for each bar.

However, the chart on the right includes a data value for every sales order. A larger distribution and outliers are shown. There is enough detail in the view to use a table calculation.

You can calculate the 90th percentile of sales for each country by using a distribution band (equivalent to a table calculation). There is more context in this visualisation.

Both calculations achieve the same values, but the insights you gather from each differ based on the level of detail (the amount of data) in the visualisation.

Basic expression or Level of Detail (LOD) expression?

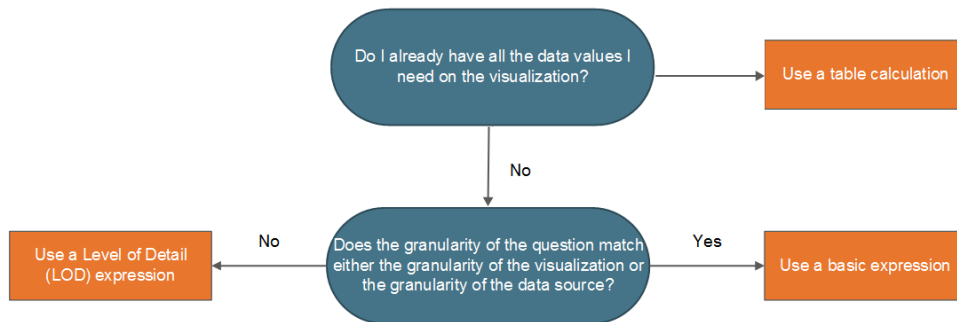

If you don't have all the data you need on the visualisation, you need your calculation to be passed through to the data source. This means you must use a basic calculation or an LOD Expression.

If you answered **no** to [question 1](#) ask yourself this:

Question 2:

Does the granularity of your question match either the granularity of the visualisation or the granularity of the data source?

- If the answer is **yes**: Use a basic expression.
- If the answer is **no**: Use a Level of Detail (LOD) expression.

Example

Consider the following visualisation. It shows the 90th percentile of sales for all orders in each country.

This example uses the Sample-Superstore data source that comes with Tableau. If you are familiar with the Sample-Superstore data source, you might know that there is one row of data per Order ID. Therefore, the granularity of the data source is Order ID. The granularity of the visualisation, however, is Country.

If you want to know what the 90th percentile value of sales is for orders in each country at the order ID level of granularity, you can use the following LOD expression:

```
{INCLUDE [Order ID] : SUM([Sales])}
```

You can then change the field to aggregate at the 90th percentile in the view.

To do so, click the field drop-down and select **Measure > Percentile > 90**.

The following diagram demonstrates how the LOD Expression works in this case:

1. The data starts completely aggregated at SUM(Sales) and then moves down to the Country level of detail: SUM(Sales) at Country.
2. The LOD calculation is applied and the data gains more granularity: SUM(Sales) at Country + Order ID.
3. The LOD calculation is aggregated to the 90th percentile: PCT90(SUM(Sales) at Country + Order ID)

The result is as follows:

Table calculation or Level of Detail (LOD) expression?

When choosing between a table calculation or an LOD calculation, the process is very similar to choosing between a table calculation and a basic expression. Ask yourself the following questions:

Do you already have all the data values you need on the visualisation?

- If the answer is **Yes**, then use a table calculation.
- If the answer is **No**, then ask yourself: *Does the granularity of the question match either the granularity of the visualisation or the granularity of the data source?* If the answer is **No**, then use an LOD calculation.

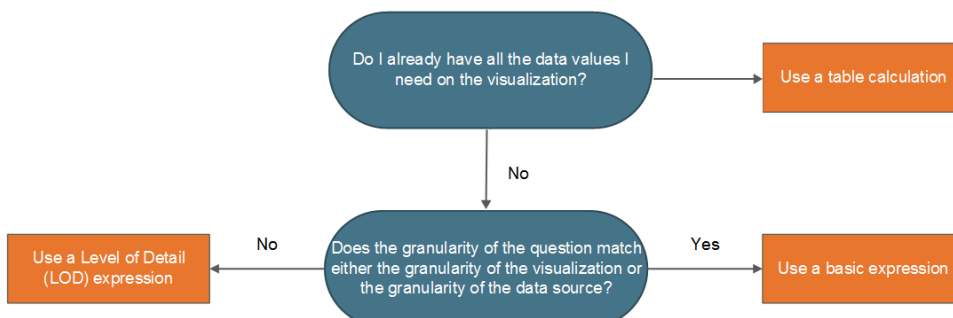

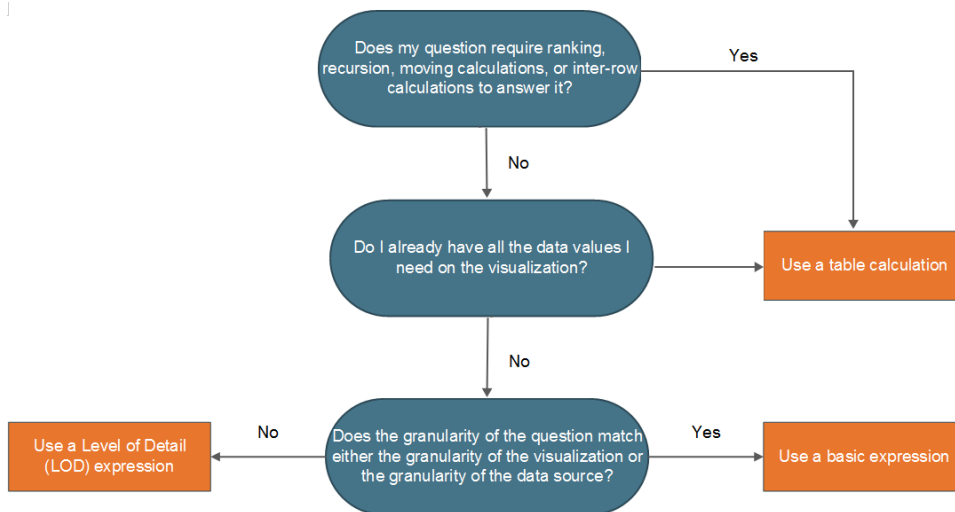

Table calculations only

There are some scenarios where only a table calculation will do. These include:

- Ranking
- Recursion (e.g. cumulative totals)
- Moving calculations (e.g. rolling averages)
- Inter-row calculations (e.g. period vs. period calculations)

If your analysis requires any of these scenarios, use a table calculation.

Example

Consider the following visualisation. It shows the average closing price for several stocks between September 2014 and September 2015.

If you want to see the number of times the closing price exceeded its record close value to date, you must use a table calculation, specifically a recursive calculation.

Why? Because table calculations can output multiple values for each partition of data (cell, pane, table), while basic and LOD expressions can only output a single value for each partition or grouping of data.

To calculate the number of times the closing price exceeded its record closing price for each stock, there are a few steps you need to take.

1. You need to consider all the previous values before to tell if you have reached a new maximum close value. You can do this with a `RUNNING_MAX` function. For example, consider the following calculation computed using Day (across the table), titled **Record to Date**:

```
RUNNING_MAX (AVG ([Close]))
```

2. Next, you can flag the days when the record was broken using the following calculation computed using Day (across the table), titled **Count Days Record Broken**:

```
IF AVG([Close]) = [Record to Date]
THEN 1
ELSE 0
END
```

- Finally, you can count these days using the following calculation computed using Day (across the table):

```
RUNNING_SUM([Count Days Record Broken])
```

When you add the final calculated field to the view in place of Avg(Close), you get something like this:

below

Also in this series:

[Understanding Calculations in Tableau](#)

[Types of Calculations in Tableau](#)

[Tips for Learning How to Create Calculations](#)

Now that you know the types of calculations and when to use them, how do you actually know how to create the formula for them? This is where things can get tricky.

There's no easy way to know exactly how to create the perfect formula; it takes practice and research. However, here are some ways you can start to learn:

Know your question or purpose

If you know the type of data you need, this can help you choose the correct function and format it properly. For example, if you need to show profit for an order, you might create a formula similar to the following: SUM (Sales) - SUM (Cost).

Learn Tableau functions

There are many different functions available in Tableau. Each type serves a different purpose. To learn more, see [Functions in Tableau on the facing page](#).

Learn how to format calculations

After you're familiar with the different types of Tableau functions and their purpose, make sure to learn how to format calculations using the proper syntax. To learn more, see [Formatting Calculations in Tableau on page 2439](#).

Learn from other examples

Learning by example is effective. Try to collect a list of common calculations to use in your everyday analysis. There are several resources available to you:

- [Tableau Blog: Top 10 Tableau table calculations](#)
- [Tableau Blog: Top 15 LOD Expressions](#)
- [Tableau Blog: Save time and stay consistent with a template of calculated fields](#)

Functions in Tableau

Tableau supports many functions for use in Tableau calculations. To learn more about the functions in Tableau, see the following articles and reference topics:

Number Functions

This article introduces number functions and their uses in Tableau. It also demonstrates how to create a number calculation using an example.

Why use number functions

Number functions allow you to perform computations on the data values in your fields. Number functions can only be used with fields that contain numerical values. For more information, see [Data Types on page 156](#).

For example, you might have a field that contains values for the variance in your budget, titled Budget Variance. One of those values might be -7. You can use the ABS function to return the absolute value of that number, and all the other numbers in that field.

The calculation might look something like this:

```
ABS[Budget Variance]
```

And for that -7 value, the output would be 7.

Number functions available in Tableau

ABS

| | |
|------------|---|
| Syntax | ABS (number) |
| Output | Number (positive) |
| Definition | Returns the absolute value of the given <number>. |
| Example | <div>ABS (-7) = 7</div> <div>ABS ([Budget Variance])</div> <div>The second example returns the absolute value for all the numbers contained in the Budget Variance field.</div> |

Notes See also [SIGN](#) on page 2049.

ACOS

Syntax `ACOS (number)`

Output Number (angle in radians)

Definition Returns the arccosine (angle) of the given `<number>`.

Example `ACOS (-1) = 3.14159265358979`

Notes The inverse function, [COS](#) on the facing page, takes the angle in radians as the argument and returns the cosine.

ASIN

Syntax `ASIN (number)`

Output Number (angle in radians)

Definition Returns the arcsine (angle) of a given `<number>`.

Example `ASIN (1) = 1.5707963267949`

Notes The inverse function, [SIN](#) on page 2049, takes the angle in radians as the argument and returns the sine.

ATAN

Syntax `ATAN (number)`

Output Number (angle in radians)

Definition Returns the arctangent (angle) of a given `<number>`.

Example `ATAN (180) = 1.5652408283942`

Notes The inverse function, [TAN](#), takes the angle in radians as the argument and

returns the tangent.

See also [ATAN2](#) below and [COT](#) on the next page.

ATAN2

| | |
|------------|--|
| Syntax | <code>ATAN2 (y number, x number)</code> |
| Output | Number (angle in radians) |
| Definition | Returns the arctangent (angle) between two numbers (x and y). The result is in radians. |
| Example | <code>ATAN2 (2, 1) = 1.10714871779409</code> |
| Notes | See also ATAN on the previous page, TAN on page 2050 and COT on the next page. |

CEILING

| | |
|----------------------|--|
| Syntax | <code>CEILING (number)</code> |
| Output | Integer |
| Definition | Rounds a <number> to the nearest integer of equal or greater value. |
| Example | <code>CEILING (2.1) = 3</code> |
| Notes | See also FLOOR on page 2043 and ROUND on page 2048. |
| Database limitations | <code>CEILING</code> is available through the following connectors: Microsoft Excel, Text File, Statistical File, Published Data Source, Amazon EMR Hadoop Hive, Amazon Redshift, Cloudera Hadoop, DataStax Enterprise, Google Analytics, Google BigQuery, Hortonworks Hadoop Hive, MapR Hadoop Hive, Microsoft SQL Server, Salesforce, Spark SQL. |

COS

| | |
|--------|---------------------------|
| Syntax | <code>COS (number)</code> |
|--------|---------------------------|

The number argument is the angle in radians.

Output Number

Definition Returns the cosine of an angle.

Example $\text{COS}(\text{PI}() / 4) = 0.707106781186548$

Notes The inverse function, [ACOS on page 2040](#), takes the cosine as the argument and returns the angle in radians.

See also [PI on page 2047](#). To convert an angle from degrees to radians, use [RADIANS on page 2048](#).

COT

Syntax $\text{COT}(\text{number})$

The number argument is the angle in radians.

Output Number

Definition Returns the cotangent of an angle.

Example $\text{COT}(\text{PI}() / 4) = 1$

Notes See also [ATAN on page 2040](#), [TAN on page 2050](#) and [PI on page 2047](#). To convert an angle from degrees to radians, use [RADIANS on page 2048](#).

DEGREES

Syntax $\text{DEGREES}(\text{number})$

The number argument is the angle in radians.

Output Number (degrees)

Definition Converts an angle in radians to degrees.

Example $\text{DEGREES}(\text{PI}() / 4) = 45.0$

| | |
|-------|---|
| Notes | <p>The inverse function, RADIANs on page 2048, takes an angle in degrees and returns the angle in radians.</p> <p>See also PI on page 2047().</p> |
|-------|---|

DIV

| | |
|------------|---|
| Syntax | <code>DIV(integer1, integer2)</code> |
| Output | Integer |
| Definition | Returns the integer part of a division operation, in which <integer1> is divided by <integer2>. |
| Example | <code>DIV(11,2) = 5</code> |

EXP

| | |
|------------|--|
| Syntax | <code>EXP(number)</code> |
| Output | Number |
| Definition | Returns e raised to the power of the given <number>. |
| Example | <code>EXP(2) = 7.389</code> <code>EXP(-[Growth Rate]*[Time])</code> |
| Notes | See also LN on page 2045. |

FLOOR

| | |
|------------|---|
| Syntax | <code>FLOOR(number)</code> |
| Output | Integer |
| Definition | Rounds a number to the nearest <number> of equal or lesser value. |
| Example | <code>FLOOR(7.9) = 7</code> |

| | |
|----------------------|---|
| Notes | See also CEILING on page 2041 and ROUND on page 2048. |
| Database limitations | <code>FLOOR</code> is available through the following connectors: Microsoft Excel, Text File, Statistical File, Published Data Source, Amazon EMR Hadoop Hive, Cloudera Hadoop, DataStax Enterprise, Google Analytics, Google BigQuery, Hortonworks Hadoop Hive, MapR Hadoop Hive, Microsoft SQL Server, Salesforce, Spark SQL. |

HEXBINX

| | |
|------------|---|
| Syntax | <code>HEXBINX(number, number)</code> |
| Output | Number |
| Definition | Maps an x, y coordinate to the x-coordinate of the nearest hexagonal bin. The bins have side length 1, so the inputs may need to be scaled appropriately. |
| Example | <code>HEXBINX([Longitude]*2.5, [Latitude]*2.5)</code> |
| Notes | <code>HEXBINX</code> and HEXBINY below are binning and plotting functions for hexagonal bins. Hexagonal bins are an efficient and elegant option for visualising data in an x/y plane such as a map. Because the bins are hexagonal, each bin closely approximates a circle and minimises variation in the distance from the data point to the centre of the bin. This makes the clustering both more accurate and informative. |

HEXBINY

| | |
|------------|---|
| Syntax | <code>HEXBINY(number, number)</code> |
| Output | Number |
| Definition | Maps an x, y coordinate to the y-coordinate of the nearest hexagonal bin. The bins have side length 1, so the inputs may need to be scaled appropriately. |
| Example | <code>HEXBINY([Longitude]*2.5, [Latitude]*2.5)</code> |

Notes See also [HEXBINX](#) on the previous page.

LN

Syntax `LN(number)`

Output Number

The output is `Null` if the argument is less than or equal to zero.

Definition Returns the natural logarithm of a `<number>`.

Example `LN(50) = 3.912023005`

Notes See also [EXP](#) on page 2043 and [LOG](#) below.

LOG

Syntax `LOG(number, [base])`

If the optional base argument isn't present, base 10 is used.

Output Number

Definition Returns the logarithm of a number for the given base.

Example `LOG(16,4) = 2`

Notes See also [POWER](#) on page 2048 [LN](#) above.

MAX

Syntax `MAX(expression)` or `MAX(expr1, expr2)`

Output Same data type as the argument, or `NULL` if any part of the argument is null.

Definition Returns the maximum of the two arguments, which must be of the same data type.

`MAX` can also be applied to a single field as an aggregation.

Example

`MAX(4, 7) = 7`

`MAX(#3/25/1986#, #2/20/2021#) = #2/20/2021#`

`MAX([Name]) = "Zander"`

Notes

For strings

`MAX` is usually the value that comes last in alphabetical order.

For database data sources, the `MAX` string value is highest in the sort sequence defined by the database for that column.

For dates

For dates, the `MAX` is the most recent date. If `MAX` is an aggregation, the result will not have a date hierarchy. If `MAX` is a comparison, the result will retain the date hierarchy.

As an aggregation

`MAX(expression)` is an aggregate function and returns a single aggregated result. This displays as `AGG(expression)` in the viz.

As a comparison

`MAX(expr1, expr2)` compares the two values and returns a row-level value.

See also [MIN](#) below.

MIN

Syntax

`MIN(expression)` or `MIN(expr1, expr2)`

Output

Same data type as the argument, or `NULL` if any part of the argument is null.

Definition

Returns the minimum of the two arguments, which must be of the same data type.

`MIN` can also be applied to a single field as an aggregation.

Example

```
MIN(4,7) = 4
MIN(#3/25/1986#, #2/20/2021#) = #3/25/1986#
MIN([Name]) = "Abebi"
```

Notes **For strings**

MIN is usually the value that comes first in alphabetical order.

For database data sources, the MIN string value is lowest in the sort sequence defined by the database for that column.

For dates

For dates, the MIN is the earliest date. If MIN is an aggregation, the result will not have a date hierarchy. If MIN is a comparison, the result will retain the date hierarchy.

As an aggregation

MIN(expression) is an aggregate function and returns a single aggregated result. This displays as AGG(expression) in the viz.

As a comparison

MIN(expr1, expr2) compares the two values and returns a row-level value.

See also [MAX](#) on page 2045.

PI

Syntax `PI()`

Output Number

Definition Returns the numeric constant pi: 3.14159...

Example `PI() = 3.14159`

Notes Useful for trig functions that take their input in radians. See also [RADIANs](#) on the next page.

POWER

| | |
|------------|--|
| Syntax | <code>POWER(number, power)</code> |
| Output | Number |
| Definition | Raises the <number> to the specified <power>. |
| Example | <code>POWER(5,3) = 125</code> <code>POWER([Temperature], 2)</code> |
| Notes | You can also use the ^ symbol, such as <code>5^3 = POWER(5,3) = 125</code> See also EXP on page 2043, LOG on page 2045 and SQUARE on page 2050. |

RADIANS

| | |
|------------|---|
| Syntax | <code>RADIANS(number)</code> |
| Output | Number (angle in radians) |
| Definition | Converts the given <number> from degrees to radians. |
| Example | <code>RADIANS(180) = 3.14159</code> |
| Notes | The inverse function, DEGREES on page 2042, takes an angle in radians and returns the angle in degrees. |

ROUND

| | |
|------------|---|
| Syntax | <code>ROUND(number, [decimals])</code> |
| Output | Number |
| Definition | Rounds <number> to a specified number of digits. The optional <code>decimals</code> argument specifies how many decimal points of precision to include in the final result. If <code>decimals</code> is omitted, number is rounded to the nearest integer. |

| | |
|---------|--|
| Example | <code>ROUND(1/3, 2) = 0.33</code> |
| Notes | <p>Some databases, such as SQL Server, allow specification of a negative length, where -1 rounds number to 10s, -2 rounds to 100s and so on. This is not true of all databases. For example, it is not true of Excel or Access.</p> <p>Tip: Because <code>ROUND</code> may run into issues due to the underlying floating point representation of numbers – such as 9.405 rounding to 9.40 – it may be preferable to format the number to the desired number of decimal points rather than rounding. Formatting 9.405 to two decimal places will yield the expected 9.41.</p> <p>See also CEILING on page 2041 and FLOOR on page 2043.</p> |

SIGN

| | |
|------------|--|
| Syntax | <code>SIGN(number)</code> |
| Output | -1, 0 or 1 |
| Definition | Returns the sign of a <number>: The possible return values are -1 if the number is negative, 0 if the number is zero or 1 if the number is positive. |
| Example | <code>SIGN(AVG(Profit)) = -1</code> |
| Notes | See also ABS on page 2039. |

SIN

| | |
|------------|--|
| Syntax | <code>SIN(number)</code> |
| | The number argument is the angle in radians. |
| Output | Number |
| Definition | Returns the sine of an angle. |
| Example | <code>SIN(0) = 1.0</code> <code>SIN(PI() / 4) = 0.707106781186548</code> |
| Notes | The inverse function, ASIN on page 2040, takes the sine as the |

argument and returns the angle in radians.

See also [PI](#) on page 2047. To convert an angle from degrees to radians, use [RADIAN](#)s on page 2048.

SQRT

| | |
|------------|--|
| Syntax | <code>SQRT (number)</code> |
| Output | Number |
| Definition | Returns the square root of a <number>. |
| Example | <code>SQRT (25) = 5</code> |
| Notes | See also SQUARE below. |

SQUARE

| | |
|------------|---|
| Syntax | <code>SQUARE (number)</code> |
| Output | Number |
| Definition | Returns the square of a <number>. |
| Example | <code>SQUARE (5) = 25</code> |
| Notes | See also SQRT above and POWER on page 2048. |

TAN

| | |
|------------|---|
| Syntax | <code>TAN (number)</code> The number argument is the angle in radians. |
| Output | Number |
| Definition | Returns the tangent of an angle. |
| Example | <code>TAN (PI () / 4) = 1.0</code> |

Notes See also [ATAN](#) on page 2040, [ATAN2](#) on page 2041, [COT](#) on page 2042 and [PI](#) on page 2047. To convert an angle from degrees to radians, use [RADIAN](#)s on page 2048.

ZN

Syntax `ZN(expression)`

Output Any, or 0

Definition Returns the <expression> if it is not null, otherwise returns zero.
Use this function to replace null values with zeros.

Example `ZN(Grade) = 0`

Notes This is a very useful function when using fields that may contain nulls in a calculation. Wrapping the field with `ZN` can prevent errors caused by calculating with nulls.

Create a number calculation

Follow along with the steps below to learn how to create a number calculation.

1. In Tableau Desktop, connect to the **Sample - Superstore** saved data source, which comes with Tableau.
2. Navigate to a worksheet and select **Analysis > Create Calculated Field**.
3. In the calculation editor that opens, do the following:
 - Name the calculated field Minimum Sales transaction
 - Enter the following formula:

```
MIN(Sales)
```

- When finished, click **OK**.

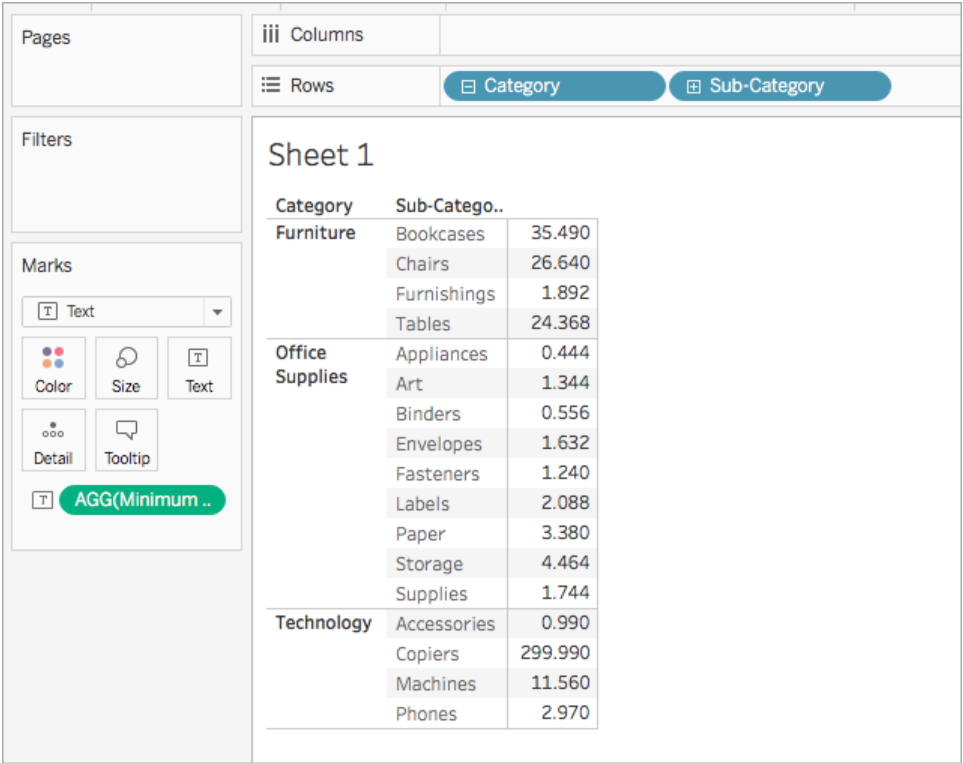

The new number calculation appears under **Measures** in the **Data** pane. Just like your other fields, you can use it in one or more visualisations.

When Minimum Sales is placed on Text on the Marks card in the worksheet, its name is changed to **AGG(Minimum Sales)**, which indicates that it cannot be aggregated any further, since it is already aggregated down to the lowest level of detail (the smallest sales value for all records).

This example shows the minimum sales per category.

When subcategory is brought into the view, the minimum sales for each subcategory are shown.

[Formatting Calculations in Tableau](#) on page 2439

String Functions

This article introduces string functions and their uses in Tableau. It also demonstrates how to create a string calculation using an example.

Why use string functions

String functions allow you to manipulate string data (i.e. data made of text). Tableau uses the current International Components for Unicode (ICU) library when comparing strings. The way strings are sorted and compared is based both on language and locale, and it's possible for vizzes to change as the ICU is continuously updated for better language support.

For example, you might have a field that contains all of your customers' first and last names. One member might be: Jane Johnson. You can pull the last names from all your customers into a new field using a string function.

The calculation might look something like this:

```
SPLIT([Customer Name], ' ', 2)
```

Therefore, `SPLIT('Jane Johnson' , ' ', 2) = 'Johnson'`.

String functions available in Tableau

ASCII

| | |
|------------|---|
| Syntax | <code>ASCII(string)</code> |
| Output | Number |
| Definition | Returns the ASCII code for the first character of a <string>. |
| Example | <code>ASCII('A') = 65</code> |
| Notes | This is the inverse of the <code>CHAR</code> function. |

CHAR

| | |
|------------|---|
| Syntax | <code>CHAR(number)</code> |
| Output | String |
| Definition | Returns the character encoded by the ASCII code <number>. |
| Example | <code>CHAR(65) = 'A'</code> |
| Notes | This is the inverse of the <code>ASCII</code> function. |

CONTAINS

| | |
|--------|--|
| Syntax | <code>CONTAINS(string, substring)</code> |
|--------|--|

| | |
|------------|--|
| Output | Boolean |
| Definition | Returns true if the given string contains the specified substring. |
| Example | <code>CONTAINS("Calculation", "alcu") = true</code> |
| Notes | <p>See also the logical function IN as well as supported RegEx in the additional functions documentation.</p> <p>Depending on the data source, CONTAINS may be case sensitive. That is, for some data sources, <code>CONTAINS("Calculation", "ALCU") = false</code> but <code>CONTAINS("Calculation", "alcu") = true</code>. See also UPPER on page 2063, LOWER on page 2057, and PROPER on page 2060.</p> |

ENDSWITH

| | |
|------------|--|
| Syntax | <code>ENDSWITH(string, substring)</code> |
| Output | Boolean |
| Definition | Returns true if the given string ends with the specified substring. Trailing white spaces are ignored. |
| Example | <code>ENDSWITH("Tableau", "leau") = true</code> |
| Notes | See also the supported RegEx in the additional functions documentation . |

FIND

| | |
|------------|--|
| Syntax | <code>FIND(string, substring, [start])</code> |
| Output | Number |
| Definition | <p>Returns the index position of substring in string, or 0 if the substring isn't found. The first character in the string is position 1.</p> <p>If the optional numeric argument <code>start</code> is added, the function ignores any instances of the substring that appear before the starting position.</p> |

Example

```
FIND("Calculation", "alcu") = 2
FIND("Calculation", "Computer") = 0
FIND("Calculation", "a", 3) = 7
FIND("Calculation", "a", 2) = 2
FIND("Calculation", "a", 8) = 0
```

Notes See also the supported RegEx in the [additional functions documentation](#).

FINDNTH

Syntax `FINDNTH(string, substring, occurrence)`

Output Number

Definition Returns the position of the nth occurrence of substring within the specified string, where n is defined by the occurrence argument.

Example `FINDNTH("Calculation", "a", 2) = 7`

Notes `FINDNTH` is not available for all data sources.

See also the supported RegEx in the [additional functions documentation](#).

LEFT

Syntax `LEFT(string, number)`

Output String

Definition Returns the left-most <number> of characters in the string.

Example `LEFT("Matador", 4) = "Mata"`

Notes See also [MID](#) on page 2058 and [RIGHT](#) on page 2061.

LEN

| | |
|------------|--|
| Syntax | <code>LEN(string)</code> |
| Output | Number |
| Definition | Returns the length of the string. |
| Example | <code>LEN("Matador") = 7</code> |
| Notes | Not to be confused with the spatial function <code>LENGTH</code> . |

LOWER

| | |
|------------|--|
| Syntax | <code>LOWER(string)</code> |
| Output | String |
| Definition | Returns the provided <code><string></code> in all lowercase characters. |
| Example | <code>LOWER("ProductVersion") = "productversion"</code> |
| Notes | See also UPPER on page 2063 and PROPER on page 2060. |

LTRIM

| | |
|------------|---|
| Syntax | <code>LTRIM(string)</code> |
| Output | String |
| Definition | Returns the provided <code><string></code> with any leading spaces removed. |
| Example | <code>LTRIM(" Matador ") = "Matador "</code> |
| Notes | See also RTRIM on page 2061. |

MAX

| | |
|--------|--|
| Syntax | <code>MAX(expression)</code> or <code>MAX(expr1, expr2)</code> |
|--------|--|

Output Same data type as the argument, or `NULL` if any part of the argument is null.

Definition Returns the maximum of the two arguments, which must be of the same data type.

`MAX` can also be applied to a single field as an aggregation.

Example

```
MAX(4, 7) = 7
MAX(#3/25/1986#, #2/20/2021#) = #2/20/2021#
MAX([Name]) = "Zander"
```

Notes **For strings**

`MAX` is usually the value that comes last in alphabetical order.

For database data sources, the `MAX` string value is highest in the sort sequence defined by the database for that column.

For dates

For dates, the `MAX` is the most recent date. If `MAX` is an aggregation, the result will not have a date hierarchy. If `MAX` is a comparison, the result will retain the date hierarchy.

As an aggregation

`MAX(expression)` is an aggregate function and returns a single aggregated result. This displays as `AGG(expression)` in the viz.

As a comparison

`MAX(expr1, expr2)` compares the two values and returns a row-level value.

See also [MIN](#) on the facing page.

MID

Syntax `(MID(string, start, [length]))`

Output String

| | |
|------------|--|
| Definition | <p>Returns a string starting at the specified <code>start</code> position. The first character in the string is position 1.</p> <p>If the optional numeric argument <code>length</code> is added, the returned string includes only that number of characters.</p> |
| Example | <pre>MID("Calculation", 2) = "alculation"</pre> <pre>MID("Calculation", 2, 5) ="alcul"</pre> |
| Notes | See also the supported RegEx in the additional functions documentation . |

MIN

| | |
|------------|--|
| Syntax | <code>MIN(expression)</code> or <code>MIN(expr1, expr2)</code> |
| Output | Same data type as the argument, or <code>NULL</code> if any part of the argument is null. |
| Definition | <p>Returns the minimum of the two arguments, which must be of the same data type.</p> <p><code>MIN</code> can also be applied to a single field as an aggregation.</p> |
| Example | <pre>MIN(4,7) = 4</pre> <pre>MIN(#3/25/1986#, #2/20/2021#) = #3/25/1986#</pre> <pre>MIN([Name]) = "Abebi"</pre> |
| Notes | <p>For strings</p> <p><code>MIN</code> is usually the value that comes first in alphabetical order.</p> |

For database data sources, the `MIN` string value is lowest in the sort sequence defined by the database for that column.

For dates

For dates, the `MIN` is the earliest date. If `MIN` is an aggregation, the result will not have a date hierarchy. If `MIN` is a comparison, the result will retain the date hierarchy.

As an aggregation

`MIN(expression)` is an aggregate function and returns a single aggregated result. This displays as `AGG(expression)` in the viz.

As a comparison

`MIN(expr1, expr2)` compares the two values and returns a row-level value.

See also [MAX](#) on page 2057.

PROPER

| | |
|----------------------|---|
| Syntax | <code>PROPER(string)</code> |
| Output | String |
| Definition | Returns the provided <code><string></code> with the first letter of each word capitalised and the remaining letters in lowercase. |
| Example | <pre>PROPER("PRODUCT name") = "Product Name"</pre> <pre>PROPER("darcy-mae") = "Darcy-Mae"</pre> |
| Notes | <p>Spaces and non-alphanumeric characters such as punctuation are treated as separators.</p> <p>See also LOWER on page 2057 and UPPER on page 2063.</p> |
| Database limitations | PROPER is only available for some flat files and in extracts. If you need to use PROPER in a data source that doesn't otherwise support it, consider using an extract. |

REPLACE

| | |
|------------|--|
| Syntax | <code>REPLACE(string, substring, replacement</code> |
| Output | String |
| Definition | Searches <code><string></code> for <code><substring></code> and replaces it with <code><replacement></code> . If <code><substring></code> is not found, the string is not changed. |

| | |
|---------|--|
| Example | <code>REPLACE("Version 3.8", "3.8", "4x") = "Version 4x"</code> |
| Notes | See also <code>REGEXP_REPLACE</code> in the additional functions documentation . |

RIGHT

| | |
|------------|--|
| Syntax | <code>RIGHT(string, number)</code> |
| Output | String |
| Definition | Returns the right-most <number> of characters in the string. |
| Example | <code>RIGHT("Calculation", 4) = "tion"</code> |
| Notes | See also LEFT on page 2056 and MID on page 2058. |

RTRIM

| | |
|------------|--|
| Syntax | <code>RTRIM(string)</code> |
| Output | String |
| Definition | Returns the provided <string> with any trailing spaces removed. |
| Example | <code>RTRIM(" Calculation ") = " Calculation"</code> |
| Notes | See also LTRIM on page 2057 and TRIM on page 2063. |

SPACE

| | |
|------------|---|
| Syntax | <code>SPACE(number)</code> |
| Output | String (specifically, just spaces) |
| Definition | Returns a string that is composed of the specified number of repeated spaces. |
| Example | <code>SPACE(2) = " "</code> |

SPLIT

| | |
|----------------------|--|
| Syntax | <code>SPLIT(string, delimiter, token number)</code> |
| Output | String |
| Definition | Returns a substring from a string, using a delimiter character to divide the string into a sequence of tokens. |
| Example | <pre>SPLIT ("a-b-c-d", "-", 2) = "b"</pre> <pre>SPLIT ("a b c d", " ", -2) = "c"</pre> |
| Notes | <p>The string is interpreted as an alternating sequence of delimiters and tokens. So for the string <code>abc-defgh-i-jkl</code>, where the delimiter character is '-', the tokens are (1) <code>abc</code>, (2) <code>defgh</code>, (3) <code>i</code> and (4) <code>jkl</code>.</p> <p><code>SPLIT</code> returns the token corresponding to the token number. When the token number is positive, tokens are counted starting from the left end of the string; when the token number is negative, tokens are counted starting from the right.</p> <p>See also supported RegEX in the additional functions documentation.</p> |
| Database limitations | <p>The split and custom split commands are available for the following data sources types: Tableau data extracts, Microsoft Excel, Text File, PDF File, Salesforce, OData, Microsoft Azure Market Place, Google Analytics, Vertica, Oracle, MySQL, PostgreSQL, Teradata, Amazon Redshift, Aster Data, Google Big Query, Cloudera Hadoop Hive, Hortonworks Hive and Microsoft SQL Server.</p> <p>Some data sources impose limits on splitting strings. See <code>SPLIT</code> function limitations later in this topic.</p> |

STARTSWITH

| | |
|------------|---|
| Syntax | <code>STARTSWITH(string, substring)</code> |
| Output | Boolean |
| Definition | Returns true if <code>string</code> starts with <code>substring</code> . Leading white spaces are |

ignored.

Example `STARTSWITH("Matador, "Ma") = TRUE`

Notes See also [CONTAINS on page 2054](#), as well as supported RegEX in the [additional functions documentation](#).

TRIM

Syntax `TRIM(string)`

Output String

Definition Returns the provided <string> with leading and trailing spaces removed.

Example `TRIM(" Calculation ") = "Calculation"`

Notes See also [LTRIM on page 2057](#) and [RTRIM on page 2061](#).

UPPER

Syntax `UPPER(string)`

Output String

Definition Returns the provided <string> in all uppercase characters.

Example `UPPER("Calculation") = "CALCULATION"`

Notes See also [PROPER on page 2060](#) and [LOWER on page 2057](#).

Create a string calculation

Follow along with the steps below to learn how to create a string calculation.

1. In Tableau Desktop, connect to the **Sample - Superstore** saved data source, which comes with Tableau.
2. Navigate to a worksheet.
3. From the **Data** pane, under Dimensions, drag **Order ID** to the **Rows** shelf.

| Order ID | Abc |
|----------------|-----|
| CA-2011-100006 | Abc |
| CA-2011-100090 | Abc |
| CA-2011-100293 | Abc |
| CA-2011-100328 | Abc |
| CA-2011-100363 | Abc |
| CA-2011-100391 | Abc |

Notice that every order ID contains values for country (CA and US, for example), year (2011) and order number (100006). For this example, you will create a calculation to pull only the order number from the field.

4. Select **Analysis > Create Calculated Field**.
5. In the calculation editor that opens, do the following:
 - Name the calculated field **Order ID Numbers**.
 - Enter the following formula:

```
RIGHT([Order ID], 6)
```

This formula takes the specified digits (6) from the right of the string and pulls them into a new field.

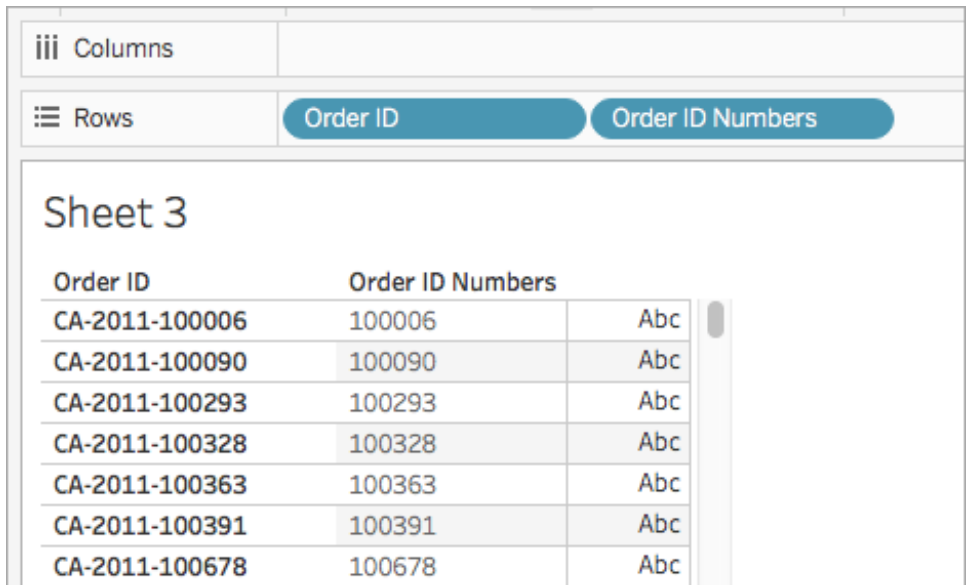

Therefore, `RIGHT('CA-2011-100006', 6) = '100006'`.

- When finished, click **OK**.

The new calculated field appears under **Dimensions** in the **Data** pane. Just like your other fields, you can use it in one or more visualisations.

6. From the **Data** pane, drag **Order ID Numbers** to the **Rows** shelf. Place it to the right of Order ID.

Notice how the fields differ now.

The screenshot shows the Tableau interface. At the top, there are two shelves: 'Columns' and 'Rows'. The 'Rows' shelf contains two fields: 'Order ID' and 'Order ID Numbers'. Below the shelves, a view titled 'Sheet 3' displays a table with three columns: 'Order ID', 'Order ID Numbers', and an unlabeled column containing the text 'Abc'. The table has eight rows of data.

| Order ID | Order ID Numbers | |
|----------------|------------------|-----|
| CA-2011-100006 | 100006 | Abc |
| CA-2011-100090 | 100090 | Abc |
| CA-2011-100293 | 100293 | Abc |
| CA-2011-100328 | 100328 | Abc |
| CA-2011-100363 | 100363 | Abc |
| CA-2011-100391 | 100391 | Abc |
| CA-2011-100678 | 100678 | Abc |

SPLIT limitations by data source

Some data sources impose limits on splitting string. The following table shows which data sources support negative token numbers (splitting from the right) and whether there is a limit on the number of splits allow per data source.

A `SPLIT` function that specifies a negative token number and would be legal with other data sources will return the error with these data sources: *"Splitting from right is not supported by the data source."*

| Data Source | Left/Right Constraints | Maximum Number of Splits | Version limitations |
|----------------------|------------------------|--------------------------|---------------------|
| Tableau Data Extract | Both | Infinite | |
| Microsoft Excel | Both | Infinite | |

| | | | |
|--------------------------------|--|----------|---|
| Text file | Both | Infinite | |
| Salesforce | Both | Infinite | |
| OData | Both | Infinite | |
| Google Analytics | Both | Infinite | |
| Tableau Data Server | Both | Infinite | Supported in version 9.0. |
| Vertica | Left only | 10 | |
| Oracle | Left only | 10 | |
| MySQL | Both | 10 | |
| PostgreSQL | Left only prior to version 9.0; both for version 9.0 and above | 10 | |
| Teradata | Left only | 10 | Version 14 and later |
| Amazon Redshift | Left only | 10 | |
| Aster Database | Left only | 10 | |
| Google BigQuery | Left only | 10 | |
| Hortonworks Hadoop Hive | Left only | 10 | |
| Cloudera Hadoop | Left only | 10 | Impala supported starting in version 2.3.0. |
| Microsoft SQL Server | Both | 10 | 2008 and later |

[Formatting Calculations in Tableau on page 2439](#)

Date Functions

Dates are a common element in many data sources. If a field contains recognizable dates, it will have a **date** or **datetime** data type. When date fields are used in the viz they get a special set of functionality, including an automatic date hierarchy drill down, date-specific filter options and specialised date formatting options. Using dates in calculations often requires the use of date-specific functions.

Gain familiarity with other date concepts

Date functions sometimes reference date-specific elements, including the `date_part` argument, the optional `[start_of_week]` parameter and date literals (`#`). These are covered in more detail at the end of this topic.

There are several other topics that might be of interest but aren't part of date functions:

- Format how a date is displayed in a viz: [Custom Date Formats on page 1173](#)
- Set default date properties: [Date Properties for a Data Source on page 1159](#)
- Work with fiscal dates: [Tax Dates on page 1170](#)
- Use the ISO-8601 calendar: [ISO-8601 Week-Based Calendar on page 1184](#)

Tip: Is your field already recognised as a date (it has a date icon in the Data pane) and you're trying to control how it appears in the viz? You might need to format it rather than use a date function. For example, you want to show 22Sept2024 as 09/24. This is handled through formatting the date, not a calculation.

See [Custom Date Formats on page 1173](#) and related topics for working with date fields. The date functions on this page allow you to manipulate dates' calculated fields, not set their display formatting.

Date functions available in Tableau

DATE

Type conversion function that changes string and number expressions into dates, as long as they are in a recognisable format.

| | |
|------------|---|
| Syntax | <code>DATE (expression)</code> |
| Output | Date |
| Definition | Returns a date given a number, string or date <expression>. |
| Example | <pre>DATE ([Employee Start Date]) DATE ("September 22, 2018") DATE ("9/22/2018") DATE (#2018-09-22 14:52#)</pre> |
| Notes | <p>Unlike DATEPARSE on page 2070, there is no need to provide a pattern as <code>DATE</code> automatically recognises many standard date formats. If <code>DATE</code> does not recognise the input, however, try using <code>DATEPARSE</code> and specifying the format.</p> <p>MAKEDATE on page 2074 is another similar function, but <code>MAKEDATE</code> requires the input of numeric values for year, month and day.</p> |

DATEADD

Adds a specified number of date parts (months, days, etc) to the starting date.

| | |
|------------|---|
| Syntax | <code>DATEADD (date_part, interval, date)</code> |
| Output | Date |
| Definition | Returns the <date> with the specified number <interval> added to the specified < date_part on page 2080 > of that date. For example, adding three months or 12 days to a starting date. |
| Example | <p>Push out all due dates by one week</p> <pre>DATEADD ('week', 1, [due date])</pre> <p>Add 280 days to the date February 20, 2021</p> <pre>DATEADD ('day', 280, #2/20/21#) = #November 27, 2021#</pre> |
| Notes | Supports ISO 8601 dates. |

DATEDIFF

Returns the number of date parts (weeks, years, etc) between two dates.

| | |
|------------|--|
| Syntax | <code>DATEDIFF(date_part, date1, date2, [start_of_week])</code> |
| Output | Integer |
| Definition | Returns the difference between <date1> and <date2> expressed in units of < date_part on page 2080 >. For example, subtracting the dates someone entered and left a band to see how long they were in the band. |
| Example | <p>Number of days between 25th March 1986 and 20th February 2021</p> <pre>DATEDIFF('day', #3/25/1986#, #2/20/2021#) = 12,751</pre> <p>How many months someone was in a band</p> <pre>DATEDIFF('month', [date joined band], [date left band])</pre> |
| Notes | Supports ISO 8601 dates. |

DATENAME

Returns the name of the specified date part as a discrete string.

| | |
|------------|---|
| Syntax | <code>DATENAME(date_part, date, [start_of_week])</code> |
| Output | String |
| Definition | Returns < date_part on page 2080 > of <date> as a string. |
| Example | <pre>DATENAME('year', #3/25/1986#) = "1986"</pre> <pre>DATENAME('month', #1986-03-25#) = "March"</pre> |
| Notes | <p>Supports ISO 8601 dates.</p> <p>A very similar calculation is DATEPART on page 2071, which returns the value of the specified date part as a continuous integer. <code>DATEPART</code> can be faster because it is a numerical operation.</p> <p>By changing the attributes of the calculation's result (dimension or measure,</p> |

continuous or discrete) and the date formatting, the results of `DATEPART` and `DATENAME` can be formatted to be identical.

An inverse function is [DATEPARSE](#) below, which takes a string value and formats it as a date.

DATEPARSE

Returns specifically formatted strings as dates.

| | |
|----------------------|---|
| Syntax | <code>DATEPARSE(date_format, date_string)</code> |
| Output | Date |
| Definition | The <code><date_format></code> argument describes how the <code><date_string></code> field is arranged. Because of the variety of ways the string field can be ordered, the <code><date_format></code> must match exactly. For a full explanation and formatting details, see Convert a Field to a Date Field . |
| Example | <code>DATEPARSE('yyyy-MM-dd', "1986-03-25") = #March 25, 1986#</code> |
| Notes | <p>DATE on page 2067 is a similar function that automatically recognises many standard date formats. <code>DATEPARSE</code> may be a better option if <code>DATE</code> does not recognise the input pattern.</p> <p>MAKEDATE on page 2074 is another similar function, but <code>MAKEDATE</code> requires the input of numeric values for year, month and day.</p> <p>Inverse functions, which take dates apart and return the value of their parts, are DATEPART on the facing page (integer output) and DATENAME on the previous page (string output).</p> |
| Database limitations | <p><code>DATEPARSE</code> is available through the following connectors: non-legacy Excel and text file connections, Amazon EMR Hadoop Hive, Cloudera Hadoop, Google Sheets, Hortonworks Hadoop Hive, MapR Hadoop Hive, MySQL, Oracle, PostgreSQL and Tableau extracts. Some formats may not be available for all connections.</p> <p><code>DATEPARSE</code> is not supported on Hive variants. Only Denodo, Drill and Snowflake are supported.</p> |

DATEPART

Returns the name of the specified date part as an integer.

Syntax `DATEPART(date_part, date, [start_of_week])`

Output Integer

Definition Returns [<date_part> on page 2080](#) of <date> as an integer.

Example `DATEPART('year', #1986-03-25#) = 1986`

`DATEPART('month', #1986-03-25#) = 3`

Notes Supports ISO 8601 dates.

A very similar calculation is [DATENAME on page 2069](#), which returns the name of the specified date part as a discrete string. `DATEPART` can be faster because it is a numerical operation. By changing the attributes of the field (dimension or measure, continuous or discrete) and the date formatting, the results of `DATEPART` and `DATENAME` can be formatted to be identical.

An inverse function is [DATEPARSE on the previous page](#), which takes a string value and formats it as a date.

DATETRUNC

This function can be thought of as date rounding. It takes a specific date and returns a version of that date at the desired specificity. Because every date must have a value for day, month, quarter and year, `DATETRUNC` sets the values as the lowest value for each date part up to the date part specified. Refer to the example for more information.

Syntax `DATETRUNC(date_part, date, [start_of_week])`

Output Date

Definition Truncates the <date> to the accuracy specified by the [<date_part> on page 2080](#). This function returns a new date. For example, when you truncate a date that is in the middle of the month at the month level, this function returns the first day of the month.

Example

```
DATETRUNC('day', #9/22/2018#) = #9/22/2018#
```

```
DATETRUNC('iso-week', #9/22/2018#) = #9/17/2018#
```

(the Monday of the week containing 22/09/2018)

```
DATETRUNC(quarter, #9/22/2018#) = #7/1/2018#
```

(the first day of the quarter containing 22/09/2018)

Note: For week and iso-week, the `start_of_week` comes into play. ISO-weeks always start on Monday. For the locale of this example, an unspecified `start_of_week` means the week starts on Sunday.

Notes

Supports ISO 8601 dates.

You shouldn't use `DATETRUNC` to, for example, stop showing the time for a datetime field in a viz. If you want to truncate the way a date displays rather than round its accuracy, [adjust the formatting](#).

For example, `DATETRUNC('day', #5/17/2022 3:12:48 PM#)`, if formatted in the viz to display seconds, would display as 5/17/2022 12:00:00 AM. The value is truncated to day, but the display goes to seconds.

DAY

Returns the day of the month (1–31) as an integer.

Syntax

```
DAY(date)
```

Output

Integer

Definition

Returns the day of the given <date> as an integer.

Example

```
Day(#September 22, 2018#) = 22
```

Notes

See also [WEEK](#) on page 2079, [MONTH](#) on page 2078, [QUARTER](#) on page 2079, [YEAR](#) on page 2080 and the ISO equivalents.

ISDATE

Checks if the string is a valid date format.

| | |
|------------|---|
| Syntax | <code>ISDATE(string)</code> |
| Output | Boolean |
| Definition | Returns true if a given <code><string></code> is a valid date. |
| Example | <code>ISDATE(09/22/2018) = true</code> <code>ISDATE(22SEP18) = false</code> |
| Notes | The required argument must be a string. ISDATE cannot be used for a field with a date data type – the calculation will return an error. |

ISOQUARTER

| | |
|------------|--|
| Syntax | <code>ISOQUARTER(date)</code> |
| Output | Integer |
| Definition | Returns the ISO8601 week-based quarter of a given <code><date></code> as an integer. |
| Example | <code>ISOQUARTER(#1986-03-25#) = 1</code> |
| Notes | See also ISOWEEK below, ISOWEEKDAY on the next page, ISOYEAR on the next page and the non-ISO equivalents. |

ISOWEEK

| | |
|------------|---|
| Syntax | <code>ISOWEEK(date)</code> |
| Output | Integer |
| Definition | Returns the ISO8601 week-based week of a given <code><date></code> as an integer. |
| Example | <code>ISOWEEK(#1986-03-25#) = 13</code> |
| Notes | See also ISOWEEKDAY on the next page, ISOQUARTER above, |

[ISOYEAR](#) below and the non-ISO equivalents.

ISOWEEKDAY

| | |
|------------|--|
| Syntax | ISOWEEKDAY (date) |
| Output | Integer |
| Definition | Returns the ISO8601 week-based weekday of a given <date> as an integer. |
| Example | ISOWEEKDAY (#1986-03-25#) = 2 |
| Notes | See also ISOWEEK on the previous page, ISOQUARTER on the previous page, ISOYEAR below and the non-ISO equivalents. |

ISOYEAR

| | |
|------------|---|
| Syntax | ISOYEAR (date) |
| Output | Integer |
| Definition | Returns the ISO8601 week-based year of a given <date> as an integer. |
| Example | ISOYEAR (#1986-03-25#) = 1,986 |
| Notes | See also ISOWEEK on the previous page, ISOWEEKDAY above, ISOQUARTER on the previous page and the non-ISO equivalents. |

MAKEDATE

| | |
|------------|--|
| Syntax | MAKEDATE (year, month, day) |
| Output | Date |
| Definition | Returns a date value constructed from the specified <year>, <month> and <day>. |

Example `MAKEDATE(1986,3,25) = #1986-03-25#`

Notes

Note: Incorrectly entered values will be adjusted into a date, such as `MAKEDATE(2020,4,31) = May 1, 2020` rather than returning an error that there is no 31st day of April.

Available for Tableau Data Extracts. Check for availability in other data sources.

`MAKEDATE` requires numerical inputs for the parts of a date. If your data is a string that should be a date, try the [DATE on page 2067](#) function. `DATE` automatically recognises many standard date formats. If `DATE` does not recognise the input, try using [DATEPARSE on page 2070](#).

MAKEDATETIME

Syntax `MAKEDATETIME(date, time)`

Output Datetime

Definition Returns a datetime that combines a <date> and a <time>. The date can be a date, datetime or a string type. The time must be a datetime.

Example `MAKEDATETIME("1899-12-30", #07:59:00#) = #12/30/1899 7:59:00 AM#`

`MAKEDATETIME([Date], [Time]) = #1/1/2001 6:00:00 AM#`

Notes This function is available only for MySQL-compatible connections (which for Tableau are MySQL and Amazon Aurora).

[MAKETIME below](#) is a similar function available for Tableau Data Extracts and some other data sources.

MAKETIME

Syntax `MAKETIME(hour, minute, second)`

Output Datetime

| | |
|------------|--|
| Definition | Returns a date value constructed from the specified <hour>, <minute> and <second>. |
| Example | <code>MAKETIME(14, 52, 40) = #1/1/1899 14:52:40#</code> |
| Notes | <p>Because Tableau does not support a time data type, only datetime, the output is a datetime. The date portion of the field will be 1/1/1899.</p> <p>Similar function to MAKEDATETIME on the previous page, which is only available for MYSQL-compatible connections.</p> |

MAX

| | |
|------------|---|
| Syntax | <code>MAX(expression) or MAX(expr1, expr2)</code> |
| Output | Same data type as the argument, or NULL if any part of the argument is null. |
| Definition | <p>Returns the maximum of the two arguments, which must be of the same data type.</p> <p>MAX can also be applied to a single field as an aggregation.</p> |
| Example | <pre>MAX(4, 7) = 7 MAX(#3/25/1986#, #2/20/2021#) = #2/20/2021# MAX([Name]) = "Zander"</pre> |
| Notes | <p>For strings</p> <p>MAX is usually the value that comes last in alphabetical order.</p> |

For database data sources, the MAX string value is highest in the sort sequence defined by the database for that column.

For dates

For dates, the MAX is the most recent date. If MAX is an aggregation, the result will not have a date hierarchy. If MAX is a comparison, the result will retain the date hierarchy.

As an aggregation

`MAX(expression)` is an aggregate function and returns a single aggregated result. This displays as `AGG(expression)` in the viz.

As a comparison

`MAX(expr1, expr2)` compares the two values and returns a row-level value.

See also [MIN](#) below.

MIN

| | |
|------------|---|
| Syntax | <code>MIN(expression)</code> or <code>MIN(expr1, expr2)</code> |
| Output | Same data type as the argument, or <code>NULL</code> if any part of the argument is null. |
| Definition | Returns the minimum of the two arguments, which must be of the same data type. |

`MIN` can also be applied to a single field as an aggregation.

| | |
|---------|--|
| Example | <pre>MIN(4, 7) = 4 MIN(#3/25/1986#, #2/20/2021#) = #3/25/1986# MIN([Name]) = "Abebi"</pre> |
|---------|--|

Notes

For strings

`MIN` is usually the value that comes first in alphabetical order.

For database data sources, the `MIN` string value is lowest in the sort sequence defined by the database for that column.

For dates

For dates, the `MIN` is the earliest date. If `MIN` is an aggregation, the result will not have a date hierarchy. If `MIN` is a comparison, the result will retain the date hierarchy.

As an aggregation

`MIN(expression)` is an aggregate function and returns a single

aggregated result. This displays as `AGG (expression)` in the viz.

As a comparison

`MIN(expr1, expr2)` compares the two values and returns a row-level value.

See also [MAX](#) on page 2076.

MONTH

| | |
|------------|---|
| Syntax | <code>MONTH(date)</code> |
| Output | Integer |
| Definition | Returns the month of the given <code><date></code> as an integer. |
| Example | <code>MONTH(#1986-03-25#) = 3</code> |
| Notes | See also DAY on page 2072, WEEK on the facing page, QUARTER on the facing page, YEAR on page 2080 and the ISO equivalents |

NOW

| | |
|------------|--|
| Syntax | <code>NOW()</code> |
| Output | Datetime |
| Definition | Returns the current local system date and time. |
| Example | <code>NOW() = 1986-03-25 1:08:21 PM</code> |
| Notes | <p><code>NOW</code> does not take an argument.</p> <p>See also TODAY on the facing page, a similar calculation that returns a date instead of a datetime.</p> <p>If the data source is a live connection, the system date and time could be in another time zone. For more information on how to address this, see the Knowledge Base.</p> |

QUARTER

| | |
|------------|--|
| Syntax | <code>QUARTER (date)</code> |
| Output | Integer |
| Definition | Returns the quarter of the given <date> as an integer. |
| Example | <code>QUARTER (#1986-03-25#) = 1</code> |
| Notes | See also DAY on page 2072, WEEK below, MONTH on the previous page, YEAR on the next page and the ISO equivalents |

TODAY

| | |
|------------|---|
| Syntax | <code>TODAY ()</code> |
| Output | Date |
| Definition | Returns the current local system date. |
| Example | <code>TODAY () = 1986-03-25</code> |
| Notes | <p><code>TODAY</code> does not take an argument.</p> <p>See also NOW on the previous page, a similar calculation that returns a datetime instead of a date.</p> <p>If the data source is a live connection, the system date could be in another time zone. For more information on how to address this, see the Knowledge Base.</p> |

WEEK

| | |
|------------|---|
| Syntax | <code>WEEK (date)</code> |
| Output | Integer |
| Definition | Returns the week of the given <date> as an integer. |

| | |
|---------|---|
| Example | <code>WEEK(#1986-03-25#) = 13</code> |
| Notes | See also DAY on page 2072, MONTH on page 2078, QUARTER on the previous page, YEAR below and the ISO equivalents |

YEAR

| | |
|------------|--|
| Syntax | <code>YEAR(date)</code> |
| Output | Integer |
| Definition | Returns the year of the given <date> as an integer. |
| Example | <code>YEAR(#1986-03-25#) = 1,986</code> |
| Notes | See also DAY on page 2072, WEEK on the previous page, MONTH on page 2078, QUARTER on the previous page and the ISO equivalents |

date_part

Many date functions in Tableau take the argument `date_part`, which is a string constant that tells the function what part of a date to consider, such as day, week, quarter, etc. The valid `date_part` values that you can use are:

| date_part | Values |
|------------------|---|
| 'year' | Four-digit year |
| 'quarter' | 1-4 |
| 'month' | 1-12 or "January", "February" and so on |
| 'dayofyear' | Day of the year; 1st Jan 1, 1st Feb is 32 and so on |
| 'day' | 1-31 |
| 'weekday' | 1-7 or "Sunday", "Monday" and so on |
| 'week' | 1-52 |
| 'hour' | 0-23 |

| date_part | Values |
|------------------|--------------------------------------|
| 'minute' | 0-59 |
| 'second' | 0-60 |
| 'iso-year' | Four-digit ISO 8601 year |
| 'iso-quarter' | 1-4 |
| 'iso-week' | 1-52, start of week is always Monday |
| 'iso-weekday' | 1-7, start of week is always Monday |

The [start_of_week] parameter

Some functions have the optional parameter [start_of_week]. The start_of_week parameter can be used to specify what day is considered the first day of the week, such as "Sunday" or "Monday". If it is omitted, the start of week is determined by the data source. See [Date Properties for a Data Source on page 1159](#).

For the examples below, 22 September is a Sunday and 24 September is a Tuesday. The DATEDIFF function is being used to calculate the weeks between these dates.

```
DATEDIFF('week', #2013-09-22#, #2013-09-24#, 'monday') = 1
```

- Because start_of_week is 'monday', these dates are in different weeks.

```
DATEDIFF('week', #2013-09-22#, #2013-09-24#, 'sunday') = 0
```

- Because start_of_week is 'sunday', these dates are in the same week.

The date literal (#)

Examples often use the pound symbol (#) with date expressions. This is the date literal, similar to using quotes for text strings, and it tells Tableau that the value inside the symbols is a date.

Without the date literals, dates may be interpreted as various other data types. For example:

| Format | Data Type | Value |
|------------------|------------------|------------------|
| 'March 25, 1986' | String | 'March 25, 1986' |
| #3/25/1986# | Date | #3/25/1986# |
| 25/03/1986 | Floating decimal | 0.00006042 |

| | | |
|----------------|---------|---------|
| 25/03/1986 | Integer | 1,958 |
| March 25, 1986 | | invalid |

| | |
|------|------------------|
| =Abc | 'March 25, 1986' |
| =# | #3/25/1986# |
| Abc | Measure Names |
| =# | 03/25/1986 |
| =# | 1986-03-25 |
| =# | March 25, 1986 ! |

For more information, see [Literal expression syntax on page 2447](#)

Create a date calculation

Practice creating a date calculation using the Superstore sample data source.

1. In Tableau Desktop, connect to the **Sample-Superstore** saved data source, which comes with Tableau.
2. Open a worksheet.
3. From the **Data** pane, under Dimensions, drag **Order Date** to the **Rows** shelf.
4. On the **Rows** shelf, click the plus icon (+) on the **YEAR(Order Date)** field.

QUARTER(Order Date) is added to the Rows shelf and the view updates.

| Columns | | |
|------------------------------------|---------------|-----|
| Rows | | |
| YEAR(Order Date) QUARTER(Order D.. | | |
| Year of Ord.. | Quarter of .. | |
| 2011 | Q1 | Abc |
| | Q2 | Abc |
| | Q3 | Abc |
| | Q4 | Abc |
| 2012 | Q1 | Abc |
| | Q2 | Abc |
| | Q3 | Abc |
| | Q4 | Abc |
| 2013 | Q1 | Abc |
| | Q2 | Abc |

5. On the **Rows** shelf, click the plus icon (+) on the **QUARTER(Order Date)** field to drill down to **MONTH(Order Date)**.

| Year of Ord.. | Quarter of .. | Month of Order Date | |
|---------------|---------------|---------------------|-----|
| 2011 | Q1 | January | Abc |
| | | February | Abc |
| | | March | Abc |
| | Q2 | April | Abc |
| | | May | Abc |
| | | June | Abc |
| | Q3 | July | Abc |
| | | August | Abc |
| | | September | Abc |
| | Q4 | October | Abc |
| | | November | Abc |
| | | December | Abc |
| 2012 | Q1 | January | Abc |
| | | February | Abc |

6. Select **Analysis > Create Calculated Field**.
7. In the calculation editor that opens, do the following:
 - Name the calculated field, Quarter Date.
 - Enter the following formula: `DATETRUNC('quarter', [Order Date])`
 - When finished, click **OK**.

The new date calculated field appears under **Dimensions** in the **Data** pane. Just like your other fields, you can use it in one or more visualisations.

8. From the **Data** pane, under Dimensions, drag **Quarter Date** to the **Rows** shelf and place it to the right of **MONTH(Order Date)**. The visualisation updates with year values. This is because Tableau rolls date data up to the highest level of detail.
9. On the Rows shelf, right-click **YEAR(Quarter Date)** and select **Exact Date**.
10. On the Rows shelf, right-click **YEAR(Quarter Date)** again and select **Discrete**.

The visualisation updates with the exact quarter date for each row in the table.

| Columns | | | | |
|--|---------------|---------------------|-----------------------|-----|
| Rows | | | | |
| <div> <div>YEAR(Order Date)</div> <div>QUARTER(Order D..)</div> <div>MONTH(Order Dat..)</div> <div>Quarter Date</div> </div> | | | | |
| Year of Ord.. | Quarter of .. | Month of Order Date | Quarter Date | |
| 2011 | Q1 | January | 1/1/2011 12:00:00 AM | Abc |
| | | February | 1/1/2011 12:00:00 AM | Abc |
| | | March | 1/1/2011 12:00:00 AM | Abc |
| | Q2 | April | 4/1/2011 12:00:00 AM | Abc |
| | | May | 4/1/2011 12:00:00 AM | Abc |
| | | June | 4/1/2011 12:00:00 AM | Abc |
| | Q3 | July | 7/1/2011 12:00:00 AM | Abc |
| | | August | 7/1/2011 12:00:00 AM | Abc |
| | | September | 7/1/2011 12:00:00 AM | Abc |
| | Q4 | October | 10/1/2011 12:00:00 AM | Abc |
| | | November | 10/1/2011 12:00:00 AM | Abc |
| | | December | 10/1/2011 12:00:00 AM | Abc |
| 2012 | Q1 | January | 1/1/2012 12:00:00 AM | Abc |
| | | February | 1/1/2012 12:00:00 AM | Abc |
| | | March | 1/1/2012 12:00:00 AM | Abc |

Type Conversion

This article introduces type conversion functions and their uses in Tableau. It also demonstrates how to create a type conversion calculation using an example.

Why use type conversion functions

Type conversion functions allow you to convert fields from one data type to another (this is called "casting"). For example, if you have date information in a field with a string data type, you won't be able to use that field in date calculations unless the field is cast (changed) to a date data type.

For example, to use a string date field in a DATEDIFF function, you'd also need to use a date type conversion:

```
DATEDIFF('day', [Date Field], DATE([String Date Field]) )
```

Without the DATE function changing the data type, you'd get an error that "DATEDIFF is being called with (string, date, string)".

Tip: Fields have default [Data Types](#) on page 156 in the Data pane. In many instances, you don't need to use a type conversion function at all. You can change the field's data type by clicking the icon. However, in some cases it can be useful to change the data type only for a specific calculation, or Tableau may not be able to correctly cast the field's contents to the desired data

type (such as not recognising the date format). Then you would need to use a type conversion function like those listed below.

Type conversion functions available in Tableau

DATE

| | |
|------------|---|
| Syntax | <code>DATE (expression)</code> |
| Output | Date |
| Definition | Returns a date, given a number, string or date expression. |
| Example | <code>DATE ([Employee Start Date])</code> <code>DATE ("September 22, 2018")</code> <code>DATE ("9/22/2018")</code> <code>DATE (#2018-09-22 14:52#)</code> |
| Notes | Unlike DATEPARSE , there is no need to provide a pattern as DATE automatically recognises many standard date formats. If DATE does not recognise the input, however, try using DATEPARSE and specifying the format. MAKEDATE is another similar function, but MAKEDATE requires the input of numeric values for year, month and day. |

DATETIME

| | |
|------------|---|
| Syntax | <code>DATETIME (expression)</code> |
| Output | Datetime |
| Definition | Returns a datetime given a number, string or date expression. |
| Example | <code>DATETIME ("April 15, 2005 07:59:00") = April 15, 2005 07:59:00</code> |

FLOAT

| | |
|------------|---|
| Syntax | <code>FLOAT(expression)</code> |
| Output | Floating point number (decimal) |
| Definition | Casts its argument as a floating point number. |
| Example | <code>FLOAT(3) = 3.000</code> |
| Notes | See also <code>INT</code> , which returns an integer. |

INT

| | |
|------------|--|
| Syntax | <code>INT(expression)</code> |
| Output | Integer |
| Definition | Casts its argument as an integer. For expressions, this function truncates results to the closest integer toward zero. |
| Example | <code>INT(8/3) = 2</code> <code>INT(-9.7) = -9</code> |
| Notes | When a string is converted to an integer it is first converted to a float and then rounded. See also <code>FLOAT</code> , which returns a decimal. See also <code>ROUND</code> , <code>CEILING</code> and <code>FLOOR</code> |

MAKEDATE

| | |
|------------|---|
| Syntax | <code>MAKEDATE(year, month, day)</code> |
| Output | Date |
| Definition | Returns a date value constructed from the specified numerical year, month and date. |
| Example | <code>MAKEDATE(1986, 3, 25) = #1986-03-25#</code> |

Note that incorrectly entered values will be adjusted into a date, such as `MAKEDATE(2020,4,31)` = May 1, 2020 rather than returning an error that there is no 31st day of April.

Notes Available for Tableau Data Extracts. Check for availability in other data sources.

`MAKEDATE` requires numerical inputs for the parts of a date. If your data is a string that should be a date, try the `DATE` function. `DATE` automatically recognises many standard date formats. If `DATE` does not recognise the input try using `DATEPARSE`.

MAKEDATETIME

Syntax `MAKEDATETIME(date, time)`

Output Datetime

Definition Returns a datetime that combines a date and a time. The date can be a date, datetime or a string type. The time must be a datetime.

Example `MAKEDATETIME("1899-12-30", #07:59:00#) = #12/30/1899 7:59:00 AM#`

`MAKEDATETIME([Date], [Time]) = #1/1/2001 6:00:00 AM#`

Notes This function is available only for MySQL-compatible connections (which for Tableau are MySQL and Amazon Aurora).

`MAKETIME` is a similar function available for Tableau Data Extracts and some other data sources.

MAKELINE

Syntax `MAKELINE(<Spatial Point1>, <Spatial Point2>)`

Output Geometry spatial object (line)

Definition Generates a line mark between two points.

| | |
|---------|--|
| Example | <pre>MAKELINE(OriginPoint, DestinationPoint) MAKELINE(MAKEPOINT(OriginLat],[OriginLong]) , MAKEPOINT ([DestinationLat],[DestinationLong])</pre> |
| Notes | Useful for building origin-destination maps or, with MAKEPOINT, turning latitude and longitude into spatial objects. |

MAKEPOINT

| | |
|------------|---|
| Syntax | <code>MAKEPOINT(<latitude>, <longitude>)</code> |
| Output | Geometry spatial object (point) |
| Definition | Converts data from latitude and longitude columns into spatial objects. |
| Example | <code>MAKEPOINT([AirportLatitude],[AirportLongitude])</code> |
| Notes | <p>You can use MAKEPOINT to spatially-enable a data source so that it can be joined with a spatial file using a spatial join. For more information, see Join Spatial Files in Tableau on page 1692.</p> <p>To use MAKEPOINT, your data must contain latitude and longitude coordinates.</p> |

MAKETIME

| | |
|------------|--|
| Syntax | <code>MAKETIME(hour, minute, second)</code> |
| Output | Datetime. See Notes. |
| Definition | Returns a date value constructed from the specified hour, minute and second. |
| Example | <code>MAKETIME(14, 52, 40) = #1/1/1899 14:52:40#</code> |
| Notes | <p>Because Tableau does not support a time data type, only datetime, the output is a datetime. The date portion of the field will be 1/1/1899.</p> <p>Similar function to MAKEDATETIME, which is only available for MySQL-</p> |

compatible connections.

STR

| | |
|------------|---------------------------------|
| Syntax | <code>STR(expression)</code> |
| Output | String |
| Definition | Casts its argument as a string. |
| Example | <code>STR([ID])</code> |

Cast Boolean expressions

A Boolean can be cast to an integer, float or string, but not a date.

- `True` maps to 1, 1.0 or "1"
- `False` maps to 0, 0.0 or "0"
- `Unknown` maps to `Null`

Create a type conversion calculation

Follow along with the steps below to learn how to create a type conversion calculation.

1. In Tableau Desktop, connect to the **Sample - Superstore** saved data source, which comes with Tableau.
2. Navigate to a worksheet.
3. Select **Analysis > Create Calculated Field**.
4. In the calculation editor that opens, convert the Postcode field from a number to a string:
 - Name the calculated field, Post Code String.
 - Enter the following formula:

```
STR([Postal Code])
```

- When finished, click **OK**.

The new calculated field appears under Dimensions in the **Data** pane. Just like your other fields, you can use it in one or more visualisations.

Converting this field from a number to a string ensures that Tableau treats it as a string and not a number (and therefore doesn't aggregate it).

Logical Functions

This article introduces logical functions and their uses in Tableau. It also demonstrates how to create a logical calculation using an example.

Why use logical calculations

Logical calculations allow you to determine whether a certain condition is true or false (Boolean logic). For example, you might want to categorise values based on certain cut-offs.

A logical calculation might look something like this:

```
IF [Profit] > 0
THEN 'Profitable'
ELSEIF [Profit] = 0 THEN 'Break even'
ELSE 'Loss'
END
```

Logical functions and operators available in Tableau

AND

| | |
|------------|---|
| Syntax | <code><expr1> AND <expr2></code> |
| Definition | Performs a logical conjunction on two expressions. (If both sides are true, the logical test returns true.) |
| Output | Boolean (true or false) |
| Example | <pre>IF [Season] = "Spring" AND "[Season] = "Fall" THEN "It's the apocalypse and footwear doesn't matter"</pre> |

END

“If both (Season = Spring) and (Season = Autumn) are true simultaneously, then return ‘It’s the apocalypse and footwear doesn’t matter’.”

Notes Often used with [IF on page 2094](#) and [IIF on page 2095](#). See also [NOT on page 2100](#) and [OR on page 2100](#).

If both expressions are TRUE (that is, not FALSE or NULL), then the result is TRUE. If either expression is NULL, then the result is NULL. In all other cases, the result is FALSE.

If you create a calculation in which the result of an AND comparison is displayed on a worksheet, Tableau displays TRUE and FALSE. If you would like to change this, use the Format area in the format dialog.

Note: The AND operator employs *short circuit evaluation*. This means that if the first expression is evaluated to be FALSE, then the second expression is not evaluated at all. This can be helpful if the second expression results in an error when the first expression is FALSE, because the second expression in this case is never evaluated.

CASE

Syntax

```
CASE <expression>
WHEN <value1> THEN <then1>
WHEN <value2> THEN <then2>
...
[ELSE <default>]
END
```

Output Depends on data type of the <then> values.

Definition Evaluates the `expression` and compares it to the specified options (<value1>, <value2>, etc.). When a value that matches expression is encountered, CASE returns the corresponding `return`. If no match is found, the (optional) default is returned. If there is no default and no values match, then Null is returned.

Example

```
CASE [Season]
WHEN 'Summer' THEN 'Sandals'
WHEN 'Winter' THEN 'Boots'
ELSE 'Sneakers'
END
```

"Look at the Season field. If the value is Summer, then return Sandals. If the value is Winter, then return Boots. If none of the options in the calculation match what is in the Season field, return Sneakers."

Notes

See also [IF on page 2094](#) and [IIF on page 2095](#).

Used with [WHEN on page 2102](#), [THEN on page 2101](#), [ELSE below](#) and [END on page 2094](#).

Tip: Many times you can use a group to get the same results as a complicated CASE function, or use CASE to replace native grouping functionality, such as in the previous example. You may want to test which is more performant for your scenario.

ELSE

Syntax

```
CASE <expression>
WHEN <value1> THEN <then1>
WHEN <value2> THEN <then2>
...
[ELSE <default>]
END
```

Definition

An optional piece of an IF or CASE expression used to specify a default value to return if none of the tested expressions are true.

Example

```
IF [Season] = "Summer" THEN 'Sandals'
ELSEIF [Season] = "Winter" THEN 'Boots'
ELSE 'Sneakers'
END

CASE [Season]
WHEN 'Summer' THEN 'Sandals'
```

```

    WHEN 'Winter' THEN 'Boots'
    ELSE 'Sneakers'
END

```

Notes Used with **CASE** on page 2091, **WHEN** on page 2102, **IF** on the next page, **ELSEIF** below, **THEN** on page 2101 and **END** on the next page

ELSE is optional with **CASE** and **IF**. In a calculation where **ELSE** is not specified, if none of the <test> are true, the overall calculation will return null.

ELSE does not require a condition (such as [Season] = "Winter") and can be thought of as a form of null handling.

ELSEIF

Syntax [**ELSEIF** <test2> THEN <then2>]

Definition An optional piece of an **IF** expression used to specify additional conditions beyond the initial **IF**.

Example

```

IF [Season] = "Summer" THEN 'Sandals'
ELSEIF [Season] = "Winter" THEN 'Boots'
ELSEIF [Season] = "Spring" THEN 'Sneakers'
ELSEIF [Season] = "Autumn" THEN 'Sneakers'
ELSE 'Bare feet'
END

```

Notes Used with **IF** on the next page, **THEN** on page 2101, **ELSE** on the previous page and **END** on the next page

ELSEIF can be thought of as additional **IF** clauses. **ELSEIF** is optional and can be repeated multiple times.

Unlike **ELSE**, **ELSEIF** requires a condition (such as [Season] = "Winter").

END

| | |
|------------|---|
| Definition | Used to close an IF or CASE expression. |
| Example | <pre>IF [Season] = "Summer" THEN 'Sandals' ELSEIF [Season] = "Winter" THEN 'Boots' ELSE 'Sneakers' END</pre> <p><i>"If Season = Summer, then return Sandals. If not, look at the next expression. If Season = Winter, then return Boots. If neither of the expressions are true, return Sneakers."</i></p> <pre>CASE [Season] WHEN 'Summer' THEN 'Sandals' WHEN 'Winter' THEN 'Boots' ELSE 'Sneakers' END</pre> <p><i>"Look at the Season field. If the value is Summer, then return Sandals. If the value is Winter, then return Boots. If none of the options in the calculation match what is in the Season field, return Sneakers."</i></p> |
| Notes | Used with CASE on page 2091, WHEN on page 2102, IF below, ELSEIF on the previous page, THEN on page 2101 and ELSE on page 2092. |

IF

| | |
|------------|--|
| Syntax | <pre>IF <test1> THEN <then1> [ELSEIF <test2> THEN <then2>...] [ELSE <default>] END</pre> |
| Output | Depends on data type of the <then> values. |
| Definition | Tests a series of expressions and returns the <then> value for the first true <test>. |
| Example | <pre>IF [Season] = "Summer" THEN 'Sandals'</pre> |

```
ELSEIF [Season] = "Winter" THEN 'Boots'
ELSE 'Sneakers'
END
```

"If Season = Summer, then return Sandals. If not, look at the next expression. If Season = Winter, then return Boots. If neither of the expressions are true, return Sneakers."

Notes See also [IF](#) on the previous page and [IIF](#) below.

Used with [ELSEIF](#) on page 2093, [THEN](#) on page 2101, [ELSE](#) on page 2092 and [END](#) on the previous page

IFNULL

Syntax `IFNULL(expr1, expr2)`

Output Depends on the data type of the `<expr>` values.

Definition Returns `<expr1>` if it's non-null, otherwise returns `<expr2>`.

Example `IFNULL([Assigned Room], "TBD")`

"If the Assigned Room field isn't null, return its value. If the Assigned room field is null, return TBD instead."

Notes Compare with [ISNULL](#) on page 2098. `IFNULL` always returns a value. `ISNULL` returns a boolean (true or false).

See also [ZN](#) on page 2103.

IIF

Syntax `IIF(<test>, <then>, <else>, [<unknown>])`

Output Depends on the data type of the values in the expression.

Definition Checks whether a condition is met (`<test>`) and returns `<then>` if the test is true, `<else>` if the test is false and an optional value for `<unknown>` if the test is null. If the optional unknown isn't specified, `IIF` returns null.

Example `IIF([Season] = 'Summer', 'Sandals', 'Other footwear')`

"If Season = Summer, then return Sandals. If not, return Other footwear"

`IIF([Season] = 'Summer', 'Sandals',
 IIF('Season' = 'Winter', 'Boots', 'Other footwear')
)`

"If Season = Summer, then return Sandals. If not, look at the next expression. If Season = Winter, then return Boots. If neither are true, return Sneakers."

`IIF('Season' = 'Summer', 'Sandals',
 IIF('Season' = 'Winter', 'Boots',
 IIF('Season' = 'Spring', 'Sneakers', 'Other footwear')
)
)`

"If Season = Summer, then return Sandals. If not, look at the next expression. If Season = Winter, then return Boots. If none of the expressions are true, return Sneakers."

Notes See also [IF on page 2094](#) and [CASE on page 2091](#).

`IIF` doesn't have an equivalent to `ELSEIF` (like `IF`) or repeated `WHEN` clauses (like `CASE`). Instead, multiple tests can be evaluated sequentially by nesting `IIF` statements as the `<unknown>` element. The first (outermost) true is returned.

That is to say, in the calculation below, the result will be Red, not Orange, because the expression stops being evaluated as soon as `A=A` is evaluated as true:

`IIF('A' = 'A', 'Red', IIF('B' = 'B', 'Orange', IIF('C' = 'D', 'Yellow', 'Green')))`

IN

Syntax `<expr1> IN <expr2>`

Output Boolean (true or false)

| | |
|------------|---|
| Definition | Returns <code>TRUE</code> if any value in <code><expr1></code> matches any value in <code><expr2></code> . |
| Example | <pre>SUM([Cost]) IN (1000, 15, 200)</pre> <p><i>"Is the value of the Cost field 1000, 15 or 200?"</i></p> <pre>[Field] IN [Set]</pre> <p><i>"Is the value of the field present in the set?"</i></p> |
| Notes | <p>The values in <code><expr2></code> can be a set, list of literal values or combined field.</p> <p>See also WHEN on page 2102.</p> |

ISDATE

| | |
|------------|---|
| Syntax | <code>ISDATE(string)</code> |
| Output | Boolean (true or false) |
| Definition | Returns true if a <code><string></code> is a valid date. The input expression must be a string (text) field. |
| Example | <pre>ISDATE("2018-09-22")</pre> <p><i>"Is the string 2018-09-22 a properly formatted date?"</i></p> |
| Notes | <p>What is considered a valid date depends on the locale of the system evaluating the calculation. For example:</p> <p>In the USA:</p> <ul style="list-style-type: none"> <code>ISDATE("2018-09-22") = TRUE</code> <code>ISDATE("2018-22-09") = FALSE</code> <p>In the UK:</p> <ul style="list-style-type: none"> <code>ISDATE("2018-09-22") = FALSE</code> <code>ISDATE("2018-22-09") = TRUE</code> |

ISNULL

| | |
|------------|---|
| Syntax | <code>ISNULL(expression)</code> |
| Output | Boolean (true or false) |
| Definition | Returns true if the <code><expression></code> is NULL (does not contain valid data). |
| Example | <code>ISNULL([Assigned Room])</code> <i>"Is the Assigned Room field null?"</i> |
| Notes | Compare with IFNULL on page 2095 . <code>IFNULL</code> always returns a value. <code>ISNULL</code> returns a boolean. See also ZN on page 2103 . |

MAX

| | |
|------------|---|
| Syntax | <code>MAX(expression)</code> or <code>MAX(expr1, expr2)</code> |
| Output | Same data type as the argument, or NULL if any part of the argument is null. |
| Definition | Returns the maximum of the two arguments, which must be of the same data type. <code>MAX</code> can also be applied to a single field as an aggregation. |
| Example | <code>MAX(4, 7) = 7</code> <code>MAX(#3/25/1986#, #2/20/2021#) = #2/20/2021#</code> <code>MAX([Name]) = "Zander"</code> |
| Notes | For strings <code>MAX</code> is usually the value that comes last in alphabetical order. |

For database data sources, the `MAX` string value is highest in the sort sequence defined by the database for that column.

For dates

For dates, the **MAX** is the most recent date. If **MAX** is an aggregation, the result will not have a date hierarchy. If **MAX** is a comparison, the result will retain the date hierarchy.

As an aggregation

MAX(*expression*) is an aggregate function and returns a single aggregated result. This displays as **AGG**(*expression*) in the viz.

As a comparison

MAX(*expr1*, *expr2*) compares the two values and returns a row-level value.

See also **MIN** below.

MIN

| | |
|------------|---|
| Syntax | MIN (<i>expression</i>) or MIN (<i>expr1</i> , <i>expr2</i>) |
| Output | Same data type as the argument, or NULL if any part of the argument is null. |
| Definition | Returns the minimum of the two arguments, which must be of the same data type. MIN can also be applied to a single field as an aggregation. |
| Example | <pre>MIN(4,7) = 4 MIN(#3/25/1986#, #2/20/2021#) = #3/25/1986# MIN([Name]) = "Abebi"</pre> |
| Notes | For strings MIN is usually the value that comes first in alphabetical order. |

For database data sources, the **MIN** string value is lowest in the sort sequence defined by the database for that column.

For dates

For dates, the **MIN** is the earliest date. If **MIN** is an aggregation, the result

will not have a date hierarchy. If **MIN** is a comparison, the result will retain the date hierarchy.

As an aggregation

MIN(*expression*) is an aggregate function and returns a single aggregated result. This displays as **AGG**(*expression*) in the viz.

As a comparison

MIN(*expr1*, *expr2*) compares the two values and returns a row-level value.

See also **MAX** on page 2098.

NOT

| | |
|------------|--|
| Syntax | NOT <expression> |
| Output | Boolean (true or false) |
| Definition | Performs logical negation on an expression. |
| Example | <pre>IF NOT [Season] = "Summer" THEN 'Don't wear sandals' ELSE 'Wear sandals' END</pre> <p><i>"If Season doesn't equal Summer, then return Don't wear sandals. If not, return Wear sandals."</i></p> |
| Notes | Often used with IF on page 2094 and IIF on page 2095. See also AND on page 2090 and OR below. |

OR

| | |
|------------|--|
| Syntax | <expr1> OR <expr2> |
| Output | Boolean (true or false) |
| Definition | Performs a logical disjunction on two expressions. |

Example

```
IF [Season] = "Spring" OR [Season] = "Fall"
THEN "Sneakers"
END
```

"If either (Season = Spring) or (Season = Fall) is true, then return Sneakers."

Notes Often used with [IF on page 2094](#) and [IIF on page 2095](#). See also [AND on page 2090](#) and [NOT on the previous page](#).

If either expression is `TRUE`, then the result is `TRUE`. If both expressions are `FALSE`, then the result is `FALSE`. If both expressions are `NULL`, then the result is `NULL`.

If you create a calculation that displays the result of an `OR` comparison on a worksheet, Tableau displays `TRUE` and `FALSE`. If you would like to change this, use the Format area in the format dialog.

Note: The `OR` operator employs *short circuit evaluation*. This means that if the first expression is evaluated to be `TRUE`, then the second expression is not evaluated at all. This can be helpful if the second expression results in an error when the first expression is `TRUE`, because the second expression in this case is never evaluated.

THEN

Syntax

```
IF <test1> THEN <then1>
[ELSEIF <test2> THEN <then2>...]
[ELSE <default>]
END
```

Definition A required part of an `IF`, `ELSEIF` or `CASE` expression, used to define what result to return if a specific value or test is true.

Example

```
IF [Season] = "Summer" THEN 'Sandals'
ELSEIF [Season] = "Winter" THEN 'Boots'
ELSE 'Sneakers'
END
```

"If Season = Summer, then return Sandals. If not, look at the next expression. If Season = Winter, then return Boots. If neither of the expressions are true, return Sneakers."

```
CASE [Season]
WHEN 'Summer' THEN 'Sandals'
WHEN 'Winter' THEN 'Boots'
ELSE 'Sneakers'
END
```

"Look at the Season field. If the value is Summer, then return Sandals. If the value is Winter, then return Boots. If none of the options in the calculation match what is in the Season field, return Sneakers."

Notes Used with [CASE](#) on page 2091, [WHEN](#) below, [IF](#) on page 2094, [ELSEIF](#) on page 2093, [THEN](#) on the previous page, [ELSE](#) on page 2092 and [END](#) on page 2094

WHEN

Syntax

```
CASE <expression>
WHEN <value1> THEN <then1>
WHEN <value2> THEN <then2>
...
[ELSE <default>]
END
```

Definition A required part of a CASE expression. Finds the first <value> that matches <expression> and returns the corresponding <then>.

Example

```
CASE [Season]
WHEN 'Summer' THEN 'Sandals'
WHEN 'Winter' THEN 'Boots'
ELSE 'Sneakers'
END
```

"Look at the Season field. If the value is Summer, then return Sandals. If the value is Winter, then return Boots. If none of the options in the

calculation match what is in the Season field, return Sneakers."

Notes Used with **CASE** on page 2091, **THEN** on page 2101, **ELSE** on page 2092 and **END** on page 2094.

CASE also supports WHEN IN construction, such as:

```
CASE <expression>
WHEN IN <set1> THEN <then1>
WHEN IN <combinedfield> THEN <then2>
...
ELSE <default>
END
```

The values that WHEN IN compare to must be a set, list of literal values or combined field. See also **IN** on page 2096.

ZN

Syntax ZN(expression)

Output Depends on the data type of the <expression>, or 0.

Definition Returns <expression> if it isn't null; otherwise returns zero.

Example ZN([Test Grade])

"If the test grade isn't null, return its value. If the test grade is null, return 0."

Notes ZN is a specialised case of **IFNULL** on page 2095 where the alternative if the expression is null is always 0 rather than being specified in the calculation.

ZN is especially useful when performing additional calculations, and a null would render the entire calculation null. However, use caution interpreting these results as null is not always synonymous with 0 and could represent missing data.

See also **ISNULL** on page 2098.

Note: Some of these are actually logical operators and appear in black, not blue. For more information, see [Operator syntax on page 2444](#).

Note on CASE, IF and IIF

CASE is often easier to use than IF or IIF. In many instances, IF, IIF and CASE can be used interchangeably. A CASE statement can always be rewritten as an IF statement, although the CASE function will generally be more concise and may be easier to understand. However, not all IF statements can be written as CASE statements, because each ELSEIF could refer to a different field.

Tip: Let's compare an example using the same logic across these three functions:

| CASE | IF | IIF |
|---|--|---|
| <pre> CASE [Region] WHEN 'West' THEN 1 WHEN 'East' THEN 2 WHEN 'South' THEN 3 WHEN 'North' Then 4 ELSE 5 END </pre> | <pre> IF [Region] = 'West' THEN 1 ELSEIF [Region] = 'East' THEN 2 ELSEIF [Region] = 'South' THEN 3 ELSEIF [Region] = 'North' THEN 4 ELSE 5 END </pre> | <pre> IIF([Region] = 'West', 1, IIF([Region] = 'East', 2, IIF([Region] = 'South', 3, IIF([Region] = 'North', 4, 5, 0)))) </pre> |
| <p>The CASE structure is very simple and easy to write and understand. However, the expression (here, [Region]) cannot be</p> | <p>The IF THEN structure permits multiple ELSEIF clauses, which makes multiple evaluations much easier than with IIF.</p> <p>Null handling: any unknown (null) results are handled by the same ELSE clause as false results. Here, any region other</p> | <p>The IIF structure handles unknown results differently than false results and has a different syntax from IF. The trade-off for specific null handling is nesting, as above, which can be clumsy to write and understand.</p> |

a logical operation, unlike with IF or IIF. Nulls are handled the same for CASE as they are for IF.

than the four specified (including null) will be assigned a value of 5.

Null handling: any non-null region other than the four specified will be assigned a value of 5, but a null value will be assigned a 0.

Note: Often, you can use a group to get the same results as a complicated case function. Test to see whether one option is more performant than the other.

Examples

CASE functions can be useful for scenarios such as realising:

```
CASE LEFT(DATENAME('weekday',[Order Date]),3)
WHEN 'Sun' THEN 0
WHEN 'Mon' THEN 1
WHEN 'Tue' THEN 2
WHEN 'Wed' THEN 3
WHEN 'Thu' THEN 4
WHEN 'Fri' THEN 5
WHEN 'Sat' THEN 6
END
```

or giving the end user the ability to select which measure to view in a chart when used with a **parameter**:

```
CASE [Choose a Measure]
WHEN "Sales" THEN SUM([Sales])
WHEN "Profit" THEN AVG([Profit])
WHEN "Quantity" THEN COUNT([Quantity])
WHEN "Shipping Cost" THEN MEDIAN([Shipping Cost])
END
```

Create a logical calculation

Follow along with the steps below to learn how to create a logical calculation.

1. In Tableau Desktop, connect to the **Sample - Superstore** saved data source, which comes with Tableau.
2. Navigate to a worksheet.
3. From the **Data** pane, drag **State** to the **Rows** shelf.
4. From the **Data** pane, drag **Category** to the **Rows** shelf and place it to the right of State.
5. From the **Data** pane, drag **Sales** to the **Columns** shelf.
6. Select **Analysis > Create Calculated Field**.
7. In the calculation editor that opens, do the following:
 - Name the calculated field KPI.
 - Enter the following formula:

```
SUM([Profit]) > 0
```

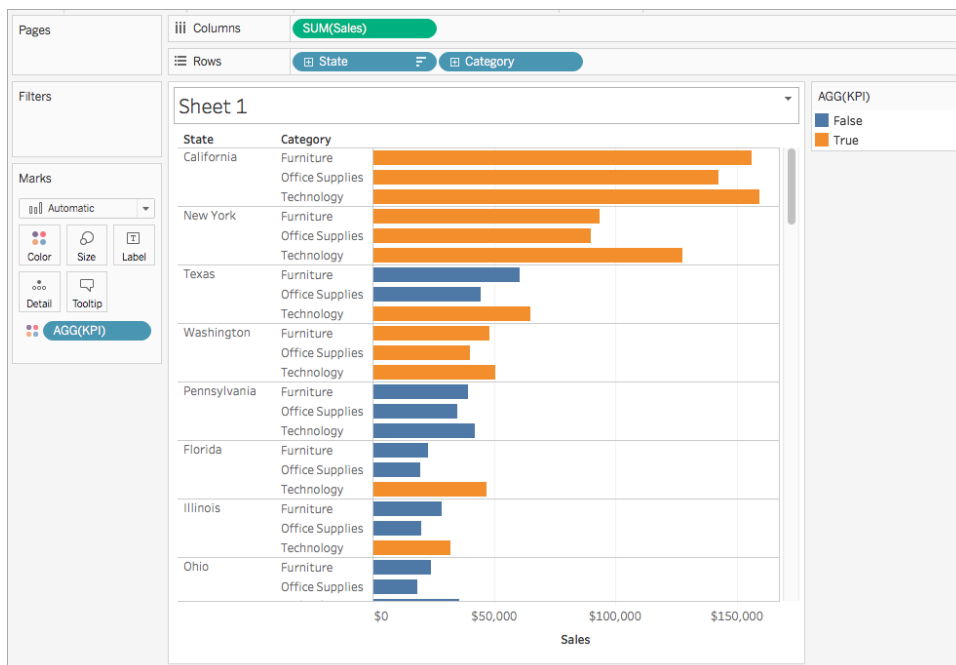

This calculation quickly checks if a member is great than zero. If so, it returns true; if not, it returns false.

- When finished, click **OK**.

The new calculated field appears under Measures in the Data pane. Just like your other fields, you can use it in onr or more visualisations.

8. From the **Data** pane, drag **KPI** to **Colour** on the Marks card.

You can now see which categories are losing money in each state.

[Tableau Functions \(Alphabetical\)](#) on page 2291

Aggregate Functions in Tableau

This article introduces aggregate functions and their uses in Tableau. It also demonstrates how to create an aggregate calculation using an example.

Why use aggregate functions

Aggregate functions allow you to summarise or change the granularity of your data.

For example, you might want to know exactly how many orders your store had for a particular year. You can use the COUNTD function to tally the exact number of unique orders your company had, and then break the visualisation down by year.

The calculation might look something like this:

```
COUNTD(Order ID)
```

The visualisation might look something like this:

Aggregate functions available in Tableau

Aggregations and floating-point arithmetic: The results of some aggregations may not always be exactly as expected. For example, you may find that the SUM function returns a value such as $-1.42e-14$ for a column of numbers that you know should sum to exactly 0. This happens because the Institute of Electrical and Electronics Engineers (IEEE) 754 floating-point standard requires that numbers be stored in binary format, which means that numbers are sometimes rounded at extremely fine levels of precision. You can eliminate this potential distraction by using

the ROUND function (see [Number Functions on page 2039](#)) or by formatting the number to show fewer decimal places.

ATTR

| | |
|------------|--|
| Syntax | <code>ATTR(expression)</code> |
| Definition | Returns the value of the expression if it has a single value for all rows. Otherwise returns an asterisk. Null values are ignored. |

AVG

| | |
|------------|---|
| Syntax | <code>AVG(expression)</code> |
| Definition | Returns the average of all the values in the expression. Null values are ignored. |
| Notes | <code>AVG</code> can only be used with numeric fields. |

COLLECT

| | |
|------------|---|
| Syntax | <code>COLLECT(spatial)</code> |
| Definition | An aggregate calculation that combines the values in the argument field. Null values are ignored. |
| Notes | <code>COLLECT</code> can only be used with spatial fields. |

CORR

| | |
|------------|---|
| Syntax | <code>CORR(expression1, expression2)</code> |
| Output | Number from -1 to 1 |
| Definition | Returns the Pearson correlation coefficient of two expressions. |
| Example | <code>example</code> |

Notes The Pearson correlation measures the linear relationship between two variables. Results range from -1 to +1 inclusive, where 1 denotes an exact positive linear relationship, 0 denotes no linear relationship between the variance and -1 is an exact negative relationship.

The square of a CORR result is equivalent to the R-Squared value for a linear trend line model. See [Trend Line Model Terms](#).

Use with table-scoped LOD expressions:

You can use CORR to visualise correlation in a disaggregated scatter using a [table-scoped level of detail expression](#). For example:

```
{CORR(Sales, Profit)}
```

With a level of detail expression, the correlation is run over all rows. If you used a formula like `CORR(Sales, Profit)` (without the surrounding brackets to make it a level of detail expression), the view would show the correlation of each individual point in the scatter plot with each other point, which is undefined.

Database limitations CORR is available with the following data sources: Tableau data extracts, Cloudera Hive, EXASolution, Firebird (version 3.0 and later), Google BigQuery, Hortonworks Hadoop Hive, IBM PDA (Netezza), Oracle, PostgreSQL, Presto, SybaseIQ, Teradata, Vertica.

For other data sources, consider either extracting the data or using `WINDOW_CORR`. See [Table Calculation Functions](#).

COUNT

Syntax `COUNT(expression)`

Definition Returns the number of items. Null values are not counted.

COUNTD

Syntax `COUNTD(expression)`

Definition Returns the number of distinct items in a group. Null values are not coun-

ted.

COVAR

| | |
|----------------------|--|
| Syntax | <code>COVAR(expression1, expression2)</code> |
| Definition | Returns the <i>sample</i> covariance of two expressions. |
| Notes | <p>Covariance quantifies how two variables change together. A positive covariance indicates that the variables tend to move in the same direction, as when larger values of one variable tend to correspond to larger values of the other variable, on average. <i>Sample covariance</i> uses the number of non-null data points $n-1$ to normalise the covariance calculation, rather than n, which is used by the population covariance (available with the <code>COVARP</code> function). Sample covariance is the appropriate choice when the data is a random sample that is being used to estimate the covariance for a larger population.</p> <p>If <code><expression1></code> and <code><expression2></code> are the same, for example <code>COVAR([profit], [profit])</code>, <code>COVAR</code> returns a value that indicates how widely values are distributed.</p> <p>The value of <code>COVAR(X, X)</code> is equivalent to the value of <code>VAR(X)</code> and also to the value of <code>STDEV(X)^2</code>.</p> |
| Database limitations | <p><code>COVAR</code> is available with the following data sources: Tableau data extracts, Cloudera Hive, EXASolution, Firebird (version 3.0 and later), Google BigQuery, Hortonworks Hadoop Hive, IBM PDA (Netezza), Oracle, PostgreSQL, Presto, SybaseIQ, Teradata, Vertica.</p> <p>For other data sources, consider either extracting the data or using <code>WINDOW_COVAR</code>. See Table Calculation Functions.</p> |

COVARP

| | |
|------------|--|
| Syntax | <code>COVARP(expression 1, expression2)</code> |
| Definition | Returns the <i>population</i> covariance of two expressions. |

Notes Covariance quantifies how two variables change together. A positive covariance indicates that the variables tend to move in the same direction, as when larger values of one variable tend to correspond to larger values of the other variable, on average. *Population covariance* is sample covariance multiplied by $(n-1)/n$, where n is the total number of non-null data points. Population covariance is the appropriate choice when there is data available for all items of interest as opposed to when there is only a random subset of items, in which case sample covariance (with the `COVAR` function) is appropriate.

If `<expression1>` and `<expression2>` are the same, for example `COVARP([profit], [profit])`, `COVARP` returns a value that indicates how widely values are distributed. Note: The value of `COVARP(X, X)` is equivalent to the value of `VARP(X)` and also to the value of `STDEVP(X)^2`.

Database limitations `COVARP` is available with the following data sources: Tableau data extracts, Cloudera Hive, EXASolution, Firebird (version 3.0 and later), Google BigQuery, Hortonworks Hadoop Hive, IBM PDA (Netezza), Oracle, PostgreSQL, Presto, SybaseIQ, Teradata, Vertica

For other data sources, consider either extracting the data or using `WINDOW_COVAR`. See [Table Calculation Functions](#).

MAX

Syntax `MAX(expression)` or `MAX(expr1, expr2)`

Output Same data type as the argument, or `NULL` if any part of the argument is null.

Definition Returns the maximum of the two arguments, which must be of the same data type.

`MAX` can also be applied to a single field as an aggregation.

Example

```
MAX(4, 7) = 7
MAX(#3/25/1986#, #2/20/2021#) = #2/20/2021#
MAX([Name]) = "Zander"
```

Notes

For strings

MAX is usually the value that comes last in alphabetical order.

For database data sources, the MAX string value is highest in the sort sequence defined by the database for that column.

For dates

For dates, the MAX is the most recent date. If MAX is an aggregation, the result will not have a date hierarchy. If MAX is a comparison, the result will retain the date hierarchy.

As an aggregation

MAX(expression) is an aggregate function and returns a single aggregated result. This displays as AGG(expression) in the viz.

As a comparison

MAX(expr1, expr2) compares the two values and returns a row-level value.

See also [MIN](#) on the facing page.

MEDIAN

Syntax

MEDIAN(expression)

Definition

Returns the median of an expression across all records. Null values are ignored.

Notes

MEDIAN can only be used with numeric fields.

Database limitations

MEDIAN is **not** available for the following data sources: Access, Amazon Redshift, Cloudera Hadoop, HP Vertica, IBM DB2, IBM PDA (Netezza), Microsoft SQL Server, MySQL, SAP HANA, Teradata.

For other data source types, you can extract your data into an extract file to use this function. See [Extract Your Data](#).

MIN

| | |
|------------|---|
| Syntax | <code>MIN(expression)</code> or <code>MIN(expr1, expr2)</code> |
| Output | Same data type as the argument, or <code>NULL</code> if any part of the argument is null. |
| Definition | Returns the minimum of the two arguments, which must be of the same data type. |

`MIN` can also be applied to a single field as an aggregation.

| | |
|---------|--|
| Example | <pre>MIN(4, 7) = 4 MIN(#3/25/1986#, #2/20/2021#) = #3/25/1986# MIN([Name]) = "Abebi"</pre> |
|---------|--|

Notes

For strings

`MIN` is usually the value that comes first in alphabetical order.

For database data sources, the `MIN` string value is lowest in the sort sequence defined by the database for that column.

For dates

For dates, the `MIN` is the earliest date. If `MIN` is an aggregation, the result will not have a date hierarchy. If `MIN` is a comparison, the result will retain the date hierarchy.

As an aggregation

`MIN(expression)` is an aggregate function and returns a single aggregated result. This displays as `AGG(expression)` in the viz.

As a comparison

`MIN(expr1, expr2)` compares the two values and returns a row-level value.

See also [MAX](#) on page 2111.

PERCENTILE

| | |
|----------------------|--|
| Syntax | <code>PERCENTILE(expression, number)</code> |
| Definition | Returns the percentile value from the given expression corresponding to the specified <number>. The <number> must be between 0 and 1 (inclusive) and must be a numeric constant. |
| Example | <code>PERCENTILE([Score], 0.9)</code> |
| Database limitations | <p>This function is available for the following data sources: Non-legacy Microsoft Excel and Text File connections, Extracts and extract-only data source types (for example, Google Analytics, OData or Salesforce), Sybase IQ 15.1 and later data sources, Oracle 10 and later data sources, Cloudera Hive and Hortonworks Hadoop Hive data sources, EXASolution 4.2 and later data sources.</p> <p>For other data source types, you can extract your data into an extract file to use this function. See Extract Your Data.</p> |

STDEV

| | |
|------------|---|
| Syntax | <code>STDEV(expression)</code> |
| Definition | Returns the statistical standard deviation of all values in the given expression based on a sample of the population. |

STDEVP

| | |
|------------|--|
| Syntax | <code>STDEVP(expression)</code> |
| Definition | Returns the statistical standard deviation of all values in the given expression based on a biased population. |

SUM

| | |
|------------|---|
| Syntax | <code>SUM(expression)</code> |
| Definition | Returns the sum of all values in the expression. Null values are ignored. |
| Notes | <code>SUM</code> can only be used with numeric fields. |

VAR

| | |
|------------|---|
| Syntax | <code>VAR(expression)</code> |
| Definition | Returns the statistical variance of all values in the given expression based on a sample of the population. |

VARP

| | |
|------------|--|
| Syntax | <code>VARP(expression)</code> |
| Definition | Returns the statistical variance of all values in the given expression on the entire population. |

Create an aggregate calculation

Follow along with the steps below to learn how to create an aggregate calculation.

1. In Tableau Desktop, connect to the **Sample - Superstore** saved data source, which comes with Tableau.
2. Navigate to a worksheet and select **Analysis > Create Calculated Field**.
3. In the calculation editor that opens, do the following:
 - Name the calculated field **Margin**.
 - Enter the following formula:

```
IIF(SUM([Sales]) !=0, SUM([Profit])/SUM([Sales]), 0)
```

Note: You can use the function reference to find and add aggregate functions and other functions (like the logical IIF function in this example) to the calculation

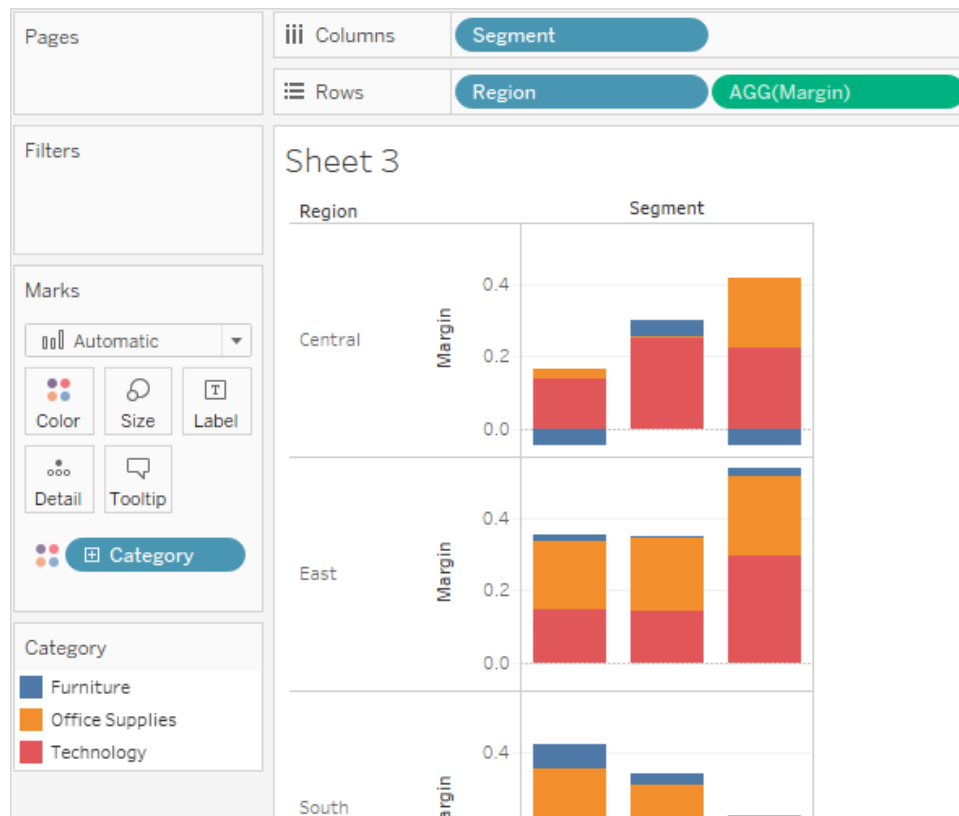

formula. For more information, see [Use the functions reference in the calculation editor on page 2459](#).

- When finished, click **OK**.

The new aggregate calculation appears under **Measures** in the **Data** pane. Just like your other fields, you can use it in one or more visualisations.

Note: Aggregation calculations are always measures.

When **Margin** is placed on a shelf or card in the worksheet, its name is changed to **AGG(Margin)**, which indicates that it is an aggregate calculation and cannot be aggregated any further.

Rules for aggregate calculations

The rules that apply to aggregate calculations are as follows:

- For any aggregate calculation, you cannot combine an aggregated value and a disaggregated value. For example, `SUM(Price) * [Items]` is not a valid expression

because `SUM(Price)` is aggregated and `Items` is not. However, `SUM(Price*Items)` and `SUM(Price)*SUM(Items)` are both valid.

- Constant terms in an expression act as aggregated or disaggregated values as appropriate. For example: `SUM(Price*7)` and `SUM(Price)*7` are both valid expressions.
- All of the functions can be evaluated on aggregated values. However, the arguments to any given function must either all be aggregated or all disaggregated. For example: `MAX(SUM(Sales), Profit)` is not a valid expression because `Sales` is aggregated and `Profit` is not. However, `MAX(SUM(Sales), SUM(Profit))` is a valid expression.
- The result of an aggregate calculation is always a measure. This includes expressions like `ATTR(Dimension)` or `MIN(Dimension)`.
- Like predefined aggregations, aggregate calculations are computed correctly for grand totals. Refer to [Grand Totals](#) for more information.

Pass-Through Functions (RAWSQL)

These RAWSQL pass-through functions can be used to send SQL expressions directly to the database, without first being interpreted by Tableau. If you have custom database functions that Tableau doesn't know about, you can use these pass-through functions to call these custom functions.

Your database usually will not understand the field names that are shown in Tableau. Because Tableau does not interpret the SQL expressions you include in the pass-through functions, using the Tableau field names in your expression may cause errors. You can use a substitution syntax to insert the correct field name or expression for a Tableau calculation into pass-through SQL. For example, if you had a function that computed the median of a set of values, you could call that function on the Tableau column `[Sales]` like this:

```
RAWSQLAGG_REAL("MEDIAN(%1)", [Sales])
```

Because Tableau does not interpret the expression, you must define the aggregation. You can use the RAWSQLAGG functions described below when you are using aggregated expressions.

RAWSQL pass-through functions will not work with published data sources or with Tableau extracts.

These functions may return different results starting in Tableau Desktop 8.2 than they did in earlier versions of Tableau Desktop. This is because Tableau now uses ODBC for pass-through functions instead of OLE DB. ODBC truncates when returning real values as integer; OLE DB rounds when returning real values as integer.

RAWSQL Functions

The following RAWSQL functions are available in Tableau.

RAWSQL_BOOL("sql_expr", [arg1], ...[argN])

Returns a Boolean result from a given SQL expression. The SQL expression is passed directly to the underlying database. Use %n in the SQL expression as a substitution syntax for database values.

Example

In the example, %1 is equal to [Sales] and %2 is equal to [Profit].

```
RAWSQL_BOOL("%1 > %2", [Sales], [Profit])
```

RAWSQL_DATE("sql_expr", [arg1], ...[argN])

Returns a Date result from a given SQL expression. The SQL expression is passed directly to the underlying database. Use %n in the SQL expression as a substitution syntax for database values.

Example

In this example, %1 is equal to [Order Date].

```
RAWSQL_DATE("%1", [Order Date])
```

RAWSQL_DATETIME("sql_expr", [arg1], ...[argN])

Returns a Date and Time result from a given SQL expression. The SQL expression is passed directly to the underlying database. Use %n in the SQL expression as a substitution syntax for database values. In this example, %1 is equal to [Delivery Date].

Example

```
RAWSQL_DATETIME("%1", [Order Date])
```

RAWSQL_INT("sql_expr", [arg1], ...[argN])

Returns an integer result from a given SQL expression. The SQL expression is passed directly to the underlying database. Use %n in the SQL expression as a substitution syntax for database values. In this example, %1 is equal to [Sales].

Example

```
RAWSQL_INT("500 + %1", [Sales])
```

RAWSQL_REAL("sql_expr", [arg1], ...[argN])

Returns a numeric result from a given SQL expression that is passed directly to the underlying database. Use %n in the SQL expression as a substitution syntax for database values. In this example, %1 is equal to [Sales]

Example

```
RAWSQL_REAL("-123.98 * %1", [Sales])
```

RAWSQL_SPATIAL

Returns a Spatial from a given SQL expression that is passed directly to the underlying data source. Use %n in the SQL expression as a substitution syntax for database values.

Example

In this example, %1 is equal to [Geometry].

```
RAWSQL_SPATIAL("%1", [Geometry])
```

RAWSQL_STR("sql_expr", [arg1], ...[argN])

Returns a string from a given SQL expression that is passed directly to the underlying database. Use %n in the SQL expression as a substitution syntax for database values. In this example, %1 is equal to [Customer Name].

Example

```
RAWSQL_STR("%1", [Customer Name])
```

RAWSQLAGG_BOOL("sql_expr", [arg1], ...[argN])

Returns a Boolean result from a given aggregate SQL expression. The SQL expression is passed directly to the underlying database. Use %n in the SQL expression as a substitution syntax for database values.

Example

In the example, %1 is equal to [Sales] and %2 is equal to [Profit].

```
RAWSQLAGG_BOOL("SUM( %1 ) > SUM( %2 )", [Sales], [Profit])
```

RAWSQLAGG_DATE("sql_expr", [arg1], ...[argN])

Returns a Date result from a given aggregate SQL expression. The SQL expression is passed directly to the underlying database. Use %n in the SQL expression as a substitution syntax for database values. In this example, %1 is equal to [Order Date].

Example

```
RAWSQLAGG_DATE("MAX(%1)", [Order Date])
```

RAWSQLAGG_DATETIME("sql_expr", [arg1], ...[argN])

Returns a Date and Time result from a given aggregate SQL expression. The SQL expression is passed directly to the underlying database. Use %n in the SQL expression as a substitution syntax for database values. In this example, %1 is equal to [Delivery Date].

Example

```
RAWSQLAGG_DATETIME("MIN(%1)", [Delivery Date])
```

RAWSQLAGG_INT("sql_expr", [arg1,] ...[argN])

Returns an integer result from a given aggregate SQL expression. The SQL expression is passed directly to the underlying database. Use %n in the SQL expression as a substitution syntax for database values. In this example, %1 is equal to [Sales].

Example

```
RAWSQLAGG_INT("500 + SUM(%1)", [Sales])
```

RAWSQLAGG_REAL("sql_expr", [arg1,] ...[argN])

Returns a numeric result from a given aggregate SQL expression that is passed directly to the underlying database. Use %n in the SQL expression as a substitution syntax for database values. In this example, %1 is equal to [Sales]

Example

```
RAWSQLAGG_REAL("SUM( %1)", [Sales])
```

RAWSQLAGG_STR("sql_expr", [arg1,] ...[argN])

Returns a string from a given aggregate SQL expression that is passed directly to the underlying database. Use %n in the SQL expression as a substitution syntax for database values. In this example, %1 is equal to [Discount].

Example

```
RAWSQLAGG_STR("AVG(%1)", [Discount])
```

User Functions

This article introduces user functions and their uses in Tableau. It also demonstrates how to create a user calculation using an example.

Why use user functions

User functions can be used to create user filters or row-level security filters that affect visualisations published to Tableau Server or Tableau Cloud so that only certain people can see your visualisation.

For example, if you have a visualisation that shows the sales performance for each employee in your department published on Tableau Server or Tableau Cloud, you might want to only allow employees to see their own sales numbers when they access that visualisation.

In this case, you can use the `ISMEMBEROF` function to create a field that returns true if the username of the person signed in to the server is a member of a specified group (on the server), such as the "Managers" group, for example. Then when you filter the view using this calculated field, only a person who is part of that group can see the data.

The calculation in this case might look something like the following:

```
ISMEMBEROF('Managers')
```

Note: If your group or user names contain certain non-alphanumeric you must use HTML URL Encoding for the special characters when using the functions below.

Some special characters are permitted without HTML URL encoding, such as underscores, parentheses and exclamation points. `_ () !` Many other characters must be encoded.

For example, the function `ISMEMBEROF("USERS+")` needs to be written as `ISMEMBEROF("USERS%2B")`, because the '%2B' is the HTML URL Encoding for the '+' symbol. For information on HTML URL encoding, please see [HTML URL Encoding Reference](#) at the W3schools Web Developer site.

For embedding workflows in Tableau Cloud and Tableau Server only

Among the user functions, a subset of user attribute functions can be used with [Tableau-connected apps](#) on Tableau Cloud or [Tableau-connected apps](#) on Tableau Server 2025.1 and later. The user attribute functions (**USERATTRIBUTE** and **USERATTRIBUTEINCLUDES**) allow user attributes to be captured by Tableau at runtime as part of the authentication workflow. When user attributes are passed from JSON Web Tokens (JWTs), embedded content authored with these functions can control and customise data displayed to users.

Notes:

- Check the [Embedding API v3](#) Help for *known issues* and *limitations* that might affect your workflow.

- User attribute functions can be included in content authored in Tableau Desktop, Tableau Cloud or Tableau Server.
- Preview of the content with these functions is not available when authoring in Tableau Desktop, Tableau Cloud or Tableau Server. User attribute functions will return NULL or FALSE values. To ensure user attribute functions work as expected, we recommend you review the content after embedding in your external application. For more information about embedding workflows that include these user functions, see the [Embedding API v3 Help](#).
- User attribute functions can't be used in non-embedding workflows, with OIDC or SAML protocols, or workflows that rely on Tableau Bridge.

User functions available in Tableau

FULLNAME()

Syntax `FULLNAME ()`

Output `String`

Definition Returns the full name for the current user.

Example `FULLNAME ()`

This returns the full name of the signed-in user, such as "Hamlin Myrer".

```
[Manager] = FULLNAME ( )
```

If manager "Hamlin Myrer" is signed in, this example returns TRUE only if the Manager field in the view contains "Hamlin Myrer".

Notes This function checks:

- Tableau Cloud and Tableau Server: the full name of the signed-in user
- Tableau Desktop: the local or network full name for the user

User filters

When used as a filter, a calculated field such as `[Username field] = FULLNAME ()` can be used to create a user filter that only shows data that is relevant to the person signed in to the server.

ISFULLNAME

| | |
|------------|---|
| Syntax | <code>ISFULLNAME("User Full Name")</code> |
| Output | Boolean |
| Definition | Returns <code>TRUE</code> if the current user's full name matches the specified full name or <code>FALSE</code> if it does not match. |
| Example | <code>ISFULLNAME("Hamlin Myrer")</code> |
| Notes | <p>The <code><"User Full Name"></code> argument must be a literal string, not a field.</p> <p>This function checks:</p> <ul style="list-style-type: none"> Tableau Cloud and Tableau Server: the full name of the signed-in user Tableau Desktop: the local or network full name for the user |

ISMEMBEROF

| | |
|------------|--|
| Syntax | <code>ISMEMBEROF("Group Name")</code> |
| Output | Boolean or null |
| Definition | Returns <code>TRUE</code> if the person currently using Tableau is a member of a group that matches the given string, <code>FALSE</code> if they're not a member and <code>NULL</code> if they're not signed in. |
| Example | <code>ISMEMBEROF('Superstars')</code> <code>ISMEMBEROF('domain.lan\Sales')</code> |
| Notes | <p>The <code><"Group Full Name"></code> argument must be a literal string, not a field.</p> <p>If the user is signed in to Tableau Cloud or Tableau Server, group membership is determined by Tableau groups. The function will return <code>TRUE</code> if the given string is "All Users"</p> <p>The <code>ISMEMBEROF()</code> function will also accept Active Directory domains. The Active Directory domain must be declared in the calculation with the group name.</p> |

If a change is made to a user's group membership, the change in the data that is based on the group membership is reflected in a workbook or view with a new session. The existing session will reflect stale data.

ISUSERNAME

| | |
|------------|--|
| Syntax | <code>ISUSERNAME ("username")</code> |
| Output | Boolean |
| Definition | Returns <code>TRUE</code> if the current user's username matches the specified username or <code>FALSE</code> if it does not match. |
| Example | <code>ISUSERNAME ("hmyrer")</code> |
| Notes | <p>The <code><"username"></code> argument must be a literal string, not a field.</p> <p>This function checks:</p> <ul style="list-style-type: none">• Tableau Cloud and Tableau Server: the username of the signed-in user• Tableau Desktop: the local or network username for the user |

USERDOMAIN()

| | |
|------------|---|
| Syntax | <code>USERDOMAIN ()</code> |
| Output | String |
| Definition | Returns the domain for the current user. |
| Notes | <p>This function checks:</p> <ul style="list-style-type: none">• Tableau Cloud and Tableau Server: the user domain of the signed-in user• Tableau Desktop: the local domain if the user is on a domain |

USERNAME()

Syntax USERNAME ()

Output String

Definition Returns the username for the current user.

Example USERNAME ()

This returns the username of the signed-in user, such as "hmyrer".

```
[Manager] = USERNAME ( )
```

If manager "hmyrer" is signed in, this example returns TRUE only if the Manager field in the view contains "hmyrer".

Notes This function checks:

- Tableau Cloud and Tableau Server: the username of the signed-in user
- Tableau Desktop: the local or network username for the user

User filters

When used as a filter, a calculated field such as [Username field] = USERNAME () can be used to create a user filter that only shows data that is relevant to the person signed in to the server.

USERATTRIBUTE

Note: Before using this function, see [For embedding workflows in Tableau Cloud and Tableau Server only on page 2122](#). For more information, see [Authentication and Embedded Views](#) in the Embedding API v3.

Syntax USERATTRIBUTE ('attribute_name')

Output String or null

Definition If <'attribute_name'> is part of the JSON web token (JWT) passed to Tableau, the calculation returns the first value of <'attribute_name'>.

Returns null if `<'attribute_name'>` does not exist.

Example

Suppose "Region" is the user attribute included in the JWT and passed to Tableau (using the connected app already configured by your site admin).

As the workbook author, you can set up your visualisation to filter data based on a specified region. In that filter, you can reference the following calculation.

```
[Region] = USERATTRIBUTE("Region")
```

When User2 from the West region views the embedded visualisation, Tableau shows the appropriate data for the West region only.

Notes

You can use the `USERATTRIBUTEINCLUDES` function if you expect `<'attribute_name'>` to return multiple values.

USERATTRIBUTEINCLUDES

Note: Before using this function, see [For embedding workflows in Tableau Cloud and Tableau Server only on page 2122](#). For more information, see [Authentication and Embedded Views](#) in the Embedding API v3.

Syntax

```
USERATTRIBUTEINCLUDES('attribute_name', 'expected_value')
```

Output

Boolean

Definition

Returns `TRUE` if both of the following are true:

- `<'attribute_name'>` is part of the JSON web token (JWT) passed to Tableau
- one of `<'attribute_name'>` values equals `<'expected_value'>`.

Returns `FALSE` otherwise.

Example

Suppose "Region" is the user attribute included in the JWT and passed to Tableau (using the connected app already configured by your site admin).

As the workbook author, you can set up your visualisation to filter data based on a specified region. In that filter, you can reference the following calculation.

```
USERATTRIBUTEINCLUDES('Region', [Region])
```

If User2 from the West region accesses the embedded visualisation, Tableau checks if the Region user attribute matches one of [Region] field values. When true, the visualisation shows the appropriate data.

When User3 from the North region accesses the same visualisation, she's unable to see any data because there's no match with [Region] field values.

Create a user calculation

User calculations work directly with the users and groups you have set up on Tableau Server or Tableau Cloud. You can create user calculations to use as filters so users only see the data that is relevant to them.

For example, if you have a map viz similar to the following, which shows sales data for 48 US states, you can create a user calculation to show only parts of the map that are relevant to each user, such as data relevant for a regional manager versus a national manager. (A national manager should be able to see data for the entire country, while a regional manager should only be able to see data for the region they manage).

When the national manager is signed in, they see the following visualisation:

When the western regional manager is signed in, they see only sales for their region:

To create a user function that performs similarly to this example, follow the steps below.

Before you begin

To follow along with this example, you must have access to Tableau Server or Tableau Cloud. You must also be a Server or Site Administrator.

Step 1: Create the users and groups

1. Sign in to Tableau Server or Tableau Cloud.
2. In Tableau Server or Tableau Cloud, add the following users:
 - Sadie Pawthorne
 - Chuck Magee
 - Fred Suzuki
 - Roxanne Rodriguez

For more information, see [Add Users to a Site](#) in the Tableau Server Help.

3. Create a new group called **National Managers**.

For more information, see [Create a Local Group](#) in the Tableau Server Help.

4. Add yourself to the National Managers group.

For more information, see [Add Users to a Group](#) in the Tableau Server Help.

Step 2: Create the visualisation

1. Open Tableau Desktop, and connect to the **Sample-Superstore** data source, which comes with Tableau.
2. In the bottom left corner of the workspace, click the Data Source tab.
3. On the Data Source page, from the Connections pane on the left, drag the People sheet to the join area.
4. Click the join icon and select **Left**.

5. Navigate to a new worksheet.
6. In the **Data** pane, under Dimensions, double-click **State**.
A map view is created.
7. From the **Data** pane, under Measures, drag **Sales** to **Colour** on the Marks card.
8. On the Columns shelf, select the Longitude field and hold down Control (Command on Mac) on your keyboard to copy it. Drag the copy to the right of the original on the Columns shelf.

Tableau Desktop and Web Authoring Help

9. On the Marks card, click the second (bottom) **Longitude** tab.
10. From the **Data** pane, drag **Region** to **Colour** on the Marks card.

The map view on the right updates with new colours.

11. On the Marks card, click the Mark Type drop-down and select **Map**.

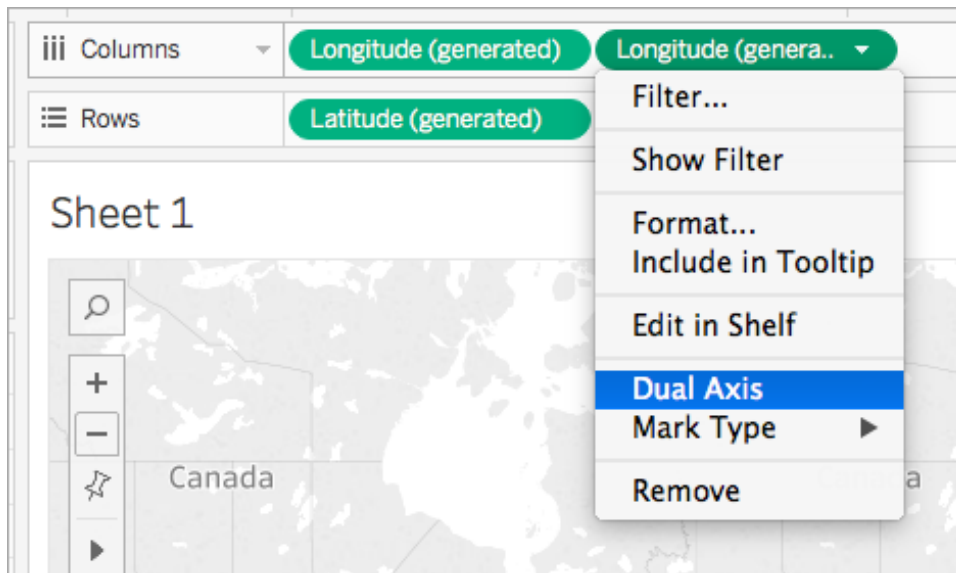

12. On the Marks card, click **Colour**, and, under Opacity, adjust the slider to **50%**.
13. On the Marks card, click the first **Longitude** tab.
14. On the Marks card, click **Colour** > **Edit Colours**, and then select **Grey** from the colour palette drop-down list.

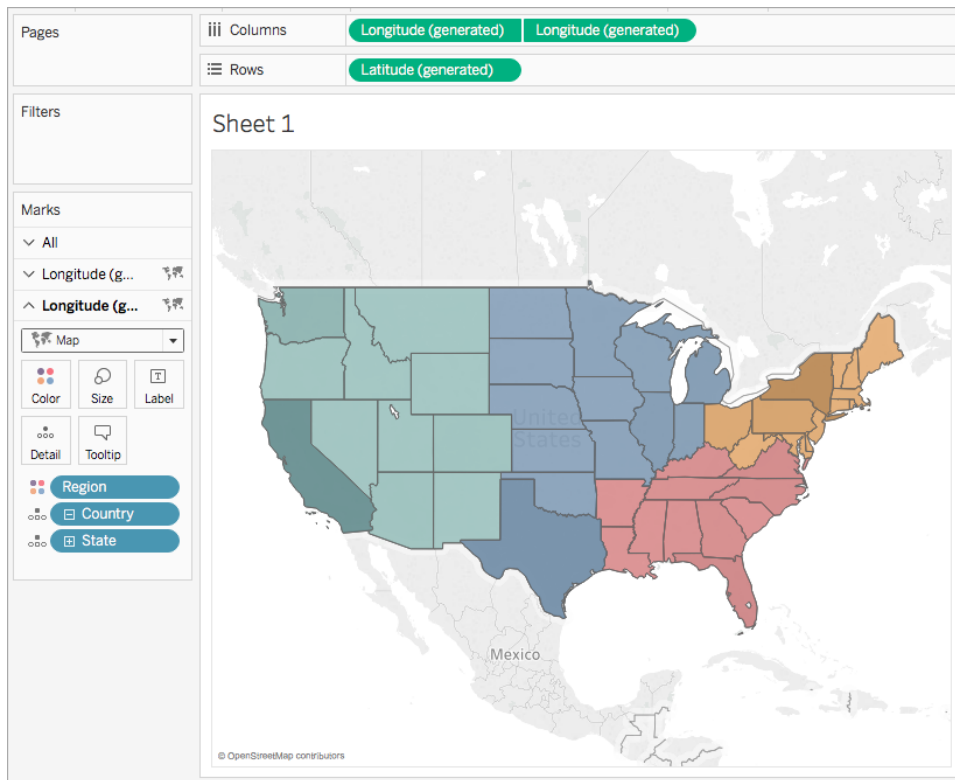

The map view on the left updates.

15. On the Columns shelf, right-click the **Longitude** field on the right and select **Dual Axis**.

The map looks like the following:

Step 3: Create the User Calculation

1. Select **Analysis > Create Calculated Field**.
2. In the calculation editor that opens, do the following:
 - Name the calculated field, User Filter.
 - Enter the following formula:

```
[Regional Manager] = USERNAME() OR ISMEMBEROF("National Managers")
```

This calculation checks if a person is included in the Region (People) field, or if a person is included in the National Managers group. If so, it returns true.

- When finished, click **OK**.

The new user calculation appears under Dimensions in the Data pane. Just like your other fields, you can use it in one or more visualisations.

Step 4: Add the user calculation to the Filters shelf

1. From the Data pane, under Dimensions, drag User Filter to the Filters shelf.
2. In the Filter dialog box that opens, select **True**, and then click **OK**.

Note: If you are not signed in to Tableau Server or Tableau Cloud, the True option is not visible. In Tableau Desktop, sign in to Tableau Server or Tableau Cloud to select it. See [Sign in to Tableau Server or Tableau Cloud on page 193](#) for more information.

Step 5: Test the calculation

1. In Tableau Desktop, in the bottom-right corner of the workspace, click on the Filter as User drop-down and change the user to **Sadie Pawthorne**.

The map updates to show only the West region of the United States because Sadie is assigned to the West region in the People sheet.

2. Select the Filter as User drop-down again and change the user to Roxanne Rodriguez.

The map updates to show only the Central region of the United States because Roxanne is assigned to the Central region in the People sheet.

3. Select the Filter as User drop-down again and change the user to Chuck Magee.

The map updates to show only the East region of the United States because Chuck is assigned to the East region in the People sheet.

4. Select the Filter as User drop-down again and change the user to Fred Suzuki.

The map updates to show only the South region of the United States because Fred is assigned to the South region in the People sheet.

5. Select the Filter as User drop-down one more time and change the user back to yourself.

The map updates to show all data because you are a part of the National Managers group on the server.

This behaviour persists when you publish the view to Tableau Server or Tableau Cloud. Users not listed in the National Managers group, or in the People sheet in the Sample Superstore data source see only a blank visualisation.

Table Calculation Functions

This article introduces table calculation functions and their uses in Tableau. It also demonstrates how to create a table calculation using the calculation editor.

Why use table calculation functions

Table calculation functions allow you to perform computations on values in a table.

For example, you can calculate the percent of total an individual sale is for the year, or for several years.

Table calculation functions available in Tableau

These are the native table calculation functions that can be used in Tableau without an external Analytics Extension.

FIRST()

Returns the number of rows from the current row to the first row in the partition. For example, the view below shows quarterly sales. When FIRST() is computed within the Date partition, the offset of the first row from the second row is -1.

| Year of Order Date | Quarter of Order Date | Region | | | | |
|--------------------|-----------------------|-----------|-----------|-----------|-----------|--------------|
| | | Central | East | South | West | |
| 2009 | Q1 | \$160,877 | \$231,411 | \$133,934 | \$185,961 | \$160,877 0 |
| | Q2 | \$197,213 | \$204,914 | \$337,813 | \$213,507 | \$197,213 -1 |
| | Q3 | \$302,678 | \$165,201 | \$283,806 | \$206,512 | \$302,678 -2 |
| | Q4 | \$297,208 | \$226,983 | \$214,845 | \$230,291 | \$297,208 -3 |
| 2010 | Q1 | \$180,609 | \$180,123 | \$273,943 | \$251,145 | \$180,609 -4 |
| | Q2 | \$195,785 | \$224,882 | \$251,391 | \$195,976 | \$195,785 -5 |
| | Q3 | \$116,613 | \$50,363 | \$194,601 | \$102,731 | \$116,613 -6 |

Example

When the current row index is 3, $FIRST() = -2$.

INDEX()

Returns the index of the current row in the partition, without any sorting with regard to value. The first row index starts at 1. For example, the table below shows quarterly sales. When INDEX() is computed within the Date partition, the index of each row is 1, 2, 3, 4..., etc.

| Year of Order Date | Quarter of Order Date | Region | | | | |
|--------------------|-----------------------|-----------|-----------|-----------|-----------|---|
| | | Central | East | South | West | |
| 2009 | Q1 | \$160,877 | \$231,411 | \$133,934 | \$185,961 | 1 |
| | Q2 | \$197,213 | \$204,914 | \$337,813 | \$213,507 | 2 |
| | Q3 | \$302,678 | \$165,201 | \$283,806 | \$206,512 | 3 |
| | Q4 | \$297,208 | \$226,983 | \$214,845 | \$230,291 | 4 |
| 2010 | Q1 | \$180,609 | \$180,123 | \$273,943 | \$251,145 | 5 |
| | Q2 | \$195,785 | \$224,882 | \$251,391 | \$195,976 | 6 |
| | Q3 | \$116,613 | \$50,363 | \$194,601 | \$102,731 | 7 |

Example

For the third row in the partition, INDEX () = 3.

LAST()

Returns the number of rows from the current row to the last row in the partition. For example, the table below shows quarterly sales. When LAST() is computed within the Date partition, the offset of the last row from the second row is 5.

| Year of Order Date | Quarter of Order Date | Region | | | | |
|--------------------|-----------------------|-----------|-----------|-----------|-----------|---|
| | | Central | East | South | West | |
| 2009 | Q1 | \$160,877 | \$231,411 | \$133,934 | \$185,961 | 6 |
| | Q2 | \$197,213 | \$204,914 | \$337,813 | \$213,507 | 5 |
| | Q3 | \$302,678 | \$165,201 | \$283,806 | \$206,512 | 4 |
| | Q4 | \$297,208 | \$226,983 | \$214,845 | \$230,291 | 3 |
| 2010 | Q1 | \$180,609 | \$180,123 | \$273,943 | \$251,145 | 2 |
| | Q2 | \$195,785 | \$224,882 | \$251,391 | \$195,976 | 1 |
| | Q3 | \$116,613 | \$50,363 | \$194,601 | \$102,731 | 0 |

Example

When the current row index is 3 of 7, LAST () = 4.

LOOKUP(expression, [offset])

Returns the value of the expression in a target row, specified as a relative offset from the current row. Use `FIRST() + n` and `LAST() - n` as part of your offset definition for a target relative to the first/last rows in the partition. If `offset` is omitted, the row to compare to can be set on the field menu. This function returns NULL if the target row cannot be determined.

The view below shows quarterly sales. When `LOOKUP (SUM(Sales), 2)` is computed within the Date partition, each row shows the sales value from 2 quarters into the future.

| Year of Order Date | Quarter of Order Date | Region | | | |
|--------------------|-----------------------|------------------|-----------|-----------|-----------|
| | | Central | East | South | West |
| 2009 | Q1 | \$160,877 | \$231,411 | \$133,934 | \$185,961 |
| | Q2 | \$197,213 | \$204,914 | \$337,813 | \$213,507 |
| | Q3 | \$302,678 | \$165,201 | \$283,806 | \$206,512 |
| | Q4 | \$297,208 | \$226,983 | \$214,845 | \$230,291 |
| 2010 | Q1 | \$180,609 | \$180,123 | \$273,943 | \$251,145 |
| | Q2 | \$195,785 | \$224,882 | \$251,391 | \$195,976 |
| | Q3 | \$116,613 | \$50,363 | \$194,601 | \$102,731 |

| Year of Order Date | Quarter of Order Date | Region | | | |
|--------------------|-----------------------|------------------|-----------|-----------|-----------|
| | | Central | East | South | West |
| 2009 | Q1 | \$302,678 | \$165,201 | \$283,806 | \$206,512 |
| | Q2 | \$297,208 | \$226,983 | \$214,845 | \$230,291 |
| | Q3 | \$180,609 | \$180,123 | \$273,943 | \$251,145 |
| | Q4 | \$195,785 | \$224,882 | \$251,391 | \$195,976 |
| 2010 | Q1 | \$116,613 | \$50,363 | \$194,601 | \$102,731 |
| | Q2 | | | | |
| | Q3 | | | | |

Example

`LOOKUP (SUM ([Profit]), FIRST() + 2)` computes the SUM(Profit) in the third row of the partition.

MODEL_EXTENSION functions

The model extension functions:

- MODEL_EXTENSION_BOOL
- MODEL_EXTENSION_INT
- MODEL_EXTENSION_REAL
- MODEL_EXTENSION_STRING

are used to pass data to a deployed model on an external service such as R, TabPy or Matlab. See [Analytics Extensions](#).

MODEL_PERCENTILE(target_expression, predictor_expression(s))

Returns the probability (between 0 and 1) of the expected value being less than or equal to the observed mark, defined by the target expression and other predictors. This is the Posterior Predictive Distribution Function, also known as the Cumulative Distribution Function (CDF).

This function is the inverse of MODEL_QUANTILE. For information on predictive modelling functions, see [How Predictive Modelling Functions Work in Tableau on page 2561](#).

Example

The following formula returns the quantile of the mark for sum of sales, adjusted for count of orders.

```
MODEL_PERCENTILE(SUM([Sales]), COUNT([Orders]))
```

MODEL_QUANTILE(quantile, target_expression, predictor_expression(s))

Returns a target numeric value within the probable range defined by the target expression and other predictors, at a specified quantile. This is the Posterior Predictive Quantile.

This function is the inverse of MODEL_PERCENTILE. For information on predictive modelling functions, see [How Predictive Modelling Functions Work in Tableau on page 2561](#).

Example

The following formula returns the median (0.5) predicted sum of sales, adjusted for count of orders.

```
MODEL_QUANTILE(0.5, SUM([Sales]), COUNT([Orders]))
```

PREVIOUS_VALUE(expression)

Returns the value of this calculation in the previous row. Returns the given expression if the current row is the first row of the partition.

Example

`SUM([Profit]) * PREVIOUS_VALUE(1)` computes the running product of SUM(Profit).

RANK(expression, ['asc' | 'desc'])

Returns the standard competition rank for the current row in the partition. Identical values are assigned an identical rank. Use the optional 'asc' | 'desc' argument to specify ascending or descending order. The default is descending.

With this function, the set of values (6, 9, 9, 14) would be ranked (4, 2, 2, 1).

Nulls are ignored in ranking functions. They are not numbered and they do not count against the total number of records in percentile rank calculations.

For information on different ranking options, see [Rank calculation on page 2378](#).

Example

The following image shows the effect of the various ranking functions (RANK, RANK_DENSE, RANK_MODIFIED, RANK_PERCENTILE and RANK_UNIQUE) on a set of values. The data set contains information on 14 students (Student A through to Student N); the **Age** column shows the current age of each student (all students are between 17 and 20 years of age). The remaining columns show the effect of each rank function on the set of age values, always assuming the default order (ascending or descending) for the function.

RANK_DENSE(expression, ['asc' | 'desc'])

Returns the dense rank for the current row in the partition. Identical values are assigned an identical rank, but no gaps are inserted into the number sequence. Use the optional 'asc' | 'desc' argument to specify ascending or descending order. The default is descending.

With this function, the set of values (6, 9, 9, 14) would be ranked (3, 2, 2, 1).

Nulls are ignored in ranking functions. They are not numbered and they do not count against the total number of records in percentile rank calculations.

For information on different ranking options, see [Rank calculation on page 2378](#).

RANK_MODIFIED(expression, ['asc' | 'desc'])

Returns the modified competition rank for the current row in the partition. Identical values are assigned an identical rank. Use the optional 'asc' | 'desc' argument to specify ascending or descending order. The default is descending.

With this function, the set of values (6, 9, 9, 14) would be ranked (4, 3, 3, 1).

Nulls are ignored in ranking functions. They are not numbered and they do not count against the total number of records in percentile rank calculations.

For information on different ranking options, see [Rank calculation on page 2378](#).

RANK_PERCENTILE(expression, ['asc' | 'desc'])

Returns the percentile rank for the current row in the partition. Use the optional 'asc' | 'desc' argument to specify ascending or descending order. The default is ascending.

With this function, the set of values (6, 9, 9, 14) would be ranked (0.00, 0.67, 0.67, 1.00).

Nulls are ignored in ranking functions. They are not numbered and they do not count against the total number of records in percentile rank calculations.

For information on different ranking options, see [Rank calculation on page 2378](#).

RANK_UNIQUE(expression, ['asc' | 'desc'])

Returns the unique rank for the current row in the partition. Identical values are assigned different ranks. Use the optional 'asc' | 'desc' argument to specify ascending or descending order. The default is descending.

With this function, the set of values (6, 9, 9, 14) would be ranked (4, 2, 3, 1).

Nulls are ignored in ranking functions. They are not numbered and they do not count against the total number of records in percentile rank calculations.

For information on different ranking options, see [Rank calculation on page 2378](#).

RUNNING_AVG(expression)

Returns the running average of the given expression, from the first row in the partition to the current row.

The view below shows quarterly sales. When `RUNNING_AVG(SUM([Sales]))` is computed within the Date partition, the result is a running average of the sales values for each quarter.

| Year of Order Date | Quarter of Order Date | Region | | | |
|--------------------|-----------------------|-----------|-----------|-----------|-----------|
| | | Central | East | South | West |
| 2009 | Q1 | \$160,877 | \$231,411 | \$133,934 | \$185,961 |
| | Q2 | \$197,213 | \$204,914 | \$337,813 | \$213,507 |
| | Q3 | \$302,678 | \$165,201 | \$283,806 | \$206,512 |
| | Q4 | \$297,208 | \$226,983 | \$214,845 | \$230,291 |
| 2010 | Q1 | \$180,609 | \$180,123 | \$273,943 | \$251,145 |
| | Q2 | \$195,785 | \$224,882 | \$251,391 | \$195,976 |
| | Q3 | \$116,613 | \$50,363 | \$194,601 | \$102,731 |

| Year of Order Date | Quarter of Order Date | Region | | | |
|--------------------|-----------------------|---------|---------|---------|---------|
| | | Central | East | South | West |
| 2009 | Q1 | 160,877 | 231,411 | 133,934 | 185,961 |
| | Q2 | 179,045 | 18,162 | 235,873 | 199,734 |
| | Q3 | 220,256 | 200,509 | 251,851 | 201,993 |
| | Q4 | 239,494 | 207,127 | 242,599 | 209,068 |
| 2010 | Q1 | 227,717 | 201,726 | 248,868 | 217,483 |
| | Q2 | 222,395 | 205,586 | 249,289 | 213,899 |
| | Q3 | 207,283 | 183,411 | 241,476 | 198,018 |

Average = \$179,045

Example

`RUNNING_AVG(SUM([Profit]))` computes the running average of `SUM(Profit)`.

RUNNING_COUNT(expression)

Returns the running count of the given expression, from the first row in the partition to the current row.

Example

`RUNNING_COUNT(SUM([Profit]))` computes the running count of `SUM(Profit)`.

RUNNING_MAX(expression)

Returns the running maximum of the given expression, from the first row in the partition to the current row.

| Year of Order Date | Quarter of Order Date | Region | | | |
|--------------------|-----------------------|-----------|-----------|-----------|-----------|
| | | Central | East | South | West |
| 2009 | Q1 | \$160,877 | \$231,411 | \$133,934 | \$185,961 |
| | Q2 | \$197,213 | \$204,914 | \$337,813 | \$213,507 |
| | Q3 | \$302,678 | \$165,201 | \$283,806 | \$206,512 |
| | Q4 | \$297,208 | \$226,983 | \$214,845 | \$230,291 |
| 2010 | Q1 | \$180,609 | \$180,123 | \$273,943 | \$251,145 |
| | Q2 | \$195,785 | \$224,882 | \$251,391 | \$195,976 |
| | Q3 | \$116,613 | \$50,363 | \$194,601 | \$102,731 |

| Year of Order Date | Quarter of Order Date | Region | | | |
|--------------------|-----------------------|---------|---------|---------|---------|
| | | Central | East | South | West |
| 2009 | Q1 | 160,877 | 231,411 | 133,934 | 185,961 |
| | Q2 | 197,213 | 231,411 | 337,813 | 213,507 |
| | Q3 | 302,678 | 165,201 | 283,813 | 206,507 |
| | Q4 | 302,678 | 231,411 | 337,813 | 230,291 |
| 2010 | Q1 | 302,678 | 231,411 | 337,813 | 251,145 |
| | Q2 | 302,678 | 231,411 | 337,813 | 251,145 |
| | Q3 | 302,678 | 231,411 | 337,813 | 251,145 |

Example

`RUNNING_MAX(SUM([Profit]))` computes the running maximum of `SUM(Profit)`.

RUNNING_MIN(expression)

Returns the running minimum of the given expression, from the first row in the partition to the current row.

| Year of Order Date | Quarter of Order Date | Region | | | |
|--------------------|-----------------------|-----------|-----------|-----------|-----------|
| | | Central | East | South | West |
| 2009 | Q1 | \$160,877 | \$231,411 | \$133,934 | \$185,961 |
| | Q2 | \$197,213 | \$204,914 | \$337,813 | \$213,507 |
| | Q3 | \$302,678 | \$165,201 | \$283,806 | \$206,512 |
| | Q4 | \$297,208 | \$226,983 | \$214,845 | \$230,291 |
| 2010 | Q1 | \$180,609 | \$180,123 | \$273,943 | \$251,145 |
| | Q2 | \$195,785 | \$224,882 | \$251,391 | \$195,976 |
| | Q3 | \$116,613 | \$50,363 | \$194,601 | \$102,731 |

| Year of Order Date | Quarter of Order Date | Region | | | |
|--------------------|-----------------------|---------|---------|---------|---------|
| | | Central | East | South | West |
| 2009 | Q1 | 160,877 | 231,411 | 133,934 | 185,961 |
| | Q2 | 160,877 | 204,914 | 133,934 | 185,961 |
| | Q3 | 160,877 | 165,201 | 133,934 | 185,961 |
| | Q4 | 160,877 | 165,201 | 133,934 | 185,961 |
| 2010 | Q1 | 160,877 | 165,201 | 133,934 | 185,961 |
| | Q2 | 160,877 | 165,201 | 133,934 | 185,961 |
| | Q3 | 116,613 | 50,363 | 133,934 | 102,731 |

Example

`RUNNING_MIN(SUM([Profit]))` computes the running minimum of `SUM(Profit)`.

RUNNING_SUM(expression)

Returns the running sum of the given expression, from the first row in the partition to the current row.

| Year of Order Date | Quarter of Order Date | Region | | | |
|--------------------|-----------------------|-----------|-----------|-----------|-----------|
| | | Central | East | South | West |
| 2009 | Q1 | \$160,877 | \$231,411 | \$133,934 | \$185,961 |
| | Q2 | \$197,213 | \$204,914 | \$337,813 | \$213,507 |
| | Q3 | \$302,678 | \$165,201 | \$283,806 | \$206,512 |
| | Q4 | \$297,208 | \$226,983 | \$214,845 | \$230,291 |
| 2010 | Q1 | \$180,609 | \$180,123 | \$273,943 | \$251,145 |
| | Q2 | \$195,785 | \$224,882 | \$251,391 | \$195,976 |
| | Q3 | \$116,613 | \$50,363 | \$194,601 | \$102,731 |

| Year of Order Date | Quarter of Order Date | Region | | | |
|--------------------|-----------------------|-----------|-----------|-----------|-----------|
| | | Central | East | South | West |
| 2009 | Q1 | 160,877 | 231,411 | 133,934 | 185,961 |
| | Q2 | 358,090 | 436,325 | 471,747 | 399,469 |
| | Q3 | 660,768 | 616,526 | 755,550 | 605,980 |
| | Q4 | 957,976 | 828,508 | 970,398 | 836,272 |
| 2010 | Q1 | 1,138,585 | 1,008,631 | 1,244,341 | 1,087,417 |
| | Q2 | 1,334,369 | 1,233,513 | 1,495,732 | 1,283,392 |
| | Q3 | 1,450,982 | 1,283,877 | 1,690,333 | 1,386,123 |

Example

`RUNNING_SUM(SUM([Profit]))` computes the running sum of `SUM(Profit)`.

SIZE()

Returns the number of rows in the partition. For example, the view below shows quarterly sales. Within the Date partition, there are seven rows, so the `Size()` of the Date partition is 7.

| Year of Order Date | Quarter of Order Date | Region | | | |
|--------------------|-----------------------|-----------|-----------|-----------|-----------|
| | | Central | East | South | West |
| 2009 | Q1 | \$160,877 | \$231,411 | \$133,934 | \$185,961 |
| | Q2 | \$197,213 | \$204,914 | \$337,813 | \$213,507 |
| | Q3 | \$302,678 | \$165,201 | \$283,806 | \$206,512 |
| | Q4 | \$297,208 | \$226,983 | \$214,845 | \$230,291 |
| 2010 | Q1 | \$180,609 | \$180,123 | \$273,943 | \$251,145 |
| | Q2 | \$195,785 | \$224,882 | \$251,391 | \$195,976 |
| | Q3 | \$116,613 | \$50,363 | \$194,601 | \$102,731 |

Example

`SIZE()` = 5 when the current partition contains five rows.

SCRIPT_ functions

The script functions:

- `SCRIPT_BOOL`
- `SCRIPT_INT`
- `SCRIPT_REAL`
- `SCRIPT_STRING`

are used to pass data to an external service such as R, TabPy or Matlab. See [Analytics Extensions](#).

TOTAL(expression)

Returns the total for the given expression in a table calculation partition.

Example

Assume you are starting with this view:

The screenshot shows the Tableau Desktop interface. The Columns shelf contains 'Region' and the Rows shelf contains 'YEAR(Order Date)' and 'QUARTER(Order Date)'. The Marks shelf is set to 'SUM(Sales)'. The view displays a table with columns for Year of Order, Quarter of Order, and sales figures for four regions: Central, East, South, and West. The data is organized by year (2011-2014) and quarter (Q1-Q4).

| Year of Order | Quarter of Order | Central | East | South | West |
|---------------|------------------|----------|----------|----------|----------|
| 2011 | Q1 | \$8,601 | \$6,579 | \$44,262 | \$15,006 |
| | Q2 | \$17,407 | \$21,064 | \$22,524 | \$25,543 |
| | Q3 | \$44,171 | \$33,443 | \$16,061 | \$49,957 |
| | Q4 | \$33,659 | \$67,594 | \$20,998 | \$57,377 |
| 2012 | Q1 | \$11,768 | \$17,146 | \$16,444 | \$23,493 |
| | Q2 | \$23,979 | \$22,703 | \$16,254 | \$26,188 |
| | Q3 | \$24,486 | \$50,777 | \$21,460 | \$33,537 |
| | Q4 | \$42,641 | \$65,706 | \$17,202 | \$56,748 |
| 2013 | Q1 | \$20,212 | \$24,134 | \$23,934 | \$24,317 |
| | Q2 | \$25,709 | \$52,807 | \$17,079 | \$39,774 |
| | Q3 | \$33,428 | \$37,528 | \$22,939 | \$50,720 |
| | Q4 | \$68,080 | \$66,060 | \$29,588 | \$72,165 |
| 2014 | Q1 | \$40,278 | \$17,341 | \$9,882 | \$51,395 |
| | Q2 | \$26,606 | \$29,978 | \$33,137 | \$44,302 |
| | Q3 | \$34,042 | \$67,712 | \$23,894 | \$74,786 |
| | Q4 | \$46,172 | \$98,209 | \$56,064 | \$80,150 |

You open the calculation editor and create a new field which you name **Totality**:

You then drop **Totality** on Text, to replace **SUM(Sales)**. Your view changes such that it sums values based on the default **Compute Using** value:

| | | Region | | | |
|---------------|------------------|---------|---------|---------|---------|
| Year of Order | Quarter of Order | Central | East | South | West |
| 2011 | Q1 | 74,448 | 74,448 | 74,448 | 74,448 |
| | Q2 | 86,539 | 86,539 | 86,539 | 86,539 |
| | Q3 | 143,633 | 143,633 | 143,633 | 143,633 |
| | Q4 | 179,628 | 179,628 | 179,628 | 179,628 |
| 2012 | Q1 | 68,852 | 68,852 | 68,852 | 68,852 |
| | Q2 | 89,124 | 89,124 | 89,124 | 89,124 |
| | Q3 | 130,260 | 130,260 | 130,260 | 130,260 |
| | Q4 | 182,297 | 182,297 | 182,297 | 182,297 |
| 2013 | Q1 | 92,596 | 92,596 | 92,596 | 92,596 |
| | Q2 | 135,370 | 135,370 | 135,370 | 135,370 |
| | Q3 | 144,614 | 144,614 | 144,614 | 144,614 |
| | Q4 | 235,893 | 235,893 | 235,893 | 235,893 |
| 2014 | Q1 | 118,896 | 118,896 | 118,896 | 118,896 |
| | Q2 | 134,023 | 134,023 | 134,023 | 134,023 |
| | Q3 | 200,433 | 200,433 | 200,433 | 200,433 |
| | Q4 | 280,595 | 280,595 | 280,595 | 280,595 |

This raises the question, What is the default **Compute Using** value? If you right-click (Control-click on a Mac) **Totality** in the Data pane and choose **Edit**, there is now an additional bit of information available:

The default **Compute Using** value is **Table (Across)**. The result is that **Totality** is summing the values across each row of your table. Thus, the value that you see across each row is the sum of the values from the original version of the table.

The values in the 2011/Q1 row in the original table were \$8601, \$6579, \$44262 and \$15006. The values in the table after **Totality** replaces **SUM(Sales)** are all \$74,448, which is the sum of the four original values.

Notice the triangle next to Totality after you drop it on Text:

This indicates that this field is using a table calculation. You can right-click the field and choose **Edit Table Calculation** to redirect your function to a different **Compute Using** value. For example, you could set it to **Table (Down)**. In that case, your table would look like this:

The screenshot shows a Tableau view with a table calculation. The Columns shelf contains 'Region' and the Rows shelf contains 'YEAR(Order Date)' and 'QUARTER(Order Date)'. The view displays a table with the following data:

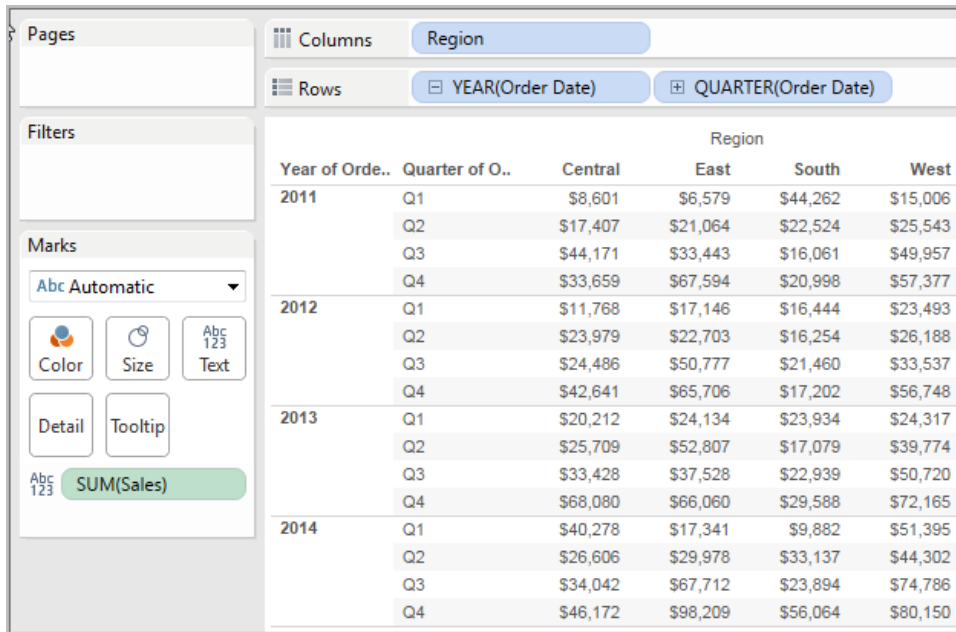

| | | Region | | | |
|---------------|------------------|---------|---------|---------|---------|
| Year of Order | Quarter of Order | Central | East | South | West |
| 2011 | Q1 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q2 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q3 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q4 | 501,240 | 678,781 | 391,722 | 725,458 |
| 2012 | Q1 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q2 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q3 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q4 | 501,240 | 678,781 | 391,722 | 725,458 |
| 2013 | Q1 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q2 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q3 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q4 | 501,240 | 678,781 | 391,722 | 725,458 |
| 2014 | Q1 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q2 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q3 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q4 | 501,240 | 678,781 | 391,722 | 725,458 |

TOTAL(expression)

Returns the total for the given expression in a table calculation partition.

Example

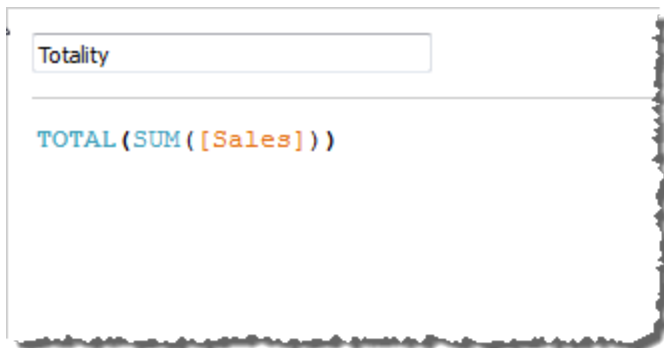

Assume you are starting with this view:

The screenshot shows the Tableau Desktop interface. The Columns shelf contains 'Region' and the Rows shelf contains 'YEAR(Order Date)' and 'QUARTER(Order Date)'. The Marks card is set to 'SUM(Sales)'. The view displays a pivot table of sales data by region, year, and quarter.

| | | Region | | | |
|---------------|------------------|----------|----------|----------|----------|
| Year of Order | Quarter of Order | Central | East | South | West |
| 2011 | Q1 | \$8,601 | \$6,579 | \$44,262 | \$15,006 |
| | Q2 | \$17,407 | \$21,064 | \$22,524 | \$25,543 |
| | Q3 | \$44,171 | \$33,443 | \$16,061 | \$49,957 |
| | Q4 | \$33,659 | \$67,594 | \$20,998 | \$57,377 |
| 2012 | Q1 | \$11,768 | \$17,146 | \$16,444 | \$23,493 |
| | Q2 | \$23,979 | \$22,703 | \$16,254 | \$26,188 |
| | Q3 | \$24,486 | \$50,777 | \$21,460 | \$33,537 |
| | Q4 | \$42,641 | \$65,706 | \$17,202 | \$56,748 |
| 2013 | Q1 | \$20,212 | \$24,134 | \$23,934 | \$24,317 |
| | Q2 | \$25,709 | \$52,807 | \$17,079 | \$39,774 |
| | Q3 | \$33,428 | \$37,528 | \$22,939 | \$50,720 |
| | Q4 | \$68,080 | \$66,060 | \$29,588 | \$72,165 |
| 2014 | Q1 | \$40,278 | \$17,341 | \$9,882 | \$51,395 |
| | Q2 | \$26,606 | \$29,978 | \$33,137 | \$44,302 |
| | Q3 | \$34,042 | \$67,712 | \$23,894 | \$74,786 |
| | Q4 | \$46,172 | \$98,209 | \$56,064 | \$80,150 |

You open the calculation editor and create a new field which you name **Totality**:

You then drop **Totality** on Text, to replace **SUM(Sales)**. Your view changes such that it sums values based on the default **Compute Using** value:

| | | Region | | | |
|---------------|------------------|---------|---------|---------|---------|
| Year of Order | Quarter of Order | Central | East | South | West |
| 2011 | Q1 | 74,448 | 74,448 | 74,448 | 74,448 |
| | Q2 | 86,539 | 86,539 | 86,539 | 86,539 |
| | Q3 | 143,633 | 143,633 | 143,633 | 143,633 |
| | Q4 | 179,628 | 179,628 | 179,628 | 179,628 |
| 2012 | Q1 | 68,852 | 68,852 | 68,852 | 68,852 |
| | Q2 | 89,124 | 89,124 | 89,124 | 89,124 |
| | Q3 | 130,260 | 130,260 | 130,260 | 130,260 |
| | Q4 | 182,297 | 182,297 | 182,297 | 182,297 |
| 2013 | Q1 | 92,596 | 92,596 | 92,596 | 92,596 |
| | Q2 | 135,370 | 135,370 | 135,370 | 135,370 |
| | Q3 | 144,614 | 144,614 | 144,614 | 144,614 |
| | Q4 | 235,893 | 235,893 | 235,893 | 235,893 |
| 2014 | Q1 | 118,896 | 118,896 | 118,896 | 118,896 |
| | Q2 | 134,023 | 134,023 | 134,023 | 134,023 |
| | Q3 | 200,433 | 200,433 | 200,433 | 200,433 |
| | Q4 | 280,595 | 280,595 | 280,595 | 280,595 |

This raises the question, What is the default **Compute Using** value? If you right-click (Control-click on a Mac) **Totality** in the Data pane and choose **Edit**, there is now an additional bit of information available:

The default **Compute Using** value is **Table (Across)**. The result is that **Totality** is summing the values across each row of your table. Thus, the value that you see across each row is the sum of the values from the original version of the table.

The values in the 2011/Q1 row in the original table were \$8601, \$6579, \$44262 and \$15006. The values in the table after **Totality** replaces **SUM(Sales)** are all \$74,448, which is the sum of the four original values.

Notice the triangle next to **Totality** after you drop it on Text:

This indicates that this field is using a table calculation. You can right-click the field and choose **Edit Table Calculation** to redirect your function to a different **Compute Using** value. For example, you could set it to **Table (Down)**. In that case, your table would look like this:

A screenshot of a Tableau worksheet. The Columns shelf contains 'Region' and the Rows shelf contains 'YEAR(Order Date)' and 'QUARTER(Order Date)'. The Marks card shows 'Totality' with a table calculation icon. The view displays a table with columns for Year of Order, Quarter of Order, and four regions: Central, East, South, and West. The data shows sales figures for each quarter from 2011 to 2014.

| Year of Orde.. | Quarter of O.. | Region | | | |
|----------------|----------------|---------|---------|---------|---------|
| | | Central | East | South | West |
| 2011 | Q1 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q2 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q3 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q4 | 501,240 | 678,781 | 391,722 | 725,458 |
| 2012 | Q1 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q2 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q3 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q4 | 501,240 | 678,781 | 391,722 | 725,458 |
| 2013 | Q1 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q2 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q3 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q4 | 501,240 | 678,781 | 391,722 | 725,458 |
| 2014 | Q1 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q2 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q3 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q4 | 501,240 | 678,781 | 391,722 | 725,458 |

WINDOW_CORR(expression1, expression2, [start, end])

Returns the Pearson correlation coefficient of two expressions within the window. The window is defined as offsets from the current row. Use FIRST()+n and LAST()-n for offsets from the first or last row in the partition. If start and end are omitted, the entire partition is used.

The Pearson correlation measures the linear relationship between two variables. Results range from -1 to +1 inclusive, where 1 denotes an exact positive linear relationship, as when a positive

change in one variable implies a positive change of corresponding magnitude in the other, 0 denotes no linear relationship between the variance and - is an exact negative relationship.

There is an equivalent aggregation function: CORR. See [Tableau Functions \(Alphabetical\)](#) on page 2291.

Example

The following formula returns the Pearson correlation of **SUM(Profit)** and **SUM(Sales)** from the five previous rows to the current row.

```
WINDOW_CORR(SUM([Profit]), SUM([Sales]), -5, 0)
```

WINDOW_COUNT(expression, [start, end])

Returns the count of the expression within the window. The window is defined by means of offsets from the current row. Use FIRST()+n and LAST()-n for offsets from the first or last row in the partition. If the start and end are omitted, the entire partition is used.

Example

WINDOW_COUNT(SUM([Profit]), FIRST()+1, 0) computes the count of SUM(Profit) from the second row to the current row

WINDOW_COVAR(expression1, expression2, [start, end])

Returns the *sample covariance* of two expressions within the window. The window is defined as offsets from the current row. Use FIRST()+n and LAST()-n for offsets from the first or last row in the partition. If the start and end arguments are omitted, the window is the entire partition.

Sample covariance uses the number of non-null data points $n - 1$ to normalise the covariance calculation, rather than n , which is used by the population covariance (with the WINDOW_COVARP function). Sample covariance is the appropriate choice when the data is a random sample that is being used to estimate the covariance for a larger population.

There is an equivalent aggregation function: COVAR. See [Tableau Functions \(Alphabetical\)](#) on page 2291.

Example

The following formula returns the sample covariance of **SUM(Profit)** and **SUM(Sales)** from the two previous rows to the current row.

```
WINDOW_COVAR(SUM([Profit]), SUM([Sales]), -2, 0)
```

WINDOW_COVARP(expression1, expression2, [start, end])

Returns the *population covariance* of two expressions within the window. The window is defined as offsets from the current row. Use FIRST()+n and LAST()-n for offsets from the first or last row in the partition. If start and end are omitted, the entire partition is used.

Population covariance is sample covariance multiplied by $(n-1)/n$, where n is the total number of non-null data points. Population covariance is the appropriate choice when there is data available for all items of interest as opposed to when there is only a random subset of items, in which case sample covariance (with the WINDOW_COVAR function) is appropriate.

There is an equivalent aggregation function: COVARP. [Tableau Functions \(Alphabetical\) on page 2291](#).

Example

The following formula returns the population covariance of **SUM(Profit)** and **SUM(Sales)** from the two previous rows to the current row.

```
WINDOW_COVARP(SUM([Profit]), SUM([Sales]), -2, 0)
```

WINDOW_MEDIAN(expression, [start, end])

Returns the median of the expression within the window. The window is defined by means of offsets from the current row. Use FIRST()+n and LAST()-n for offsets from the first or last row in the partition. If the start and end are omitted, the entire partition is used.

For example, the view below shows quarterly profit. A window median within the Date partition returns the median profit across all dates.

WINDOW_MEDIAN(SUM([Profit]), FIRST(), LAST())

| Year of Order Date | Quarter of Order Date | Region | | | |
|--------------------|-----------------------|----------|----------|----------|----------|
| | | Central | East | South | West |
| 2011 | Q1 | \$8,921 | \$20,575 | \$29,654 | \$22,647 |
| | Q2 | \$22,009 | \$11,477 | \$14,893 | \$30,791 |
| | Q3 | \$37,861 | \$258 | \$31,257 | \$25,006 |
| | Q4 | \$57,840 | \$13,313 | \$23,784 | \$31,171 |
| 2012 | Q1 | \$26,269 | \$30,699 | \$30,278 | \$18,861 |
| | Q2 | \$39,999 | \$28,438 | \$23,672 | (\$922) |
| | Q3 | \$9,030 | \$22,096 | \$20,973 | \$22,535 |
| | Q4 | \$34,545 | \$12,001 | \$20,074 | \$3,353 |

| Year of Order Date | Quarter of Order Date | Region | | | |
|--------------------|-----------------------|---------|--------|--------|--------|
| | | Central | East | South | West |
| 2011 | Q1 | 30,407 | 16,944 | 23,728 | 22,591 |
| | Q2 | 30,407 | 16,944 | 23,728 | 22,591 |
| | Q3 | 30,407 | 16,944 | 23,728 | 22,591 |
| | Q4 | 30,407 | 16,944 | 23,728 | 22,591 |
| 2012 | Q1 | 30,407 | 16,944 | 23,728 | 22,591 |
| | Q2 | 30,407 | 16,944 | 23,728 | 22,591 |
| | Q3 | 30,407 | 16,944 | 23,728 | 22,591 |
| | Q4 | 30,407 | 16,944 | 23,728 | 22,591 |

Example

WINDOW_MEDIAN(SUM([Profit]), FIRST()+1, 0) computes the median of SUM(Profit) from the second row to the current row.

WINDOW_MAX(expression, [start, end])

Returns the maximum of the expression within the window. The window is defined by means of offsets from the current row. Use FIRST()+n and LAST()-n for offsets from the first or last row in the partition. If the start and end are omitted, the entire partition is used.

For example, the view below shows quarterly sales. A window maximum within the Date partition returns the maximum sales across all dates.

Example

`WINDOW_MAX(SUM([Profit]), FIRST()+1, 0)` computes the maximum of SUM(Profit) from the second row to the current row.

WINDOW_MIN(expression, [start, end])

Returns the minimum of the expression within the window. The window is defined by means of offsets from the current row. Use `FIRST()+n` and `LAST()-n` for offsets from the first or last row in the partition. If the start and end are omitted, the entire partition is used.

For example, the view below shows quarterly sales. A window minimum within the Date partition returns the minimum sales across all dates.

WINDOW_MIN(SUM([Sales]), FIRST(), LAST())

| Year of Order Date | Quarter of Order Date | Central | East | South | West |

| | Q3 | 116,613 | 50,363 | 133,934 | 102,731 |

Example

`WINDOW_MIN(SUM([Profit]), FIRST()+1, 0)` computes the minimum of `SUM(Profit)` from the second row to the current row.

WINDOW_PERCENTILE(expression, number, [start, end])

Returns the value corresponding to the specified percentile within the window. The window is defined by means of offsets from the current row. Use `FIRST()+n` and `LAST()-n` for offsets from the first or last row in the partition. If the start and end are omitted, the entire partition is used.

Example

`WINDOW_PERCENTILE(SUM([Profit]), 0.75, -2, 0)` returns the 75th percentile for `SUM(Profit)` from the two previous rows to the current row.

WINDOW_STDEV(expression, [start, end])

Returns the sample standard deviation of the expression within the window. The window is defined by means of offsets from the current row. Use `FIRST()+n` and `LAST()-n` for offsets from the first or last row in the partition. If the start and end are omitted, the entire partition is used.

Example

`WINDOW_STDEV(SUM([Profit]), FIRST()+1, 0)` computes the standard deviation of `SUM(Profit)` from the second row to the current row.

WINDOW_STDEVP(expression, [start, end])

Returns the biased standard deviation of the expression within the window. The window is defined by means of offsets from the current row. Use `FIRST()+n` and `LAST()-n` for offsets from the first or last row in the partition. If the start and end are omitted, the entire partition is used.

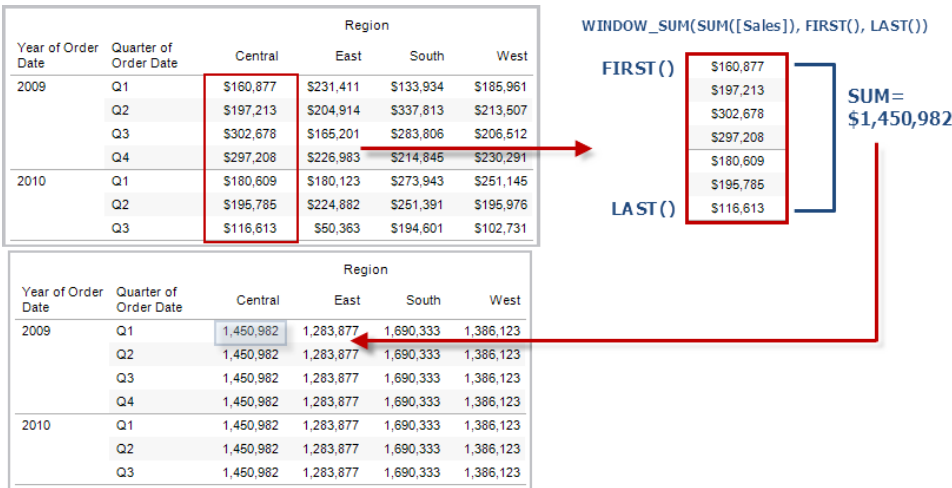

Example

`WINDOW_STDEVP(SUM([Profit]), FIRST()+1, 0)` computes the standard deviation of `SUM(Profit)` from the second row to the current row.

WINDOW_SUM(expression, [start, end])

Returns the sum of the expression within the window. The window is defined by means of offsets from the current row. Use `FIRST()+n` and `LAST()-n` for offsets from the first or last row in the partition. If the start and end are omitted, the entire partition is used.

For example, the view below shows quarterly sales. A window sum computed within the Date partition returns the summation of sales across all quarters.

Example

`WINDOW_SUM(SUM([Profit]), FIRST()+1, 0)` computes the sum of `SUM(Profit)` from the second row to the current row.

WINDOW_VAR(expression, [start, end])

Returns the sample variance of the expression within the window. The window is defined by means of offsets from the current row. Use `FIRST()+n` and `LAST()-n` for offsets from the first or last row in the partition. If the start and end are omitted, the entire partition is used.

Example

`WINDOW_VAR((SUM([Profit])), FIRST()+1, 0)` computes the variance of `SUM(Profit)` from the second row to the current row.

WINDOW_VARP(expression, [start, end])

Returns the biased variance of the expression within the window. The window is defined by means of offsets from the current row. Use `FIRST()+n` and `LAST()-n` for offsets from the first or last row in the partition. If the start and end are omitted, the entire partition is used.

Example

`WINDOW_VARP(SUM([Profit]), FIRST()+1, 0)` computes the variance of `SUM(Profit)` from the second row to the current row.

Analytics Extension table calculation functions available in Tableau

Analytic Extensions are connections between Tableau and an external service such as TabPy for Python, Matlab and R. To use Analytics Extensions in your analysis, you must first **configure a connection** between Tableau and an external service such as a TabPy server. Then you can use scripts inside specific table calculations (`MODEL_EXTENSION_` for using published named models, or `SCRIPT_` for passing an expression to the external service). The data in the viz (the "table" of the table calc) is passed securely to the external server, the script is run and the results are passed back as the output of the calculation.

Model extension functions

For use with named models deployed on a TabPy external service.

MODEL_EXTENSION_BOOL (model_name, arguments, expression)

Returns the boolean result of an expression as calculated by a named model deployed on a TabPy external service.

Model_name is the name of the deployed analytics model you want to use.

Each argument is a single string that sets the input values that the deployed model accepts and is defined by the analytics model.

Use expressions to define the values that are sent from Tableau to the analytics model. Be sure to use aggregation functions (SUM, AVG, etc.) to aggregate the results.

When using the function, the data types and order of the expressions must match those of the input arguments.

Example

```
MODEL_EXTENSION_BOOL ("isProfitable","inputSales", "inputCosts", SUM  
([Sales]), SUM([Costs]))
```

MODEL_EXTENSION_INT (model_name, arguments, expression)

Returns an integer result of an expression as calculated by a named model deployed on a TabPy external service.

Model_name is the name of the deployed analytics model you want to use.

Each argument is a single string that sets the input values that the deployed model accepts and is defined by the analytics model.

Use expressions to define the values that are sent from Tableau to the analytics model. Be sure to use aggregation functions (SUM, AVG, etc.) to aggregate the results.

When using the function, the data types and order of the expressions must match those of the input arguments.

Example

```
MODEL_EXTENSION_INT ("getPopulation", "inputCity", "inputState", MAX  
([City]), MAX ([State]))
```

MODEL_EXTENSION_REAL (model_name, arguments, expression)

Returns a real result of an expression as calculated by a named model deployed on a TabPy external service.

Model_name is the name of the deployed analytics model you want to use.

Each argument is a single string that sets the input values that the deployed model accepts and is defined by the analytics model.

Use expressions to define the values that are sent from Tableau to the analytics model. Be sure to use aggregation functions (SUM, AVG, etc.) to aggregate the results.

When using the function, the data types and order of the expressions must match those of the input arguments.

Example

```
MODEL_EXTENSION_REAL ("profitRatio", "inputSales", "inputCosts", SUM  
([Sales]), SUM([Costs]))
```

MODEL_EXTENSION_STRING (model_name, arguments, expression)

Returns the string result of an expression as calculated by a named model deployed on a TabPy external service.

Model_name is the name of the deployed analytics model you want to use.

Each argument is a single string that sets the input values that the deployed model accepts and is defined by the analytics model.

Use expressions to define the values that are sent from Tableau to the analytics model. Be sure to use aggregation functions (SUM, AVG, etc.) to aggregate the results.

When using the function, the data types and order of the expressions must match those of the input arguments.

Example

```
MODEL_EXTENSION_STR ("mostPopulatedCity", "inputCountry", "inputYear",
MAX ([Country]), MAX([Year]))
```

Script functions

Instead of using a defined external model like `MODEL_EXPRESSION` functions, `SCRIPT` functions are used to specify the expression directly in the table calculation.

SCRIPT_BOOL

Returns a Boolean result from the specified expression. The expression is passed directly to a running analytics extension service instance.

In R expressions, use `.argn` (with a leading dot) to reference parameters (`.arg1`, `.arg2`, etc.).

In Python expressions, use `_argn` (with a leading underscore).

Examples

In this R example, `.arg1` is equal to `SUM([Profit])`:

```
SCRIPT_BOOL("is.finite(.arg1)", SUM([Profit]))
```

The next example returns True for store IDs in Washington state, and False otherwise. This example could be the definition for a calculated field titled `IsStoreInWA`.

```
SCRIPT_BOOL('grepl(".*_WA", .arg1, perl=TRUE)',ATTR([Store ID]))
```

A command for Python would take this form:

```
SCRIPT_BOOL("return map(lambda x : x > 0, _arg1)", SUM([Profit]))
```

SCRIPT_INT

Returns an integer result from the specified expression. The expression is passed directly to a running analytics extension service instance.

In R expressions, use `.argn` (with a leading dot) to reference parameters (`.arg1`, `.arg2`, etc.)

In Python expressions, use `_argn` (with a leading underscore).

Examples

In this R example, `.arg1` is equal to `SUM([Profit])`:

```
SCRIPT_INT("is.finite(.arg1)", SUM([Profit]))
```

In the next example, k-means clustering is used to create three clusters:

```
SCRIPT_INT('result <- kmeans(data.frame(.arg1,.arg2,.arg3,.arg4),
3);result$cluster;', SUM([Petal length]), SUM([Petal width]),SUM
([Sepal length]),SUM([Sepal width]))
```

A command for Python would take this form:

```
SCRIPT_INT("return map(lambda x : int(x * 5), _arg1)", SUM([Profit]))
```

SCRIPT_REAL

Returns a real result from the specified expression. The expression is passed directly to a running analytics extension service instance. In

R expressions, use `.argn` (with a leading dot) to reference parameters (`.arg1`, `.arg2`, etc.)

In Python expressions, use `_argn` (with a leading underscore).

Examples

In this R example, `.arg1` is equal to `SUM([Profit])`:

```
SCRIPT_REAL("is.finite(.arg1)", SUM([Profit]))
```

The next example converts temperature values from Celsius to Fahrenheit.

```
SCRIPT_REAL('library(udunits2);ud.convert(.arg1, "celsius", "degree_
fahrenheit")',AVG([Temperature]))
```

A command for Python would take this form:

```
SCRIPT_REAL("return map(lambda x : x * 0.5, _arg1)", SUM([Profit]))
```

SCRIPT_STR

Returns a string result from the specified expression. The expression is passed directly to a running analytics extension service instance.

In R expressions, use `.argn` (with a leading dot) to reference parameters (`.arg1`, `.arg2`, etc.)

In Python expressions, use `_argn` (with a leading underscore).

Examples

In this R example, `.arg1` is equal to `SUM([Profit])`:

```
SCRIPT_STR("is.finite(.arg1)", SUM([Profit]))
```

The next example extracts a state abbreviation from a more complicated string (in the original form `13XSL_CA`, `A13_WA`):

```
SCRIPT_STR('gsub(".*_", "", .arg1)', ATTR([Store ID]))
```

A command for Python would take this form:

```
SCRIPT_STR("return map(lambda x : x[:2], _arg1)", ATTR([Region]))
```

Create a table calculation using the calculation editor

Follow along with the steps below to learn how to create a table calculation using the calculation editor.

Note: There are several ways to create table calculations in Tableau. This example demonstrates only one of those ways. For more information, see [Transform Values with Table Calculations on page 2355](#).

Step 1: Create the visualisation

1. In Tableau Desktop, connect to the **Sample-Superstore** saved data source, which comes with Tableau.
2. Navigate to a worksheet.
3. From the **Data** pane, under Dimensions, drag **Order Date** to the **Columns** shelf.
4. From the **Data** pane, under Dimensions, drag **Sub-Category** to the **Rows** shelf.
5. From the **Data** pane, under Measures, drag **Sales** to **Text** on the Marks card.

Your visualisation updates to a text table.

| Sub-Catego.. | Order Date | | | |
|--------------|------------|----------|----------|-----------|
| | 2014 | 2015 | 2016 | 2017 |
| Accessories | \$25,014 | \$40,524 | \$41,896 | \$59,946 |
| Appliances | \$15,314 | \$23,241 | \$26,050 | \$42,927 |
| Art | \$6,058 | \$6,237 | \$5,961 | \$8,863 |
| Binders | \$43,488 | \$37,453 | \$49,683 | \$72,788 |
| Bookcases | \$20,037 | \$38,544 | \$26,275 | \$30,024 |
| Chairs | \$77,242 | \$71,735 | \$83,919 | \$95,554 |
| Copiers | \$10,850 | \$26,179 | \$49,599 | \$62,899 |
| Envelopes | \$3,856 | \$4,512 | \$4,730 | \$3,379 |
| Fasteners | \$661 | \$545 | \$960 | \$858 |
| Furnishings | \$13,826 | \$21,090 | \$27,874 | \$28,915 |
| Labels | \$2,841 | \$2,956 | \$2,827 | \$3,861 |
| Machines | \$62,023 | \$27,764 | \$55,907 | \$43,545 |
| Paper | \$14,835 | \$15,288 | \$20,662 | \$27,695 |
| Phones | \$77,391 | \$68,314 | \$78,962 | \$105,341 |
| Storage | \$50,329 | \$45,048 | \$58,789 | \$69,678 |
| Supplies | \$14,394 | \$1,952 | \$14,278 | \$16,049 |
| Tables | \$46,088 | \$39,150 | \$60,833 | \$60,894 |

Step 2: Create the table calculation

1. Select **Analysis > Create Calculated Field**.
2. In the calculation editor that opens, do the following:
 - Name the calculated field, Running Sum of Profit.
 - Enter the following formula:

```
RUNNING_SUM(SUM([Profit]))
```

This formula calculates the running sum of profit sales. It is computed across the entire table.

- When finished, click **OK**.

The new table calculation field appears under Measures in the Data pane. Just like your other fields, you can use it in one or more visualisations.

Step 3: Use the table calculation in the visualisation

1. From the Data pane, under Measures, drag **Running Sum of Profit** to **Colour** on the Marks card.
2. On the Marks card, click the Mark Type drop-down and select **Square**.

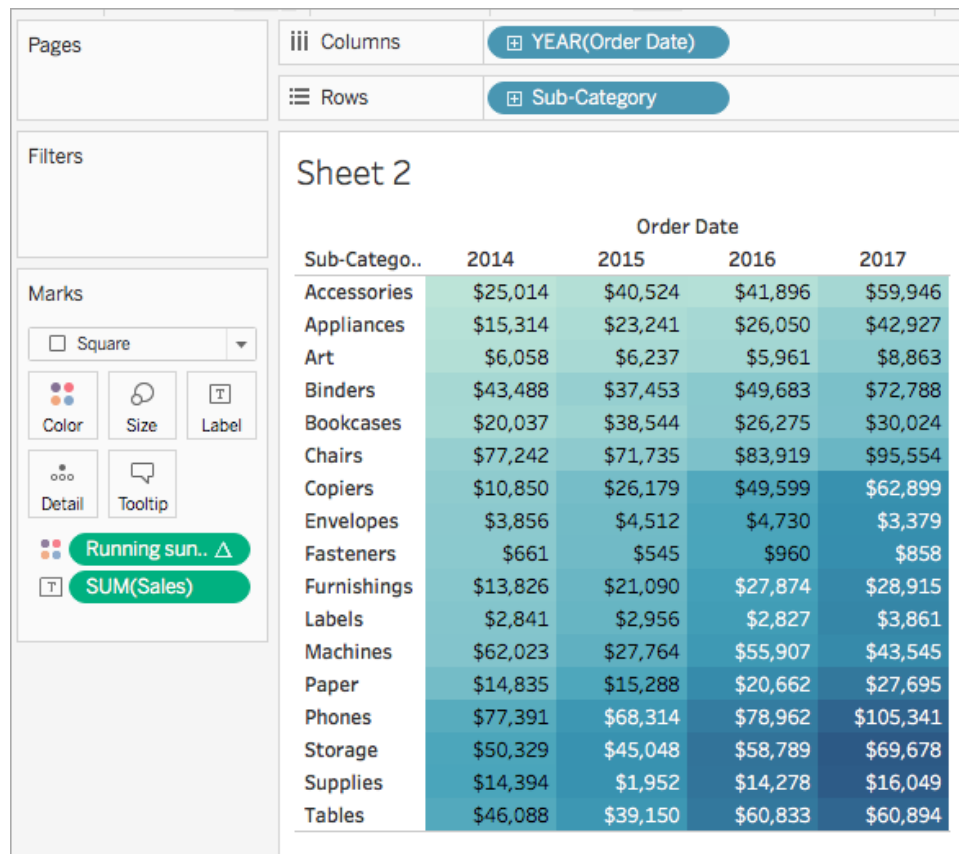

The visualisation updates to a highlight table:

Step 4: Edit the table calculation

1. On the Marks card, right-click **Running Sum of Profit** and select **Edit Table Calculation**.
2. In the Table Calculation dialog box that opens, under Compute Using, select **Table (down)**.

The visualisation updates to the following:

Spatial Functions

Spatial functions allow you to perform advanced spatial analysis and combine spatial files with data in other formats like text files or spreadsheets. For example, you might have a spatial file of

city council districts, and a text file containing latitude and longitude coordinates of reported potholes. You can use a spatial calculation when creating your data source to join these files and analyse which district takes the longest to repair potholes.

You can also create a line that connects two data points for origin-destination maps. For example, you might have a spreadsheet of public transportation data that tells you where commuters began and ended their trips. You can use a spatial calculation to see what paths commuters are taking.

Spatial functions available in Tableau

AREA

| | |
|------------|--|
| Syntax | <code>AREA(Spatial Polygon, 'units')</code> |
| Output | Number |
| Definition | Returns the total surface area of a <spatial polygon>. |
| Example | <code>AREA([Geometry], 'feet')</code> |
| Notes | Supported unit names (must be in quotation marks in the calculation, such as 'miles'): <ul style="list-style-type: none"> • <i>metres</i>: meters, metres, m • <i>kilometres</i>: kilometers, kilometres, km • <i>miles</i>: miles, mi • <i>feet</i>: feet, ft |

BUFFER

| | |
|--------|---|
| Syntax | <code>BUFFER(Spatial Point, distance, 'units')</code> <code>BUFFER(Linestring, distance, 'units')</code> <ul style="list-style-type: none"> • <i>metres</i>: meters, metres, m • <i>kilometres</i>: kilometers, kilometres, km • <i>miles</i>: miles, mi • <i>feet</i>: feet, ft |
|--------|---|

| | |
|------------|---|
| Output | Geometry |
| Definition | <p>For spatial points, returns a polygon shape centred over a <spatial point>, with a radius determined by the <distance> and <unit> values.</p> <p>For linestrings, computes the polygons formed by including all points within the radius distance from the linestring.</p> |
| Example | <pre> BUFFER([Spatial Point Geometry], 25, 'mi') BUFFER(MAKEPOINT(47.59, -122.32), 3, 'km') BUFFER(MAKELINE(MAKEPOINT(0, 20), MAKEPOINT(30, 30)), 20, 'km') </pre> |
| Notes | <p>Supported unit names (must be in quotation marks in the calculation, such as 'miles'):</p> <ul style="list-style-type: none"> • <i>metres</i>: meters, metres, m • <i>kilometres</i>: kilometers, kilometres, km • <i>miles</i>: miles, mi • <i>feet</i>: feet, ft |

DIFFERENCE

| | |
|------------|---|
| Syntax | <code>DIFFERENCE(Spatial, Spatial)</code> |
| Output | Spatial Polygon |
| Definition | Computes the portions of regions remaining when all regions in the second argument are carved out of the first argument in areas that overlap. Discards regions from the second argument in areas that don't overlap. |
| Example | <code>DIFFERENCE(Spatial Polygon1, Spatial Polygon2)</code> |
| Notes | Supports spatial polygons and multipolygons, not spatial points or lines. |

DISTANCE

| | |
|--------|--|
| Syntax | <code>DISTANCE(SpatialPoint1, SpatialPoint2, 'units')</code> |
|--------|--|

| | |
|----------------------|--|
| Output | Number |
| Definition | Returns the distance measurement between two points in the specified <unit>. |
| Example | <code>DISTANCE([Origin Point],[Destination Point], 'km')</code> |
| Notes | Supported unit names (must be in quotation marks in the calculation, such as 'miles'): <ul style="list-style-type: none"> • <i>metres</i>: meters, metres, m • <i>kilometres</i>: kilometers, kilometres, km • <i>miles</i>: miles, mi • <i>feet</i>: feet, ft |
| Database limitations | This function can only be created with a live connection but will continue to work if the data source is converted to an extract. |

INTERSECTION

| | |
|------------|---|
| Syntax | <code>INTERSECTION (spatial, spatial)</code> |
| Output | Polygon |
| Definition | Computes and returns the portions of regions in the second argument that overlap regions in the first argument. |
| Example | <code>INTERSECTION (Spatial Polygon1, Spatial Polygon2)</code> |
| Notes | Supports spatial polygons and multipolygons, not spatial points or lines. |

INTERSECTS

| | |
|------------|---|
| Syntax | <code>INTERSECTS (geometry1, geometry2)</code> |
| Output | Boolean |
| Definition | Returns true or false indicating whether two geometries overlap in space. |
| Notes | Supported combinations: point/polygon, line/polygon and polygon/polygon. |

MAKELINE

| | |
|------------|---|
| Syntax | <code>MAKELINE(SpatialPoint1, SpatialPoint2)</code> |
| Output | Geometry (line) |
| Definition | Generates a line mark between two points |
| Example | <code>MAKELINE(MAKEPOINT(47.59, -122.32), MAKEPOINT(48.5, -123.1))</code> |
| Notes | Useful for building origin-destination maps. |

MAKEPOINT

| | |
|------------|---|
| Syntax | <code>MAKEPOINT(latitude, longitude, [SRID])</code> |
| Output | Geometry (point) |
| Definition | <p>Converts data from <latitude> and <longitude> columns into spatial objects.</p> <p>If the optional <SRID> argument is added, the inputs can be other projected geographic coordinates.</p> |
| Example | <pre>MAKEPOINT(48.5, -123.1) MAKEPOINT([AirportLatitude], [AirportLongitude]) MAKEPOINT([Xcoord], [Ycoord], 3493)</pre> |
| Notes | <p><code>MAKEPOINT</code> can't use the automatically generated latitude and longitude fields. The data source must contain the coordinates natively.</p> <p><code>SRID</code> is a spatial reference identifier that uses ESPG reference system codes to specify coordinate systems. If <code>SRID</code> is not specified, WGS84 is assumed and parameters are treated as latitude/longitude in degrees.</p> <p>You can use <code>MAKEPOINT</code> to spatially enable a data source so that it can be joined with a spatial file using a spatial join. For more information, see Join Spatial Files in Tableau on page 1692.</p> |

LENGTH

| | |
|------------|--|
| Syntax | <code>LENGTH(geometry, 'units')</code> |
| Output | Number |
| Definition | Returns the geodetic path length of the line string or strings in the <code><geometry></code> using the given <code><units></code> . |
| Example | <code>LENGTH([Spatial], 'metres')</code> |
| Notes | The result is <code><NaN></code> if the geometry argument has no linestrings, though other elements are permitted. |

OUTLINE

| | |
|------------|--|
| Syntax | <code>OUTLINE(spatial polygon)</code> |
| Output | Geometry |
| Definition | Converts a polygon geometry into linestrings. |
| Notes | Useful for creating a separate layer for an outline that can be styled differently than the fill. Supports polygons within multipolygons. |

SHAPETYPE

| | |
|------------|---|
| Syntax | <code>SHAPETYPE(geometry)</code> |
| Output | String |
| Definition | Returns a string describing the structure of the spatial <code><geometry></code> , such as Empty, Point, MultiPoint, LineString, MultiLinestring, Polygon, MultiPolygon, Mixed and unsupported. |
| Example | <code>SHAPETYPE(MAKEPOINT(48.5, -123.1)) = "Point"</code> |

SYMDIFFERENCE

| | |
|------------|---|
| Syntax | <code>SYMDIFFERENCE(spatial, spatial)</code> |
| Output | Geometry |
| Definition | Computes any portions of regions from the second argument that overlap regions in the first argument and discards from both. Returns the remaining portions of regions from both arguments. |
| Example | <code>SYMDIFFERENCE(Spatial Polygon1, Spatial Polygon2)</code> |

VALIDATE

| | |
|------------|---|
| Syntax | <code>VALIDATE(spatial geometry)</code> |
| Output | Geometry |
| Definition | Confirms topological correctness of the geometry in your spatial value. If the value cannot be used for analysis due to problems such as a polygon's perimeter intersecting itself, then the result will be a null. If the geometry is correct, the result will be the original geometry. |
| Example | <code>UNION(VALIDATE([Geometry]))</code> |

Use a spatial calculation

Create a spatial data source using MAKEPOINT

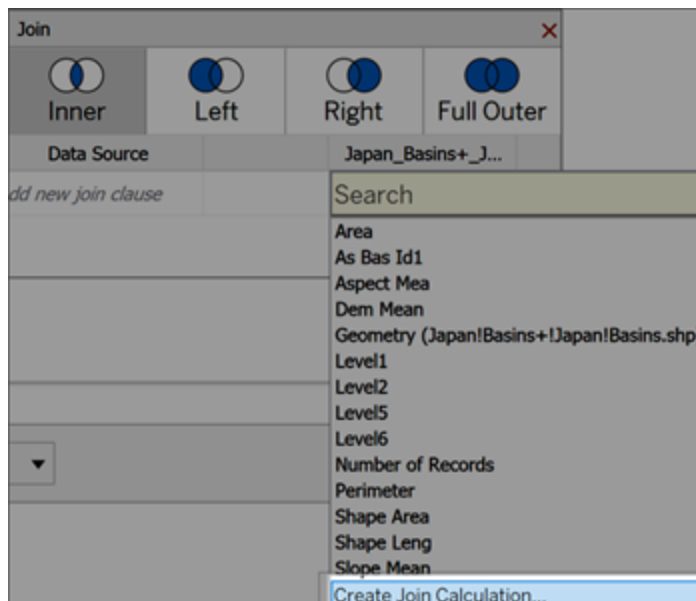

You can use MAKEPOINT to spatially-enable a data source so that it can be joined with a spatial file using a spatial join. To use MAKEPOINT, your data must contain latitude and longitude coordinates.

1. Open Tableau and connect to a spatial data source.
2. Under Connections, click Add to add a second, non-spatial data source.

The two data sources are added to the canvas.

Tip: To get the Join dialog box to appear, double-click (control + click on Mac) a data source on the canvas.

3. Drag the non-spatial data source onto the Join dialog box.
4. Click on the Join icon.
5. In the Join dialog box that appears, do the following:
 - Select a join type.
 - Under Data Source, select a spatial field from your spatial file to join by. Spatial fields have a globe icon next to them.
6. For the non-spatial data source, select Create Join Calculation as the join clause.

The calculation should look something like this:

```
MAKEPOINT (Latitude, Longitude)
```

7. Select **OK**.
8. Select the Intersects join clause operator to create a data source for spatial analysis.
9. When finished, close the Join dialog box.

For more information on spatial joins, see [Join Spatial Files in Tableau](#) on page 1692.

Create a visualisation using MAKELINE

In Tableau Desktop, download the Flight Path workbook from Tableau Public, [available here](#).

1. Navigate to a new worksheet.
2. Select Analysis > Create Calculated Field.

3. In the calculation that opens, do the following:
 - Name the calculated field Flight Paths
 - Enter the following formula

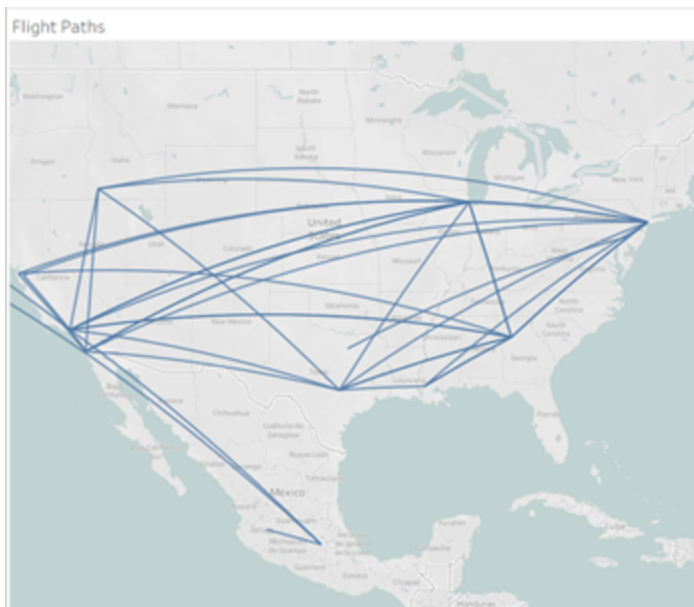

```
MAKELINE (MAKEPOINT ([Lat], [Lng]), MAKEPOINT ([Dest Lat], [Dest  
Lng]))
```

This formula takes latitude and longitude coordinates from your origin and destination cities and turns them into geographic points for spatial analysis. Those coordinates are used to build two-point lines between origin and destination.

4. When finished, click **OK**.

The new calculated field appears under Dimensions in the Data pane. Just like your other fields, you can use it in one or more visualisations.

5. From the Data pane, double-click Flight Paths to add it to your visualisation, which should automatically render as a map.

The calculation automatically produces curved geodesic lines when the lines span longer expanses of the globe.

Visualise an area with BUFFER

In Tableau Desktop, download the Flight Path workbook from Tableau Public, [available here](#).

1. Navigate to a new worksheet.
2. Right-click on the Data pane and select **Create Parameter**.
3. In the Parameter dialog that opens, set the options below:
 - Name the parameter Buffer Distance
 - Set the Data Type to Integer
 - Set Allowable values to Range
 - Set the Minimum range to 100, the Maximum range to 1000, and the step size to 100.

Create Parameter

Name
Buffer Distance

Properties

Data type: Integer
Display format: 100

Current value: 100
Value when workbook opens: Current value

Allowable values
☐ All ☐ List ☒ Range

Range of values

☒ Minimum: 100
☒ Maximum: 1,000
☒ Step size: 100

☒ Fixed
☐ When workbook opens
Add values from ▾

Cancel OK

4. When finished, click **OK**.

This parameter allows us to customise the radius of our buffer, ranging from 100 to 1000 miles. Right-click the parameter and select **Show Parameter**.

5. Select **Analysis > Create Calculated Field**.
6. In the calculation that opens, do the following:

- Name the calculated field Buffer
- Enter the following formula

```
BUFFER(MAKEPOINT([Dest Lat],[Dest Lng]),[Buffer
Distance],"miles")
```

The BUFFER calculation takes point spatial data and converts it into shapes with a radius in miles determined by the Buffer Distance parameter.

Note: Because BUFFER can only be used with point spatial data, we're converting the latitude and longitude data into a point with Makepoint, as demonstrated in the previous example.

7. When finished, click **OK**.

The new calculated field appears in the Data pane. Just like your other fields, you can use it in one or more visualisations.

8. From the Data pane, double-click on **Buffer** to add it to your visualisation, which should automatically be rendered as a map.
9. Drag **Destination** to the Colour panel on the Marks card to complete the visualisation.

Note: If your view does not look like the image above, make sure that the Mark type is set to **Map** and not **Circle**. For more information on Marks type, see [Change the Type of Mark in the View](#) on page 1245.

Predictive Modelling Functions

This article introduces predictive modelling functions and their uses in Tableau. It also demonstrates with an example how to create table calculations using the predictive modelling functions.

Why use predictive modelling functions

Predictive modelling functions can help you quickly generate predictions that can be manipulated, visualised and exported like data using [table calculations](#).

Before, you may have had to integrate Tableau with R and Python in order to perform advanced statistical calculations and visualise them in Tableau. Now, you can select targets and predictors by updating the variables and visualising multiple models with different combinations of predictors. The data can be filtered, aggregated and transformed at all levels of detail, with inputs and predictions automatically recalculated to match the data in the view.

For more information about predictive modelling functions in Tableau, see [How Predictive Modelling Functions Work in Tableau](#) on page 2561

Predictive modelling functions available in Tableau

MODEL_PERCENTILE

| | |
|------------|---|
| Syntax | <code>MODEL_PERCENTILE (model_specification (optional), target_expression, predictor_expression(s))</code> |
| Definition | Returns the probability (between 0 and 1) of the expected value being less than or equal to the observed mark, defined by the target expression and other predictors. This is the Posterior Predictive Distribution Function, also known as the Cumulative Distribution Function (CDF). |
| Example | <code>MODEL_PERCENTILE (SUM([Sales]),COUNT([Orders]))</code> |

MODEL_QUANTILE

| | |
|--------|--|
| Syntax | <code>MODEL_QUANTILE (model_specification (optional),</code> |
|--------|--|

```
quantile,  
target_expression,  
predictor_expression(s))
```

Definition Returns a target numeric value within the probable range defined by the target expression and other predictors, at a specified quantile. This is the Posterior Predictive Quantile.

Example `MODEL_QUANTILE(0.5, SUM([Sales]), COUNT([Orders]))`

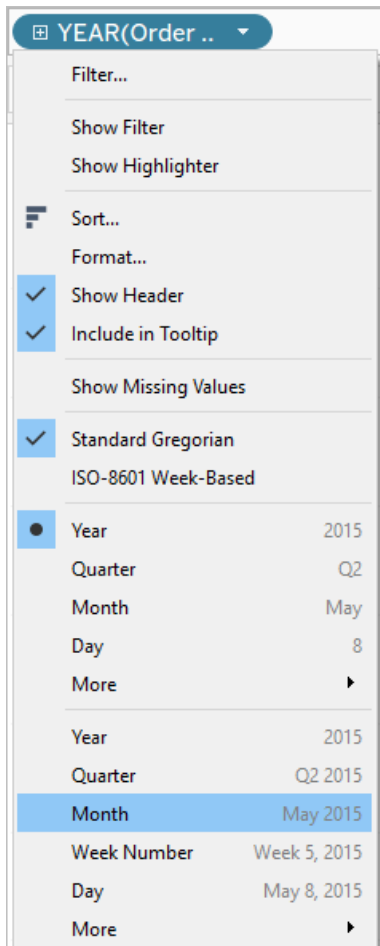

Create a prediction calculation

Follow along with the steps below to learn how to create a simple prediction calculation using the `MODEL_QUANTILE` function. For a more detailed example, see [Example – Explore Female Life Expectancy with Predictive Modelling Functions](#) on page 2591

Step 1: Create a Visualisation

1. In Tableau Desktop, connect to the **Sample - Superstore** saved data source, which comes with Tableau.
2. Navigate to a worksheet.
3. From the **Data** pane, drag the **Order Date** dimension to the Columns shelf.

4. Open the measure's context menu to change its list level to Month and Year:

5. Drag **Sales** to the Rows shelf.

Step 2: Create the Calculated Field

1. Click to open the **Analysis** menu at the top, and then select **Create Calculated Field**.
2. In the Calculation Editor, do the following:
 - Name the calculation: **Predict Median Sales**.
 - Enter the following formula:

```
MODEL_QUANTILE(0.5, SUM([Sales]), ATTR(DATETRUNC('month',
[Order Date])))
```

Remember: The MODEL_QUANTILE function takes a given quantile and predicts values based on the predictors you input.

Let's break this down:

- In this case, the quantile = 0.5, which predicts the median.
 - We want to predict sales, so the target expression is SUM([Sales]).
 - We want to base the prediction on past performance, so we include date as a predictor, which is the last argument in the calculation.
3. When finished, click **OK**.

The prediction calculation is now added as a calculated field in the Data pane.

Step 3: Add the Prediction Calculation to the View

1. Drag the prediction calculation to the Rows shelf, to the right of SUM(Sales).
2. Right-click (Control-click on Mac) the measure and select **Dual Axis**.
3. To align the two axes in a dual axes chart to use the same scale, right-click (Control-click on Mac) the secondary axis, in this case **Predict Median Sales**, and select **Synchronise Axis**. This aligns the scale of the two axes.

That's all there is to it. To find out how you can extend a date axis and predict the future, see [Predictive Modelling Functions in Time Series Visualisations](#) on page 2603.

Rules for Prediction Calculations

- You can't mix aggregate and non-aggregate arguments. If the target expression is an aggregate, so must the predictor.
- The functions are best used to predict values for individual records, on vizzes where each mark represents a discrete entity, such as a person, a product, a sale, etc.
- The functions are best used to predict values for aggregated target expressions using SUM and COUNT.
- The functions aren't recommended to predict values for aggregated target expressions using AVG, MEDIAN, MIN or MAX.
- The functions should use predictors that are at the same level of detail or higher than the viz.

Additional Functions

REGEXP_REPLACE(string, pattern, replacement)

Returns a copy of the given string where the regular expression pattern is replaced by the replacement string. This function is available for Text File, Hadoop Hive, Google BigQuery, PostgreSQL, Tableau Data Extract, Microsoft Excel, Salesforce, Vertica, Pivotal Greenplum, Teradata (version 14.1 and above), Snowflake and Oracle data sources.

For Tableau data extracts, the pattern and the replacement must be constants.

For information on regular expression syntax, see your data source's documentation. For Tableau extracts, regular expression syntax conforms to the standards of the current International Components for Unicode (ICU), an open-source project of mature C/C++ and Java libraries for Unicode support, software internationalisation and software globalisation. See the [Regular Expressions](#) page in the online ICU User Guide.

Example

```
REGEXP_REPLACE('abc 123', '\s', '-') = 'abc-123'
```

REGEXP_MATCH(string, pattern)

Returns true if a substring of the specified string matches the regular expression pattern. This function is available for Text File, Google BigQuery, PostgreSQL, Tableau Data Extract, Microsoft Excel, Salesforce, Vertica, Pivotal Greenplum, Teradata (version 14.1 and above), Impala 2.3.0 (through Cloudera Hadoop data sources), Snowflake and Oracle data sources.

For Tableau data extracts, the pattern must be a constant.

For information on regular expression syntax, see your data source's documentation. For Tableau extracts, regular expression syntax conforms to the standards of the current International Components for Unicode (ICU), an open-source project of mature C/C++ and Java libraries for Unicode support, software internationalisation and software globalisation. See the [Regular Expressions](#) page in the online ICU User Guide.

Example

```
REGEXP_MATCH('-[1234].[The.Market]','-','\[s*(\w*\.) (\w*s*)\])'=true
```

REGEXP_EXTRACT(string, pattern)

Returns the portion of the string that matches the regular expression pattern. This function is available for Text File, Hadoop Hive, Google BigQuery, PostgreSQL, Tableau Data Extract, Microsoft Excel, Salesforce, Vertica, Pivotal Greenplum, Teradata (version 14.1 and above), Snowflake and Oracle data sources.

For Tableau data extracts, the pattern must be a constant.

For information on regular expression syntax, see your data source's documentation. For Tableau extracts, regular expression syntax conforms to the standards of the current International Components for Unicode (ICU), an open-source project of mature C/C++ and Java libraries for Unicode support, software internationalisation and software globalisation. See the [Regular Expressions](#) page in the online ICU User Guide.

Example

```
REGEXP_EXTRACT('abc 123', '[a-z]+\s+(\d+)') = '123'
```

REGEXP_EXTRACT_NTH(string, pattern, index)

Returns the portion of the string that matches the regular expression pattern. The substring is matched to the nth capturing group, where n is the given index. If index is 0, the entire string is returned. This function is available for Text File, PostgreSQL, Tableau Data Extract, Microsoft Excel, Salesforce, Vertica, Pivotal Greenplum, Teradata (version 14.1 and above) and Oracle data sources.

For Tableau data extracts, the pattern must be a constant.

For information on regular expression syntax, see your data source's documentation. For Tableau extracts, regular expression syntax conforms to the standards of the current International Components for Unicode (ICU), an open-source project of mature C/C++ and Java libraries for Unicode support, software internationalisation and software globalisation. See the [Regular Expressions](#) page in the online ICU User Guide.

Example

```
REGEXP_EXTRACT_NTH('abc 123', '([a-z]+)\s+(\d+)', 2) = '123'
```

Hadoop Hive Specific Functions

Note: Only the PARSE_URL and PARSE_URL_QUERY functions are available for Cloudera Impala data sources.

GET_JSON_OBJECT(JSON string, JSON path)

Returns the JSON object within the JSON string based on the JSON path.

PARSE_URL(string, url_part)

Returns a component of the given URL string where the component is defined by url_part. Valid url_part values include: 'HOST', 'PATH', 'QUERY', 'REF', 'PROTOCOL', 'AUTHORITY', 'FILE' and 'USERINFO'.

Example

```
PARSE_URL('http://www.tableau.com', 'HOST') = 'www.tableau.com'
```

PARSE_URL_QUERY(string, key)

Returns the value of the specified query parameter in the given URL string. The query parameter is defined by the key.

Example

```
PARSE_URL_QUERY('http://www.tableau.com?page=1&cat=4', 'page') = '1'
```

XPATH_BOOLEAN(XML string, XPath expression string)

Returns true if the XPath expression matches a node or evaluates to true.

Example

```
XPATH_BOOLEAN('<values> <value id="0">1</value><value id="1">5</value>', 'values/value[@id="1"] = 5') = true
```

XPATH_DOUBLE(XML string, XPath expression string)

Returns the floating-point value of the XPath expression.

Example

```
XPATH_DOUBLE(' <values><value>1.0</value><value>5.5</value> </values>',
'sum(value/*)') = 6.5
```

XPATH_FLOAT(XML string, XPath expression string)

Returns the floating-point value of the XPath expression.

Example

```
XPATH_FLOAT(' <values><value>1.0</value><value>5.5</value>
</values>', 'sum(value/*)') = 6.5
```

XPATH_INT(XML string, XPath expression string)

Returns the numerical value of the XPath expression, or zero if the XPath expression cannot evaluate to a number.

Example

```
XPATH_INT(' <values><value>1</value><value>5</value> </values>', 'sum
(value/*)') = 6
```

XPATH_LONG(XML string, XPath expression string)

Returns the numerical value of the XPath expression, or zero if the XPath expression cannot evaluate to a number.

Example

```
XPATH_LONG(' <values><value>1</value><value>5</value> </values>', 'sum
(value/*)') = 6
```

XPATH_SHORT(XML string, XPath expression string)

Returns the numerical value of the XPath expression, or zero if the XPath expression cannot evaluate to a number.

Example

```
XPATH_SHORT(' <values><value>1</value><value>5</value> </values>', 'sum
(value/*)') = 6
```

XPATH_STRING(XML string, XPath expression string)

Returns the text of the first matching node.

Example

```
XPATH_STRING('<sites ><url domain="org">http://www.w3.org</url> <url domain="com">http://www.tableau.com</url></sites>', 'sites/url[@domain="com"]') = 'http://www.tableau.com'
```

Google BigQuery Specific Functions

DOMAIN(string_url)

Given a URL string, returns the domain as a string.

Example

```
DOMAIN('http://www.google.com:80/index.html') = 'google.com'
```

GROUP_CONCAT(expression)

Concatenates values from each record into a single comma-delimited string. This function acts like a SUM() for strings.

Example

```
GROUP_CONCAT(Region) = "Central,East,West"
```

HOST(string_url)

Given a URL string, returns the host name as a string.

Example

```
HOST('http://www.google.com:80/index.html') = 'www.google.com:80'
```

LOG2(number)

Returns the logarithm base 2 of a number.

Example

```
LOG2(16) = '4.00'
```

LTRIM_THIS(string, string)

Returns the first string with any leading occurrence of the second string removed.

Example

```
LTRIM_THIS('[-Sales-]', '[-']') = 'Sales-'
```

RTRIM_THIS(string, string)

Returns the first string with any trailing occurrence of the second string removed.

Example

```
RTRIM_THIS('[-Market-]', '[-']') = '[-Market'
```

TIMESTAMP_TO_USEC(expression)

Converts a TIMESTAMP data type to a UNIX timestamp in microseconds.

Example

```
TIMESTAMP_TO_USEC(#2012-10-01 01:02:03#)=1349053323000000
```

USEC_TO_TIMESTAMP(expression)

Converts a UNIX timestamp in microseconds to a TIMESTAMP data type.

Example

```
USEC_TO_TIMESTAMP(1349053323000000) = #2012-10-01 01:02:03#
```

TLD(string_url)

Given a URL string, returns the top level domain plus any country domain in the URL.

Example

```
TLD('http://www.google.com:80/index.html') = '.com'
```

```
TLD('http://www.google.co.uk:80/index.html') = '.co.uk'
```

FORMAT() Function Workarounds in Tableau

Tableau has no FORMAT() function for formatting fields, but it does provide a variety of means to change the structure and appearance of fields in a workbook:

- Geographic fields, see [Assign Geographic Roles](#) on page 1717.
- Date or number fields, see [Set the default number format](#) on page 1072.
 - Custom date formats, see [Custom Date Formats](#) on page 1173.
- Symbols and conventions that you can use to specify field formats, see [Literal expression syntax](#) on page 2447.
- Numbers and null values, see [Format Numbers and Null Values](#) on page 2991.

Tableau also provides a range of string functions that you can use to customise the appearance of string fields in a view. See [String Functions](#) on page 2053.

Tableau Functions (by Category)

The Tableau functions in this reference are organised by category. Click a category to browse its functions. Or press Ctrl+F (Command-F on a Mac) to open a search box that you can use to search the page for a specific function.

Number functions

ABS

| | |
|------------|--|
| Syntax | <code>ABS (number)</code> |
| Output | Number (positive) |
| Definition | Returns the absolute value of the given <code><number></code> . |
| Example | <code>ABS (-7) = 7</code> <code>ABS ([Budget Variance])</code> The second example returns the absolute value for all the numbers contained in the Budget Variance field. |
| Notes | See also SIGN on page 2200. |

ACOS

| | |
|--------|----------------------------|
| Syntax | <code>ACOS (number)</code> |
|--------|----------------------------|

| | |
|------------|---|
| Output | Number (angle in radians) |
| Definition | Returns the arccosine (angle) of the given <number>. |
| Example | $\text{ACOS}(-1) = 3.14159265358979$ |
| Notes | The inverse function, COS on the next page , takes the angle in radians as the argument and returns the cosine. |

ASIN

| | |
|------------|---|
| Syntax | $\text{ASIN}(\text{number})$ |
| Output | Number (angle in radians) |
| Definition | Returns the arcsine (angle) of a given <number>. |
| Example | $\text{ASIN}(1) = 1.5707963267949$ |
| Notes | The inverse function, SIN on page 2200 , takes the angle in radians as the argument and returns the sine. |

ATAN

| | |
|------------|--|
| Syntax | $\text{ATAN}(\text{number})$ |
| Output | Number (angle in radians) |
| Definition | Returns the arctangent (angle) of a given <number>. |
| Example | $\text{ATAN}(180) = 1.5652408283942$ |
| Notes | <p>The inverse function, TAN, takes the angle in radians as the argument and returns the tangent.</p> <p>See also ATAN2 on the next page and COT on page 2193.</p> |

ATAN2

| | |
|------------|--|
| Syntax | <code>ATAN2 (y number, x number)</code> |
| Output | Number (angle in radians) |
| Definition | Returns the arctangent (angle) between two numbers (x and y). The result is in radians. |
| Example | <code>ATAN2 (2, 1) = 1.10714871779409</code> |
| Notes | See also ATAN on the previous page, TAN on page 2201 and COT on the facing page. |

CEILING

| | |
|----------------------|--|
| Syntax | <code>CEILING (number)</code> |
| Output | Integer |
| Definition | Rounds a <number> to the nearest integer of equal or greater value. |
| Example | <code>CEILING (2.1) = 3</code> |
| Notes | See also FLOOR on page 2194 and ROUND on page 2199. |
| Database limitations | <code>CEILING</code> is available through the following connectors: Microsoft Excel, Text File, Statistical File, Published Data Source, Amazon EMR Hadoop Hive, Amazon Redshift, Cloudera Hadoop, DataStax Enterprise, Google Analytics, Google BigQuery, Hortonworks Hadoop Hive, MapR Hadoop Hive, Microsoft SQL Server, Salesforce, Spark SQL. |

COS

| | |
|--------|---|
| Syntax | <code>COS (number)</code> The number argument is the angle in radians. |
| Output | Number |

| | |
|------------|--|
| Definition | Returns the cosine of an angle. |
| Example | $\text{COS}(\text{PI}() / 4) = 0.707106781186548$ |
| Notes | <p>The inverse function, ACOS on page 2190, takes the cosine as the argument and returns the angle in radians.</p> <p>See also PI on page 2198. To convert an angle from degrees to radians, use RADIANS on page 2199.</p> |

COT

| | |
|------------|---|
| Syntax | $\text{COT}(\text{number})$ |
| | The number argument is the angle in radians. |
| Output | Number |
| Definition | Returns the cotangent of an angle. |
| Example | $\text{COT}(\text{PI}() / 4) = 1$ |
| Notes | <p>See also ATAN on page 2191, TAN on page 2201 and PI on page 2198. To convert an angle from degrees to radians, use RADIANS on page 2199.</p> |

DEGREES

| | |
|------------|---|
| Syntax | $\text{DEGREES}(\text{number})$ |
| | The number argument is the angle in radians. |
| Output | Number (degrees) |
| Definition | Converts an angle in radians to degrees. |
| Example | $\text{DEGREES}(\text{PI}() / 4) = 45.0$ |
| Notes | <p>The inverse function, RADIANS on page 2199, takes an angle in degrees and returns the angle in radians.</p> <p>See also PI on page 2198().</p> |

DIV

| | |
|------------|--|
| Syntax | <code>DIV(integer1, integer2)</code> |
| Output | Integer |
| Definition | Returns the integer part of a division operation, in which <code><integer1></code> is divided by <code><integer2></code> . |
| Example | <code>DIV(11,2) = 5</code> |

EXP

| | |
|------------|--|
| Syntax | <code>EXP(number)</code> |
| Output | Number |
| Definition | Returns e raised to the power of the given <code><number></code> . |
| Example | <code>EXP(2) = 7.389</code> <code>EXP(-[Growth Rate]*[Time])</code> |
| Notes | See also LN on the facing page. |

FLOOR

| | |
|----------------------|--|
| Syntax | <code>FLOOR(number)</code> |
| Output | Integer |
| Definition | Rounds a number to the nearest <code><number></code> of equal or lesser value. |
| Example | <code>FLOOR(7.9) = 7</code> |
| Notes | See also CEILING on page 2192 and ROUND on page 2199. |
| Database limitations | <code>FLOOR</code> is available through the following connectors: Microsoft Excel, Text File, Statistical File, Published Data Source, Amazon EMR Hadoop Hive, Cloudera Hadoop, DataStax Enterprise, Google Analytics, Google BigQuery, Hortonworks Hadoop Hive, MapR Hadoop Hive, Microsoft |

SQL Server, Salesforce, Spark SQL.

HEXBINX

| | |
|------------|--|
| Syntax | <code>HEXBINX(number, number)</code> |
| Output | Number |
| Definition | Maps an x, y coordinate to the x-coordinate of the nearest hexagonal bin. The bins have side length 1, so the inputs may need to be scaled appropriately. |
| Example | <code>HEXBINX([Longitude]*2.5, [Latitude]*2.5)</code> |
| Notes | <code>HEXBINX</code> and <code>HEXBINY</code> below are binning and plotting functions for hexagonal bins. Hexagonal bins are an efficient and elegant option for visualising data in an x/y plane such as a map. Because the bins are hexagonal, each bin closely approximates a circle and minimises variation in the distance from the data point to the centre of the bin. This makes the clustering both more accurate and informative. |

HEXBINY

| | |
|------------|---|
| Syntax | <code>HEXBINY(number, number)</code> |
| Output | Number |
| Definition | Maps an x, y coordinate to the y-coordinate of the nearest hexagonal bin. The bins have side length 1, so the inputs may need to be scaled appropriately. |
| Example | <code>HEXBINY([Longitude]*2.5, [Latitude]*2.5)</code> |
| Notes | See also <code>HEXBINX</code> above. |

LN

| | |
|--------|-------------------------|
| Syntax | <code>LN(number)</code> |
|--------|-------------------------|

| | |
|------------|--|
| Output | Number The output is <code>Null</code> if the argument is less than or equal to zero. |
| Definition | Returns the natural logarithm of a <code><number></code> . |
| Example | <code>LN(50) = 3.912023005</code> |
| Notes | See also EXP on page 2194 and LOG below. |

LOG

| | |
|------------|---|
| Syntax | <code>LOG(number, [base])</code> If the optional base argument isn't present, base 10 is used. |
| Output | Number |
| Definition | Returns the logarithm of a number for the given base. |
| Example | <code>LOG(16, 4) = 2</code> |
| Notes | See also POWER on page 2198 LN on the previous page. |

MAX

| | |
|------------|---|
| Syntax | <code>MAX(expression)</code> or <code>MAX(expr1, expr2)</code> |
| Output | Same data type as the argument, or <code>NULL</code> if any part of the argument is null. |
| Definition | Returns the maximum of the two arguments, which must be of the same data type. <code>MAX</code> can also be applied to a single field as an aggregation. |
| Example | <code>MAX(4, 7) = 7</code> <code>MAX(#3/25/1986#, #2/20/2021#) = #2/20/2021#</code> <code>MAX([Name]) = "Zander"</code> |
| Notes | For strings |

`MAX` is usually the value that comes last in alphabetical order.

For database data sources, the `MAX` string value is highest in the sort sequence defined by the database for that column.

For dates

For dates, the `MAX` is the most recent date. If `MAX` is an aggregation, the result will not have a date hierarchy. If `MAX` is a comparison, the result will retain the date hierarchy.

As an aggregation

`MAX (expression)` is an aggregate function and returns a single aggregated result. This displays as `AGG (expression)` in the viz.

As a comparison

`MAX (expr1, expr2)` compares the two values and returns a row-level value.

See also [MIN](#) below.

MIN

| | |
|------------|---|
| Syntax | <code>MIN (expression)</code> or <code>MIN (expr1, expr2)</code> |
| Output | Same data type as the argument, or <code>NULL</code> if any part of the argument is null. |
| Definition | Returns the minimum of the two arguments, which must be of the same data type. <code>MIN</code> can also be applied to a single field as an aggregation. |
| Example | <pre>MIN (4, 7) = 4 MIN (#3/25/1986#, #2/20/2021#) = #3/25/1986# MIN ([Name]) = "Abebi"</pre> |
| Notes | For strings <code>MIN</code> is usually the value that comes first in alphabetical order. |

For database data sources, the `MIN` string value is lowest in the sort sequence defined by the database for that column.

For dates

For dates, the `MIN` is the earliest date. If `MIN` is an aggregation, the result will not have a date hierarchy. If `MIN` is a comparison, the result will retain the date hierarchy.

As an aggregation

`MIN(expression)` is an aggregate function and returns a single aggregated result. This displays as `AGG(expression)` in the viz.

As a comparison

`MIN(expr1, expr2)` compares the two values and returns a row-level value.

See also [MAX](#) on page 2196.

PI

| | |
|------------|---|
| Syntax | <code>PI()</code> |
| Output | Number |
| Definition | Returns the numeric constant pi: 3.14159... |
| Example | <code>PI() = 3.14159</code> |
| Notes | Useful for trig functions that take their input in radians. See also RADIAN on the facing page . |

POWER

| | |
|------------|---|
| Syntax | <code>POWER(number, power)</code> |
| Output | Number |
| Definition | Raises the <number> to the specified <power>. |

| | |
|---------|---|
| Example | <code>POWER(5,3) = 125</code> <code>POWER([Temperature], 2)</code> |
| Notes | <p>You can also use the ^ symbol, such as <code>5^3 = POWER(5,3) = 125</code></p> <p>See also EXP on page 2194, LOG on page 2196 and SQUARE on page 2201.</p> |

RADIANS

| | |
|------------|---|
| Syntax | <code>RADIANS(number)</code> |
| Output | Number (angle in radians) |
| Definition | Converts the given <code><number></code> from degrees to radians. |
| Example | <code>RADIANS(180) = 3.14159</code> |
| Notes | The inverse function, DEGREES on page 2193, takes an angle in radians and returns the angle in degrees. |

ROUND

| | |
|------------|--|
| Syntax | <code>ROUND(number, [decimals])</code> |
| Output | Number |
| Definition | <p>Rounds <code><number></code> to a specified number of digits.</p> <p>The optional <code>decimals</code> argument specifies how many decimal points of precision to include in the final result. If <code>decimals</code> is omitted, number is rounded to the nearest integer.</p> |
| Example | <code>ROUND(1/3, 2) = 0.33</code> |
| Notes | <p>Some databases, such as SQL Server, allow specification of a negative length, where -1 rounds number to 10s, -2 rounds to 100s and so on. This is not true of all databases. For example, it is not true of Excel or Access.</p> <p>Tip: Because <code>ROUND</code> may run into issues due to the underlying floating</p> |

point representation of numbers – such as 9.405 rounding to 9.40 – it may be preferable to **format the number** to the desired number of decimal points rather than rounding. Formatting 9.405 to two decimal places will yield the expected 9.41.

See also [CEILING](#) on page 2192 and [FLOOR](#) on page 2194.

SIGN

| | |
|------------|--|
| Syntax | <code>SIGN(number)</code> |
| Output | -1, 0 or 1 |
| Definition | Returns the sign of a <number>: The possible return values are -1 if the number is negative, 0 if the number is zero or 1 if the number is positive. |
| Example | <code>SIGN(AVG(Profit)) = -1</code> |
| Notes | See also ABS on page 2190. |

SIN

| | |
|------------|---|
| Syntax | <code>SIN(number)</code> The number argument is the angle in radians. |
| Output | Number |
| Definition | Returns the sine of an angle. |
| Example | <code>SIN(0) = 1.0</code> <code>SIN(PI() / 4) = 0.707106781186548</code> |
| Notes | The inverse function, ASIN on page 2191, takes the sine as the argument and returns the angle in radians. See also PI on page 2198. To convert an angle from degrees to radians, use RADIANS on the previous page. |

SQRT

| | |
|------------|--|
| Syntax | <code>SQRT (number)</code> |
| Output | Number |
| Definition | Returns the square root of a <number>. |
| Example | <code>SQRT(25) = 5</code> |
| Notes | See also SQUARE below. |

SQUARE

| | |
|------------|---|
| Syntax | <code>SQUARE (number)</code> |
| Output | Number |
| Definition | Returns the square of a <number>. |
| Example | <code>SQUARE(5) = 25</code> |
| Notes | See also SQRT above and POWER on page 2198. |

TAN

| | |
|------------|--|
| Syntax | <code>TAN (number)</code> The number argument is the angle in radians. |
| Output | Number |
| Definition | Returns the tangent of an angle. |
| Example | <code>TAN(PI ()/4) = 1.0</code> |
| Notes | See also ATAN on page 2191, ATAN2 on page 2192, COT on page 2193 and PI on page 2198. To convert an angle from degrees to radians, use RADIANS on page 2199. |

ZN

| | |
|------------|--|
| Syntax | <code>ZN(expression)</code> |
| Output | Any, or 0 |
| Definition | Returns the <code><expression></code> if it is not null, otherwise returns zero. Use this function to replace null values with zeros. |
| Example | <code>ZN(Grade) = 0</code> |
| Notes | This is a very useful function when using fields that may contain nulls in a calculation. Wrapping the field with <code>ZN</code> can prevent errors caused by calculating with nulls. |

String functions

ASCII

| | |
|------------|---|
| Syntax | <code>ASCII(string)</code> |
| Output | Number |
| Definition | Returns the ASCII code for the first character of a <code><string></code> . |
| Example | <code>ASCII('A') = 65</code> |
| Notes | This is the inverse of the <code>CHAR</code> function. |

CHAR

| | |
|------------|---|
| Syntax | <code>CHAR(number)</code> |
| Output | String |
| Definition | Returns the character encoded by the ASCII code <code><number></code> . |

| | |
|---------|---|
| Example | <code>CHAR(65) = 'A'</code> |
| Notes | This is the inverse of the <code>ASCII</code> function. |

CONTAINS

| | |
|------------|--|
| Syntax | <code>CONTAINS(string, substring)</code> |
| Output | Boolean |
| Definition | Returns true if the given string contains the specified substring. |
| Example | <code>CONTAINS("Calculation", "alcu") = true</code> |
| Notes | <p>See also the logical function <code>IN</code> as well as supported RegEx in the additional functions documentation.</p> <p>Depending on the data source, <code>CONTAINS</code> may be case sensitive. That is, for some data sources, <code>CONTAINS("Calculation", "ALCU") = false</code> but <code>CONTAINS("Calculation", "alcu") = true</code>. See also UPPER on page 2211, LOWER on page 2205, and PROPER on page 2208.</p> |

ENDSWITH

| | |
|------------|--|
| Syntax | <code>ENDSWITH(string, substring)</code> |
| Output | Boolean |
| Definition | Returns true if the given string ends with the specified substring. Trailing white spaces are ignored. |
| Example | <code>ENDSWITH("Tableau", "leau") = true</code> |
| Notes | See also the supported RegEx in the additional functions documentation . |

FIND

| | |
|------------|--|
| Syntax | <code>FIND(string, substring, [start])</code> |
| Output | Number |
| Definition | <p>Returns the index position of substring in string, or 0 if the substring isn't found. The first character in the string is position 1.</p> <p>If the optional numeric argument <code>start</code> is added, the function ignores any instances of the substring that appear before the starting position.</p> |
| Example | <pre>FIND("Calculation", "alcu") = 2</pre> <pre>FIND("Calculation", "Computer") = 0</pre> <pre>FIND("Calculation", "a", 3) = 7</pre> <pre>FIND("Calculation", "a", 2) = 2</pre> <pre>FIND("Calculation", "a", 8) = 0</pre> |
| Notes | See also the supported RegEx in the additional functions documentation . |

FINDNTH

| | |
|------------|---|
| Syntax | <code>FINDNTH(string, substring, occurrence)</code> |
| Output | Number |
| Definition | Returns the position of the nth occurrence of substring within the specified string, where n is defined by the occurrence argument. |
| Example | <pre>FINDNTH("Calculation", "a", 2) = 7</pre> |
| Notes | <p><code>FINDNTH</code> is not available for all data sources.</p> <p>See also the supported RegEx in the additional functions documentation.</p> |

LEFT

| | |
|------------|--|
| Syntax | <code>LEFT(string, number)</code> |
| Output | String |
| Definition | Returns the left-most <number> of characters in the string. |
| Example | <code>LEFT("Matador", 4) = "Mata"</code> |
| Notes | See also MID on page 2207 and RIGHT on page 2209 . |

LEN

| | |
|------------|--|
| Syntax | <code>LEN(string)</code> |
| Output | Number |
| Definition | Returns the length of the string. |
| Example | <code>LEN("Matador") = 7</code> |
| Notes | Not to be confused with the spatial function <code>LENGTH</code> . |

LOWER

| | |
|------------|---|
| Syntax | <code>LOWER(string)</code> |
| Output | String |
| Definition | Returns the provided <string> in all lowercase characters. |
| Example | <code>LOWER("ProductVersion") = "productversion"</code> |
| Notes | See also UPPER on page 2211 and PROPER on page 2208 . |

LTRIM

| | |
|--------|----------------------------|
| Syntax | <code>LTRIM(string)</code> |
|--------|----------------------------|

| | |
|------------|--|
| Output | String |
| Definition | Returns the provided <string> with any leading spaces removed. |
| Example | <code>LTRIM(" Matador ") = "Matador "</code> |
| Notes | See also RTRIM on page 2209. |

MAX

| | |
|------------|---|
| Syntax | <code>MAX(expression)</code> or <code>MAX(expr1, expr2)</code> |
| Output | Same data type as the argument, or <code>NULL</code> if any part of the argument is null. |
| Definition | Returns the maximum of the two arguments, which must be of the same data type. <code>MAX</code> can also be applied to a single field as an aggregation. |
| Example | <code>MAX(4, 7) = 7</code> <code>MAX(#3/25/1986#, #2/20/2021#) = #2/20/2021#</code> <code>MAX([Name]) = "Zander"</code> |
| Notes | For strings <code>MAX</code> is usually the value that comes last in alphabetical order. |

For database data sources, the `MAX` string value is highest in the sort sequence defined by the database for that column.

For dates

For dates, the `MAX` is the most recent date. If `MAX` is an aggregation, the result will not have a date hierarchy. If `MAX` is a comparison, the result will retain the date hierarchy.

As an aggregation

`MAX(expression)` is an aggregate function and returns a single aggregated result. This displays as `AGG(expression)` in the viz.

As a comparison

`MAX(expr1, expr2)` compares the two values and returns a row-level value.

See also [MIN](#) on page 2197.

MID

| | |
|------------|--|
| Syntax | <code>MID(string, start, [length])</code> |
| Output | String |
| Definition | <p>Returns a string starting at the specified <code>start</code> position. The first character in the string is position 1.</p> <p>If the optional numeric argument <code>length</code> is added, the returned string includes only that number of characters.</p> |
| Example | <pre>MID("Calculation", 2) = "alculation" MID("Calculation", 2, 5) ="alcul"</pre> |
| Notes | See also the supported RegEx in the additional functions documentation . |

MIN

| | |
|------------|--|
| Syntax | <code>MIN(expression)</code> or <code>MIN(expr1, expr2)</code> |
| Output | Same data type as the argument, or <code>NULL</code> if any part of the argument is null. |
| Definition | <p>Returns the minimum of the two arguments, which must be of the same data type.</p> <p><code>MIN</code> can also be applied to a single field as an aggregation.</p> |
| Example | <pre>MIN(4, 7) = 4 MIN(#3/25/1986#, #2/20/2021#) = #3/25/1986# MIN([Name]) = "Abebi"</pre> |

Notes

For strings

MIN is usually the value that comes first in alphabetical order.

For database data sources, the MIN string value is lowest in the sort sequence defined by the database for that column.

For dates

For dates, the MIN is the earliest date. If MIN is an aggregation, the result will not have a date hierarchy. If MIN is a comparison, the result will retain the date hierarchy.

As an aggregation

MIN(expression) is an aggregate function and returns a single aggregated result. This displays as AGG(expression) in the viz.

As a comparison

MIN(expr1, expr2) compares the two values and returns a row-level value.

See also [MAX](#) on page 2196.

PROPER

Syntax

PROPER(string)

Output

String

Definition

Returns the provided <string> with the first letter of each word capitalised and the remaining letters in lowercase.

Example

PROPER("PRODUCT name") = "Product Name"

PROPER("darcy-mae") = "Darcy-Mae"

Notes

Spaces and non-alphanumeric characters such as punctuation are treated as separators.

See also [LOWER](#) on page 2205 and [UPPER](#) on page 2211.

| | |
|----------------------|--|
| Database limitations | PROPER is only available for some flat files and in extracts. If you need to use PROPER in a data source that doesn't otherwise support it, consider using an extract. |
|----------------------|--|

REPLACE

| | |
|------------|---|
| Syntax | <code>REPLACE(string, substring, replacement</code> |
| Output | String |
| Definition | Searches <string> for <substring> and replaces it with <replacement>. If <substring> is not found, the string is not changed. |
| Example | <code>REPLACE("Version 3.8", "3.8", "4x") = "Version 4x"</code> |
| Notes | See also <code>REGEXP_REPLACE</code> in the additional functions documentation . |

RIGHT

| | |
|------------|--|
| Syntax | <code>RIGHT(string, number)</code> |
| Output | String |
| Definition | Returns the right-most <number> of characters in the string. |
| Example | <code>RIGHT("Calculation", 4) = "tion"</code> |
| Notes | See also LEFT on page 2205 and MID on page 2207. |

RTRIM

| | |
|------------|---|
| Syntax | <code>RTRIM(string)</code> |
| Output | String |
| Definition | Returns the provided <string> with any trailing spaces removed. |
| Example | <code>RTRIM(" Calculation ") = " Calculation"</code> |

Notes See also [LTRIM](#) on page 2205 and [TRIM](#) on the facing page.

SPACE

| | |
|------------|---|
| Syntax | <code>SPACE (number)</code> |
| Output | String (specifically, just spaces) |
| Definition | Returns a string that is composed of the specified number of repeated spaces. |
| Example | <code>SPACE (2) = " "</code> |

SPLIT

| | |
|----------------------|--|
| Syntax | <code>SPLIT(string, delimiter, token number)</code> |
| Output | String |
| Definition | Returns a substring from a string, using a delimiter character to divide the string into a sequence of tokens. |
| Example | <code>SPLIT ("a-b-c-d", "-", 2) = "b"</code> <code>SPLIT ("a b c d", " ", -2) = "c"</code> |
| Notes | <p>The string is interpreted as an alternating sequence of delimiters and tokens. So for the string <code>abc-defgh-i-jkl</code>, where the delimiter character is '-', the tokens are (1) <code>abc</code>, (2) <code>defgh</code>, (3) <code>i</code> and (4) <code>jkl</code>.</p> <p><code>SPLIT</code> returns the token corresponding to the token number. When the token number is positive, tokens are counted starting from the left end of the string; when the token number is negative, tokens are counted starting from the right.</p> <p>See also supported RegEX in the additional functions documentation.</p> |
| Database limitations | The split and custom split commands are available for the following data sources types: Tableau data extracts, Microsoft Excel, Text File, PDF File, Salesforce, OData, Microsoft Azure Market Place, Google Analytics, |

Vertica, Oracle, MySQL, PostgreSQL, Teradata, Amazon Redshift, Aster Data, Google Big Query, Cloudera Hadoop Hive, Hortonworks Hive and Microsoft SQL Server.

Some data sources impose limits on splitting strings. See [SPLIT function limitations](#) later in this topic.

STARTSWITH

| | |
|------------|--|
| Syntax | <code>STARTSWITH(string, substring)</code> |
| Output | Boolean |
| Definition | Returns true if <code>string</code> starts with <code>substring</code> . Leading white spaces are ignored. |
| Example | <code>STARTSWITH("Matador", "Ma") = TRUE</code> |
| Notes | See also CONTAINS on page 2203, as well as supported RegEX in the additional functions documentation . |

TRIM

| | |
|------------|--|
| Syntax | <code>TRIM(string)</code> |
| Output | String |
| Definition | Returns the provided <code><string></code> with leading and trailing spaces removed. |
| Example | <code>TRIM(" Calculation ") = "Calculation"</code> |
| Notes | See also LTRIM on page 2205 and RTRIM on page 2209. |

UPPER

| | |
|--------|----------------------------|
| Syntax | <code>UPPER(string)</code> |
| Output | String |

| | |
|------------|---|
| Definition | Returns the provided <string> in all uppercase characters. |
| Example | <code>UPPER("Calculation") = "CALCULATION"</code> |
| Notes | See also PROPER on page 2208 and LOWER on page 2205 . |

Date functions

Note: Date functions do not take account of the configured fiscal year start. See [Tax Dates on page 1170](#).

DATE

Type conversion function that changes string and number expressions into dates, as long as they are in a recognisable format.

| | |
|------------|---|
| Syntax | <code>DATE (expression)</code> |
| Output | Date |
| Definition | Returns a date given a number, string or date <expression>. |
| Example | <code>DATE([Employee Start Date])</code> <code>DATE("September 22, 2018")</code> <code>DATE("9/22/2018")</code> <code>DATE(#2018-09-22 14:52#)</code> |
| Notes | <p>Unlike DATEPARSE on page 2214, there is no need to provide a pattern as <code>DATE</code> automatically recognises many standard date formats. If <code>DATE</code> does not recognise the input, however, try using <code>DATEPARSE</code> and specifying the format.</p> <p>MAKEDATE on page 2219 is another similar function, but <code>MAKEDATE</code> requires the input of numeric values for year, month and day.</p> |

DATEADD

Adds a specified number of date parts (months, days, etc) to the starting date.

| | |
|------------|---|
| Syntax | <code>DATEADD(date_part, interval, date)</code> |
| Output | Date |
| Definition | Returns the <date> with the specified number <interval> added to the specified < date_part on page 2225 > of that date. For example, adding three months or 12 days to a starting date. |
| Example | <p>Push out all due dates by one week</p> <pre>DATEADD('week', 1, [due date])</pre> <p>Add 280 days to the date February 20, 2021</p> <pre>DATEADD('day', 280, #2/20/21#) = #November 27, 2021#</pre> |
| Notes | Supports ISO 8601 dates. |

DATEDIFF

Returns the number of date parts (weeks, years, etc) between two dates.

| | |
|------------|--|
| Syntax | <code>DATEDIFF(date_part, date1, date2, [start_of_week])</code> |
| Output | Integer |
| Definition | Returns the difference between <date1> and <date2> expressed in units of < date_part on page 2225 >. For example, subtracting the dates someone entered and left a band to see how long they were in the band. |
| Example | <p>Number of days between 25th March 1986 and 20th February 2021</p> <pre>DATEDIFF('day', #3/25/1986#, #2/20/2021#) = 12,751</pre> <p>How many months someone was in a band</p> <pre>DATEDIFF('month', [date joined band], [date left band])</pre> |
| Notes | Supports ISO 8601 dates. |

DATENAME

Returns the name of the specified date part as a discrete string.

Syntax `DATENAME(date_part, date, [start_of_week])`

Output String

Definition Returns [<date_part> on page 2225](#) of <date> as a string.

Example

```
DATENAME('year', #3/25/1986#) = "1986"

DATENAME('month', #1986-03-25#) = "March"
```

Notes Supports ISO 8601 dates.

A very similar calculation is [DATEPART on the facing page](#), which returns the value of the specified date part as a continuous integer. DATEPART can be faster because it is a numerical operation.

By changing the attributes of the calculation's result (dimension or measure, continuous or discrete) and the date formatting, the results of DATEPART and DATENAME can be formatted to be identical.

An inverse function is [DATEPARSE below](#), which takes a string value and formats it as a date.

DATEPARSE

Returns specifically formatted strings as dates.

Syntax `DATEPARSE(date_format, date_string)`

Output Date

Definition The <date_format> argument describes how the <date_string> field is arranged. Because of the variety of ways the string field can be ordered, the <date_format> must match exactly. For a full explanation and formatting details, see [Convert a Field to a Date Field](#).

Example `DATEPARSE('yyyy-MM-dd', "1986-03-25") = #March 25, 1986#`

Notes [DATE on page 2212](#) is a similar function that automatically recognises many

standard date formats. `DATEPARSE` may be a better option if `DATE` does not recognise the input pattern.

[MAKEDATE](#) on page 2219 is another similar function, but `MAKEDATE` requires the input of numeric values for year, month and day.

Inverse functions, which take dates apart and return the value of their parts, are [DATEPART](#) below (integer output) and [DATENAME](#) on the previous page (string output).

Database limitations `DATEPARSE` is available through the following connectors: non-legacy Excel and text file connections, Amazon EMR Hadoop Hive, Cloudera Hadoop, Google Sheets, Hortonworks Hadoop Hive, MapR Hadoop Hive, MySQL, Oracle, PostgreSQL and Tableau extracts. Some formats may not be available for all connections.

`DATEPARSE` is not supported on Hive variants. Only Denodo, Drill and Snowflake are supported.

DATEPART

Returns the name of the specified date part as an integer.

Syntax `DATEPART(date_part, date, [start_of_week])`

Output Integer

Definition Returns [<date_part>](#) on page 2225 of `<date>` as an integer.

Example `DATEPART('year', #1986-03-25#) = 1986`

`DATEPART('month', #1986-03-25#) = 3`

Notes Supports ISO 8601 dates.

A very similar calculation is [DATENAME](#) on the previous page, which returns the name of the specified date part as a discrete string. `DATEPART` can be faster because it is a numerical operation. By changing the attributes of the field (dimension or measure, continuous or discrete) and the date formatting, the results of `DATEPART` and `DATENAME` can be formatted to be identical.

An inverse function is [DATEPARSE](#) on [page 2214](#), which takes a string value and formats it as a date.

DATETRUNC

This function can be thought of as date rounding. It takes a specific date and returns a version of that date at the desired specificity. Because every date must have a value for day, month, quarter and year, `DATETRUNC` sets the values as the lowest value for each date part up to the date part specified. Refer to the example for more information.

| | |
|------------|---|
| Syntax | <code>DATETRUNC (date_part, date, [start_of_week])</code> |
| Output | Date |
| Definition | Truncates the <code><date></code> to the accuracy specified by the <code><date_part on page 2225></code> . This function returns a new date. For example, when you truncate a date that is in the middle of the month at the month level, this function returns the first day of the month. |
| Example | <pre>DATETRUNC ('day', #9/22/2018#) = #9/22/2018#</pre> <pre>DATETRUNC ('iso-week', #9/22/2018#) = #9/17/2018#</pre> <p>(the Monday of the week containing 22/09/2018)</p> <pre>DATETRUNC (quarter, #9/22/2018#) = #7/1/2018#</pre> <p>(the first day of the quarter containing 22/09/2018)</p> |

Note: For week and iso-week, the `start_of_week` comes into play. ISO-weeks always start on Monday. For the locale of this example, an unspecified `start_of_week` means the week starts on Sunday.

| | |
|-------|--|
| Notes | <p>Supports ISO 8601 dates.</p> <p>You shouldn't use <code>DATETRUNC</code> to, for example, stop showing the time for a datetime field in a viz. If you want to truncate the way a date displays rather than round its accuracy, adjust the formatting.</p> |
|-------|--|

For example, `DATETRUNC('day', #5/17/2022 3:12:48 PM#)`, if formatted in the viz to display seconds, would display as 5/17/2022 12:00:00 AM. The value is truncated to day, but the display goes to seconds.

DAY

Returns the day of the month (1–31) as an integer.

| | |
|------------|--|
| Syntax | <code>DAY (date)</code> |
| Output | Integer |
| Definition | Returns the day of the given <date> as an integer. |
| Example | <code>Day(#September 22, 2018#) = 22</code> |
| Notes | See also WEEK on page 2224, MONTH on page 2222, QUARTER on page 2223, YEAR on page 2224 and the ISO equivalents. |

ISDATE

Checks if the string is a valid date format.

| | |
|------------|---|
| Syntax | <code>ISDATE (string)</code> |
| Output | Boolean |
| Definition | Returns true if a given <string> is a valid date. |
| Example | <code>ISDATE(09/22/2018) = true</code> <code>ISDATE(22SEP18) = false</code> |
| Notes | The required argument must be a string. ISDATE cannot be used for a field with a date data type – the calculation will return an error. |

ISOQUARTER

| | |
|------------|---|
| Syntax | ISOQUARTER (date) |
| Output | Integer |
| Definition | Returns the ISO8601 week-based quarter of a given <date> as an integer. |
| Example | ISOQUARTER (#1986-03-25#) = 1 |
| Notes | See also ISOWEEK below, ISOWEEKDAY below, ISOYEAR on the facing page and the non-ISO equivalents. |

ISOWEEK

| | |
|------------|--|
| Syntax | ISOWEEK (date) |
| Output | Integer |
| Definition | Returns the ISO8601 week-based week of a given <date> as an integer. |
| Example | ISOWEEK (#1986-03-25#) = 13 |
| Notes | See also ISOWEEKDAY below, ISOQUARTER above, ISOYEAR on the facing page and the non-ISO equivalents. |

ISOWEEKDAY

| | |
|------------|---|
| Syntax | ISOWEEKDAY (date) |
| Output | Integer |
| Definition | Returns the ISO8601 week-based weekday of a given <date> as an integer. |
| Example | ISOWEEKDAY (#1986-03-25#) = 2 |
| Notes | See also ISOWEEK above, ISOQUARTER above, ISOYEAR on the facing page and the non-ISO equivalents. |

ISOYEAR

| | |
|------------|--|
| Syntax | <code>ISOYEAR (date)</code> |
| Output | Integer |
| Definition | Returns the ISO8601 week-based year of a given <date> as an integer. |
| Example | <code>ISOYEAR (#1986-03-25#) = 1,986</code> |
| Notes | See also ISOWEEK on the previous page, ISOWEEKDAY on the previous page, ISOQUARTER on the previous page and the non-ISO equivalents. |

MAKEDATE

| | |
|------------|--|
| Syntax | <code>MAKEDATE (year, month, day)</code> |
| Output | Date |
| Definition | Returns a date value constructed from the specified <year>, <month> and <day>. |
| Example | <code>MAKEDATE (1986, 3, 25) = #1986-03-25#</code> |
| Notes | |

Note: Incorrectly entered values will be adjusted into a date, such as `MAKEDATE (2020, 4, 31) = May 1, 2020` rather than returning an error that there is no 31st day of April.

Available for Tableau Data Extracts. Check for availability in other data sources.

`MAKEDATE` requires numerical inputs for the parts of a date. If your data is a string that should be a date, try the [DATE](#) on page 2212 function. `DATE` automatically recognises many standard date formats. If `DATE` does not recognise the input, try using [DATEPARSE](#) on page 2214.

MAKEDATETIME

| | |
|------------|---|
| Syntax | <code>MAKEDATETIME (date, time)</code> |
| Output | Datetime |
| Definition | Returns a datetime that combines a <date> and a <time>. The date can be a date, datetime or a string type. The time must be a datetime. |
| Example | <pre>MAKEDATETIME ("1899-12-30", #07:59:00#) = #12/30/1899 7:59:00 AM#</pre> <pre>MAKEDATETIME ([Date], [Time]) = #1/1/2001 6:00:00 AM#</pre> |
| Notes | <p>This function is available only for MySQL-compatible connections (which for Tableau are MySQL and Amazon Aurora).</p> <p>MAKETIME below is a similar function available for Tableau Data Extracts and some other data sources.</p> |

MAKETIME

| | |
|------------|---|
| Syntax | <code>MAKETIME (hour, minute, second)</code> |
| Output | Datetime |
| Definition | Returns a date value constructed from the specified <hour>, <minute> and <second>. |
| Example | <pre>MAKETIME (14, 52, 40) = #1/1/1899 14:52:40#</pre> |
| Notes | <p>Because Tableau does not support a time data type, only datetime, the output is a datetime. The date portion of the field will be 1/1/1899.</p> <p>Similar function to MAKEDATETIME above, which is only available for MYSQL-compatible connections.</p> |

MAX

| | |
|--------|---|
| Syntax | <code>MAX (expression) or MAX (expr1, expr2)</code> |
|--------|---|

Output Same data type as the argument, or `NULL` if any part of the argument is null.

Definition Returns the maximum of the two arguments, which must be of the same data type.

`MAX` can also be applied to a single field as an aggregation.

Example

```
MAX(4, 7) = 7
MAX(#3/25/1986#, #2/20/2021#) = #2/20/2021#
MAX([Name]) = "Zander"
```

Notes **For strings**

`MAX` is usually the value that comes last in alphabetical order.

For database data sources, the `MAX` string value is highest in the sort sequence defined by the database for that column.

For dates

For dates, the `MAX` is the most recent date. If `MAX` is an aggregation, the result will not have a date hierarchy. If `MAX` is a comparison, the result will retain the date hierarchy.

As an aggregation

`MAX(expression)` is an aggregate function and returns a single aggregated result. This displays as `AGG(expression)` in the viz.

As a comparison

`MAX(expr1, expr2)` compares the two values and returns a row-level value.

See also [MIN](#) on page 2197.

MIN

Syntax `MIN(expression)` or `MIN(expr1, expr2)`

Output Same data type as the argument, or `NULL` if any part of the argument is null.

Definition Returns the minimum of the two arguments, which must be of the same data type.

`MIN` can also be applied to a single field as an aggregation.

Example

```
MIN(4,7) = 4
MIN(#3/25/1986#, #2/20/2021#) = #3/25/1986#
MIN([Name]) = "Abebi"
```

Notes **For strings**

`MIN` is usually the value that comes first in alphabetical order.

For database data sources, the `MIN` string value is lowest in the sort sequence defined by the database for that column.

For dates

For dates, the `MIN` is the earliest date. If `MIN` is an aggregation, the result will not have a date hierarchy. If `MIN` is a comparison, the result will retain the date hierarchy.

As an aggregation

`MIN(expression)` is an aggregate function and returns a single aggregated result. This displays as `AGG(expression)` in the viz.

As a comparison

`MIN(expr1, expr2)` compares the two values and returns a row-level value.

See also [MAX](#) on page 2196.

MONTH

Syntax `MONTH(date)`

Output Integer

Definition Returns the month of the given `<date>` as an integer.

| | |
|---------|--|
| Example | <code>MONTH (#1986-03-25#) = 3</code> |
| Notes | See also DAY on page 2217, WEEK on the next page, QUARTER below, YEAR on the next page and the ISO equivalents |

NOW

| | |
|------------|--|
| Syntax | <code>NOW ()</code> |
| Output | Datetime |
| Definition | Returns the current local system date and time. |
| Example | <code>NOW () = 1986-03-25 1:08:21 PM</code> |
| Notes | <p><code>NOW</code> does not take an argument.</p> <p>See also TODAY on the next page, a similar calculation that returns a date instead of a datetime.</p> <p>If the data source is a live connection, the system date and time could be in another time zone. For more information on how to address this, see the Knowledge Base.</p> |

QUARTER

| | |
|------------|---|
| Syntax | <code>QUARTER (date)</code> |
| Output | Integer |
| Definition | Returns the quarter of the given <date> as an integer. |
| Example | <code>QUARTER (#1986-03-25#) = 1</code> |
| Notes | See also DAY on page 2217, WEEK on the next page, MONTH on the previous page, YEAR on the next page and the ISO equivalents |

TODAY

| | |
|------------|---|
| Syntax | <code>TODAY ()</code> |
| Output | Date |
| Definition | Returns the current local system date. |
| Example | <code>TODAY () = 1986-03-25</code> |
| Notes | <p><code>TODAY</code> does not take an argument.</p> <p>See also NOW on the previous page, a similar calculation that returns a datetime instead of a date.</p> <p>If the data source is a live connection, the system date could be in another time zone. For more information on how to address this, see the Knowledge Base.</p> |

WEEK

| | |
|------------|---|
| Syntax | <code>WEEK (date)</code> |
| Output | Integer |
| Definition | Returns the week of the given <date> as an integer. |
| Example | <code>WEEK (#1986-03-25#) = 13</code> |
| Notes | See also DAY on page 2217, MONTH on page 2222, QUARTER on the previous page, YEAR below and the ISO equivalents |

YEAR

| | |
|------------|---|
| Syntax | <code>YEAR (date)</code> |
| Output | Integer |
| Definition | Returns the year of the given <date> as an integer. |

Example `YEAR(#1986-03-25#) = 1,986`

Notes See also [DAY](#) on page 2217, [WEEK](#) on the previous page, [MONTH](#) on page 2222, [QUARTER](#) on page 2223 and the ISO equivalents

date_part

Many date functions in Tableau take the argument `date_part`, which is a string constant that tells the function what part of a date to consider, such as day, week, quarter, etc. The valid `date_part` values that you can use are:

| date_part | Values |
|------------------|---|
| 'year' | Four-digit year |
| 'quarter' | 1-4 |
| 'month' | 1-12 or "January", "February" and so on |
| 'dayofyear' | Day of the year; 1st Jan 1, 1st Feb is 32 and so on |
| 'day' | 1-31 |
| 'weekday' | 1-7 or "Sunday", "Monday" and so on |
| 'week' | 1-52 |
| 'hour' | 0-23 |
| 'minute' | 0-59 |
| 'second' | 0-60 |
| 'iso-year' | Four-digit ISO 8601 year |
| 'iso-quarter' | 1-4 |
| 'iso-week' | 1-52, start of week is always Monday |
| 'iso-weekday' | 1-7, start of week is always Monday |

Logical functions

AND

| | |
|------------|--|
| Syntax | <code><expr1> AND <expr2></code> |
| Definition | Performs a logical conjunction on two expressions. (If both sides are true, the logical test returns true.) |
| Output | Boolean (true or false) |
| Example | <pre>IF [Season] = "Spring" AND "[Season] = "Fall" THEN "It's the apocalypse and footwear doesn't matter" END</pre> <p><i>"If both (Season = Spring) and (Season = Autumn) are true simultaneously, then return 'It's the apocalypse and footwear doesn't matter'."</i></p> |
| Notes | <p>Often used with IF on page 2229 and IIF on page 2231. See also NOT on page 2235 and OR on page 2236.</p> <p>If both expressions are <code>TRUE</code> (that is, not <code>FALSE</code> or <code>NULL</code>), then the result is <code>TRUE</code>. If either expression is <code>NULL</code>, then the result is <code>NULL</code>. In all other cases, the result is <code>FALSE</code>.</p> <p>If you create a calculation in which the result of an <code>AND</code> comparison is displayed on a worksheet, Tableau displays <code>TRUE</code> and <code>FALSE</code>. If you would like to change this, use the Format area in the format dialog.</p> |

Note: The `AND` operator employs *short circuit evaluation*. This means that if the first expression is evaluated to be `FALSE`, then the second expression is not evaluated at all. This can be helpful if the second expression results in an error when the first expression is `FALSE`, because the second expression in this case is never evaluated.

CASE

| | |
|--------|---|
| Syntax | <pre>CASE <expression> WHEN <value1> THEN <then1> WHEN <value2> THEN <then2></pre> |
|--------|---|

```

...
[ELSE <default>]
END

```

| | |
|------------|---|
| Output | Depends on data type of the <then> values. |
| Definition | Evaluates the <code>expression</code> and compares it to the specified options (<value1>, <value2>, etc.). When a value that matches expression is encountered, CASE returns the corresponding <code>return</code> . If no match is found, the (optional) default is returned. If there is no default and no values match, then Null is returned. |
| Example | <pre> CASE [Season] WHEN 'Summer' THEN 'Sandals' WHEN 'Winter' THEN 'Boots' ELSE 'Sneakers' END </pre> <p><i>"Look at the Season field. If the value is Summer, then return Sandals. If the value is Winter, then return Boots. If none of the options in the calculation match what is in the Season field, return Sneakers."</i></p> |
| Notes | <p>See also IF on page 2229 and IIF on page 2231.</p> <p>Used with WHEN on page 2237, THEN on page 2236, ELSE below and END on page 2229.</p> <p>Tip: Many times you can use a group to get the same results as a complicated CASE function, or use CASE to replace native grouping functionality, such as in the previous example. You may want to test which is more performant for your scenario.</p> |

ELSE

| | |
|--------|--|
| Syntax | <pre> CASE <expression> WHEN <value1> THEN <then1> WHEN <value2> THEN <then2> ... [ELSE <default>] </pre> |
|--------|--|

END

Definition An optional piece of an **IF** or **CASE** expression used to specify a default value to return if none of the tested expressions are true.

Example

```
IF [Season] = "Summer" THEN 'Sandals'
ELSEIF [Season] = "Winter" THEN 'Boots'
ELSE 'Sneakers'
END
```

```
CASE [Season]
WHEN 'Summer' THEN 'Sandals'
WHEN 'Winter' THEN 'Boots'
ELSE 'Sneakers'
END
```

Notes Used with **CASE** on page 2226, **WHEN** on page 2237, **IF** on the facing page, **ELSEIF** below, **THEN** on page 2236 and **END** on the facing page

ELSE is optional with **CASE** and **IF**. In a calculation where **ELSE** is not specified, if none of the <test> are true, the overall calculation will return null.

ELSE does not require a condition (such as [Season] = "Winter") and can be thought of as a form of null handling.

ELSEIF

Syntax [**ELSEIF** <test2> THEN <then2>]

Definition An optional piece of an **IF** expression used to specify additional conditions beyond the initial **IF**.

Example

```
IF [Season] = "Summer" THEN 'Sandals'
ELSEIF [Season] = "Winter" THEN 'Boots'
ELSEIF [Season] = "Spring" THEN 'Sneakers'
ELSEIF [Season] = "Autumn" THEN 'Sneakers'
ELSE 'Bare feet'
END
```

Notes Used with [IF](#) below, [THEN](#) on page 2236, [ELSE](#) on page 2227 and [END](#) below

ELSEIF can be thought of as additional IF clauses. ELSEIF is optional and can be repeated multiple times.

Unlike ELSE, ELSEIF requires a condition (such as [Season] = "Winter").

END

Definition Used to close an IF or CASE expression.

Example

```
IF [Season] = "Summer" THEN 'Sandals'
ELSEIF [Season] = "Winter" THEN 'Boots'
ELSE 'Sneakers'
END
```

"If Season = Summer, then return Sandals. If not, look at the next expression. If Season = Winter, then return Boots. If neither of the expressions are true, return Sneakers."

```
CASE [Season]
WHEN 'Summer' THEN 'Sandals'
WHEN 'Winter' THEN 'Boots'
ELSE 'Sneakers'
END
```

"Look at the Season field. If the value is Summer, then return Sandals. If the value is Winter, then return Boots. If none of the options in the calculation match what is in the Season field, return Sneakers."

Notes Used with [CASE](#) on page 2226, [WHEN](#) on page 2237, [IF](#) below, [ELSEIF](#) on the previous page, [THEN](#) on page 2236 and [ELSE](#) on page 2227.

IF

Syntax **IF** <test1> THEN <then1>

```
[ELSEIF <test2> THEN <then2>...]
[ELSE <default>]
END
```

| | |
|------------|---|
| Output | Depends on data type of the <then> values. |
| Definition | Tests a series of expressions and returns the <then> value for the first true <test>. |
| Example | <pre>IF [Season] = "Summer" THEN 'Sandals' ELSEIF [Season] = "Winter" THEN 'Boots' ELSE 'Sneakers' END</pre> <p><i>"If Season = Summer, then return Sandals. If not, look at the next expression. If Season = Winter, then return Boots. If neither of the expressions are true, return Sneakers."</i></p> |
| Notes | <p>See also IF on the previous page and IIF on the facing page.</p> <p>Used with ELSEIF on page 2228, THEN on page 2236, ELSE on page 2227 and END on the previous page</p> |

IFNULL

| | |
|------------|--|
| Syntax | IFNULL(expr1, expr2) |
| Output | Depends on the data type of the <expr> values. |
| Definition | Returns <expr1> if it's non-null, otherwise returns <expr2>. |
| Example | <pre>IFNULL([Assigned Room], "TBD")</pre> <p><i>"If the Assigned Room field isn't null, return its value. If the Assigned room field is null, return TBD instead."</i></p> |
| Notes | <p>Compare with ISNULL on page 2233. IFNULL always returns a value. ISNULL returns a boolean (true or false).</p> <p>See also ZN on page 2202.</p> |

IIF

| | |
|------------|---|
| Syntax | IIF (<test>, <then>, <else>, [<unknown>]) |
| Output | Depends on the data type of the values in the expression. |
| Definition | Checks whether a condition is met (<test>) and returns <then> if the test is true, <else> if the test is false and an optional value for <unknown> if the test is null. If the optional unknown isn't specified, IIF returns null. |
| Example | <p><code>IIF([Season] = 'Summer', 'Sandals', 'Other footwear')</code></p> <p><i>"If Season = Summer, then return Sandals. If not, return Other footwear"</i></p> <p><code>IIF([Season] = 'Summer', 'Sandals', IIF('Season' = 'Winter', 'Boots', 'Other footwear'))</code></p> <p><i>"If Season = Summer, then return Sandals. If not, look at the next expression. If Season = Winter, then return Boots. If neither are true, return Sneakers."</i></p> <p><code>IIF('Season' = 'Summer', 'Sandals', IIF('Season' = 'Winter', 'Boots', IIF('Season' = 'Spring', 'Sneakers', 'Other footwear'))</code></p> <p><i>"If Season = Summer, then return Sandals. If not, look at the next expression. If Season = Winter, then return Boots. If none of the expressions are true, return Sneakers."</i></p> |
| Notes | <p>See also IF on page 2229 and CASE on page 2226.</p> <p>IIF doesn't have an equivalent to ELSEIF (like IF) or repeated WHEN clauses (like CASE). Instead, multiple tests can be evaluated sequentially by nesting IIF statements as the <unknown> element. The first (outermost) true is returned.</p> <p>That is to say, in the calculation below, the result will be Red, not Orange, because the expression stops being evaluated as soon as A=A is evaluated as true:</p> |

```
IIF('A' = 'A', 'Red', IIF('B' = 'B', 'Orange', IIF('C' =
'D', 'Yellow', 'Green')))
```

IN

| | |
|------------|---|
| Syntax | <code><expr1> IN <expr2></code> |
| Output | Boolean (true or false) |
| Definition | Returns TRUE if any value in <code><expr1></code> matches any value in <code><expr2></code> . |
| Example | <pre>SUM([Cost]) IN (1000, 15, 200)</pre> <p><i>"Is the value of the Cost field 1000, 15 or 200?"</i></p> <pre>[Field] IN [Set]</pre> <p><i>"Is the value of the field present in the set?"</i></p> |
| Notes | <p>The values in <code><expr2></code> can be a set, list of literal values or combined field.</p> <p>See also WHEN on page 2237.</p> |

ISDATE

| | |
|------------|--|
| Syntax | <code>ISDATE(string)</code> |
| Output | Boolean (true or false) |
| Definition | Returns true if a <code><string></code> is a valid date. The input expression must be a string (text) field. |
| Example | <pre>ISDATE("2018-09-22")</pre> <p><i>"Is the string 2018-09-22 a properly formatted date?"</i></p> |
| Notes | <p>What is considered a valid date depends on the locale of the system evaluating the calculation. For example:</p> <p>In the USA:</p> <ul style="list-style-type: none"> <code>ISDATE("2018-09-22") = TRUE</code> |

- `ISDATE("2018-22-09") = FALSE`

In the UK:

- `ISDATE("2018-09-22") = FALSE`
- `ISDATE("2018-22-09") = TRUE`

ISNULL

| | |
|------------|---|
| Syntax | <code>ISNULL(expression)</code> |
| Output | Boolean (true or false) |
| Definition | Returns true if the <code><expression></code> is <code>NULL</code> (does not contain valid data). |
| Example | <code>ISNULL([Assigned Room])</code> <i>"Is the Assigned Room field null?"</i> |
| Notes | Compare with IFNULL on page 2230 . <code>IFNULL</code> always returns a value. <code>ISNULL</code> returns a boolean. See also ZN on page 2202 . |

MAX

| | |
|------------|---|
| Syntax | <code>MAX(expression)</code> or <code>MAX(expr1, expr2)</code> |
| Output | Same data type as the argument, or <code>NULL</code> if any part of the argument is null. |
| Definition | Returns the maximum of the two arguments, which must be of the same data type. <code>MAX</code> can also be applied to a single field as an aggregation. |
| Example | <code>MAX(4, 7) = 7</code> <code>MAX(#3/25/1986#, #2/20/2021#) = #2/20/2021#</code> <code>MAX([Name]) = "Zander"</code> |
| Notes | For strings |

MAX is usually the value that comes last in alphabetical order.

For database data sources, the MAX string value is highest in the sort sequence defined by the database for that column.

For dates

For dates, the MAX is the most recent date. If MAX is an aggregation, the result will not have a date hierarchy. If MAX is a comparison, the result will retain the date hierarchy.

As an aggregation

MAX(expression) is an aggregate function and returns a single aggregated result. This displays as AGG(expression) in the viz.

As a comparison

MAX(expr1, expr2) compares the two values and returns a row-level value.

See also [MIN](#) on page 2197.

MIN

| | |
|------------|--|
| Syntax | MIN(expression) or MIN(expr1, expr2) |
| Output | Same data type as the argument, or NULL if any part of the argument is null. |
| Definition | Returns the minimum of the two arguments, which must be of the same data type. MIN can also be applied to a single field as an aggregation. |
| Example | <pre>MIN(4,7) = 4 MIN(#3/25/1986#, #2/20/2021#) = #3/25/1986# MIN([Name]) = "Abebi"</pre> |
| Notes | For strings MIN is usually the value that comes first in alphabetical order. |

For database data sources, the `MIN` string value is lowest in the sort sequence defined by the database for that column.

For dates

For dates, the `MIN` is the earliest date. If `MIN` is an aggregation, the result will not have a date hierarchy. If `MIN` is a comparison, the result will retain the date hierarchy.

As an aggregation

`MIN(expression)` is an aggregate function and returns a single aggregated result. This displays as `AGG(expression)` in the viz.

As a comparison

`MIN(expr1, expr2)` compares the two values and returns a row-level value.

See also [MAX](#) on page 2196.

NOT

| | |
|------------|--|
| Syntax | <code>NOT <expression></code> |
| Output | Boolean (true or false) |
| Definition | Performs logical negation on an expression. |
| Example | <pre>IF NOT [Season] = "Summer" THEN 'Don't wear sandals' ELSE 'Wear sandals' END</pre> <p><i>"If Season doesn't equal Summer, then return Don't wear sandals. If not, return Wear sandals."</i></p> |
| Notes | Often used with IF on page 2229 and IIF on page 2231. See also DATE on page 2212 and OR on the next page. |

OR

| | |
|------------|---|
| Syntax | <code><expr1> OR <expr2></code> |
| Output | Boolean (true or false) |
| Definition | Performs a logical disjunction on two expressions. |
| Example | <pre>IF [Season] = "Spring" OR [Season] = "Fall" THEN "Sneakers" END</pre> <p><i>"If either (Season = Spring) or (Season = Fall) is true, then return Sneakers."</i></p> |
| Notes | <p>Often used with IF on page 2229 and IIF on page 2231. See also DATE on page 2212 and NOT on the previous page.</p> <p>If either expression is <code>TRUE</code>, then the result is <code>TRUE</code>. If both expressions are <code>FALSE</code>, then the result is <code>FALSE</code>. If both expressions are <code>NULL</code>, then the result is <code>NULL</code>.</p> <p>If you create a calculation that displays the result of an <code>OR</code> comparison on a worksheet, Tableau displays <code>TRUE</code> and <code>FALSE</code>. If you would like to change this, use the Format area in the format dialog.</p> |

Note: The `OR` operator employs *short circuit evaluation*. This means that if the first expression is evaluated to be `TRUE`, then the second expression is not evaluated at all. This can be helpful if the second expression results in an error when the first expression is `TRUE`, because the second expression in this case is never evaluated.

THEN

| | |
|--------|--|
| Syntax | <pre>IF <test1> THEN <then1> [ELSEIF <test2> THEN <then2>...] [ELSE <default>] END</pre> |
|--------|--|

Definition A required part of an **IF**, **ELSEIF** or **CASE** expression, used to define what result to return if a specific value or test is true.

Example

```
IF [Season] = "Summer" THEN 'Sandals'
ELSEIF [Season] = "Winter" THEN 'Boots'
ELSE 'Sneakers'
END
```

"If Season = Summer, then return Sandals. If not, look at the next expression. If Season = Winter, then return Boots. If neither of the expressions are true, return Sneakers."

```
CASE [Season]
WHEN 'Summer' THEN 'Sandals'
WHEN 'Winter' THEN 'Boots'
ELSE 'Sneakers'
END
```

"Look at the Season field. If the value is Summer, then return Sandals. If the value is Winter, then return Boots. If none of the options in the calculation match what is in the Season field, return Sneakers."

Notes Used with **CASE** on page 2226, **WHEN** below, **IF** on page 2229, **ELSEIF** on page 2228, **THEN** on the previous page, **ELSE** on page 2227 and **END** on page 2229

WHEN

Syntax

```
CASE <expression>
WHEN <value1> THEN <then1>
WHEN <value2> THEN <then2>
...
[ELSE <default>]
END
```

Definition A required part of a **CASE** expression. Finds the first <value> that matches <expression> and returns the corresponding <then>.

| | |
|---------|---|
| Example | <pre> CASE [Season] WHEN 'Summer' THEN 'Sandals' WHEN 'Winter' THEN 'Boots' ELSE 'Sneakers' END </pre> <p><i>"Look at the Season field. If the value is Summer, then return Sandals. If the value is Winter, then return Boots. If none of the options in the calculation match what is in the Season field, return Sneakers."</i></p> |
| Notes | <p>Used with CASE on page 2226, THEN on page 2236, ELSE on page 2227 and END on page 2229.</p> <p>CASE also supports WHEN IN construction, such as:</p> <pre> CASE <expression> WHEN IN <set1> THEN <then1> WHEN IN <combinedfield> THEN <then2> ... ELSE <default> END </pre> <p>The values that WHEN IN compare to must be a set, list of literal values or combined field. See also IN on page 2232.</p> |

ZN

| | |
|------------|---|
| Syntax | ZN(expression) |
| Output | Depends on the data type of the <expression>, or 0. |
| Definition | Returns <expression> if it isn't null; otherwise returns zero. |
| Example | <pre>ZN([Test Grade])</pre> <p><i>"If the test grade isn't null, return its value. If the test grade is null, return 0."</i></p> |
| Notes | ZN is a specialised case of IFNULL on page 2230 where the alternative if the expression is null is always 0 rather than being specified in the calculation. |

`ZN` is especially useful when performing additional calculations, and a null would render the entire calculation null. However, use caution interpreting these results as null is not always synonymous with 0 and could represent missing data.

See also [ISNULL](#) on page 2233.

Aggregate functions

ATTR

| | |
|------------|--|
| Syntax | <code>ATTR(expression)</code> |
| Definition | Returns the value of the expression if it has a single value for all rows. Otherwise returns an asterisk. Null values are ignored. |

AVG

| | |
|------------|---|
| Syntax | <code>AVG(expression)</code> |
| Definition | Returns the average of all the values in the expression. Null values are ignored. |
| Notes | <code>AVG</code> can only be used with numeric fields. |

COLLECT

| | |
|------------|---|
| Syntax | <code>COLLECT(spatial)</code> |
| Definition | An aggregate calculation that combines the values in the argument field. Null values are ignored. |
| Notes | <code>COLLECT</code> can only be used with spatial fields. |

CORR

| | |
|----------------------|---|
| Syntax | <code>CORR(expression1, expression2)</code> |
| Output | Number from -1 to 1 |
| Definition | Returns the Pearson correlation coefficient of two expressions. |
| Example | <code>example</code> |
| Notes | <p>The Pearson correlation measures the linear relationship between two variables. Results range from -1 to +1 inclusive, where 1 denotes an exact positive linear relationship, 0 denotes no linear relationship between the variance and -1 is an exact negative relationship.</p> <p>The square of a CORR result is equivalent to the R-Squared value for a linear trend line model. See Trend Line Model Terms.</p> <p>Use with table-scoped LOD expressions:</p> <p>You can use CORR to visualise correlation in a disaggregated scatter using a table-scoped level of detail expression. For example:</p> <pre>{CORR(Sales, Profit)}</pre> <p>With a level of detail expression, the correlation is run over all rows. If you used a formula like <code>CORR(Sales, Profit)</code> (without the surrounding brackets to make it a level of detail expression), the view would show the correlation of each individual point in the scatter plot with each other point, which is undefined.</p> |
| Database limitations | <p>CORR is available with the following data sources: Tableau data extracts, Cloudera Hive, EXASolution, Firebird (version 3.0 and later), Google BigQuery, Hortonworks Hadoop Hive, IBM PDA (Netezza), Oracle, PostgreSQL, Presto, SybaseIQ, Teradata, Vertica.</p> <p>For other data sources, consider either extracting the data or using <code>WINDOW_CORR</code>. See Table Calculation Functions.</p> |

COUNT

| | |
|------------|---|
| Syntax | <code>COUNT(expression)</code> |
| Definition | Returns the number of items. Null values are not counted. |

COUNTD

| | |
|------------|---|
| Syntax | <code>COUNTD(expression)</code> |
| Definition | Returns the number of distinct items in a group. Null values are not counted. |

COVAR

| | |
|----------------------|--|
| Syntax | <code>COVAR(expression1, expression2)</code> |
| Definition | Returns the <i>sample</i> covariance of two expressions. |
| Notes | <p>Covariance quantifies how two variables change together. A positive covariance indicates that the variables tend to move in the same direction, as when larger values of one variable tend to correspond to larger values of the other variable, on average. <i>Sample covariance</i> uses the number of non-null data points $n-1$ to normalise the covariance calculation, rather than n, which is used by the population covariance (available with the <code>COVARP</code> function). Sample covariance is the appropriate choice when the data is a random sample that is being used to estimate the covariance for a larger population.</p> <p>If <code><expression1></code> and <code><expression2></code> are the same, for example <code>COVAR([profit], [profit])</code>, <code>COVAR</code> returns a value that indicates how widely values are distributed.</p> <p>The value of <code>COVAR(X, X)</code> is equivalent to the value of <code>VAR(X)</code> and also to the value of <code>STDEV(X)^2</code>.</p> |
| Database limitations | <code>COVAR</code> is available with the following data sources: Tableau data extracts, Cloudera Hive, EXASolution, Firebird (version 3.0 and later), Google |

BigQuery, Hortonworks Hadoop Hive, IBM PDA (Netezza), Oracle, PostgreSQL, Presto, SybaseIQ, Teradata, Vertica.

For other data sources, consider either extracting the data or using `WINDOW_COVAR`. See [Table Calculation Functions](#).

COVARP

| | |
|----------------------|--|
| Syntax | <code>COVARP(expression 1, expression2)</code> |
| Definition | Returns the <i>population</i> covariance of two expressions. |
| Notes | <p>Covariance quantifies how two variables change together. A positive covariance indicates that the variables tend to move in the same direction, as when larger values of one variable tend to correspond to larger values of the other variable, on average. <i>Population covariance</i> is sample covariance multiplied by $(n-1)/n$, where n is the total number of non-null data points. Population covariance is the appropriate choice when there is data available for all items of interest as opposed to when there is only a random subset of items, in which case sample covariance (with the <code>COVAR</code> function) is appropriate.</p> <p>If <code><expression1></code> and <code><expression2></code> are the same, for example <code>COVARP([profit], [profit])</code>, <code>COVARP</code> returns a value that indicates how widely values are distributed. Note: The value of <code>COVARP(X, X)</code> is equivalent to the value of <code>VARP(X)</code> and also to the value of <code>STDEVP(X)^2</code>.</p> |
| Database limitations | <p><code>COVARP</code> is available with the following data sources: Tableau data extracts, Cloudera Hive, EXASolution, Firebird (version 3.0 and later), Google BigQuery, Hortonworks Hadoop Hive, IBM PDA (Netezza), Oracle, PostgreSQL, Presto, SybaseIQ, Teradata, Vertica</p> <p>For other data sources, consider either extracting the data or using <code>WINDOW_COVAR</code>. See Table Calculation Functions.</p> |

MAX

| | |
|------------|---|
| Syntax | <code>MAX(expression)</code> or <code>MAX(expr1, expr2)</code> |
| Output | Same data type as the argument, or <code>NULL</code> if any part of the argument is null. |
| Definition | Returns the maximum of the two arguments, which must be of the same data type. |

`MAX` can also be applied to a single field as an aggregation.

| | |
|---------|---|
| Example | <code>MAX(4, 7) = 7</code> <code>MAX(#3/25/1986#, #2/20/2021#) = #2/20/2021#</code> <code>MAX([Name]) = "Zander"</code> |
|---------|---|

Notes

For strings

`MAX` is usually the value that comes last in alphabetical order.

For database data sources, the `MAX` string value is highest in the sort sequence defined by the database for that column.

For dates

For dates, the `MAX` is the most recent date. If `MAX` is an aggregation, the result will not have a date hierarchy. If `MAX` is a comparison, the result will retain the date hierarchy.

As an aggregation

`MAX(expression)` is an aggregate function and returns a single aggregated result. This displays as `AGG(expression)` in the viz.

As a comparison

`MAX(expr1, expr2)` compares the two values and returns a row-level value.

See also [MIN](#) on page 2197.

MEDIAN

| | |
|----------------------|---|
| Syntax | <code>MEDIAN(expression)</code> |
| Definition | Returns the median of an expression across all records. Null values are ignored. |
| Notes | <code>MEDIAN</code> can only be used with numeric fields. |
| Database limitations | <p><code>MEDIAN</code> is not available for the following data sources: Access, Amazon Redshift, Cloudera Hadoop, HP Vertica, IBM DB2, IBM PDA (Netezza), Microsoft SQL Server, MySQL, SAP HANA, Teradata.</p> <p>For other data source types, you can extract your data into an extract file to use this function. See Extract Your Data.</p> |

MIN

| | |
|------------|--|
| Syntax | <code>MIN(expression)</code> or <code>MIN(expr1, expr2)</code> |
| Output | Same data type as the argument, or <code>NULL</code> if any part of the argument is null. |
| Definition | <p>Returns the minimum of the two arguments, which must be of the same data type.</p> <p><code>MIN</code> can also be applied to a single field as an aggregation.</p> |
| Example | <pre>MIN(4,7) = 4 MIN(#3/25/1986#, #2/20/2021#) = #3/25/1986# MIN([Name]) = "Abebi"</pre> |
| Notes | <p>For strings</p> <p><code>MIN</code> is usually the value that comes first in alphabetical order.</p> |

For database data sources, the `MIN` string value is lowest in the sort sequence defined by the database for that column.

For dates

For dates, the `MIN` is the earliest date. If `MIN` is an aggregation, the result will not have a date hierarchy. If `MIN` is a comparison, the result will retain the date hierarchy.

As an aggregation

`MIN(expression)` is an aggregate function and returns a single aggregated result. This displays as `AGG(expression)` in the viz.

As a comparison

`MIN(expr1, expr2)` compares the two values and returns a row-level value.

See also [MAX](#) on page 2196.

PERCENTILE

| | |
|----------------------|--|
| Syntax | <code>PERCENTILE(expression, number)</code> |
| Definition | Returns the percentile value from the given expression corresponding to the specified <code><number></code> . The <code><number></code> must be between 0 and 1 (inclusive) and must be a numeric constant. |
| Example | <code>PERCENTILE([Score], 0.9)</code> |
| Database limitations | <p>This function is available for the following data sources: Non-legacy Microsoft Excel and Text File connections, Extracts and extract-only data source types (for example, Google Analytics, OData or Salesforce), Sybase IQ 15.1 and later data sources, Oracle 10 and later data sources, Cloudera Hive and Hortonworks Hadoop Hive data sources, EXASolution 4.2 and later data sources.</p> <p>For other data source types, you can extract your data into an extract file to use this function. See Extract Your Data.</p> |

STDEV

| | |
|--------|--------------------------------|
| Syntax | <code>STDEV(expression)</code> |
|--------|--------------------------------|

| | |
|------------|---|
| Definition | Returns the statistical standard deviation of all values in the given expression based on a sample of the population. |
|------------|---|

STDEVP

| | |
|--------|---------------------------------|
| Syntax | <code>STDEVP(expression)</code> |
|--------|---------------------------------|

| | |
|------------|--|
| Definition | Returns the statistical standard deviation of all values in the given expression based on a biased population. |
|------------|--|

SUM

| | |
|--------|------------------------------|
| Syntax | <code>SUM(expression)</code> |
|--------|------------------------------|

| | |
|------------|---|
| Definition | Returns the sum of all values in the expression. Null values are ignored. |
|------------|---|

| | |
|-------|--|
| Notes | <code>SUM</code> can only be used with numeric fields. |
|-------|--|

VAR

| | |
|--------|------------------------------|
| Syntax | <code>VAR(expression)</code> |
|--------|------------------------------|

| | |
|------------|---|
| Definition | Returns the statistical variance of all values in the given expression based on a sample of the population. |
|------------|---|

VARP

| | |
|--------|-------------------------------|
| Syntax | <code>VARP(expression)</code> |
|--------|-------------------------------|

| | |
|------------|--|
| Definition | Returns the statistical variance of all values in the given expression on the entire population. |
|------------|--|

User functions

FULLNAME()

Syntax `FULLNAME ()`

Output **String**

Definition Returns the full name for the current user.

Example `FULLNAME ()`

This returns the full name of the signed-in user, such as "Hamlin Myrer".

```
[Manager] = FULLNAME ( )
```

If manager "Hamlin Myrer" is signed in, this example returns TRUE only if the Manager field in the view contains "Hamlin Myrer".

Notes This function checks:

- Tableau Cloud and Tableau Server: the full name of the signed-in user
- Tableau Desktop: the local or network full name for the user

User filters

When used as a filter, a calculated field such as `[Username field] = FULLNAME ()` can be used to create a user filter that only shows data that is relevant to the person signed in to the server.

ISFULLNAME

Syntax `ISFULLNAME ("User Full Name")`

Output **Boolean**

Definition Returns **TRUE** if the current user's full name matches the specified full name or **FALSE** if it does not match.

Example `ISFULLNAME ("Hamlin Myrer")`

Notes The `<"User Full Name">` argument must be a literal string, not a field.

This function checks:

- Tableau Cloud and Tableau Server: the full name of the signed-in user
- Tableau Desktop: the local or network full name for the user

ISMEMBEROF

| | |
|------------|---|
| Syntax | <code>ISMEMBEROF("Group Name")</code> |
| Output | Boolean or null |
| Definition | Returns <code>TRUE</code> if the person currently using Tableau is a member of a group that matches the given string, <code>FALSE</code> if they're not a member and <code>NULL</code> if they're not signed in. |
| Example | <pre>ISMEMBEROF('Superstars')</pre> <pre>ISMEMBEROF('domain.lan\Sales')</pre> |
| Notes | <p>The <code><"Group Full Name"></code> argument must be a literal string, not a field.</p> <p>If the user is signed in to Tableau Cloud or Tableau Server, group membership is determined by Tableau groups. The function will return <code>TRUE</code> if the given string is "All Users"</p> <p>The <code>ISMEMBEROF()</code> function will also accept Active Directory domains. The Active Directory domain must be declared in the calculation with the group name.</p> <p>If a change is made to a user's group membership, the change in the data that is based on the group membership is reflected in a workbook or view with a new session. The existing session will reflect stale data.</p> |

ISUSERNAME

| | |
|------------|---|
| Syntax | <code>ISUSERNAME("username")</code> |
| Output | Boolean |
| Definition | Returns <code>TRUE</code> if the current user's username matches the specified username or <code>FALSE</code> if it does not match. |

| | |
|---------|--|
| Example | <code>ISUSERNAME ("hmyrer")</code> |
| Notes | <p>The <"username"> argument must be a literal string, not a field.</p> <p>This function checks:</p> <ul style="list-style-type: none"> • Tableau Cloud and Tableau Server: the username of the signed-in user • Tableau Desktop: the local or network username for the user |

USERDOMAIN()

| | |
|------------|--|
| Syntax | <code>USERDOMAIN ()</code> |
| Output | String |
| Definition | Returns the domain for the current user. |
| Notes | <p>This function checks:</p> <ul style="list-style-type: none"> • Tableau Cloud and Tableau Server: the user domain of the signed-in user • Tableau Desktop: the local domain if the user is on a domain |

USERNAME()

| | |
|------------|--|
| Syntax | <code>USERNAME ()</code> |
| Output | String |
| Definition | Returns the username for the current user. |
| Example | <p><code>USERNAME ()</code></p> <p>This returns the username of the signed-in user, such as "hmyrer".</p> <pre>[Manager] = USERNAME ()</pre> <p>If manager "hmyrer" is signed in, this example returns TRUE only if the Manager field in the view contains "hmyrer".</p> |

| | |
|-------|--|
| Notes | <p>This function checks:</p> <ul style="list-style-type: none"> • Tableau Cloud and Tableau Server: the username of the signed-in user • Tableau Desktop: the local or network username for the user <p>User filters</p> <p>When used as a filter, a calculated field such as <code>[Username field] = USERNAME ()</code> can be used to create a user filter that only shows data that is relevant to the person signed in to the server.</p> |
|-------|--|

USERATTRIBUTE

Note: Before using this function, see [For embedding workflows in Tableau Cloud and Tableau Server only on page 2122](#). For more information, see [Authentication and Embedded Views](#) in the Embedding API v3.

| | |
|------------|--|
| Syntax | <code>USERATTRIBUTE('attribute_name')</code> |
| Output | String or null |
| Definition | <p>If <code><'attribute_name'></code> is part of the JSON web token (JWT) passed to Tableau, the calculation returns the first value of <code><'attribute_name'></code>.</p> <p>Returns null if <code><'attribute_name'></code> does not exist.</p> |
| Example | <p>Suppose "Region" is the user attribute included in the JWT and passed to Tableau (using the connected app already configured by your site admin).</p> <p>As the workbook author, you can set up your visualisation to filter data based on a specified region. In that filter, you can reference the following calculation.</p> <pre>[Region] = USERATTRIBUTE("Region")</pre> <p>When User2 from the West region views the embedded visualisation, Tableau shows the appropriate data for the West region only.</p> |
| Notes | <p>You can use the <code>USERATTRIBUTEINCLUDES</code> function if you expect <code><'attribute_name'></code> to return multiple values.</p> |

USERATTRIBUTEINCLUDES

Note: Before using this function, see [For embedding workflows in Tableau Cloud and Tableau Server only on page 2122](#). For more information, see [Authentication and Embedded Views](#) in the Embedding API v3.

| | |
|------------|---|
| Syntax | <code>USERATTRIBUTEINCLUDES('attribute_name', 'expected_value')</code> |
| Output | Boolean |
| Definition | <p>Returns <code>TRUE</code> if both of the following are true:</p> <ul style="list-style-type: none"> • <code><'attribute_name'></code> is part of the JSON web token (JWT) passed to Tableau • one of <code><'attribute_name'></code> values equals <code><'expected_value'></code>. <p>Returns <code>FALSE</code> otherwise.</p> |
| Example | <p>Suppose "Region" is the user attribute included in the JWT and passed to Tableau (using the connected app already configured by your site admin).</p> <p>As the workbook author, you can set up your visualisation to filter data based on a specified region. In that filter, you can reference the following calculation.</p> <pre>USERATTRIBUTEINCLUDES('Region', [Region])</pre> <p>If User2 from the West region accesses the embedded visualisation, Tableau checks if the Region user attribute matches one of [Region] field values. When true, the visualisation shows the appropriate data.</p> <p>When User3 from the North region accesses the same visualisation, she's unable to see any data because there's no match with [Region] field values.</p> |

Table calculations

FIRST()

Returns the number of rows from the current row to the first row in the partition. For example, the view below shows quarterly sales. When `FIRST()` is computed within the Date partition, the offset of the first row from the second row is -1.

| Year of Order Date | Quarter of Order Date | Region | | | | | |
|--------------------|-----------------------|-----------|-----------|-----------|-----------|-----------|----|
| | | Central | East | South | West | | |
| 2009 | Q1 | \$160,877 | \$231,411 | \$133,934 | \$185,961 | \$160,877 | 0 |
| | Q2 | \$197,213 | \$204,914 | \$337,813 | \$213,507 | \$197,213 | -1 |
| | Q3 | \$302,678 | \$165,201 | \$283,806 | \$206,512 | \$302,678 | -2 |
| | Q4 | \$297,208 | \$226,983 | \$214,845 | \$230,291 | \$297,208 | -3 |
| 2010 | Q1 | \$180,609 | \$180,123 | \$273,943 | \$251,145 | \$180,609 | -4 |
| | Q2 | \$195,785 | \$224,882 | \$251,391 | \$195,976 | \$195,785 | -5 |
| | Q3 | \$116,613 | \$50,363 | \$194,601 | \$102,731 | \$116,613 | -6 |

Example

When the current row index is 3, `FIRST()` = -2.

INDEX()

Returns the index of the current row in the partition, without any sorting with regard to value. The first row index starts at 1. For example, the table below shows quarterly sales. When `INDEX()` is computed within the Date partition, the index of each row is 1, 2, 3, 4..., etc.

| Year of Order Date | Quarter of Order Date | Region | | | | | |
|--------------------|-----------------------|-----------|-----------|-----------|-----------|-----------|---|
| | | Central | East | South | West | | |
| 2009 | Q1 | \$160,877 | \$231,411 | \$133,934 | \$185,961 | \$160,877 | 1 |
| | Q2 | \$197,213 | \$204,914 | \$337,813 | \$213,507 | \$197,213 | 2 |
| | Q3 | \$302,678 | \$165,201 | \$283,806 | \$206,512 | \$302,678 | 3 |
| | Q4 | \$297,208 | \$226,983 | \$214,845 | \$230,291 | \$297,208 | 4 |
| 2010 | Q1 | \$180,609 | \$180,123 | \$273,943 | \$251,145 | \$180,609 | 5 |
| | Q2 | \$195,785 | \$224,882 | \$251,391 | \$195,976 | \$195,785 | 6 |
| | Q3 | \$116,613 | \$50,363 | \$194,601 | \$102,731 | \$116,613 | 7 |

Example

For the third row in the partition, `INDEX()` = 3.

LAST()

Returns the number of rows from the current row to the last row in the partition. For example, the table below shows quarterly sales. When `LAST()` is computed within the Date partition, the offset of the last row from the second row is 5.

| Year of Order Date | Quarter of Order Date | Region | | | |
|--------------------|-----------------------|-----------|-----------|-----------|-----------|
| | | Central | East | South | West |
| 2009 | Q1 | \$160,877 | \$231,411 | \$133,934 | \$185,961 |
| | Q2 | \$197,213 | \$204,914 | \$337,813 | \$213,507 |
| | Q3 | \$302,678 | \$165,201 | \$283,806 | \$206,512 |
| | Q4 | \$297,208 | \$226,983 | \$214,845 | \$230,291 |
| 2010 | Q1 | \$180,609 | \$180,123 | \$273,943 | \$251,145 |
| | Q2 | \$195,785 | \$224,882 | \$251,391 | \$195,976 |
| | Q3 | \$116,613 | \$50,363 | \$194,601 | \$102,731 |

`LAST()`

| | |
|-----------|---|
| \$160,877 | 6 |
| \$197,213 | 5 |
| \$302,678 | 4 |
| \$297,208 | 3 |
| \$180,609 | 2 |
| \$195,785 | 1 |
| \$116,613 | 0 |

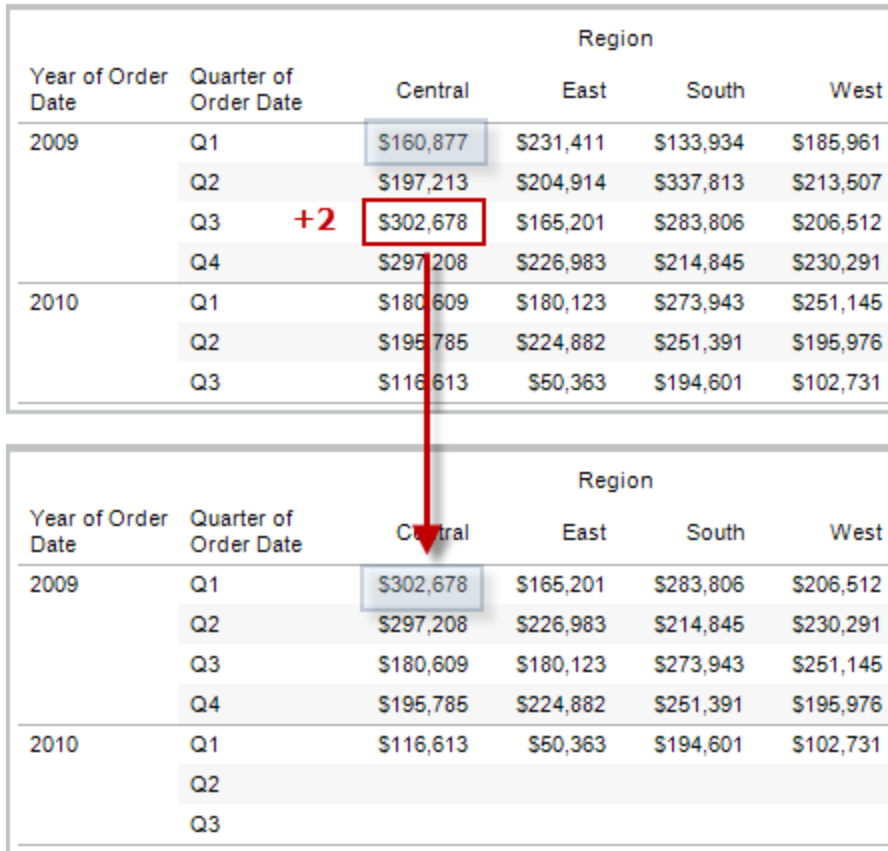

Example

When the current row index is 3 of 7, `LAST()` = 4.

LOOKUP(expression, [offset])

Returns the value of the expression in a target row, specified as a relative offset from the current row. Use `FIRST() + n` and `LAST() - n` as part of your offset definition for a target relative to the first/last rows in the partition. If `offset` is omitted, the row to compare to can be set on the field menu. This function returns NULL if the target row cannot be determined.

The view below shows quarterly sales. When `LOOKUP (SUM(Sales), 2)` is computed within the Date partition, each row shows the sales value from 2 quarters into the future.

| Year of Order Date | Quarter of Order Date | Region | | | |
|--------------------|-----------------------|-----------|-----------|-----------|-----------|
| | | Central | East | South | West |
| 2009 | Q1 | \$160,877 | \$231,411 | \$133,934 | \$185,961 |
| | Q2 | \$197,213 | \$204,914 | \$337,813 | \$213,507 |
| | Q3 | \$302,678 | \$165,201 | \$283,806 | \$206,512 |
| | Q4 | \$297,208 | \$226,983 | \$214,845 | \$230,291 |
| 2010 | Q1 | \$180,609 | \$180,123 | \$273,943 | \$251,145 |
| | Q2 | \$195,785 | \$224,882 | \$251,391 | \$195,976 |
| | Q3 | \$116,613 | \$50,363 | \$194,601 | \$102,731 |

| Year of Order Date | Quarter of Order Date | Region | | | |
|--------------------|-----------------------|-----------|-----------|-----------|-----------|
| | | Central | East | South | West |
| 2009 | Q1 | \$302,678 | \$165,201 | \$283,806 | \$206,512 |
| | Q2 | \$297,208 | \$226,983 | \$214,845 | \$230,291 |
| | Q3 | \$180,609 | \$180,123 | \$273,943 | \$251,145 |
| | Q4 | \$195,785 | \$224,882 | \$251,391 | \$195,976 |
| 2010 | Q1 | \$116,613 | \$50,363 | \$194,601 | \$102,731 |
| | Q2 | | | | |
| | Q3 | | | | |

Example

`LOOKUP(SUM([Profit]), FIRST()+2)` computes the `SUM(Profit)` in the third row of the partition.

MODEL_EXTENSION functions

The model extension functions:

- `MODEL_EXTENSION_BOOL`
- `MODEL_EXTENSION_INT`
- `MODEL_EXTENSION_REAL`
- `MODEL_EXTENSION_STRING`

are used to pass data to a deployed model on an external service such as R, TabPy or Matlab.

See [Analytics Extensions](#).

MODEL_PERCENTILE(target_expression, predictor_expression(s))

Returns the probability (between 0 and 1) of the expected value being less than or equal to the observed mark, defined by the target expression and other predictors. This is the Posterior Predictive Distribution Function, also known as the Cumulative Distribution Function (CDF).

This function is the inverse of MODEL_QUANTILE. For information on predictive modelling functions, see [How Predictive Modelling Functions Work in Tableau on page 2561](#).

Example

The following formula returns the quantile of the mark for sum of sales, adjusted for count of orders.

```
MODEL_PERCENTILE(SUM([Sales]), COUNT([Orders]))
```

MODEL_QUANTILE(quantile, target_expression, predictor_expression(s))

Returns a target numeric value within the probable range defined by the target expression and other predictors, at a specified quantile. This is the Posterior Predictive Quantile.

This function is the inverse of MODEL_PERCENTILE. For information on predictive modelling functions, see [How Predictive Modelling Functions Work in Tableau on page 2561](#).

Example

The following formula returns the median (0.5) predicted sum of sales, adjusted for count of orders.

```
MODEL_QUANTILE(0.5, SUM([Sales]), COUNT([Orders]))
```

PREVIOUS_VALUE(expression)

Returns the value of this calculation in the previous row. Returns the given expression if the current row is the first row of the partition.

Example

`SUM([Profit]) * PREVIOUS_VALUE(1)` computes the running product of `SUM(Profit)`.

RANK(expression, ['asc' | 'desc'])

Returns the standard competition rank for the current row in the partition. Identical values are assigned an identical rank. Use the optional 'asc' | 'desc' argument to specify ascending or descending order. The default is descending.

With this function, the set of values (6, 9, 9, 14) would be ranked (4, 2, 2, 1).

Nulls are ignored in ranking functions. They are not numbered and they do not count against the total number of records in percentile rank calculations.

For information on different ranking options, see [Rank calculation on page 2378](#).

Example

The following image shows the effect of the various ranking functions (RANK, RANK_DENSE, RANK_MODIFIED, RANK_PERCENTILE and RANK_UNIQUE) on a set of values. The data set contains information on 14 students (Student A through to Student N); the **Age** column shows the current age of each student (all students are between 17 and 20 years of age). The remaining columns show the effect of each rank function on the set of age values, always assuming the default order (ascending or descending) for the function.

RANK_DENSE(expression, ['asc' | 'desc'])

Returns the dense rank for the current row in the partition. Identical values are assigned an identical rank, but no gaps are inserted into the number sequence. Use the optional 'asc' | 'desc' argument to specify ascending or descending order. The default is descending.

With this function, the set of values (6, 9, 9, 14) would be ranked (3, 2, 2, 1).

Nulls are ignored in ranking functions. They are not numbered and they do not count against the total number of records in percentile rank calculations.

For information on different ranking options, see [Rank calculation on page 2378](#).

RANK_MODIFIED(expression, ['asc' | 'desc'])

Returns the modified competition rank for the current row in the partition. Identical values are assigned an identical rank. Use the optional 'asc' | 'desc' argument to specify ascending or descending order. The default is descending.

With this function, the set of values (6, 9, 9, 14) would be ranked (4, 3, 3, 1).

Nulls are ignored in ranking functions. They are not numbered and they do not count against the total number of records in percentile rank calculations.

For information on different ranking options, see [Rank calculation on page 2378](#).

RANK_PERCENTILE(expression, ['asc' | 'desc'])

Returns the percentile rank for the current row in the partition. Use the optional 'asc' | 'desc' argument to specify ascending or descending order. The default is ascending.

With this function, the set of values (6, 9, 9, 14) would be ranked (0.00, 0.67, 0.67, 1.00).

Nulls are ignored in ranking functions. They are not numbered and they do not count against the total number of records in percentile rank calculations.

For information on different ranking options, see [Rank calculation on page 2378](#).

RANK_UNIQUE(expression, ['asc' | 'desc'])

Returns the unique rank for the current row in the partition. Identical values are assigned different ranks. Use the optional 'asc' | 'desc' argument to specify ascending or descending order. The default is descending.

With this function, the set of values (6, 9, 9, 14) would be ranked (4, 2, 3, 1).

Nulls are ignored in ranking functions. They are not numbered and they do not count against the total number of records in percentile rank calculations.

For information on different ranking options, see [Rank calculation on page 2378](#).

RUNNING_AVG(expression)

Returns the running average of the given expression, from the first row in the partition to the current row.

The view below shows quarterly sales. When `RUNNING_AVG(SUM([Sales]))` is computed within the Date partition, the result is a running average of the sales values for each quarter.

| Year of Order Date | Quarter of Order Date | Region | | | |
|--------------------|-----------------------|-----------|-----------|-----------|-----------|
| | | Central | East | South | West |
| 2009 | Q1 | \$160,877 | \$231,411 | \$133,934 | \$185,961 |
| | Q2 | \$197,213 | \$204,914 | \$337,813 | \$213,507 |
| | Q3 | \$302,678 | \$165,201 | \$283,806 | \$206,512 |
| | Q4 | \$297,208 | \$226,983 | \$214,845 | \$230,291 |
| 2010 | Q1 | \$180,609 | \$180,123 | \$273,943 | \$251,145 |
| | Q2 | \$195,785 | \$224,882 | \$251,391 | \$195,976 |
| | Q3 | \$116,613 | \$50,363 | \$194,601 | \$102,731 |

| Year of Order Date | Quarter of Order Date | Central | East | South | West |
|--------------------|-----------------------|---------|---------|---------|---------|
| 2009 | Q1 | 160,877 | 231,411 | 133,934 | 185,961 |
| | Q2 | 179,045 | 18,162 | 236,873 | 199,734 |
| | Q3 | 220,256 | 200,509 | 251,851 | 201,993 |
| | Q4 | 239,494 | 207,127 | 242,599 | 209,068 |
| 2010 | Q1 | 227,717 | 201,726 | 248,868 | 217,483 |
| | Q2 | 222,395 | 205,586 | 249,289 | 213,899 |
| | Q3 | 207,283 | 183,411 | 241,476 | 198,018 |

\$160,877
\$197,213
\$302,678
\$297,208
Average =
\$179,045

Example

`RUNNING_AVG(SUM([Profit]))` computes the running average of `SUM(Profit)`.

RUNNING_COUNT(expression)

Returns the running count of the given expression, from the first row in the partition to the current row.

Example

`RUNNING_COUNT(SUM([Profit]))` computes the running count of `SUM(Profit)`.

RUNNING_MAX(expression)

Returns the running maximum of the given expression, from the first row in the partition to the current row.

| Year of Order Date | Quarter of Order Date | Region | | | |
|--------------------|-----------------------|-----------|-----------|-----------|-----------|
| | | Central | East | South | West |
| 2009 | Q1 | \$160,877 | \$231,411 | \$133,934 | \$185,961 |

Max = \$302,678

Example

`RUNNING_MAX(SUM([Profit]))` computes the running maximum of `SUM(Profit)`.

RUNNING_MIN(expression)

Returns the running minimum of the given expression, from the first row in the partition to the current row.

| Year of Order Date | Quarter of Order Date | Region | | | |

| | Q3 | 160,877 | 165,201 | 133,934 | 185,961 |
| | Q4 | 160,877 | 165,201 | 133,934 | 185,961 |
| 2010 | Q1 | 160,877 | 165,201 | 133,934 | 185,961 |
| | Q2 | 160,877 | 165,201 | 133,934 | 185,961 |
| | Q3 | 116,613 | 50,363 | 133,934 | 102,731 |

Min =
\$160,877

Example

`RUNNING_MIN(SUM([Profit]))` computes the running minimum of `SUM(Profit)`.

RUNNING_SUM(expression)

Returns the running sum of the given expression, from the first row in the partition to the current row.

| Year of Order Date | Quarter of Order Date | Region | | | |
|--------------------|-----------------------|-----------|-----------|-----------|-----------|
| | | Central | East | South | West |
| 2009 | Q1 | \$160,877 | \$231,411 | \$133,934 | \$185,961 |
| | Q2 | \$197,213 | \$204,914 | \$337,813 | \$213,507 |
| | Q3 | \$302,678 | \$165,201 | \$283,806 | \$206,512 |
| | Q4 | \$297,208 | \$226,983 | \$214,845 | \$230,291 |
| 2010 | Q1 | \$180,609 | \$180,123 | \$273,943 | \$251,145 |
| | Q2 | \$195,785 | \$224,882 | \$251,391 | \$195,976 |
| | Q3 | \$116,613 | \$50,363 | \$194,601 | \$102,731 |

| Year of Order Date | Quarter of Order Date | Region | | | |
|--------------------|-----------------------|-----------|-----------|-----------|-----------|
| | | Central | East | South | West |
| 2009 | Q1 | 160,877 | 231,411 | 133,934 | 185,961 |
| | Q2 | 358,090 | 436,325 | 471,747 | 399,469 |
| | Q3 | 660,768 | 601,526 | 755,559 | 605,966 |
| | Q4 | 957,976 | 828,508 | 970,398 | 836,272 |
| 2010 | Q1 | 1,138,585 | 1,008,631 | 1,244,341 | 1,087,417 |
| | Q2 | 1,334,369 | 1,233,513 | 1,495,732 | 1,283,392 |
| | Q3 | 1,450,982 | 1,283,877 | 1,690,333 | 1,386,123 |

SUM =
\$660,768

Example

`RUNNING_SUM(SUM([Profit]))` computes the running sum of `SUM(Profit)`

SIZE()

Returns the number of rows in the partition. For example, the view below shows quarterly sales. Within the Date partition, there are seven rows, so the `Size()` of the Date partition is 7.

| Year of Order Date | Quarter of Order Date | Region | | | |
|--------------------|-----------------------|-----------|-----------|-----------|-----------|
| | | Central | East | South | West |
| 2009 | Q1 | \$160,877 | \$231,411 | \$133,934 | \$185,961 |
| | Q2 | \$197,213 | \$204,914 | \$337,813 | \$213,507 |
| | Q3 | \$302,678 | \$165,201 | \$283,806 | \$206,512 |
| | Q4 | \$297,208 | \$226,983 | \$214,845 | \$230,291 |
| 2010 | Q1 | \$180,609 | \$180,123 | \$273,943 | \$251,145 |
| | Q2 | \$195,785 | \$224,882 | \$251,391 | \$195,976 |
| | Q3 | \$116,613 | \$50,363 | \$194,601 | \$102,731 |

\$160,877
 \$197,213
 \$302,678
 \$297,208
 \$180,609
 \$195,785
 \$116,613

Size = 7

Example

`SIZE()` = 5 when the current partition contains five rows.

SCRIPT_ functions

The script functions:

- `SCRIPT_BOOL`
- `SCRIPT_INT`
- `SCRIPT_REAL`
- `SCRIPT_STRING`

are used to pass data to an external service such as R, TabPy or Matlab. See [Analytics Extensions](#).

TOTAL(expression)

Returns the total for the given expression in a table calculation partition.

Example

Assume you are starting with this view:

The screenshot shows a Tableau interface with a worksheet view. The Columns shelf contains 'Region' and the Rows shelf contains 'YEAR(Order Date)' and 'QUARTER(Order Date)'. The Marks card is set to 'SUM(Sales)'. The view displays a table with columns for Year of Order, Quarter of Order, and sales for four regions: Central, East, South, and West. The data is grouped by year (2011-2014) and quarter (Q1-Q4).

| Year of Order | Quarter of Order | Central | East | South | West |
|---------------|------------------|----------|----------|----------|----------|
| 2011 | Q1 | \$8,601 | \$6,579 | \$44,262 | \$15,006 |
| | Q2 | \$17,407 | \$21,064 | \$22,524 | \$25,543 |
| | Q3 | \$44,171 | \$33,443 | \$16,061 | \$49,957 |
| | Q4 | \$33,659 | \$67,594 | \$20,998 | \$57,377 |
| 2012 | Q1 | \$11,768 | \$17,146 | \$16,444 | \$23,493 |
| | Q2 | \$23,979 | \$22,703 | \$16,254 | \$26,188 |
| | Q3 | \$24,486 | \$50,777 | \$21,460 | \$33,537 |
| | Q4 | \$42,641 | \$65,706 | \$17,202 | \$56,748 |
| 2013 | Q1 | \$20,212 | \$24,134 | \$23,934 | \$24,317 |
| | Q2 | \$25,709 | \$52,807 | \$17,079 | \$39,774 |
| | Q3 | \$33,428 | \$37,528 | \$22,939 | \$50,720 |
| | Q4 | \$68,080 | \$66,060 | \$29,588 | \$72,165 |
| 2014 | Q1 | \$40,278 | \$17,341 | \$9,882 | \$51,395 |
| | Q2 | \$26,606 | \$29,978 | \$33,137 | \$44,302 |
| | Q3 | \$34,042 | \$67,712 | \$23,894 | \$74,786 |
| | Q4 | \$46,172 | \$98,209 | \$56,064 | \$80,150 |

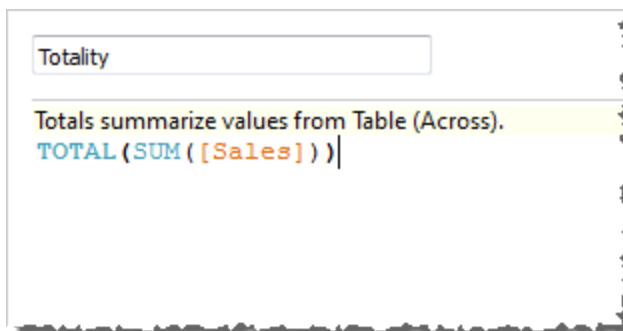

You open the calculation editor and create a new field which you name **Totality**:

You then drop **Totality** on Text, to replace **SUM(Sales)**. Your view changes such that it sums values based on the default **Compute Using** value:

| | | Region | | | |
|---------------|------------------|---------|---------|---------|---------|
| Year of Order | Quarter of Order | Central | East | South | West |
| 2011 | Q1 | 74,448 | 74,448 | 74,448 | 74,448 |
| | Q2 | 86,539 | 86,539 | 86,539 | 86,539 |
| | Q3 | 143,633 | 143,633 | 143,633 | 143,633 |
| | Q4 | 179,628 | 179,628 | 179,628 | 179,628 |
| 2012 | Q1 | 68,852 | 68,852 | 68,852 | 68,852 |
| | Q2 | 89,124 | 89,124 | 89,124 | 89,124 |
| | Q3 | 130,260 | 130,260 | 130,260 | 130,260 |
| | Q4 | 182,297 | 182,297 | 182,297 | 182,297 |
| 2013 | Q1 | 92,596 | 92,596 | 92,596 | 92,596 |
| | Q2 | 135,370 | 135,370 | 135,370 | 135,370 |
| | Q3 | 144,614 | 144,614 | 144,614 | 144,614 |
| | Q4 | 235,893 | 235,893 | 235,893 | 235,893 |
| 2014 | Q1 | 118,896 | 118,896 | 118,896 | 118,896 |
| | Q2 | 134,023 | 134,023 | 134,023 | 134,023 |
| | Q3 | 200,433 | 200,433 | 200,433 | 200,433 |
| | Q4 | 280,595 | 280,595 | 280,595 | 280,595 |

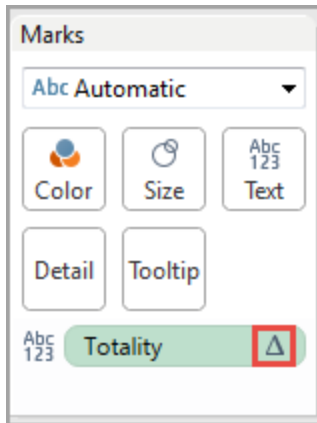

This raises the question, What is the default **Compute Using** value? If you right-click (Control-click on a Mac) **Totality** in the Data pane and choose **Edit**, there is now an additional bit of information available:

The default **Compute Using** value is **Table (Across)**. The result is that **Totality** is summing the values across each row of your table. Thus, the value that you see across each row is the sum of the values from the original version of the table.

The values in the 2011/Q1 row in the original table were \$8601, \$6579, \$44262 and \$15006. The values in the table after **Totality** replaces **SUM(Sales)** are all \$74,448, which is the sum of the four original values.

Notice the triangle next to **Totality** after you drop it on **Text**:

This indicates that this field is using a table calculation. You can right-click the field and choose **Edit Table Calculation** to redirect your function to a different **Compute Using** value. For example, you could set it to **Table (Down)**. In that case, your table would look like this:

The screenshot shows a Tableau view with a table calculation. The Columns shelf contains 'Region' and the Rows shelf contains 'YEAR(Order Date)' and 'QUARTER(Order Date)'. The Marks card shows 'Totality' with the table calculation icon. The resulting table is as follows:

| | | Region | | | |
|----------------|----------------|---------|---------|---------|---------|
| Year of Orde.. | Quarter of O.. | Central | East | South | West |
| 2011 | Q1 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q2 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q3 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q4 | 501,240 | 678,781 | 391,722 | 725,458 |
| 2012 | Q1 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q2 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q3 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q4 | 501,240 | 678,781 | 391,722 | 725,458 |
| 2013 | Q1 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q2 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q3 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q4 | 501,240 | 678,781 | 391,722 | 725,458 |
| 2014 | Q1 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q2 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q3 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q4 | 501,240 | 678,781 | 391,722 | 725,458 |

TOTAL(expression)

Returns the total for the given expression in a table calculation partition.

Example

Assume you are starting with this view:

The screenshot shows the Tableau Desktop interface. The Columns shelf contains 'Region' and the Rows shelf contains 'YEAR(Order Date)' and 'QUARTER(Order Date)'. The Marks card is set to 'Automatic' and shows 'SUM(Sales)'. The view displays a pivot table of sales data by region and quarter.

| | | Region | | | |
|---------------|------------------|----------|----------|----------|----------|
| Year of Order | Quarter of Order | Central | East | South | West |
| 2011 | Q1 | \$8,601 | \$6,579 | \$44,262 | \$15,006 |
| | Q2 | \$17,407 | \$21,064 | \$22,524 | \$25,543 |
| | Q3 | \$44,171 | \$33,443 | \$16,061 | \$49,957 |
| | Q4 | \$33,659 | \$67,594 | \$20,998 | \$57,377 |
| 2012 | Q1 | \$11,768 | \$17,146 | \$16,444 | \$23,493 |
| | Q2 | \$23,979 | \$22,703 | \$16,254 | \$26,188 |
| | Q3 | \$24,486 | \$50,777 | \$21,460 | \$33,537 |
| | Q4 | \$42,641 | \$65,706 | \$17,202 | \$56,748 |
| 2013 | Q1 | \$20,212 | \$24,134 | \$23,934 | \$24,317 |
| | Q2 | \$25,709 | \$52,807 | \$17,079 | \$39,774 |
| | Q3 | \$33,428 | \$37,528 | \$22,939 | \$50,720 |
| | Q4 | \$68,080 | \$66,060 | \$29,588 | \$72,165 |
| 2014 | Q1 | \$40,278 | \$17,341 | \$9,882 | \$51,395 |
| | Q2 | \$26,606 | \$29,978 | \$33,137 | \$44,302 |
| | Q3 | \$34,042 | \$67,712 | \$23,894 | \$74,786 |
| | Q4 | \$46,172 | \$98,209 | \$56,064 | \$80,150 |

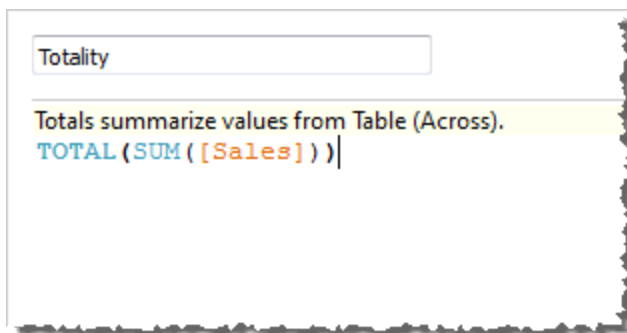

You open the calculation editor and create a new field which you name **Totality**:

You then drop **Totality** on Text, to replace **SUM(Sales)**. Your view changes such that it sums values based on the default **Compute Using** value:

| | | Region | | | |
|---------------|------------------|---------|---------|---------|---------|
| Year of Order | Quarter of Order | Central | East | South | West |
| 2011 | Q1 | 74,448 | 74,448 | 74,448 | 74,448 |
| | Q2 | 86,539 | 86,539 | 86,539 | 86,539 |
| | Q3 | 143,633 | 143,633 | 143,633 | 143,633 |
| | Q4 | 179,628 | 179,628 | 179,628 | 179,628 |
| 2012 | Q1 | 68,852 | 68,852 | 68,852 | 68,852 |
| | Q2 | 89,124 | 89,124 | 89,124 | 89,124 |
| | Q3 | 130,260 | 130,260 | 130,260 | 130,260 |
| | Q4 | 182,297 | 182,297 | 182,297 | 182,297 |

| | Q4 | 235,893 | 235,893 | 235,893 | 235,893 |
| 2014 | Q1 | 118,896 | 118,896 | 118,896 | 118,896 |
| | Q2 | 134,023 | 134,023 | 134,023 | 134,023 |
| | Q3 | 200,433 | 200,433 | 200,433 | 200,433 |
| | Q4 | 280,595 | 280,595 | 280,595 | 280,595 |

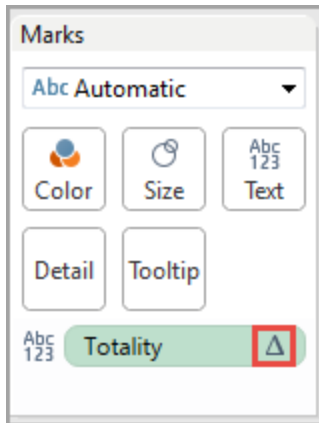

This raises the question, What is the default **Compute Using** value? If you right-click (Control-click on a Mac) **Totality** in the Data pane and choose **Edit**, there is now an additional bit of information available:

The default **Compute Using** value is **Table (Across)**. The result is that **Totality** is summing the values across each row of your table. Thus, the value that you see across each row is the sum of the values from the original version of the table.

The values in the 2011/Q1 row in the original table were \$8601, \$6579, \$44262 and \$15006. The values in the table after **Totality** replaces **SUM(Sales)** are all \$74,448, which is the sum of the four original values.

Notice the triangle next to **Totality** after you drop it on Text:

This indicates that this field is using a table calculation. You can right-click the field and choose **Edit Table Calculation** to redirect your function to a different **Compute Using** value. For example, you could set it to **Table (Down)**. In that case, your table would look like this:

A screenshot of a Tableau worksheet. The Columns shelf contains 'Region' and the Rows shelf contains 'YEAR(Order Date)' and 'QUARTER(Order Date)'. The Marks card shows 'Automatic' with 'Totality' on the shelf. The resulting table is as follows:

| | | Region | | | |
|----------------|----------------|---------|---------|---------|---------|
| Year of Orde.. | Quarter of O.. | Central | East | South | West |
| 2011 | Q1 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q2 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q3 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q4 | 501,240 | 678,781 | 391,722 | 725,458 |
| 2012 | Q1 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q2 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q3 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q4 | 501,240 | 678,781 | 391,722 | 725,458 |
| 2013 | Q1 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q2 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q3 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q4 | 501,240 | 678,781 | 391,722 | 725,458 |
| 2014 | Q1 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q2 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q3 | 501,240 | 678,781 | 391,722 | 725,458 |
| | Q4 | 501,240 | 678,781 | 391,722 | 725,458 |

WINDOW_CORR(expression1, expression2, [start, end])

Returns the Pearson correlation coefficient of two expressions within the window. The window is defined as offsets from the current row. Use FIRST()+n and LAST()-n for offsets from the first or last row in the partition. If start and end are omitted, the entire partition is used.

The Pearson correlation measures the linear relationship between two variables. Results range from -1 to +1 inclusive, where 1 denotes an exact positive linear relationship, as when a positive

change in one variable implies a positive change of corresponding magnitude in the other, 0 denotes no linear relationship between the variance and - is an exact negative relationship.

There is an equivalent aggregation function: CORR. See [Tableau Functions \(Alphabetical\)](#) on page 2291.

Example

The following formula returns the Pearson correlation of **SUM(Profit)** and **SUM(Sales)** from the five previous rows to the current row.

```
WINDOW_CORR(SUM([Profit]), SUM([Sales]), -5, 0)
```

WINDOW_COUNT(expression, [start, end])

Returns the count of the expression within the window. The window is defined by means of offsets from the current row. Use FIRST()+n and LAST()-n for offsets from the first or last row in the partition. If the start and end are omitted, the entire partition is used.

Example

WINDOW_COUNT(SUM([Profit]), FIRST()+1, 0) computes the count of SUM(Profit) from the second row to the current row

WINDOW_COVAR(expression1, expression2, [start, end])

Returns the *sample covariance* of two expressions within the window. The window is defined as offsets from the current row. Use FIRST()+n and LAST()-n for offsets from the first or last row in the partition. If the start and end arguments are omitted, the window is the entire partition.

Sample covariance uses the number of non-null data points $n - 1$ to normalise the covariance calculation, rather than n , which is used by the population covariance (with the WINDOW_COVARP function). Sample covariance is the appropriate choice when the data is a random sample that is being used to estimate the covariance for a larger population.

There is an equivalent aggregation function: COVAR. See [Tableau Functions \(Alphabetical\)](#) on page 2291.

Example

The following formula returns the sample covariance of **SUM(Profit)** and **SUM(Sales)** from the two previous rows to the current row.

```
WINDOW_COVAR(SUM([Profit]), SUM([Sales]), -2, 0)
```

WINDOW_COVARP(expression1, expression2, [start, end])

Returns the *population covariance* of two expressions within the window. The window is defined as offsets from the current row. Use FIRST()+n and LAST()-n for offsets from the first or last row in the partition. If start and end are omitted, the entire partition is used.

Population covariance is sample covariance multiplied by $(n-1)/n$, where n is the total number of non-null data points. Population covariance is the appropriate choice when there is data available for all items of interest as opposed to when there is only a random subset of items, in which case sample covariance (with the WINDOW_COVAR function) is appropriate.

There is an equivalent aggregation function: COVARP. [Tableau Functions \(Alphabetical\) on page 2291](#).

Example

The following formula returns the population covariance of **SUM(Profit)** and **SUM(Sales)** from the two previous rows to the current row.

```
WINDOW_COVARP(SUM([Profit]), SUM([Sales]), -2, 0)
```

WINDOW_MEDIAN(expression, [start, end])

Returns the median of the expression within the window. The window is defined by means of offsets from the current row. Use FIRST()+n and LAST()-n for offsets from the first or last row in the partition. If the start and end are omitted, the entire partition is used.

For example, the view below shows quarterly profit. A window median within the Date partition returns the median profit across all dates.

WINDOW_MEDIAN(SUM([Profit]), FIRST(), LAST())

| Year of Order Date | Quarter of Order Date | Central | East | South | West |
|--------------------|-----------------------|----------|----------|----------|----------|
| 2011 | Q1 | \$8,921 | \$20,575 | \$29,654 | \$22,647 |
| | Q2 | \$22,009 | \$11,477 | \$14,893 | \$30,791 |
| | Q3 | \$37,861 | \$258 | \$31,257 | \$25,006 |
| | Q4 | \$57,840 | \$13,313 | \$23,784 | \$31,171 |

Example

WINDOW_MEDIAN(SUM([Profit]), FIRST()+1, 0) computes the median of SUM(Profit) from the second row to the current row.

WINDOW_MAX(expression, [start, end])

Returns the maximum of the expression within the window. The window is defined by means of offsets from the current row. Use FIRST()+n and LAST()-n for offsets from the first or last row in the partition. If the start and end are omitted, the entire partition is used.

For example, the view below shows quarterly sales. A window maximum within the Date partition returns the maximum sales across all dates.

WINDOW_MAX(SUM([Sales]), FIRST(), LAST())

FIRST ()

LAST ()

MAX = \$302,678

| Year of Order Date | Quarter of Order Date | Central | East | South | West |

| | Q3 | 302,678 | 231,411 | 337,813 | 251,145 |

Example

`WINDOW_MAX(SUM([Profit]), FIRST()+1, 0)` computes the maximum of SUM(Profit) from the second row to the current row.

WINDOW_MIN(expression, [start, end])

Returns the minimum of the expression within the window. The window is defined by means of offsets from the current row. Use `FIRST()+n` and `LAST()-n` for offsets from the first or last row in the partition. If the start and end are omitted, the entire partition is used.

For example, the view below shows quarterly sales. A window minimum within the Date partition returns the minimum sales across all dates.

WINDOW_MIN(SUM([Sales]), FIRST(), LAST())

| | Q3 | 116,613 | 50,363 | 133,934 | 102,731 |

Example

`WINDOW_MIN(SUM([Profit]), FIRST()+1, 0)` computes the minimum of `SUM(Profit)` from the second row to the current row.

WINDOW_PERCENTILE(expression, number, [start, end])

Returns the value corresponding to the specified percentile within the window. The window is defined by means of offsets from the current row. Use `FIRST()+n` and `LAST()-n` for offsets from the first or last row in the partition. If the start and end are omitted, the entire partition is used.

Example

`WINDOW_PERCENTILE(SUM([Profit]), 0.75, -2, 0)` returns the 75th percentile for `SUM(Profit)` from the two previous rows to the current row.

WINDOW_STDEV(expression, [start, end])

Returns the sample standard deviation of the expression within the window. The window is defined by means of offsets from the current row. Use `FIRST()+n` and `LAST()-n` for offsets from the first or last row in the partition. If the start and end are omitted, the entire partition is used.

Example

`WINDOW_STDEV(SUM([Profit]), FIRST()+1, 0)` computes the standard deviation of `SUM(Profit)` from the second row to the current row.

WINDOW_STDEVP(expression, [start, end])

Returns the biased standard deviation of the expression within the window. The window is defined by means of offsets from the current row. Use `FIRST()+n` and `LAST()-n` for offsets from the first or last row in the partition. If the start and end are omitted, the entire partition is used.

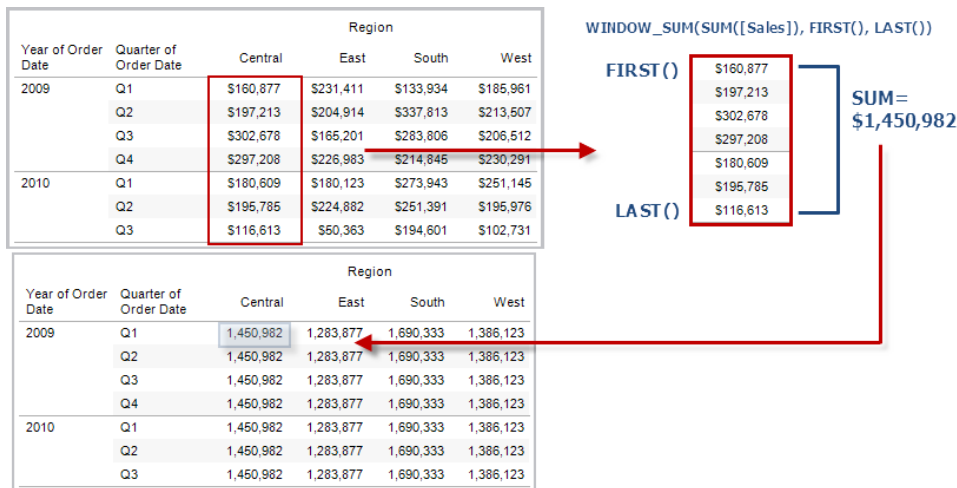

Example

`WINDOW_STDEVP(SUM([Profit]), FIRST()+1, 0)` computes the standard deviation of `SUM(Profit)` from the second row to the current row.

WINDOW_SUM(expression, [start, end])

Returns the sum of the expression within the window. The window is defined by means of offsets from the current row. Use `FIRST()+n` and `LAST()-n` for offsets from the first or last row in the partition. If the start and end are omitted, the entire partition is used.

For example, the view below shows quarterly sales. A window sum computed within the Date partition returns the summation of sales across all quarters.

Example

`WINDOW_SUM(SUM([Profit]), FIRST()+1, 0)` computes the sum of `SUM(Profit)` from the second row to the current row.

WINDOW_VAR(expression, [start, end])

Returns the sample variance of the expression within the window. The window is defined by means of offsets from the current row. Use `FIRST()+n` and `LAST()-n` for offsets from the first or last row in the partition. If the start and end are omitted, the entire partition is used.

Example

`WINDOW_VAR((SUM([Profit])), FIRST()+1, 0)` computes the variance of `SUM(Profit)` from the second row to the current row.

WINDOW_VARP(expression, [start, end])

Returns the biased variance of the expression within the window. The window is defined by means of offsets from the current row. Use `FIRST()+n` and `LAST()-n` for offsets from the first or last row in the partition. If the start and end are omitted, the entire partition is used.

Example

`WINDOW_VARP(SUM([Profit]), FIRST()+1, 0)` computes the variance of `SUM(Profit)` from the second row to the current row.

Pass-Through functions (RAWSQL)

These RAWSQL pass-through functions can be used to send SQL expressions directly to the database, without first being interpreted by Tableau. If you have custom database functions that Tableau doesn't know about, you can use these pass-through functions to call these custom functions.

Your database usually will not understand the field names that are shown in Tableau. Because Tableau does not interpret the SQL expressions you include in the pass-through functions, using the Tableau field names in your expression may cause errors. You can use a substitution

syntax to insert the correct field name or expression for a Tableau calculation into pass-through SQL. For example, if you had a function that computed the median of a set of values, you could call that function on the Tableau column [Sales] like this:

```
RAWSQLAGG_REAL("MEDIAN(%1)", [Sales])
```

Because Tableau does not interpret the expression, you must define the aggregation. You can use the RAWSQLAGG functions described below when you are using aggregated expressions.

RAWSQL pass-through functions may not work with extracts or published data sources if they contain relationships.

RAWSQL Functions

The following RAWSQL functions are available in Tableau.

RAWSQL_BOOL("sql_expr", [arg1], ...[argN])

Returns a Boolean result from a given SQL expression. The SQL expression is passed directly to the underlying database. Use %n in the SQL expression as a substitution syntax for database values.

Example

In the example, %1 is equal to [Sales] and %2 is equal to [Profit].

```
RAWSQL_BOOL("IIF( %1 > %2, True, False)", [Sales], [Profit])
```

RAWSQL_DATE("sql_expr", [arg1], ...[argN])

Returns a Date result from a given SQL expression. The SQL expression is passed directly to the underlying database. Use %n in the SQL expression as a substitution syntax for database values.

Example

In this example, %1 is equal to [Order Date].

```
RAWSQL_DATE("`%1", [Order Date])
```

RAWSQL_DATETIME("sql_expr", [arg1], ...[argN])

Returns a Date and Time result from a given SQL expression. The SQL expression is passed directly to the underlying database. Use %n in the SQL expression as a substitution syntax for database values. In this example, %1 is equal to [Delivery Date].

Example

```
RAWSQL_DATETIME("MIN(%1)", [Delivery Date])
```

RAWSQL_INT("sql_expr", [arg1], ...[argN])

Returns an integer result from a given SQL expression. The SQL expression is passed directly to the underlying database. Use %n in the SQL expression as a substitution syntax for database values. In this example, %1 is equal to [Sales].

Example

```
RAWSQL_INT("500 + %1", [Sales])
```

RAWSQL_REAL("sql_expr", [arg1], ...[argN])

Returns a numeric result from a given SQL expression that is passed directly to the underlying database. Use %n in the SQL expression as a substitution syntax for database values. In this example, %1 is equal to [Sales]

Example

```
RAWSQL_REAL("-123.98 * %1", [Sales])
```

RAWSQL_SPATIAL

Returns a Spatial from a given SQL expression that is passed directly to the underlying data source. Use %n in the SQL expression as a substitution syntax for database values.

Example

In this example, %1 is equal to [Geometry].

```
RAWSQL_SPATIAL("%1", [Geometry])
```

RAWSQL_STR("sql_expr", [arg1], ...[argN])

Returns a string from a given SQL expression that is passed directly to the underlying database. Use %n in the SQL expression as a substitution syntax for database values. In this example, %1 is equal to [Customer Name].

Example

```
RAWSQL_STR("%1", [Customer Name])
```

RAWSQLAGG_BOOL("sql_expr", [arg1], ...[argN])

Returns a Boolean result from a given aggregate SQL expression. The SQL expression is passed directly to the underlying database. Use %n in the SQL expression as a substitution syntax for database values.

Example

In the example, %1 is equal to [Sales] and %2 is equal to [Profit].

```
RAWSQLAGG_BOOL("SUM( %1 ) > SUM( %2 )", [Sales], [Profit])
```

RAWSQLAGG_DATE("sql_expr", [arg1], ...[argN])

Returns a Date result from a given aggregate SQL expression. The SQL expression is passed directly to the underlying database. Use %n in the SQL expression as a substitution syntax for database values. In this example, %1 is equal to [Order Date].

Example

```
RAWSQLAGG_DATE("MAX(%1)", [Order Date])
```

RAWSQLAGG_DATETIME("sql_expr", [arg1], ...[argN])

Returns a Date and Time result from a given aggregate SQL expression. The SQL expression is passed directly to the underlying database. Use %n in the SQL expression as a substitution syntax for database values. In this example, %1 is equal to [Delivery Date].

Example

```
RAWSQLAGG_DATETIME("MIN(%1)", [Delivery Date])
```

RAWSQLAGG_INT("sql_expr", [arg1,] ...[argN])

Returns an integer result from a given aggregate SQL expression. The SQL expression is passed directly to the underlying database. Use %n in the SQL expression as a substitution syntax for database values. In this example, %1 is equal to [Sales].

Example

```
RAWSQLAGG_INT("500 + SUM(%1)", [Sales])
```

RAWSQLAGG_REAL("sql_expr", [arg1,] ...[argN])

Returns a numeric result from a given aggregate SQL expression that is passed directly to the underlying database. Use %n in the SQL expression as a substitution syntax for database values. In this example, %1 is equal to [Sales]

Example

```
RAWSQLAGG_REAL("SUM( %1)", [Sales])
```

RAWSQLAGG_STR("sql_expr", [arg1,] ...[argN])

Returns a string from a given aggregate SQL expression that is passed directly to the underlying database. Use %n in the SQL expression as a substitution syntax for database values. In this example, %1 is equal to [Discount].

Example

```
RAWSQLAGG_STR("AVG(%1)", [Discount])
```

Spatial functions

Spatial functions allow you to perform advanced spatial analysis and combine spatial files with data in other formats like text files or spreadsheets.

AREA

| | |
|------------|---|
| Syntax | <code>AREA(Spatial Polygon, 'units')</code> |
| Output | Number |
| Definition | Returns the total surface area of a <spatial polygon>. |
| Example | <code>AREA([Geometry], 'feet')</code> |
| Notes | Supported unit names (must be in quotation marks in the calculation, such as 'miles'): |
| | <ul style="list-style-type: none"> • <i>metres</i>: meters, metres, m • <i>kilometres</i>: kilometers, kilometres, km • <i>miles</i>: miles, mi • <i>feet</i>: feet, ft |

BUFFER

| | |
|--------|---|
| Syntax | <code>BUFFER(Spatial Point, distance, 'units')</code> <code>BUFFER(Linestring, distance, 'units')</code> |
| | <ul style="list-style-type: none"> • <i>metres</i>: meters, metres, m • <i>kilometres</i>: kilometers, kilometres, km • <i>miles</i>: miles, mi • <i>feet</i>: feet, ft |
| Output | Geometry |

Definition For spatial points, returns a polygon shape centred over a <spatial point>, with a radius determined by the <distance> and <unit> values.

For linestrings, computes the polygons formed by including all points within the radius distance from the linestring.

Example

```

BUFFER([Spatial Point Geometry], 25, 'mi')

BUFFER(MAKEPOINT(47.59, -122.32), 3, 'km')

BUFFER(MAKELINE(MAKEPOINT(0, 20), MAKEPOINT(30, 30)), 20, 'km')

```

Notes Supported unit names (must be in quotation marks in the calculation, such as 'miles'):

- *metres*: meters, metres, m
- *kilometres*: kilometers, kilometres, km
- *miles*: miles, mi
- *feet*: feet, ft

DIFFERENCE

Syntax `DIFFERENCE(Spatial, Spatial)`

Output Spatial Polygon

Definition Computes the portions of regions remaining when all regions in the second argument are carved out of the first argument in areas that overlap. Discards regions from the second argument in areas that don't overlap.

Example `DIFFERENCE(Spatial Polygon1, Spatial Polygon2)`

Notes Supports spatial polygons and multipolygons, not spatial points or lines.

DISTANCE

Syntax `DISTANCE(SpatialPoint1, SpatialPoint2, 'units')`

Output Number

| | |
|----------------------|--|
| Definition | Returns the distance measurement between two points in the specified <unit>. |
| Example | <code>DISTANCE([Origin Point],[Destination Point], 'km')</code> |
| Notes | Supported unit names (must be in quotation marks in the calculation, such as 'miles'): <ul style="list-style-type: none"> • <i>metres</i>: meters, metres, m • <i>kilometres</i>: kilometers, kilometres, km • <i>miles</i>: miles, mi • <i>feet</i>: feet, ft |
| Database limitations | This function can only be created with a live connection but will continue to work if the data source is converted to an extract. |

INTERSECTION

| | |
|------------|---|
| Syntax | <code>INTERSECTION (spatial, spatial)</code> |
| Output | Polygon |
| Definition | Computes and returns the portions of regions in the second argument that overlap regions in the first argument. |
| Example | <code>INTERSECTION (Spatial Polygon1, Spatial Polygon2)</code> |
| Notes | Supports spatial polygons and multipolygons, not spatial points or lines. |

INTERSECTS

| | |
|------------|---|
| Syntax | <code>INTERSECTS (geometry1, geometry2)</code> |
| Output | Boolean |
| Definition | Returns true or false indicating whether two geometries overlap in space. |
| Notes | Supported combinations: point/polygon, line/polygon and polygon/polygon. |

MAKELINE

| | |
|------------|---|
| Syntax | <code>MAKELINE(SpatialPoint1, SpatialPoint2)</code> |
| Output | Geometry (line) |
| Definition | Generates a line mark between two points |
| Example | <code>MAKELINE(MAKEPOINT(47.59, -122.32), MAKEPOINT(48.5, -123.1))</code> |
| Notes | Useful for building origin-destination maps. |

MAKEPOINT

| | |
|------------|---|
| Syntax | <code>MAKEPOINT(latitude, longitude, [SRID])</code> |
| Output | Geometry (point) |
| Definition | <p>Converts data from <code><latitude></code> and <code><longitude></code> columns into spatial objects.</p> <p>If the optional <code><SRID></code> argument is added, the inputs can be other projected geographic coordinates.</p> |
| Example | <pre>MAKEPOINT(48.5, -123.1) MAKEPOINT([AirportLatitude], [AirportLongitude]) MAKEPOINT([Xcoord], [Ycoord], 3493)</pre> |
| Notes | <p><code>MAKEPOINT</code> can't use the automatically generated latitude and longitude fields. The data source must contain the coordinates natively.</p> <p><code>SRID</code> is a spatial reference identifier that uses ESPG reference system codes to specify coordinate systems. If <code>SRID</code> is not specified, WGS84 is assumed and parameters are treated as latitude/longitude in degrees.</p> <p>You can use <code>MAKEPOINT</code> to spatially enable a data source so that it can be joined with a spatial file using a spatial join. For more information, see Join Spatial Files in Tableau on page 1692.</p> |

LENGTH

| | |
|------------|--|
| Syntax | <code>LENGTH(geometry, 'units')</code> |
| Output | Number |
| Definition | Returns the geodetic path length of the line string or strings in the <code><geometry></code> using the given <code><units></code> . |
| Example | <code>LENGTH([Spatial], 'metres')</code> |
| Notes | The result is <code><NaN></code> if the geometry argument has no linestrings, though other elements are permitted. |

OUTLINE

| | |
|------------|--|
| Syntax | <code>OUTLINE(spatial polygon)</code> |
| Output | Geometry |
| Definition | Converts a polygon geometry into linestrings. |
| Notes | Useful for creating a separate layer for an outline that can be styled differently than the fill. Supports polygons within multipolygons. |

SHAPETYPE

| | |
|------------|---|
| Syntax | <code>SHAPETYPE(geometry)</code> |
| Output | String |
| Definition | Returns a string describing the structure of the spatial <code><geometry></code> , such as Empty, Point, MultiPoint, LineString, MultiLinestring, Polygon, MultiPolygon, Mixed and unsupported. |
| Example | <code>SHAPETYPE(MAKEPOINT(48.5, -123.1)) = "Point"</code> |

SYMDIFFERENCE

| | |
|------------|---|
| Syntax | <code>SYMDIFFERENCE(spatial, spatial)</code> |
| Output | Geometry |
| Definition | Computes any portions of regions from the second argument that overlap regions in the first argument and discards from both. Returns the remaining portions of regions from both arguments. |
| Example | <code>SYMDIFFERENCE(Spatial Polygon1, Spatial Polygon2)</code> |

VALIDATE

| | |
|------------|---|
| Syntax | <code>VALIDATE(spatial geometry)</code> |
| Output | Geometry |
| Definition | Confirms topological correctness of the geometry in your spatial value. If the value cannot be used for analysis due to problems such as a polygon's perimeter intersecting itself, then the result will be a null. If the geometry is correct, the result will be the original geometry. |
| Example | <code>UNION(VALIDATE([Geometry]))</code> |

Additional functions

For more information, see [Pass-Through Functions \(RAWSQL\)](#).

- [Regular Expressions](#) below
- [Hadoop Hive Specific Functions](#) on page 2286
- [Google BigQuery Specific Functions](#) on page 2289

Regular Expressions

`REGEXP_REPLACE(string, pattern, replacement)`

Returns a copy of the given string where the regular expression pattern is replaced by the replacement string. This function is available for Text File, Hadoop Hive, Google BigQuery, PostgreSQL, Tableau Data Extract, Microsoft Excel, Salesforce, Vertica, Pivotal Greenplum, Teradata (version 14.1 and above), Snowflake and Oracle data sources.

For Tableau data extracts, the pattern and the replacement must be constants.

For information on regular expression syntax, see your data source's documentation. For Tableau extracts, regular expression syntax conforms to the standards of the ICU (International Components for Unicode), an open source project of mature C/C++ and Java libraries for Unicode support, software internationalisation and software globalisation. See the [Regular Expressions](#) page in the online ICU User Guide.

Example

```
REGEXP_REPLACE('abc 123', 's', '-') = 'abc-123'
```

REGEXP_MATCH(string, pattern)

Returns true if a substring of the specified string matches the regular expression pattern. This function is available for Text File, Google BigQuery, PostgreSQL, Tableau Data Extract, Microsoft Excel, Salesforce, Vertica, Pivotal Greenplum, Teradata (version 14.1 and above), Impala 2.3.0 (through Cloudera Hadoop data sources), Snowflake and Oracle data sources.

For Tableau data extracts, the pattern must be a constant.

For information on regular expression syntax, see your data source's documentation. For Tableau extracts, regular expression syntax conforms to the standards of the ICU (International Components for Unicode), an open source project of mature C/C++ and Java libraries for Unicode support, software internationalisation and software globalisation. See the [Regular Expressions](#) page in the online ICU User Guide.

Example

```
REGEXP_MATCH('-[1234].[The.Market]','-','[s*(\w*\.)](\w*s*)')=true
```

REGEXP_EXTRACT(string, pattern)

Returns the portion of the string that matches the regular expression pattern. This function is available for Text File, Hadoop Hive, Google BigQuery, PostgreSQL, Tableau Data Extract, Microsoft Excel, Salesforce, Vertica, Pivotal Greenplum, Teradata (version 14.1 and above), Snowflake and Oracle data sources.

For Tableau data extracts, the pattern must be a constant.

For information on regular expression syntax, see your data source's documentation. For Tableau extracts, regular expression syntax conforms to the standards of the ICU (International Components for Unicode), an open source project of mature C/C++ and Java libraries for Unicode support, software internationalisation and software globalisation. See the [Regular Expressions](#) page in the online ICU User Guide.

Example

```
REGEXP_EXTRACT('abc 123', '[a-z]+\s+(\d+)') = '123'
```

REGEXP_EXTRACT_NTH(string, pattern, index)

Returns the portion of the string that matches the regular expression pattern. The substring is matched to the nth capturing group, where n is the given index. If index is 0, the entire string is returned. This function is available for Text File, PostgreSQL, Tableau Data Extract, Microsoft Excel, Salesforce, Vertica, Pivotal Greenplum, Teradata (version 14.1 and above) and Oracle data sources.

For Tableau data extracts, the pattern must be a constant.

For information on regular expression syntax, see your data source's documentation. For Tableau extracts, regular expression syntax conforms to the standards of the ICU (International Components for Unicode), an open source project of mature C/C++ and Java libraries for Unicode support, software internationalisation and software globalisation. See the [Regular Expressions](#) page in the online ICU User Guide.

Example

```
REGEXP_EXTRACT_NTH('abc 123', '([a-z+)\s+(\d+)', 2) = '123'
```

Hadoop Hive Specific Functions

Note: Only the PARSE_URL and PARSE_URL_QUERY functions are available for Cloudera Impala data sources.

GET_JSON_OBJECT(JSON string, JSON path)

Returns the JSON object within the JSON string based on the JSON path.

PARSE_URL(string, url_part)

Returns a component of the given URL string where the component is defined by url_part. Valid url_part values include: 'HOST', 'PATH', 'QUERY', 'REF', 'PROTOCOL', 'AUTHORITY', 'FILE' and 'USERINFO'.

Example

```
PARSE_URL('http://www.tableau.com', 'HOST') = 'www.tableau.com'
```

PARSE_URL_QUERY(string, key)

Returns the value of the specified query parameter in the given URL string. The query parameter is defined by the key.

Example

```
PARSE_URL_QUERY('http://www.tableau.com?page=1&cat=4', 'page') = '1'
```

XPATH_BOOLEAN(XML string, XPath expression string)

Returns true if the XPath expression matches a node or evaluates to true.

Example

```
XPATH_BOOLEAN('<values> <value id="0">1</value><value id="1">5</value>', 'values/value [@id="1"] = 5') = true
```

XPATH_DOUBLE(XML string, XPath expression string)

Returns the floating-point value of the XPath expression.

Example

```
XPATH_DOUBLE('<values><value>1.0</value><value>5.5</value> </values>', 'sum(value/*)')  
= 6.5
```

XPATH_FLOAT(XML string, XPath expression string)

Returns the floating-point value of the XPath expression.

Example

```
XPATH_FLOAT('<values><value>1.0</value><value>5.5</value> </values>', 'sum(value/*)') = 6.5
```

XPATH_INT(XML string, XPath expression string)

Returns the numerical value of the XPath expression, or zero if the XPath expression cannot evaluate to a number.

Example

```
XPATH_INT('<values><value>1</value><value>5</value> </values>', 'sum(value/*)') = 6
```

XPATH_LONG(XML string, XPath expression string)

Returns the numerical value of the XPath expression, or zero if the XPath expression cannot evaluate to a number.

Example

```
XPATH_LONG('<values><value>1</value><value>5</value> </values>', 'sum(value/*)') = 6
```

XPATH_SHORT(XML string, XPath expression string)

Returns the numerical value of the XPath expression, or zero if the XPath expression cannot evaluate to a number.

Example

```
XPATH_SHORT('<values><value>1</value><value>5</value> </values>', 'sum(value/*)') = 6
```

XPATH_STRING(XML string, XPath expression string)

Returns the text of the first matching node.

Example

```
XPATH_STRING('<sites ><url domain="org">http://www.w3.org</url> <url domain="com">http://www.tableau.com</url></sites>', 'sites/url[@domain="com"]') = 'http://www.tableau.com'
```

Google BigQuery Specific Functions

DOMAIN(string_url)

Given a URL string, returns the domain as a string.

Example

```
DOMAIN('http://www.google.com:80/index.html') = 'google.com'
```

GROUP_CONCAT(expression)

Concatenates values from each record into a single comma-delimited string. This function acts like a SUM() for strings.

Example

```
GROUP_CONCAT(Region) = "Central,East,West"
```

HOST(string_url)

Given a URL string, returns the host name as a string.

Example

```
HOST('http://www.google.com:80/index.html') = 'www.google.com:80'
```

LOG2(number)

Returns the logarithm base 2 of a number.

Example

```
LOG2(16) = '4.00'
```

LTRIM_THIS(string, string)

Returns the first string with any leading occurrence of the second string removed.

Example

```
LTRIM_THIS('[-Sales-]',['-']) = 'Sales-'
```

RTRIM_THIS(string, string)

Returns the first string with any trailing occurrence of the second string removed.

Example

```
RTRIM_THIS('[-Market-]', '-') = '[-Market'
```

TIMESTAMP_TO_USEC(expression)

Converts a TIMESTAMP data type to a UNIX timestamp in microseconds.

Example

```
TIMESTAMP_TO_USEC(#2012-10-01 01:02:03#)=1349053323000000
```

USEC_TO_TIMESTAMP(expression)

Converts a UNIX timestamp in microseconds to a TIMESTAMP data type.

Example

```
USEC_TO_TIMESTAMP(1349053323000000) = #2012-10-01 01:02:03#
```

TLD(string_url)

Given a URL string, returns the top level domain plus any country/region domain in the URL.

Example

```
TLD('http://www.google.com:80/index.html') = '.com'
```

```
TLD('http://www.google.co.uk:80/index.html') = '.co.uk'
```

Tableau Functions (Alphabetical)

The Tableau functions in this reference are organised alphabetically. Click a letter to jump to that location in the list. You can also use Ctrl+F (Command-F on a Mac) to open a search box to look for a specific function.

A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

A

ABS

| | |
|------------|--|
| Syntax | <code>ABS (number)</code> |
| Output | Number (positive) |
| Definition | Returns the absolute value of the given <code><number></code> . |
| Example | $\text{ABS}(-7) = 7$ $\text{ABS}([\text{Budget Variance}])$ <p>The second example returns the absolute value for all the numbers contained in the Budget Variance field.</p> |
| Notes | See also SIGN on page 2342. |

ACOS

| | |
|------------|--|
| Syntax | <code>ACOS (number)</code> |
| Output | Number (angle in radians) |
| Definition | Returns the arccosine (angle) of the given <code><number></code> . |
| Example | $\text{ACOS}(-1) = 3.14159265358979$ |
| Notes | The inverse function, COS on page 2299, takes the angle in radians as the argument and returns the cosine. |

AND

| | |
|------------|--|
| Syntax | <code><expr1> AND <expr2></code> |
| Definition | Performs a logical conjunction on two expressions. (If both sides are true, the logical test returns true.) |
| Output | Boolean |
| Example | <pre>IF [Season] = "Spring" AND "[Season] = "Fall" THEN "It's the apocalypse and footwear doesn't matter" END</pre> <p><i>"If both (Season = Spring) and (Season = Fall) are true simultaneously, then return It's the apocalypse and footwear doesn't matter."</i></p> |
| Notes | <p>Often used with IF on page 2316 and IIF on page 2317. See also NOT on page 2333 and OR on page 2334.</p> <p>If both expressions are <code>TRUE</code> (that is, not <code>FALSE</code> or <code>NULL</code>), then the result is <code>TRUE</code>. If either expression is <code>NULL</code>, then the result is <code>NULL</code>. In all other cases, the result is <code>FALSE</code>.</p> <p>If you create a calculation in which the result of an <code>AND</code> comparison is displayed on a worksheet, Tableau displays <code>TRUE</code> and <code>FALSE</code>. If you would like to change this, use the Format area in the format dialog.</p> |

Note: The `AND` operator employs *short circuit evaluation*. This means that if the first expression is evaluated to be `FALSE`, then the second expression is not evaluated at all. This can be helpful if the second expression results in an error when the first expression is `FALSE`, because the second expression in this case is never evaluated.

AREA

| | |
|--------|---|
| Syntax | <code>AREA(Spatial Polygon, 'units')</code> |
| Output | Number |

| | |
|------------|---|
| Definition | Returns the total surface area of a <code><spatial polygon></code> . |
| Example | <code>AREA([Geometry], 'feet')</code> |
| Notes | Supported unit names (must be in quotation marks in the calculation, such as <code>'miles'</code>): <ul style="list-style-type: none">• <i>metres</i>: meters, metres, m• <i>kilometres</i>: kilometers, kilometres, km• <i>miles</i>: miles, mi• <i>feet</i>: feet, ft |

ASCII

| | |
|------------|---|
| Syntax | <code>ASCII(string)</code> |
| Output | Number |
| Definition | Returns the ASCII code for the first character of a <code><string></code> . |
| Example | <code>ASCII('A') = 65</code> |
| Notes | This is the inverse of the <code>CHAR</code> function. |

ASIN

| | |
|------------|--|
| Syntax | <code>ASIN(number)</code> |
| Output | Number (angle in radians) |
| Definition | Returns the arcsine (angle) of a given <code><number></code> . |
| Example | <code>ASIN(1) = 1.5707963267949</code> |
| Notes | The inverse function, SIN on page 2343, takes the angle in radians as the argument and returns the sine. |

ATAN

| | |
|------------|--|
| Syntax | <code>ATAN (number)</code> |
| Output | Number (angle in radians) |
| Definition | Returns the arctangent (angle) of a given <number>. |
| Example | <code>ATAN(180) = 1.5652408283942</code> |
| Notes | <p>The inverse function, TAN, takes the angle in radians as the argument and returns the tangent.</p> <p>See also ATAN2 below and COT on page 2299.</p> |

ATAN2

| | |
|------------|---|
| Syntax | <code>ATAN2 (y number, x number)</code> |
| Output | Number (angle in radians) |
| Definition | Returns the arctangent (angle) between two numbers (<y number> and <x number>). The result is in radians. |
| Example | <code>ATAN2(2, 1) = 1.10714871779409</code> |
| Notes | See also ATAN above, TAN on page 2346 and COT on page 2299. |

ATTR

| | |
|------------|--|
| Syntax | <code>ATTR (expression)</code> |
| Definition | Returns the value of the <expression> if it has a single value for all rows. Otherwise returns an asterisk. Null values are ignored. |

AVG

| | |
|--------|-------------------------------|
| Syntax | <code>AVG (expression)</code> |
|--------|-------------------------------|

Definition Returns the average of all the values in the <expression>. Null values are ignored.

Notes AVG can only be used with numeric fields.

[back to top](#)

B

BUFFER

Syntax `BUFFER(Spatial Point, distance, 'units')`

Output Geometry

Definition Returns a polygon shape centred over a <spatial point>, with a radius determined by the <distance> and <unit> values.

Example

```
BUFFER([Spatial Point Geometry], 25, 'mi')  
  
BUFFER(MAKEPOINT(47.59, -122.32), 3, 'km')
```

Notes Supported unit names (must be in quotation marks in the calculation, such as 'miles'):

- *metres*: meters, metres, m
- *kilometres*: kilometers, kilometres, km
- *miles*: miles, mi
- *feet*: feet, ft

[back to top](#)

C

CASE

Syntax

```
CASE <expression>  
WHEN <value1> THEN <then1>  
WHEN <value2> THEN <then2>  
...
```

```
[ELSE <default>]
END
```

| | |
|------------|--|
| Output | Depends on data type of the <then> values. |
| Definition | Evaluates the <code>expression</code> and compares it to the specified options (<value1>, <value2>, etc.). When a value that matches expression is encountered, CASE returns the corresponding <code>return</code> . If no match is found, the (optional) default is returned. If there is no default and no values match, then Null is returned. |
| Example | <pre>CASE [Season] WHEN 'Summer' THEN 'Sandals' WHEN 'Winter' THEN 'Boots' ELSE 'Sneakers' END</pre> <p><i>"Look at the Season field. If the value is Summer, then return Sandals. If the value is Winter, then return Boots. If none of the options in the calculation match what is in the Season field, return Sneakers."</i></p> |
| Notes | <p>See also IF on page 2316 and IIF on page 2317.</p> <p>Used with WHEN on page 2352, THEN on page 2347, ELSE on page 2308 and END on page 2310.</p> <p>Tip: Many times you can use a group to get the same results as a complicated CASE function, or use CASE to replace native grouping functionality, such as in the previous example. You may want to test which is more performant for your scenario.</p> |

CEILING

| | |
|------------|---|
| Syntax | <code>CEILING (number)</code> |
| Output | Integer |
| Definition | Rounds a <number> to the nearest integer of equal or greater value. |
| Example | <code>CEILING(2.1) = 3</code> |

| | |
|----------------------|--|
| Notes | See also FLOOR on page 2313 and ROUND on page 2340. |
| Database limitations | <code>CEILING</code> is available through the following connectors: Microsoft Excel, Text File, Statistical File, Published Data Source, Amazon EMR Hadoop Hive, Amazon Redshift, Cloudera Hadoop, DataStax Enterprise, Google Analytics, Google BigQuery, Hortonworks Hadoop Hive, MapR Hadoop Hive, Microsoft SQL Server, Salesforce, Spark SQL. |

CHAR

| | |
|------------|---|
| Syntax | <code>CHAR(number)</code> |
| Output | String |
| Definition | Returns the character encoded by the ASCII code <code><number></code> . |
| Example | <code>CHAR(65) = 'A'</code> |
| Notes | This is the inverse of the <code>ASCII</code> function. |

COLLECT

| | |
|------------|---|
| Syntax | <code>COLLECT(spatial)</code> |
| Definition | An aggregate calculation that combines the values in the argument field. Null values are ignored. |
| Notes | <code>COLLECT</code> can only be used with spatial fields. |

CONTAINS

| | |
|------------|---|
| Syntax | <code>CONTAINS(string, substring)</code> |
| Output | Boolean |
| Definition | Returns true if the given <code><string></code> contains the specified <code><substring></code> . |
| Example | <code>CONTAINS("Calculation", "alcu") = true</code> |

Notes See also the [logical function](#) `IN` as well as supported RegEx in the [additional functions documentation](#).

CORR

Syntax `CORR(expression1, expression2)`

Output Number from -1 to 1

Definition Returns the Pearson correlation coefficient of two expressions.

Example `example`

Notes The Pearson correlation measures the linear relationship between two variables. Results range from -1 to +1 inclusive, where 1 denotes an exact positive linear relationship, 0 denotes no linear relationship between the variance and -1 is an exact negative relationship.

The square of a CORR result is equivalent to the R-Squared value for a linear trend line model. See [Trend Line Model Terms](#).

Use with table-scoped LOD expressions:

You can use CORR to visualise correlation in a disaggregated scatter using a [table-scoped level of detail expression](#). For example:

```
{CORR(Sales, Profit)}
```

With a level of detail expression, the correlation is run over all rows. If you used a formula like `CORR(Sales, Profit)` (without the surrounding brackets to make it a level of detail expression), the view would show the correlation of each individual point in the scatter plot with each other point, which is undefined.

Database limitations `CORR` is available with the following data sources: Tableau data extracts, Cloudera Hive, EXASolution, Firebird (version 3.0 and later), Google BigQuery, Hortonworks Hadoop Hive, IBM PDA (Netezza), Oracle, PostgreSQL, Presto, SybaseIQ, Teradata, Vertica.

For other data sources, consider either extracting the data or using `WINDOW_CORR`. See [Table Calculation Functions](#).

COS

| | |
|------------|--|
| Syntax | <code>COS (number)</code> The number argument is the angle in radians. |
| Output | Number |
| Definition | Returns the cosine of an angle. |
| Example | <code>COS (PI () /4) = 0.707106781186548</code> |
| Notes | The inverse function, ACOS on page 2291, takes the cosine as the argument and returns the angle in radians. See also PI on page 2337. |

COT

| | |
|------------|---|
| Syntax | <code>COT (number)</code> The number argument is the angle in radians. |
| Output | Number |
| Definition | Returns the cotangent of an angle. |
| Example | <code>COT (PI () /4) = 1</code> |
| Notes | See also ATAN on page 2294, TAN on page 2346 and PI on page 2337. |

COUNT

| | |
|------------|---|
| Syntax | <code>COUNT (expression)</code> |
| Definition | Returns the number of items. Null values are not counted. |

COUNTD

| | |
|------------|---|
| Syntax | <code>COUNTD (expression)</code> |
| Definition | Returns the number of distinct items in a group. Null values are not counted. |

COVAR

| | |
|----------------------|--|
| Syntax | <code>COVAR (expression1, expression2)</code> |
| Definition | Returns the <i>sample</i> covariance of two expressions. |
| Notes | <p>Covariance quantifies how two variables change together. A positive covariance indicates that the variables tend to move in the same direction, as when larger values of one variable tend to correspond to larger values of the other variable, on average. <i>Sample covariance</i> uses the number of non-null data points $n-1$ to normalise the covariance calculation, rather than n, which is used by the population covariance (available with the <code>COVARP</code> function). Sample covariance is the appropriate choice when the data is a random sample that is being used to estimate the covariance for a larger population.</p> <p>If <code><expression1></code> and <code><expression2></code> are the same, for example <code>COVAR([profit], [profit])</code>, <code>COVAR</code> returns a value that indicates how widely values are distributed.</p> <p>The value of <code>COVAR (X, X)</code> is equivalent to the value of <code>VAR (X)</code> and also to the value of <code>STDEV (X) ^2</code>.</p> |
| Database limitations | <p><code>COVAR</code> is available with the following data sources: Tableau data extracts, Cloudera Hive, EXASolution, Firebird (version 3.0 and later), Google BigQuery, Hortonworks Hadoop Hive, IBM PDA (Netezza), Oracle, PostgreSQL, Presto, SybaseIQ, Teradata, Vertica.</p> <p>For other data sources, consider either extracting the data or using <code>WINDOW_COVAR</code>. See Table Calculation Functions.</p> |

COVARP

| | |
|----------------------|--|
| Syntax | <code>COVARP(expression 1, expression2)</code> |
| Definition | Returns the <i>population</i> covariance of two expressions. |
| Notes | <p>Covariance quantifies how two variables change together. A positive covariance indicates that the variables tend to move in the same direction, as when larger values of one variable tend to correspond to larger values of the other variable, on average. <i>Population covariance</i> is sample covariance multiplied by $(n-1)/n$, where n is the total number of non-null data points. Population covariance is the appropriate choice when there is data available for all items of interest as opposed to when there is only a random subset of items, in which case sample covariance (with the <code>COVAR</code> function) is appropriate.</p> <p>If <code><expression1></code> and <code><expression2></code> are the same, for example <code>COVARP([profit], [profit])</code>, <code>COVARP</code> returns a value that indicates how widely values are distributed. Note: The value of <code>COVARP(X, X)</code> is equivalent to the value of <code>VARP(X)</code> and also to the value of <code>STDEVP(X)^2</code>.</p> |
| Database limitations | <p><code>COVARP</code> is available with the following data sources: Tableau data extracts, Cloudera Hive, EXASolution, Firebird (version 3.0 and later), Google BigQuery, Hortonworks Hadoop Hive, IBM PDA (Nettezza), Oracle, PostgreSQL, Presto, SybaseIQ, Teradata, Vertica</p> <p>For other data sources, consider either extracting the data or using <code>WINDOW_COVAR</code>. See Table Calculation Functions.</p> |

[back to top](#)

D

DATE

Type conversion function that changes string and number expressions into dates, as long as they are in a recognisable format.

| | |
|--------|-------------------------------|
| Syntax | <code>DATE(expression)</code> |
|--------|-------------------------------|

| | |
|------------|---|
| Output | Date |
| Definition | Returns a date given a number, string or date <expression>. |
| Example | <pre>DATE([Employee Start Date]) DATE("September 22, 2018") DATE("9/22/2018") DATE(#2018-09-22 14:52#)</pre> |
| Notes | <p>Unlike DATEPARSE on page 2304, there is no need to provide a pattern as DATE automatically recognises many standard date formats. If DATE does not recognise the input, however, try using DATEPARSE and specifying the format.</p> <p>MAKEDATE on page 2326 is another similar function, but MAKEDATE requires the input of numeric values for year, month and day.</p> |

DATEADD

Adds a specified number of date parts (months, days, etc) to the starting date.

| | |
|------------|---|
| Syntax | <code>DATEADD(date_part, interval, date)</code> |
| Output | Date |
| Definition | Returns the specified date with the specified number <interval> added to the specified ><date_part of that date. For example, adding three months or 12 days to a starting date. |
| Example | <p>Push out all due dates by one week</p> <pre>DATEADD('week', 1, [due date])</pre> <p>Add 280 days to the date February 20, 2021</p> <pre>DATEADD('day', 280, #2/20/21#) = #November 27, 2021#</pre> |
| Notes | Supports ISO 8601 dates. |

DATEDIFF

Returns the number of date parts (weeks, years, etc) between two dates.

| | |
|------------|--|
| Syntax | <code>DATEDIFF(date_part, date1, date2, [start_of_week])</code> |
| Output | Integer |
| Definition | Returns the difference between <code>date1</code> and <code>date2</code> expressed in units of <code>date_part</code> . For example, subtracting the dates someone entered and left a band to see how long they were in the band. |
| Example | <p>Number of days between 25th March 1986 and 20th February 2021</p> <pre>DATEDIFF('day', #3/25/1986#, #2/20/2021#) = 12,751</pre> <p>How many months someone was in a band</p> <pre>DATEDIFF('month', [date joined band], [date left band])</pre> |
| Notes | Supports ISO 8601 dates. |

DATENAME

Returns the name of the specified date part as a discrete string.

| | |
|------------|---|
| Syntax | <code>DATENAME(date_part, date, [start_of_week])</code> |
| Output | String |
| Definition | Returns <code><date_part></code> of date as a string. |
| Example | <pre>DATENAME('year', #3/25/1986#) = "1986"</pre> <pre>DATENAME('month', #1986-03-25#) = "March"</pre> |
| Notes | <p>Supports ISO 8601 dates.</p> <p>A very similar calculation is DATEPART on page 2305, which returns the value of the specified date part as a continuous integer. <code>DATEPART</code> can be faster because it is a numerical operation.</p> <p>By changing the attributes of the calculation's result (dimension or measure,</p> |

continuous or discrete) and the date formatting, the results of `DATEPART` and `DATENAME` can be formatted to be identical.

An inverse function is [DATEPARSE](#) below, which takes a string value and formats it as a date.

DATEPARSE

Returns specifically formatted strings as dates.

| | |
|----------------------|---|
| Syntax | <code>DATEPARSE(date_format, date_string)</code> |
| Output | Date |
| Definition | The <code><date_format></code> argument describes how the <code><date_string></code> field is arranged. Because of the variety of ways the string field can be ordered, the <code><date_format></code> must match exactly. For a full explanation, see Convert a Field to a Date Field . |
| Example | <code>DATEPARSE('yyyy-MM-dd', "1986-03-25") = #March 25, 1986#</code> |
| Notes | <p>DATE on page 2301 is a similar function that automatically recognises many standard date formats. <code>DATEPARSE</code> may be a better option if <code>DATE</code> does not recognise the input pattern.</p> <p>MAKEDATE on page 2326 is another similar function, but <code>MAKEDATE</code> requires the input of numeric values for year, month and day.</p> <p>Inverse functions, which take dates apart and return the value of their parts, are DATEPART on the facing page (integer output) and DATENAME on the previous page (string output).</p> |
| Database limitations | <p><code>DATEPARSE</code> is available through the following connectors: non-legacy Excel and text file connections, Amazon EMR Hadoop Hive, Cloudera Hadoop, Google Sheets, Hortonworks Hadoop Hive, MapR Hadoop Hive, MySQL, Oracle, PostgreSQL and Tableau extracts. Some formats may not be available for all connections.</p> <p><code>DATEPARSE</code> is not supported on Hive variants. Only Denodo, Drill and Snowflake are supported.</p> |

DATEPART

Returns the name of the specified date part as an integer.

Syntax `DATEPART(date_part, date, [start_of_week])`

Output Integer

Definition Returns <date_part> of date as an integer.

Example `DATEPART('year', #1986-03-25#) = 1986`

`DATEPART('month', #1986-03-25#) = 3`

Notes Supports ISO 8601 dates.

A very similar calculation is [DATENAME](#) on page 2303, which returns the name of the specified date part as a discrete string. `DATEPART` can be faster because it is a numerical operation. By changing the attributes of the field (dimension or measure, continuous or discrete) and the date formatting, the results of `DATEPART` and `DATENAME` can be formatted to be identical.

An inverse function is [DATEPARSE](#) on the previous page, which takes a string value and formats it as a date.

DATETIME

Syntax `DATETIME(expression)`

Output Datetime

Definition Returns a datetime given a number, string or date expression.

Example `DATETIME("April 15, 2005 07:59:00") = April 15, 2005 07:59:00`

DATETRUNC

This function can be thought of as date rounding. It takes a specific date and returns a version of that date at the desired specificity. Because every date must have a value for day, month, quarter

and year, `DATETRUNC` sets the values as the lowest value for each date part up to the date part specified. Refer to the example for more information.

| | |
|------------|---|
| Syntax | <code>DATETRUNC (date_part, date, [start_of_week])</code> |
| Output | Date |
| Definition | Truncates the <code><date></code> to the accuracy specified by the <code><date_part></code> . This function returns a new date. For example, when you truncate a date that is in the middle of the month at the month level, this function returns the first day of the month. |
| Example | <pre>DATETRUNC ('day', #9/22/2018#) = #9/22/2018#</pre> <pre>DATETRUNC ('iso-week', #9/22/2018#) = #9/17/2018#</pre> <p>(the Monday of the week containing 22/09/2018)</p> <pre>DATETRUNC (quarter, #9/22/2018#) = #7/1/2018#</pre> <p>(the first day of the quarter containing 22/09/2018)</p> |

Note: For week and iso-week, the `start_of_week` comes into play. ISO-weeks always start on Monday. For the locale of this example, an unspecified `start_of_week` means the week starts on Sunday.

| | |
|-------|---|
| Notes | <p>Supports ISO 8601 dates.</p> <p>You shouldn't use <code>DATETRUNC</code> to, for example, stop showing the time for a datetime field in a viz. If you want to truncate the <i>display</i> of a date rather than round its accuracy, adjust the formatting.</p> <p>For example, <code>DATETRUNC ('day', #5/17/2022 3:12:48 PM#)</code>, if formatted in the viz to display seconds, would display as 5/17/2022 12:00:00 AM.</p> |
|-------|---|

DAY

Returns the day of the month (1–31) as an integer.

| | |
|------------|---|
| Syntax | DAY (date) |
| Output | Integer |
| Definition | Returns the day of the given <date> as an integer. |
| Example | Day(#September 22, 2018#) = 22 |
| Notes | See also WEEK on page 2351, MONTH on page 2333, Quarter on page 2338, YEAR on page 2353 and the ISO equivalents |

DEGREES

| | |
|------------|---|
| Syntax | DEGREES (number) |
| | The number argument is the angle in radians. |
| Output | Number (degrees) |
| Definition | Converts an angle in radians to degrees. |
| Example | DEGREES (PI () / 4) = 45.0 |
| Notes | The inverse function, RADIAN s on page 2338, takes an angle in degrees and returns the angle in radians. See also PI on page 2337(). |

DISTANCE

| | |
|------------|--|
| Syntax | DISTANCE(<SpatialPoint1>, <SpatialPoint2>, 'units') |
| Output | Number |
| Definition | Returns the distance measurement between two points in the specified units. |
| Example | DISTANCE([Origin Point],[Destination Point], 'km') |
| Notes | Supported unit names (must be in quotation marks in the calculation): <ul style="list-style-type: none"> <i>metres</i>: meters, metres, m |

- *kilometres*: kilometers, kilometres, km
- *miles*: miles, mi
- *feet*: feet, ft

Database limitations This function can only be created with a live connection but will continue to work if the data source is converted to an extract.

DIV

Syntax `DIV(integer1, integer2)`

Output Integer

Definition Returns the integer part of a division operation, in which `<integer1>` is divided by `<integer2>`.

Example `DIV(11,2) = 5`

DOMAIN

`DOMAIN(string_url)`

Only supported when connected to Google BigQuery. For more information, see [Additional Functions](#).

[back to top](#)

E

ELSE

Syntax `CASE <expression>`
 `WHEN <value1> THEN <then1>`
 `WHEN <value2> THEN <then2>`
 `...`
 `[ELSE <default>]`
 `END`

Definition An optional piece of an IF or CASE expression used to specify a default

value to return if none of the tested expressions are true.

Example

```
IF [Season] = "Summer" THEN 'Sandals'
ELSEIF [Season] = "Winter" THEN 'Boots'
ELSE 'Sneakers'
END

CASE [Season]
WHEN 'Summer' THEN 'Sandals'
WHEN 'Winter' THEN 'Boots'
ELSE 'Sneakers'
END
```

Notes

Used with **CASE** on page 2295, **WHEN** on page 2352, **IF** on page 2316, **ELSEIF** below, **THEN** on page 2347 and **END** on the next page

ELSE is optional with **CASE** and **IF**. In a calculation where **ELSE** is not specified, if none of the <test> are true, the overall calculation will return null.

ELSE does not require a condition (such as [Season] = "Winter") and can be thought of as a form of null handling.

ELSEIF

Syntax

```
[ELSEIF <test2> THEN <then2>]
```

Definition

An optional piece of an **IF** expression used to specify additional conditions beyond the initial **IF**.

Example

```
IF [Season] = "Summer" THEN 'Sandals'
ELSEIF [Season] = "Winter" THEN 'Boots'
ELSEIF [Season] = "Spring" THEN 'Sneakers'
ELSEIF [Season] = "Autumn" THEN 'Sneakers'
ELSE 'Bare feet'
END
```

Notes

Used with **IF** on page 2316, **THEN** on page 2347, **ELSE** on the previous page and **END** on the next page

ELSEIF can be thought of as additional **IF** clauses. **ELSEIF** is optional and can be repeated multiple times.

Unlike **ELSE**, **ELSEIF** requires a condition (such as `[Season] = "Winter"`).

END

Definition Used to close an **IF** or **CASE** expression.

Example

```
IF [Season] = "Summer" THEN 'Sandals'
ELSEIF [Season] = "Winter" THEN 'Boots'
ELSE 'Sneakers'
END
```

"If Season = Summer, then return Sandals. If not, look at the next expression. If Season = Winter, then return Boots. If neither of the expressions are true, return Sneakers."

```
CASE [Season]
WHEN 'Summer' THEN 'Sandals'
WHEN 'Winter' THEN 'Boots'
ELSE 'Sneakers'
END
```

"Look at the Season field. If the value is Summer, then return Sandals. If the value is Winter, then return Boots. If none of the options in the calculation match what is in the Season field, return Sneakers."

Notes Used with **CASE** on page 2295, **WHEN** on page 2352, **IF** on page 2316, **ELSEIF** on the previous page, **THEN** on page 2347 and **ELSE** on page 2308.

ENDSWITH

ENDSWITH

| | |
|------------|--|
| Syntax | <code>ENDSWITH(string, substring)</code> |
| Output | Boolean |
| Definition | Returns true if the given <string> ends with the specified <substring>. Trailing white spaces are ignored. |
| Example | <code>ENDSWITH("Tableau", "leau") = true</code> |
| Notes | See also the supported RegEx in the additional functions documentation . |

EXCLUDE

For more information, see [Level of Detail Expressions](#).

EXP

| | |
|------------|--|
| Syntax | <code>EXP(number)</code> |
| Output | Number |
| Definition | Returns e raised to the power of the given <number>. |
| Example | <code>EXP(2) = 7.389</code> <code>EXP(-[Growth Rate]*[Time])</code> |
| Notes | See also LN on page 2325. |

[back to top](#)

F

FIND

| | |
|------------|--|
| Syntax | <code>FIND(string, substring, [start])</code> |
| Output | Number |
| Definition | <p>Returns the index position of <substring> in <string>, or 0 if the substring isn't found. The first character in the string is position 1.</p> <p>If the optional numeric argument <code>start</code> is added, the function ignores any instances of the substring that appear before the starting position.</p> |
| Example | <pre>FIND("Calculation", "alcu") = 2</pre> <pre>FIND("Calculation", "Computer") = 0</pre> <pre>FIND("Calculation", "a", 3) = 7</pre> <pre>FIND("Calculation", "a", 2) = 2</pre> <pre>FIND("Calculation", "a", 8) = 0</pre> |
| Notes | See also the supported RegEx in the additional functions documentation . |

FINDNTH

| | |
|------------|---|
| Syntax | <code>FINDNTH(string, substring, occurrence)</code> |
| Output | Number |
| Definition | Returns the position of the nth occurrence of <substring> within the specified <string>, where n is defined by the <occurrence> argument. |
| Example | <pre>FINDNTH("Calculation", "a", 2) = 7</pre> |
| Notes | <p><code>FINDNTH</code> is not available for all data sources.</p> <p>See also the supported RegEx in the additional functions documentation.</p> |

FIRST

`FIRST()`

For more information, see [Table Calculation Functions](#).

FIXED

For more information, see [Level of Detail Expressions](#).

FLOAT

| | |
|------------|--|
| Syntax | <code>FLOAT(expression)</code> |
| Output | Floating point number (decimal) |
| Definition | Casts its argument as a floating point number. |
| Example | <code>FLOAT(3) = 3.000</code> |
| Notes | See also INT on page 2319, which returns an integer. |

FLOOR

| | |
|----------------------|---|
| Syntax | <code>FLOOR(number)</code> |
| Output | Integer |
| Definition | Rounds a <number> to the nearest integer of equal or lesser value. |
| Example | <code>FLOOR(7.9) = 7</code> |
| Notes | See also CEILING on page 2296 and ROUND on page 2340. |
| Database limitations | <code>FLOOR</code> is available through the following connectors: Microsoft Excel, Text File, Statistical File, Published Data Source, Amazon EMR Hadoop Hive, Cloudera Hadoop, DataStax Enterprise, Google Analytics, Google BigQuery, Hortonworks Hadoop Hive, MapR Hadoop Hive, Microsoft SQL Server, Salesforce, Spark SQL. |

FULLNAME

Syntax `FULLNAME ()`

Output String

Definition Returns the full name for the current user.

Example `FULLNAME ()`

This returns the full name of the signed-in user, such as "Hamlin Myrer".

```
[Manager] = FULLNAME ( )
```

If manager "Hamlin Myrer" is signed in, this example returns TRUE only if the Manager field in the view contains "Hamlin Myrer".

Notes This function checks:

- Tableau Cloud and Tableau Server: the full name of the signed-in user
- Tableau Desktop: the local or network full name for the user

User filters

When used as a filter, a calculated field such as `[Username field] = FULLNAME ()` can be used to create a user filter that only shows data that is relevant to the person signed in to the server.

[back to top](#)

G

GET_JSON_OBJECT

`GET_JSON_OBJECT(JSON string, JSON path)`

Only supported when connected to Hadoop Hive. For more information, see [Additional Functions](#).

GROUP_CONCAT

`GROUP_CONCAT(expression)`

Only supported when connected to Google BigQuery. For more information, see [Additional Functions](#).

[back to top](#)

H

HEXBINX

| | |
|------------|--|
| Syntax | <code>HEXBINX(number, number)</code> |
| Output | Number |
| Definition | Maps an x, y coordinate to the x-coordinate of the nearest hexagonal bin. The bins have side length 1, so the inputs may need to be scaled appropriately. |
| Example | <code>HEXBINX([Longitude]*2.5, [Latitude]*2.5)</code> |
| Notes | <code>HEXBINX</code> and <code>HEXBINY</code> below are binning and plotting functions for hexagonal bins. Hexagonal bins are an efficient and elegant option for visualising data in an x/y plane such as a map. Because the bins are hexagonal, each bin closely approximates a circle and minimises variation in the distance from the data point to the centre of the bin. This makes the clustering both more accurate and informative. |

HEXBINY

| | |
|------------|---|
| Syntax | <code>HEXBINY(number, number)</code> |
| Output | Number |
| Definition | Maps an x, y coordinate to the y-coordinate of the nearest hexagonal bin. The bins have side length 1, so the inputs may need to be scaled appropriately. |
| Example | <code>HEXBINY([Longitude]*2.5, [Latitude]*2.5)</code> |
| Notes | See also <code>HEXBINX</code> above. |

HOST

HOST(string_url)

Only supported when connected to Google BigQuery. For more information, see [Additional Functions](#).

[back to top](#)

I

IF

| | |
|------------|---|
| Syntax | <pre> IF <test1> THEN <then1> [ELSEIF <test2> THEN <then2>...] [ELSE <default>] END </pre> |
| Output | Depends on data type of the <then> values. |
| Definition | Tests a series of expressions and returns the <then> value for the first true <test>. |
| Example | <pre> IF [Season] = "Summer" THEN 'Sandals' ELSEIF [Season] = "Winter" THEN 'Boots' ELSE 'Sneakers' END </pre> <p><i>"If Season = Summer, then return Sandals. If not, look at the next expression. If Season = Winter, then return Boots. If neither of the expressions are true, return Sneakers."</i></p> |
| Notes | <p>See also IF above and IIF on the facing page.</p> <p>Used with ELSEIF on page 2309, THEN on page 2347, ELSE on page 2308 and END on page 2310</p> |

IFNULL

Syntax IFNULL(expr1, expr2)

| | |
|------------|--|
| Output | Depends on the data type of the <expr> values. |
| Definition | Returns <expr1> if it's non-null, otherwise returns <expr2>. |
| Example | <pre>IFNULL([Assigned Room], "TBD")</pre> <p><i>"If the Assigned Room field isn't null, return its value. If the Assigned room field is null, return TBD instead."</i></p> |
| Notes | <p>Compare with ISNULL on page 2321. IFNULL always returns a value. ISNULL returns a boolean (true or false).</p> <p>See also ZN on page 2354.</p> |

IIF

| | |
|------------|---|
| Syntax | IIF (<test>, <then>, <else>, [<unknown>]) |
| Output | Depends on the data type of the values in the expression. |
| Definition | Checks whether a condition is met (<test>) and returns <then> if the test is true, <else> if the test is false and an optional value for <unknown> if the test is null. If the optional unknown isn't specified, IIF returns null. |
| Example | <pre>IIF([Season] = 'Summer', 'Sandals', 'Other footwear')</pre> <p><i>"If Season = Summer, then return Sandals. If not, return Other footwear"</i></p> <pre>IIF([Season] = 'Summer', 'Sandals', IIF('Season' = 'Winter', 'Boots', 'Other footwear'))</pre> <p><i>"If Season = Summer, then return Sandals. If not, look at the next expression. If Season = Winter, then return Boots. If neither are true, return Sneakers."</i></p> <pre>IIF('Season' = 'Summer', 'Sandals', IIF('Season' = 'Winter', 'Boots', IIF('Season' = 'Spring', 'Sneakers', 'Other footwear')))</pre> |

"If Season = Summer, then return Sandals. If not, look at the next expression. If Season = Winter, then return Boots. If none of the expressions are true, return Sneakers."

Notes See also [IF on page 2316](#) and [CASE on page 2295](#).

IIF doesn't have an equivalent to ELSEIF (like IF) or repeated WHEN clauses (like CASE). Instead, multiple tests can be evaluated sequentially by nesting IIF statements as the <unknown> element. The first (outermost) true is returned.

That is to say, in the calculation below, the result will be Red, not Orange, because the expression stops being evaluated as soon as A=A is evaluated as true:

```
IIF('A' = 'A', 'Red', IIF('B' = 'B', 'Orange', IIF('C' = 'D', 'Yellow', 'Green')))
```

IN

Syntax <expr1> IN <expr2>

Output Boolean (true or false)

Definition Returns TRUE if any value in <expr1> matches any value in <expr2>.

Example SUM([Cost]) IN (1000, 15, 200)

"Is the value of the Cost field 1000, 15 or 200?"

```
[Field] IN [Set]
```

"Is the value of the field present in the set?"

Notes The values in <expr2> can be a set, list of literal values or combined field.

See also [WHEN on page 2352](#).

INCLUDE

For more information, see [Level of Detail Expressions](#).

INDEX

INDEX ()

For more information, see [Table Calculation Functions](#).

INT

| | |
|------------|---|
| Syntax | <code>INT(expression)</code> |
| Output | Integer |
| Definition | Casts its argument as an integer. For expressions, this function truncates results to the closest integer toward zero. |
| Example | $\text{INT}(8/3) = 2$ $\text{INT}(-9.7) = -9$ |
| Notes | <p>When a string is converted to an integer it is first converted to a float and then rounded.</p> <p>See also FLOAT on page 2313, which returns a decimal.</p> <p>See also ROUND on page 2340, CEILING on page 2296 and FLOOR on page 2313</p> |

INTERSECTS

| | |
|------------|---|
| Syntax | <code>INTERSECTS (<geometry1>, <geometry2>)</code> |
| Output | Boolean |
| Definition | Returns true or false indicating whether two geometries overlap in space. |
| Notes | Supported combinations: point/polygon, line/polygon and polygon/polygon. |

ISDATE

Checks if the string is a valid date format.

| | |
|------------|---|
| Syntax | <code>ISDATE(string)</code> |
| Output | Boolean |
| Definition | Returns true if a given <string> is a valid date. |
| Example | <pre>ISDATE(09/22/2018) = true</pre> <pre>ISDATE(22SEP18) = false</pre> |
| Notes | The required argument must be a string. ISDATE cannot be used for a field with a date data type – the calculation will return an error. |

ISFULLNAME

| | |
|------------|--|
| Syntax | <code>ISFULLNAME("User Full Name")</code> |
| Output | Boolean |
| Definition | Returns <code>TRUE</code> if the current user's full name matches the specified full name or <code>FALSE</code> if it does not match. |
| Example | <code>ISFULLNAME("Hamlin Myrer")</code> |
| Notes | <p>The <"User Full Name"> argument must be a literal string, not a field.</p> <p>This function checks:</p> <ul style="list-style-type: none"> Tableau Cloud and Tableau Server: the full name of the signed-in user Tableau Desktop: the local or network full name for the user |

ISMEMBEROF

| | |
|------------|--|
| Syntax | <code>ISMEMBEROF("Group Name")</code> |
| Output | Boolean or null |
| Definition | Returns <code>TRUE</code> if the person currently using Tableau is a member of a group that matches the given string, <code>FALSE</code> if they're not a member and <code>NULL</code> if they're not signed in. |

| | |
|---------|--|
| Example | <pre>ISMEMBEROF('Superstars')</pre> <pre>ISMEMBEROF('domain.lan\Sales')</pre> |
| Notes | <p>The <"Group Full Name"> argument must be a literal string, not a field.</p> <p>If the user is signed in to Tableau Cloud or Tableau Server, group membership is determined by Tableau groups. The function will return TRUE if the given string is "All Users"</p> <p>The <code>ISMEMBEROF()</code> function will also accept Active Directory domains. The Active Directory domain must be declared in the calculation with the group name.</p> |

ISNULL

| | |
|------------|--|
| Syntax | <code>ISNULL(expression)</code> |
| Output | Boolean (true or false) |
| Definition | Returns true if the <expression> is NULL (does not contain valid data). |
| Example | <pre>ISNULL([Assigned Room])</pre> <p><i>"Is the Assigned Room field null?"</i></p> |
| Notes | <p>Compare with IFNULL on page 2316. <code>IFNULL</code> always returns a value. <code>ISNULL</code> returns a boolean.</p> <p>See also ZN on page 2354.</p> |

ISOQUARTER

| | |
|------------|---|
| Syntax | <code>ISOQUARTER(date)</code> |
| Output | Integer |
| Definition | Returns the ISO8601 week-based quarter of a given <date> as an integer. |
| Example | <code>ISOQUARTER(#1986-03-25#) = 1</code> |

Notes See also [ISOWEEK](#) below, [ISOWEEKDAY](#) below, [ISOYEAR](#) below and the non-ISO equivalents.

ISOWEEK

Syntax `ISOWEEK (date)`

Output Integer

Definition Returns the ISO8601 week-based week of a given <date> as an integer.

Example `ISOWEEK (#1986-03-25#) = 13`

Notes See also [ISOWEEKDAY](#) below, [ISOQUARTER](#) on the previous page, [ISOYEAR](#) below and the non-ISO equivalents.

ISOWEEKDAY

Syntax `ISOWEEKDAY (date)`

Output Integer

Definition Returns the ISO8601 week-based weekday of a given <date> as an integer.

Example `ISOWEEKDAY (#1986-03-25#) = 2`

Notes See also [ISOWEEK](#) above, [ISOQUARTER](#) on the previous page, [ISOYEAR](#) below and the non-ISO equivalents

ISOYEAR

Syntax `ISOYEAR (date)`

Output Integer

Definition Returns the ISO8601 week-based year of a given date as an integer.

| | |
|---------|--|
| Example | <code>ISOYEAR(#1986-03-25#) = 1,986</code> |
| Notes | See also ISOWEEK on the previous page, ISOWEEKDAY on the previous page, ISOQUARTER on page 2321 and the non-ISO equivalents. |

ISUSERNAME

| | |
|------------|--|
| Syntax | <code>ISUSERNAME("username")</code> |
| Output | Boolean |
| Definition | Returns <code>TRUE</code> if the current user's username matches the specified <code><username></code> or <code>FALSE</code> if it does not match. |
| Example | <code>ISUSERNAME("hmyrer")</code> |
| Notes | The <code><"username"></code> argument must be a literal string, not a field. |

This function checks:

- Tableau Cloud and Tableau Server: the username of the signed-in user
- Tableau Desktop: the local or network username for the user

[back to top](#)

J

[back to top](#)

K

[back to top](#)

L

LAST

`LAST()`

For more information, see [Table Calculation Functions](#).

LEFT

| | |
|------------|--|
| Syntax | <code>LEFT(string, number)</code> |
| Output | String |
| Definition | Returns the left-most <number> of characters in the string. |
| Example | <code>LEFT("Matador", 4) = "Mata"</code> |
| Notes | See also MID on page 2330 and RIGHT on page 2340 . |

LEN

| | |
|------------|--|
| Syntax | <code>LEN(string)</code> |
| Output | Number |
| Definition | Returns the length of the <string>. |
| Example | <code>LEN("Matador") = 7</code> |
| Notes | Not to be confused with the spatial function LENGTH below. |

LENGTH

| | |
|------------|--|
| Syntax | <code>LENGTH(geometry, 'units')</code> |
| Output | Number |
| Definition | Returns the geodetic path length of the line string or strings in the <geometry> using the given <units>. |
| Example | <code>LENGTH([Spatial], 'metres')</code> |
| Notes | <p>The result is <NaN> if the geometry argument has no linestrings, though other elements are permitted.</p> <p>Not to be confused with the string function LEN above.</p> |

LN

| | |
|------------|--|
| Syntax | <code>LN (number)</code> |
| Output | Number The output is <code>Null</code> if the argument is less than or equal to zero. |
| Definition | Returns the natural logarithm of a <code><number></code> . |
| Example | <code>LN(50) = 3.912023005</code> |
| Notes | See also EXP on page 2311 and LOG below. |

LOG

| | |
|------------|--|
| Syntax | <code>LOG (number, [base])</code> If the optional base argument isn't present, base 10 is used. |
| Output | Number |
| Definition | Returns the logarithm of a <code><number></code> for the given <code><base></code> . |
| Example | <code>LOG(16,4) = 2</code> |
| Notes | See also POWER on page 2337 LN above. |

LOG2

`LOG2 (number)`

Only supported when connected to Google BigQuery. For more information, see [Additional Functions](#).

LOOKUP

`LOOKUP (expression, [offset])`

For more information, see [Table Calculation Functions](#).

LOWER

| | |
|------------|---|
| Syntax | <code>LOWER(string)</code> |
| Output | String |
| Definition | Returns the provided <string> in all lowercase characters. |
| Example | <code>LOWER("ProductVersion") = "productversion"</code> |
| Notes | See also UPPER on page 2349 and PROPER on page 2337 . |

LTRIM

| | |
|------------|--|
| Syntax | <code>LTRIM(string)</code> |
| Output | String |
| Definition | Returns the provided <string> with any leading spaces removed. |
| Example | <code>LTRIM(" Matador ") = "Matador "</code> |
| Notes | See also RTRIM on page 2341 . |

LTRIM_THIS

`LTRIM_THIS(string, string)`

Only supported when connected to Google BigQuery. For more information, see [Additional Functions](#).

[back to top](#)

M

MAKEDATE

| | |
|--------|---|
| Syntax | <code>MAKEDATE(year, month, day)</code> |
| Output | Date |

Definition Returns a date value constructed from the specified <year>, <month> and <day>.

Example `MAKEDATE(1986,3,25) = #1986-03-25#`

Notes

Note: Incorrectly entered values will be adjusted into a date, such as `MAKEDATE(2020,4,31) = May 1, 2020` rather than returning an error that there is no 31st day of April.

Available for Tableau Data Extracts. Check for availability in other data sources.

`MAKEDATE` requires numerical inputs for the parts of a date. If your data is a string that should be a date, try the [DATE](#) on page 2301 function. `DATE` automatically recognises many standard date formats. If `DATE` does not recognise the input, try using [DATEPARSE](#) on page 2304.

MAKEDATETIME

Syntax `MAKEDATETIME(date, time)`

Output Datetime

Definition Returns a datetime that combines a <date> and a <time>. The date can be a date, datetime or a string type. The time must be a datetime.

Example `MAKEDATETIME("1899-12-30", #07:59:00#) = #12/30/1899 7:59:00 AM#`

`MAKEDATETIME([Date], [Time]) = #1/1/2001 6:00:00 AM#`

Notes This function is available only for MySQL-compatible connections (which for Tableau are MySQL and Amazon Aurora).

[MAKETIME](#) on page 2329 is a similar function available for Tableau Data Extracts and some other data sources.

MAKELINE

| | |
|------------|---|
| Syntax | <code>MAKELINE(SpatialPoint1, SpatialPoint2)</code> |
| Output | Geometry (line) |
| Definition | Generates a line mark between two points |
| Example | <code>MAKELINE(MAKEPOINT(47.59, -122.32), MAKEPOINT(48.5, -123.1))</code> |
| Notes | Useful for building origin-destination maps. |

MAKEPOINT

| | |
|------------|--|
| Syntax | <code>MAKEPOINT(latitude, longitude, [SRID])</code> |
| Output | Geometry (point) |
| Definition | <p>Converts data from <latitude> and <longitude> columns into spatial objects.</p> <p>If the optional <SRID> argument is added, the inputs can be other projected geographic coordinates.</p> |
| Example | <pre>MAKEPOINT(48.5, -123.1) MAKEPOINT([AirportLatitude], [AirportLongitude]) MAKEPOINT([Xcoord], [Ycoord], 3493)</pre> |
| Notes | <p><code>MAKEPOINT</code> can't use the automatically generated latitude and longitude fields. The data source must contain the coordinates natively.</p> <p>SRID is a spatial reference identifier that uses ESPG reference system codes to specify coordinate systems. If SRID is not specified, WGS84 is assumed and parameters are treated as latitude/longitude in degrees.</p> <p>You can use <code>MAKEPOINT</code> to spatially enable a data source so that it can be joined with a spatial file using a spatial join. For more information, see Join Spatial Files in Tableau.</p> |

MAKETIME

| | |
|------------|--|
| Syntax | <code>MAKETIME(hour, minute, second)</code> |
| Output | Datetime |
| Definition | Returns a date value constructed from the specified <hour>, <minute> and <second>. |
| Example | <code>MAKETIME(14, 52, 40) = #1/1/1899 14:52:40#</code> |
| Notes | <p>Because Tableau does not support a time data type, only datetime, the output is a datetime. The date portion of the field will be 1/1/1899.</p> <p>Similar function to MAKEDATETIME on page 2327, which is only available for MYSQL-compatible connections.</p> |

MAX

| | |
|------------|--|
| Syntax | <code>MAX(expression)</code> or <code>MAX(expr1, expr2)</code> |
| Output | Same data type as the argument, or <code>NULL</code> if any part of the argument is null. |
| Definition | <p>Returns the maximum of the two arguments, which must be of the same data type.</p> <p><code>MAX</code> can also be applied to a single field as an aggregation.</p> |
| Example | <code>MAX(4, 7) = 7</code> <code>MAX(#3/25/1986#, #2/20/2021#) = #2/20/2021#</code> <code>MAX([Name]) = "Zander"</code> |
| Notes | <p>For strings</p> <p><code>MAX</code> is usually the value that comes last in alphabetical order.</p> |

For database data sources, the `MAX` string value is highest in the sort sequence defined by the database for that column.

For dates

For dates, the `MAX` is the most recent date. If `MAX` is an aggregation, the result will not have a date hierarchy. If `MAX` is a comparison, the result will retain the date hierarchy.

As an aggregation

`MAX(expression)` is an aggregate function and returns a single aggregated result. This displays as `AGG(expression)` in the viz.

As a comparison

`MAX(expr1, expr2)` compares the two values and returns a row-level value.

See also [MIN](#) on the facing page.

MEDIAN

| | |
|----------------------|---|
| Syntax | <code>MEDIAN(expression)</code> |
| Definition | Returns the median of an expression across all records. Null values are ignored. |
| Notes | <code>MEDIAN</code> can only be used with numeric fields. |
| Database limitations | <p><code>MEDIAN</code> is not available for the following data sources: Access, Amazon Redshift, Cloudera Hadoop, HP Vertica, IBM DB2, IBM PDA (Netezza), Microsoft SQL Server, MySQL, SAP HANA, Teradata.</p> <p>For other data source types, you can extract your data into an extract file to use this function. See Extract Your Data.</p> |

MID

| | |
|------------|--|
| Syntax | <code>(MID(string, start, [length]))</code> |
| Output | String |
| Definition | Returns a string starting at the specified <code><start></code> position. The first character in the string is position 1. |

If the optional numeric argument `<length>` is added, the returned string includes only that number of characters.

Example `MID("Calculation", 2) = "alculation"`

`MID("Calculation", 2, 5) ="alcul"`

Notes See also the supported RegEx in the [additional functions documentation](#).

MIN

Syntax `MIN(expression)` or `MIN(expr1, expr2)`

Output Same data type as the argument, or `NULL` if any part of the argument is null.

Definition Returns the minimum of the two arguments, which must be of the same data type.

`MIN` can also be applied to a single field as an aggregation.

Example `MIN(4,7) = 4`
`MIN(#3/25/1986#, #2/20/2021#) = #3/25/1986#`
`MIN([Name]) = "Abebi"`

Notes **For strings**

`MIN` is usually the value that comes first in alphabetical order.

For database data sources, the `MIN` string value is lowest in the sort sequence defined by the database for that column.

For dates

For dates, the `MIN` is the earliest date. If `MIN` is an aggregation, the result will not have a date hierarchy. If `MIN` is a comparison, the result will retain the date hierarchy.

As an aggregation

`MIN(expression)` is an aggregate function and returns a single aggregated result. This displays as `AGG(expression)` in the viz.

As a comparison

`MIN(expr1, expr2)` compares the two values and returns a row-level value.

See also [MAX](#) on page 2329.

Model Extensions

For more information, see [Table Calculation Functions](#).

- `MODEL_EXTENSION_BOOL`
- `MODEL_EXTENSION_INT`
- `MODEL_EXTENSION_REAL`
- `MODEL_EXTENSION_STR`

MODEL_PERCENTILE

| | |
|------------|---|
| Syntax | <pre>MODEL_PERCENTILE (model_specification (optional), target_expression, predictor_expression(s))</pre> |
| Definition | Returns the probability (between 0 and 1) of the expected value being less than or equal to the observed mark, defined by the target expression and other predictors. This is the Posterior Predictive Distribution Function, also known as the Cumulative Distribution Function (CDF). |
| Example | <pre>MODEL_PERCENTILE (SUM([Sales]),COUNT([Orders]))</pre> |

MODEL_QUANTILE

| | |
|--------|---|
| Syntax | <pre>MODEL_QUANTILE (model_specification (optional), quantile, target_expression, predictor_expression(s))</pre> |
|--------|---|

Definition Returns a target numeric value within the probable range defined by the target expression and other predictors, at a specified quantile. This is the Posterior Predictive Quantile.

Example `MODEL_QUANTILE(0.5, SUM([Sales]), COUNT([Orders]))`

MONTH

Syntax `MONTH(date)`

Output Integer

Definition Returns the month of the given <date> as an integer.

Example `MONTH(#1986-03-25#) = 3`

Notes See also [DAY](#) on page 2306, [WEEK](#) on page 2351, [Quarter](#) on page 2338, [YEAR](#) on page 2353 and the ISO equivalents

[back to top](#)

N

NOT

Syntax `NOT <expression>`

Output Boolean (true or false)

Definition Performs logical negation on an expression.

Example

```
IF NOT [Season] = "Summer"
THEN 'Don't wear sandals'
ELSE 'Wear sandals'
END
```

"If Season doesn't equal Summer, then return Don't wear sandals. If not, return Wear sandals."

Notes Often used with [IF](#) on page 2316 and [IIF](#) on page 2317. See also [The](#)

Tableau functions in this reference are organised alphabetically. Click a letter to jump to that location in the list. You can also use **Ctrl+F** (**Command-F** on a Mac) to open a search box to look for a specific function. on page 2291 and **OR** below.

NOW

| | |
|------------|---|
| Syntax | NOW () |
| Output | Datetime |
| Definition | Returns the current local system date and time. |
| Example | NOW () = 1986-03-25 1:08:21 PM |
| Notes | <p>NOW does not take an argument.</p> <p>See also TODAY on page 2348, a similar calculation that returns a date instead of a datetime.</p> <p>If the data source is a live connection, the system date and time could be in another time zone. For more information on how to address this, see the Knowledge Base.</p> |

[back to top](#)

O

OR

| | |
|------------|--|
| Syntax | <expr1> OR <expr2> |
| Output | Boolean (true or false) |
| Definition | Performs a logical disjunction on two expressions. |
| Example | <pre>IF [Season] = "Spring" OR [Season] = "Fall" THEN "Sneakers" END</pre> |

"If either (Season = Spring) or (Season = Fall) is true, then return Sneakers."

Notes

Often used with **IF** on page 2316 and **IIF** on page 2317. See also **The Tableau functions in this reference are organised alphabetically. Click a letter to jump to that location in the list. You can also use Ctrl+F (Command-F on a Mac) to open a search box to look for a specific function. on page 2291 and NOT on page 2333.**

If either expression is **TRUE**, then the result is **TRUE**. If both expressions are **FALSE**, then the result is **FALSE**. If both expressions are **NULL**, then the result is **NULL**.

If you create a calculation which displays the result of an **OR** comparison on a worksheet, Tableau displays **TRUE** and **FALSE**. If you would like to change this, use the Format area in the format dialog.

Note: The **OR** operator employs *short circuit evaluation*. This means that if the first expression is evaluated to be **TRUE**, then the second expression is not evaluated at all. This can be helpful if the second expression results in an error when the first expression is **TRUE**, because the second expression in this case is never evaluated.

OUTLINE

Syntax `OUTLINE (<spatial polygon>)`

Output Geometry

Definition Converts a polygon geometry into linestrings.

Notes Useful for creating a separate layer for an outline that can be styled differently than the fill.

Supports polygons within multipolygons.

[back to top](#)

P

PARSE_URL

```
PARSE_URL(string, url_part)
```

Only supported when connected to Cloudera Impala. For more information, see [Additional Functions](#).

PARSE_URL_QUERY

```
PARSE_URL_QUERY(string, key)
```

Only supported when connected to Cloudera Impala. For more information, see [Additional Functions](#).

PERCENTILE

| | |
|----------------------|--|
| Syntax | <code>PERCENTILE(expression, number)</code> |
| Definition | Returns the percentile value from the given <expression> corresponding to the specified <number>. The <number> must be between 0 and 1 (inclusive) and must be a numeric constant. |
| Example | <code>PERCENTILE([Score], 0.9)</code> |
| Database limitations | <p>This function is available for the following data sources: Non-legacy Microsoft Excel and Text File connections, Extracts and extract-only data source types (for example, Google Analytics, OData or Salesforce), Sybase IQ 15.1 and later data sources, Oracle 10 and later data sources, Cloudera Hive and Hortonworks Hadoop Hive data sources, EXASolution 4.2 and later data sources.</p> <p>For other data source types, you can extract your data into an extract file to use this function. See Extract Your Data.</p> |

PI

| | |
|------------|---|
| Syntax | <code>PI()</code> |
| Output | Number |
| Definition | Returns the numeric constant pi: 3.14159... |
| Example | <code>PI() = 3.14159</code> |
| Notes | Useful for trig functions that take their input in radians. |

POWER

| | |
|------------|---|
| Syntax | <code>POWER(number, power)</code> |
| Output | Number |
| Definition | Raises the <number> to the specified <power>. |
| Example | <code>POWER(5,3) = 125</code> <code>POWER([Temperature], 2)</code> |
| Notes | <p>You can also use the ^ symbol, such as <code>5^3 = POWER(5,3) = 125</code></p> <p>See also EXP on page 2311, LOG on page 2325 and SQUARE on page 2345.</p> |

PREVIOUS_VALUE

`PREVIOUS_VALUE(expression)`

For more information, see [Table Calculation Functions](#).

PROPER

| | |
|--------|-----------------------------|
| Syntax | <code>PROPER(string)</code> |
| Output | String |

Definition Returns the provided `<string>` with the first letter of each word capitalised and the remaining letters in lowercase.

Example `PROPER("PRODUCT name") = "Product Name"`

`PROPER("darcy-mae") = "Darcy-Mae"`

Notes Spaces and non-alphanumeric characters such as punctuation are treated as separators.

See also [LOWER](#) on page 2326 and [UPPER](#) on page 2349.

[back to top](#)

Q

Quarter

Syntax `QUARTER(date)`

Output Integer

Definition Returns the quarter of the given `<date>` as an integer.

Example `QUARTER(#1986-03-25#) = 1`

Notes See also [DAY](#) on page 2306, [WEEK](#) on page 2351, [MONTH](#) on page 2333, [YEAR](#) on page 2353 and the ISO equivalents

[back to top](#)

R

RADIANS

Syntax `RADIANS(number)`

Output Number (angle in radians)

Definition Converts the given `<number>` from degrees to radians.

Example `RADIANS(180) = 3.14159`

Notes The inverse function, [DEGREES](#) on page 2307, takes an angle in radians and returns the angle in degrees.

RANK Table Calculation functions

For more information, see [Table Calculation Functions](#).

- `RANK(expression, ['asc' | 'desc'])`
- `RANK_DENSE(expression, ['asc' | 'desc'])`
- `RANK_MODIFIED(expression, ['asc' | 'desc'])`
- `RANK_PERCENTILE(expression, ['asc' | 'desc'])`
- `RANK_UNIQUE(expression, ['asc' | 'desc'])`

RAWSQL functions

For more information, see [Pass-Through Functions \(RAWSQL\)](#).

- `RAWSQL_BOOL("sql_expr", [arg1], ... [argN])`
- `RAWSQL_DATE("sql_expr", [arg1], ... [argN])`
- `RAWSQL_DATETIME("sql_expr", [arg1], ... [argN])`
- `RAWSQL_INT("sql_expr", [arg1], ... [argN])`
- `RAWSQL_REAL("sql_expr", [arg1], ... [argN])`
- `RAWSQL_SPATIAL`
- `RAWSQL_STR("sql_expr", [arg1], ... [argN])`
- `RAWSQLAGG_BOOL("sql_expr", [arg1], ... [argN])`
- `RAWSQLAGG_DATE("sql_expr", [arg1], ... [argN])`
- `RAWSQLAGG_DATETIME("sql_expr", [arg1], ... [argN])`
- `RAWSQLAGG_INT("sql_expr", [arg1], ... [argN])`
- `RAWSQLAGG_REAL("sql_expr", [arg1], ... [argN])`
- `RAWSQLAGG_STR("sql_expr", [arg1], ... [argN])`

REGEXP functions

For more information, see [Additional Functions](#).

- `REGEXP_EXTRACT(string, pattern)`
- `REGEXP_EXTRACT_NTH(string, pattern, index)`

- `REGEXP_EXTRACT_NTH(string, pattern, index)`
- `REGEXP_MATCH(string, pattern)`
- `REGEXP_REPLACE(string, pattern, replacement)`

REPLACE

| | |
|------------|---|
| Syntax | <code>REPLACE(string, substring, replacement</code> |
| Output | String |
| Definition | Searches <string> for <substring> and replaces it with <replacement>. If <substring> is not found, the string is not changed. |
| Example | <code>REPLACE("Version 3.8", "3.8", "4x") = "Version 4x"</code> |
| Notes | See also <code>REGEXP_REPLACE</code> in the additional functions documentation . |

RIGHT

| | |
|------------|---|
| Syntax | <code>RIGHT(string, number)</code> |
| Output | String |
| Definition | Returns the right-most <number> of characters in the string. |
| Example | <code>RIGHT("Calculation", 4) = "tion"</code> |
| Notes | See also LEFT on page 2324 and MID on page 2330 . |

ROUND

| | |
|------------|--|
| Syntax | <code>ROUND(number, [decimals])</code> |
| Output | Number |
| Definition | <p>Rounds the <number> to a specified number of digits.</p> <p>The optional <code>decimals</code> argument specifies how many decimal points of precision to include in the final result. If <code>decimals</code> is omitted, number is rounded to the nearest integer.</p> |

| | |
|---------|--|
| Example | <code>ROUND(1/3, 2) = 0.33</code> |
| Notes | <p>Some databases, such as SQL Server, allow specification of a negative length, where -1 rounds number to the tens place, -2 rounds to the hundreds place and so on. This is not true of all databases. For example, it is not true of Excel or Access.</p> <p>Tip: Because ROUND may run into issues due to the underlying floating point representation of numbers – such as 9.405 rounding to 9.40 – it may be preferable to format the number to the desired number of decimal points rather than rounding. Formatting 9.405 to two decimal places will yield the expected 9.41.</p> <p>See also CEILING on page 2296 and FLOOR on page 2313.</p> |

RTRIM

| | |
|------------|--|
| Syntax | <code>RTRIM(string)</code> |
| Output | String |
| Definition | Returns the provided <string> with any trailing spaces removed. |
| Example | <code>RTRIM(" Calculation ") = " Calculation"</code> |
| Notes | See also LTRIM on page 2326 and TRIM on page 2349. |

RTRIM_THIS

`RTRIM_THIS(string, string)`

Only supported when connected to Google BigQuery. For more information, see [Additional Functions](#).

RUNNING Table Calculation functions

For more information, see [Table Calculation Functions](#).

- `RUNNING_AVG(expression)`
- `RUNNING_COUNT(expression)`

- `RUNNING_MAX(expression)`
- `RUNNING_MIN(expression)`
- `RUNNING_SUM(expression)`

[back to top](#)

S

SCRIPT Analytics Extensions

For more information, see [Table Calculation Functions](#).

- `SCRIPT_BOOL`
- `SCRIPT_INT`
- `SCRIPT_REAL`
- `SCRIPT_STR`

SHAPETYPE

| | |
|------------|--|
| Syntax | <code>SHAPETYPE(<geometry>)</code> |
| Output | String |
| Definition | Returns a string describing the structure of the spatial geometry, such as Empty, Point, MultiPoint, LineString, MultiLineString, Polygon, MultiPolygon, Mixed and unsupported |
| Example | <code>SHAPETYPE(MAKEPOINT(48.5, -123.1)) = "Point"</code> |

SIGN

| | |
|------------|--|
| Syntax | <code>SIGN(number)</code> |
| Output | -1, 0 or 1 |
| Definition | Returns the sign of a <number>: The possible return values are -1 if the number is negative, 0 if the number is zero or 1 if the number is positive. |
| Example | <code>SIGN(AVG(Profit)) = -1</code> |

Notes See also [ABS](#) on page 2291.

SIN

Syntax `SIN(number)`

Output Number

Definition Returns the sine of an angle in radians.

Example $\text{SIN}(0) = 1.0$
 $\text{SIN}(\text{PI}() / 4) = 0.707106781186548$

Notes The inverse function, [ASIN](#) on page 2293, takes the sine as the argument and returns the angle in radians.

See also [PI](#) on page 2337. To convert an angle from degrees to radians, use [RADIANS](#) on page 2338.

SIZE

`SIZE()`

For more information, see [Table Calculation Functions](#).

SPACE

Syntax `SPACE(number)`

Output String (specifically, just spaces)

Definition Returns a string that is composed of the specified number of repeated spaces.

Example `SPACE(2) = " "`

SPLIT

| | |
|----------------------|--|
| Syntax | <code>SPLIT(string, delimiter, token number)</code> |
| Output | String |
| Definition | Returns a substring from a <string>, using a <delimiter> character to divide the string into a sequence of <tokens>. |
| Example | <pre>SPLIT ("a-b-c-d", "-", 2) = "b"</pre> <pre>SPLIT ("a b c d", " ", -2) = "c"</pre> |
| Notes | <p>The string is interpreted as an alternating sequence of delimiters and tokens. So for the string <code>abc-defgh-i-jkl</code>, where the delimiter character is '-', the tokens are (1) <code>abc</code>, (2) <code>defgh</code>, (3) <code>i</code> and (4) <code>jkl</code>.</p> <p><code>SPLIT</code> returns the token corresponding to the token number. When the token number is positive, tokens are counted starting from the left end of the string; when the token number is negative, tokens are counted starting from the right.</p> <p>See also supported RegEX in the additional functions documentation.</p> |
| Database limitations | <p>The split and custom split commands are available for the following data sources types: Tableau data extracts, Microsoft Excel, Text File, PDF File, Salesforce, OData, Microsoft Azure Market Place, Google Analytics, Vertica, Oracle, MySQL, PostgreSQL, Teradata, Amazon Redshift, Aster Data, Google Big Query, Cloudera Hadoop Hive, Hortonworks Hive and Microsoft SQL Server.</p> <p>Some data sources impose limits on splitting strings. See <code>SPLIT</code> function limitations later in this topic.</p> |

SQRT

| | |
|------------|--|
| Syntax | <code>SQRT(number)</code> |
| Output | Number |
| Definition | Returns the square root of a <number>. |

| | |
|---------|--|
| Example | <code>SQRT(25) = 5</code> |
| Notes | See also SQUARE below. |

SQUARE

| | |
|------------|--|
| Syntax | <code>SQUARE(number)</code> |
| Output | Number |
| Definition | Returns the square of a <number>. |
| Example | <code>SQUARE(5) = 25</code> |
| Notes | See also SQRT on the previous page and POWER on page 2337. |

STARTSWITH

| | |
|------------|--|
| Syntax | <code>STARTSWITH(string, substring)</code> |
| Output | Boolean |
| Definition | Returns true if <code>string</code> starts with <code>substring</code> . Leading white spaces are ignored. |
| Example | <code>STARTSWITH("Matador", "Ma") = TRUE</code> |
| Notes | See also CONTAINS on page 2297, as well as supported RegEX in the additional functions documentation . |

STDEV

| | |
|------------|---|
| Syntax | <code>STDEV(expression)</code> |
| Definition | Returns the statistical standard deviation of all values in the given <expression> based on a sample of the population. |

STDEVP

| | |
|------------|---|
| Syntax | <code>STDEVP(expression)</code> |
| Definition | Returns the statistical standard deviation of all values in the given <code><expression></code> based on a biased population. |

STR

| | |
|------------|---------------------------------|
| Syntax | <code>STR(expression)</code> |
| Output | String |
| Definition | Casts its argument as a string. |
| Example | <code>STR([ID])</code> |

SUM

| | |
|------------|---|
| Syntax | <code>SUM(expression)</code> |
| Definition | Returns the sum of all values in the <code><expression></code> . Null values are ignored. |
| Notes | <code>SUM</code> can only be used with numeric fields. |

[back to top](#)

T

TAN

| | |
|------------|---|
| Syntax | <code>TAN(number)</code> The <code><number></code> argument is the angle in radians. |
| Output | Number |
| Definition | Returns the tangent of an angle. |

Example `TAN(PI ()/4) = 1.0`

Notes See also [ATAN](#) on page 2294, [ATAN2](#) on page 2294, [COT](#) on page 2299 and [PI](#) on page 2337. To convert an angle from degrees to radians, use [RADIAN](#)s on page 2338.

THEN

Syntax

```
IF <test1> THEN <then1>
[ELSEIF <test2> THEN <then2>...]
[ELSE <default>]
END
```

Definition A required part of an IF, ELSEIF or CASE expression, used to define what result to return if a specific value or test is true.

Example

```
IF [Season] = "Summer" THEN 'Sandals'
ELSEIF [Season] = "Winter" THEN 'Boots'
ELSE 'Sneakers'
END
```

"If Season = Summer, then return Sandals. If not, look at the next expression. If Season = Winter, then return Boots. If neither of the expressions are true, return Sneakers."

```
CASE [Season]
WHEN 'Summer' THEN 'Sandals'
WHEN 'Winter' THEN 'Boots'
ELSE 'Sneakers'
END
```

"Look at the Season field. If the value is Summer, then return Sandals. If the value is Winter, then return Boots. If none of the options in the calculation match what is in the Season field, return Sneakers."

Notes Used with [CASE](#) on page 2295, [WHEN](#) on page 2352, [IF](#) on page 2316, [ELSEIF](#) on page 2309, [THEN](#) above, [ELSE](#) on page 2308 and [END](#) on page 2310

TIMESTAMP_TO_USEC

`TIMESTAMP_TO_USEC(expression)`

Only supported when connected to Google BigQuery. For more information, see [Additional Functions](#).

TLD

`TLD(string_url)`

Only supported when connected to Google BigQuery. For more information, see [Additional Functions](#).

TODAY

Syntax `TODAY ()`

Output `Date`

Definition Returns the current local system date.

Example `TODAY () = 1986-03-25`

Notes `TODAY` does not take an argument.

See also [NOW](#) on page 2334, a similar calculation that returns a datetime instead of a date.

If the data source is a live connection, the system date could be in another time zone. For more information on how to address this, see [the Knowledge Base](#).

TOTAL

`TOTAL(expression)`

For more information, see [Table Calculation Functions](#).

TRIM

| | |
|------------|--|
| Syntax | <code>TRIM(string)</code> |
| Output | String |
| Definition | Returns the provided <code><string></code> with leading and trailing spaces removed. |
| Example | <code>TRIM(" Calculation ") = "Calculation"</code> |
| Notes | See also LTRIM on page 2326 and RTRIM on page 2341 . |

[back to top](#)

U

UPPER

| | |
|------------|---|
| Syntax | <code>UPPER(string)</code> |
| Output | String |
| Definition | Returns the provided <code><string></code> in all uppercase characters. |
| Example | <code>UPPER("Calculation") = "CALCULATION"</code> |
| Notes | See also PROPER on page 2337 and LOWER on page 2326 . |

USEC_TO_TIMESTAMP

`USEC_TO_TIMESTAMP(expression)`

Only supported when connected to Google BigQuery. For more information, see [Additional Functions](#).

USERDOMAIN

| | |
|--------|-----------------------------|
| Syntax | <code>USERDOMAIN ()</code> |
| Output | String |

| | |
|------------|--|
| Definition | Returns the domain for the current user. |
| Notes | <p>This function checks:</p> <ul style="list-style-type: none"> • Tableau Cloud and Tableau Server: the user domain of the signed-in user • Tableau Desktop: the local domain if the user is on a domain |

USERNAME

| | |
|------------|--|
| Syntax | USERNAME () |
| Output | String |
| Definition | Returns the username for the current user. |
| Example | <p>USERNAME ()</p> <p>This returns the username of the signed-in user, such as "hmyrer".</p> <pre>[Manager] = USERNAME ()</pre> <p>If manager "hmyrer" is signed in, this example returns TRUE only if the Manager field in the view contains "hmyrer".</p> |
| Notes | <p>This function checks:</p> <ul style="list-style-type: none"> • Tableau Cloud and Tableau Server: the username of the signed-in user • Tableau Desktop: the local or network username for the user <p>User filters</p> <p>When used as a filter, a calculated field such as <code>[Username field] = USERNAME ()</code> can be used to create a user filter that only shows data that is relevant to the person signed in to the server.</p> |

USER ATTRIBUTE JSON web token functions

- USERATTRIBUTE('attribute_name')
- USERATTRIBUTEINCLUDES('attribute_name', 'expected_value')

For more information, see [User Functions](#).

[back to top](#)

V

VAR

| | |
|------------|---|
| Syntax | <code>VAR (expression)</code> |
| Definition | Returns the statistical variance of all values in the given expression based on a sample of the population. |

VARP

| | |
|------------|--|
| Syntax | <code>VARP (expression)</code> |
| Definition | Returns the statistical variance of all values in the given expression on the entire population. |

[back to top](#)

W

WEEK

| | |
|------------|--|
| Syntax | <code>WEEK (date)</code> |
| Output | Integer |
| Definition | Returns the week of the given <date> as an integer. |
| Example | <code>WEEK (#1986-03-25#) = 13</code> |
| Notes | See also DAY on page 2306, MONTH on page 2333, Quarter on page 2338, YEAR on page 2353 and the ISO equivalents |

WHEN

| | |
|------------|---|
| Syntax | <pre> CASE <expression> WHEN <value1> THEN <then1> WHEN <value2> THEN <then2> ... [ELSE <default>] END </pre> |
| Definition | A required part of a CASE expression. Finds the first <value> that matches <expression> and returns the corresponding <then>. |
| Example | <pre> CASE [Season] WHEN 'Summer' THEN 'Sandals' WHEN 'Winter' THEN 'Boots' ELSE 'Sneakers' END </pre> <p><i>"Look at the Season field. If the value is Summer, then return Sandals. If the value is Winter, then return Boots. If none of the options in the calculation match what is in the Season field, return Sneakers."</i></p> |
| Notes | <p>Used with CASE on page 2295, THEN on page 2347, ELSE on page 2308 and END on page 2310.</p> <p>CASE also supports WHEN IN construction, such as:</p> <pre> CASE <expression> WHEN IN <set1> THEN <then1> WHEN IN <combinedfield> THEN <then2> ... ELSE <default> END </pre> <p>The values that WHEN IN compare to must be a set, list of literal values or combined field. See also IN on page 2318.</p> |

Window Table Calcs

For more information, see [Table Calculation Functions](#).

- `WINDOW_AVG(expression, [start, end])`
- `WINDOW_CORR(expression1, expression2, [start, end])`
- `WINDOW_COUNT(expression, [start, end])`
- `WINDOW_COVAR(expression1, expression2, [start, end])`
- `WINDOW_COVARP(expression1, expression2, [start, end])`
- `WINDOW_MAX(expression, [start, end])`
- `WINDOW_MEDIAN(expression, [start, end])`
- `WINDOW_MIN(expression, [start, end])`
- `WINDOW_PERCENTILE(expression, number, [start, end])`
- `WINDOW_STDEV(expression, [start, end])`
- `WINDOW_STDEVP(expression, [start, end])`
- `WINDOW_SUM(expression, [start, end])`
- `WINDOW_VAR(expression, [start, end])`
- `WINDOW_VARP(expression, [start, end])`

[back to top](#)

X

XPATH functions.

Only supported when connected to Hadoop Hive. For more information, see [Pass-Through Functions \(RAWSQL\)](#).

- `XPATH_BOOLEAN(XML string, XPath expression string)`
- `XPATH_DOUBLE(XML string, XPath expression string)`
- `XPATH_FLOAT(XML string, XPath expression string)`
- `XPATH_INT(XML string, XPath expression string)`
- `XPATH_LONG(XML string, XPath expression string)`
- `XPATH_SHORT(XML string, XPath expression string)`
- `XPATH_STRING(XML string, XPath expression string)`

[back to top](#)

Y

YEAR

Syntax `YEAR(date)`

| | |
|------------|--|
| Output | Integer |
| Definition | Returns the year of the given <date> as an integer. |
| Example | <code>YEAR(#1986-03-25#) = 1,986</code> |
| Notes | See also DAY on page 2306, WEEK on page 2351, MONTH on page 2333, Quarter on page 2338 and the ISO equivalents |

[back to top](#)

Z

ZN

| | |
|------------|--|
| Syntax | <code>ZN(expression)</code> |
| Output | Depends on the data type of the <expression>, or 0. |
| Definition | Returns <expression> if it isn't null; otherwise returns zero. |
| Example | <code>ZN([Test Grade])</code> <i>"If the test grade isn't null, return its value. If the test grade is null, return 0."</i> |
| Notes | <p><code>ZN</code> is a specialised case of IFNULL on page 2316 where the alternative if the expression is null is always 0 rather than being specified in the calculation.</p> <p><code>ZN</code> is especially useful when performing additional calculations, and a null would render the entire calculation null. However, use caution interpreting these results as null is not always synonymous with 0 and could represent missing data.</p> <p>See also ISNULL on page 2321.</p> |

Transform Values with Table Calculations

This article explains the basics of table calculations and how to create them in Tableau.

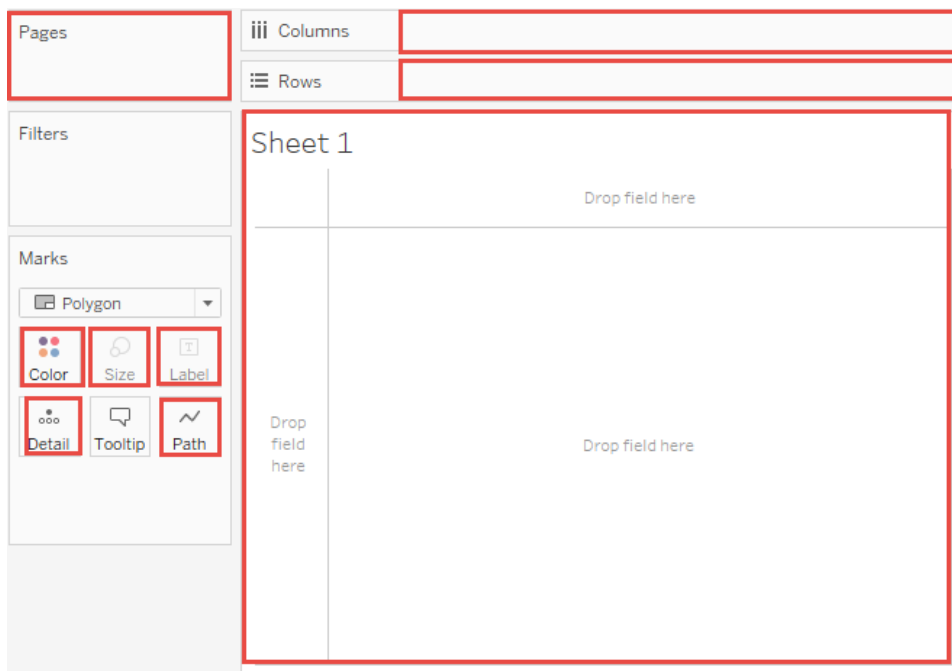

What is a table calculation?

A table calculation is a transformation that you apply to the values in a visualisation. Table calculations are a special type of calculated field that computes on the local data in Tableau. They are calculated based on what is currently in the visualisation and do not consider any measures or dimensions that are filtered out of the visualisation.

You can use table calculations for a variety of purposes, including:

- Transforming values to rankings
- Transforming values to show running totals
- Transforming values to show percent of total

For any Tableau visualisation, there is a virtual table that is determined by the dimensions in the view. This table is not the same as the tables in your data source. Specifically, the virtual table is determined by the dimensions within the “level of detail,” which means the dimensions on any of the following shelves or cards in a Tableau worksheet:

The basics: addressing and partitioning

When you add a table calculation, you must use all dimensions in the level of detail either for partitioning (scoping) or for addressing (direction).

The dimensions that define how to group the calculation (the scope of data it is performed on) are called **partitioning fields**. The table calculation is performed separately within each partition.

The remaining dimensions, upon which the table calculation is performed, are called **addressing fields**, and determine the direction of the calculation.

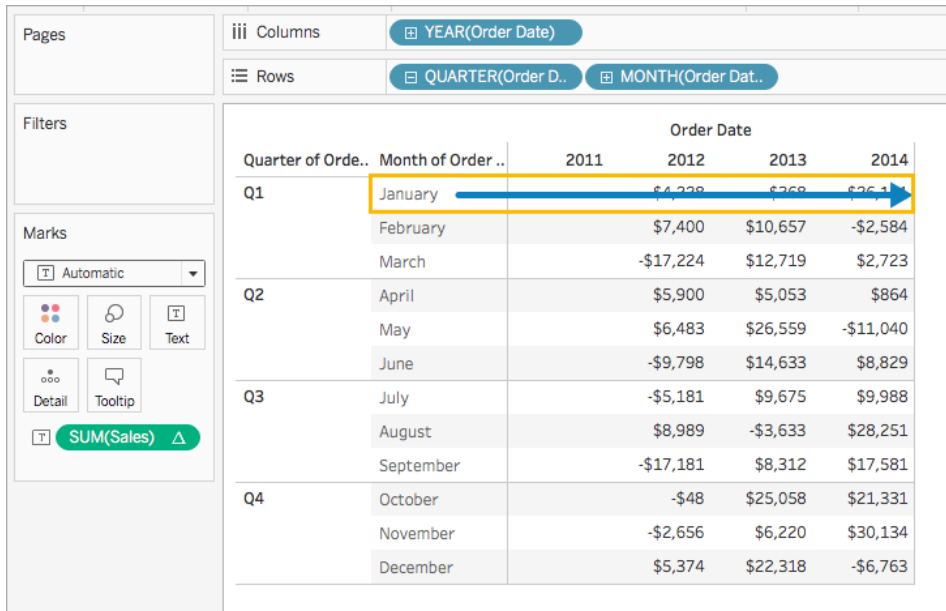

Partitioning fields break the view up into multiple sub-views (or sub-tables), and then the table calculation is applied to the marks within each such partition. The direction in which the calculation moves (for example, in calculating a running sum, or computing the difference between values) is determined by the addressing fields. So when you order the fields in the Specific Dimensions section of the Table Calculation dialog box from top to bottom, you are specifying the direction in which the calculation moves through the various marks in the partition.

When you add a table calculation using the Compute Using options, Tableau identifies some dimensions as addressing and others as partitioning automatically, as a result of your selections. But when you use Specific Dimensions, it's up to you to determine which dimensions are for addressing and which for partitioning.

Table (across)

Computes across the length of the table and restarts after every partition.

For example, in the following table, the calculation is computed across columns (YEAR(Order Date)) for every row (MONTH(Order Date)).

Columns: YEAR(Order Date)

Rows: QUARTER(Order Date), MONTH(Order Date)

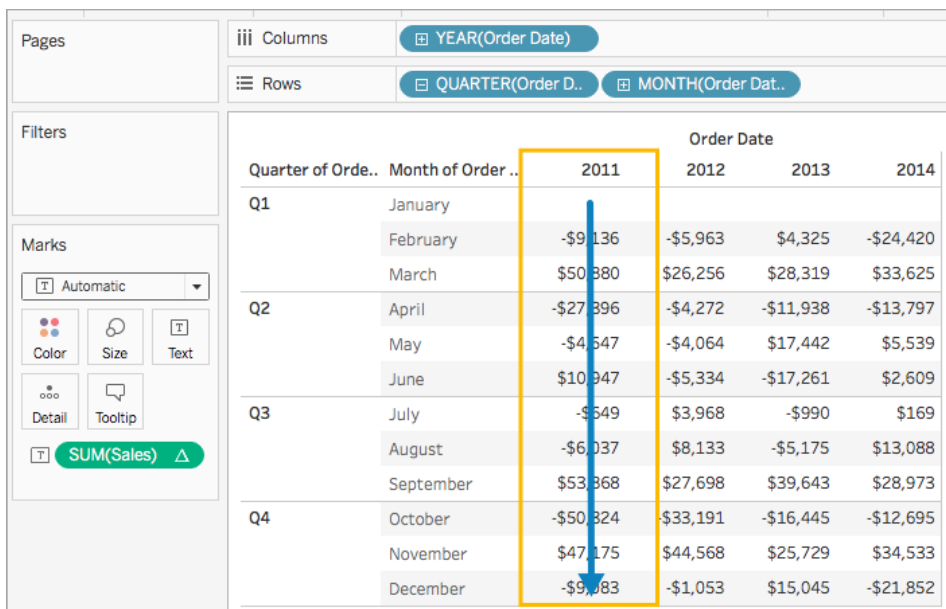

Marks: SUM(Sales)

| Quarter of Order | Month of Order | 2011 | 2012 | 2013 | 2014 |
|------------------|----------------|------|-----------|----------|-----------|
| Q1 | January | | \$4,338 | \$368 | \$26,111 |
| | February | | \$7,400 | \$10,657 | -\$2,584 |
| | March | | -\$17,224 | \$12,719 | \$2,723 |
| Q2 | April | | \$5,900 | \$5,053 | \$864 |
| | May | | \$6,483 | \$26,559 | -\$11,040 |
| | June | | -\$9,798 | \$14,633 | \$8,829 |
| Q3 | July | | -\$5,181 | \$9,675 | \$9,988 |
| | August | | \$8,989 | -\$3,633 | \$28,251 |
| | September | | -\$17,181 | \$8,312 | \$17,581 |
| Q4 | October | | -\$48 | \$25,058 | \$21,331 |
| | November | | -\$2,656 | \$6,220 | \$30,134 |
| | December | | \$5,374 | \$22,318 | -\$6,763 |

Table (down)

Computes down the length of the table and restarts after every partition.

For example, in the following table, the calculation is computed down rows (MONTH(Order Date)) for every column (YEAR(Order Date)).

Columns: YEAR(Order Date)

Rows: QUARTER(Order Date), MONTH(Order Date)

Marks: SUM(Sales)

| Quarter of Order | Month of Order | 2011 | 2012 | 2013 | 2014 |
|------------------|----------------|-----------|----------|-----------|-----------|
| Q1 | January | | | | |
| | February | -\$9,136 | -\$5,963 | \$4,325 | -\$24,420 |
| | March | \$50,880 | \$26,256 | \$28,319 | \$33,625 |
| Q2 | April | -\$27,896 | -\$4,272 | -\$11,938 | -\$13,797 |
| | May | -\$4,547 | -\$4,064 | \$17,442 | \$5,539 |
| | June | \$10,947 | -\$5,334 | -\$17,261 | \$2,609 |
| Q3 | July | -\$549 | \$3,968 | -\$990 | \$169 |
| | August | -\$6,037 | \$8,133 | -\$5,175 | \$13,088 |
| | September | \$53,868 | \$27,698 | \$39,643 | \$28,973 |
| Q4 | October | -\$50,824 | \$33,191 | -\$16,445 | -\$12,695 |
| | November | \$47,175 | \$44,568 | \$25,729 | \$34,533 |
| | December | -\$9,983 | -\$1,053 | \$15,045 | -\$21,852 |

Table (across then down)

Computes across the length of the table, and then down the length of the table.

For example, in the following table, the calculation is computed across columns (YEAR(Order Date)), down a row (MONTH(Order Date)), and then across columns again for the entire table.

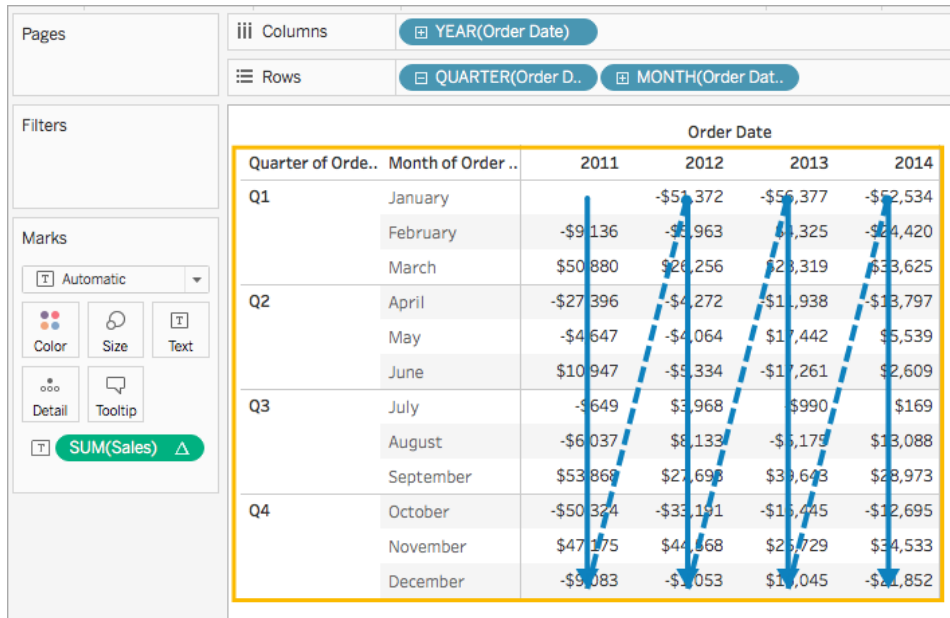

Table (down then across)

Computes down the length of the table, and then across the length of the table.

For example, in the following table, the calculation is computed down rows (MONTH(Order Date)), across a column (YEAR(Order Date)), and then down rows again.

Pane (down)

Computes down an entire pane.

For example, in the following table, the calculation is computed down rows (MONTH(Order Date)) for a single pane.

Pane (across then down)

Computes across an entire pane and then down the pane.

For example, in the following table, the calculation is computed across columns (YEAR(Order Date)) for the length of the pane, down a row (MONTH(Order Date)), and then across columns for the length of the pane again.

| | | Order Date | | | |
|-------------------|-------------------|------------|-----------|----------|-----------|
| Quarter of Orde.. | Month of Order .. | 2011 | 2012 | 2013 | 2014 |
| Q1 | January | | \$4,228 | \$368 | \$26,161 |
| | February | \$55,893 | \$7,488 | \$10,667 | \$2,557 |
| | March | \$35,407 | -\$17,224 | \$12,719 | \$2,723 |
| Q2 | April | | \$5,900 | \$5,053 | \$864 |
| | May | -\$16,464 | \$6,483 | \$26,559 | -\$11,040 |
| | June | -\$11,056 | -\$9,798 | \$14,633 | \$8,829 |
| Q3 | July | | -\$5,181 | \$9,675 | \$9,988 |
| | August | -\$20,519 | \$8,989 | -\$3,633 | \$28,251 |
| | September | \$20,261 | -\$17,181 | \$8,312 | \$17,581 |
| Q4 | October | | -\$48 | \$25,058 | \$21,331 |
| | November | \$835 | -\$2,656 | \$6,220 | \$30,134 |
| | December | -\$42,781 | \$5,374 | \$22,318 | -\$6,763 |

Pane (down then across)

Computes down an entire pane and then across the pane.

For example, in the following table, the calculation is computed down rows (MONTH(Order Date)) for the length of the pane, across a column (YEAR(Order Date)), and then down the length of the pane again.

| | December | \$0 | \$0 | \$0 | \$0 |

Specific Dimensions

Computes only within the dimensions you specify.

For example, in the following visualisation the dimensions, Month of Order Date and Quarter of Order Date, are the addressing fields (since they are selected), and Year of Order Date is the partitioning field (since it is not selected). So the calculation transforms the difference from each month across all quarters within a year. The calculation starts over for every year.

Note that if all dimensions are selected, then the entire table is in scope.

The screenshot shows a Tableau worksheet named 'Sheet 1'. The Columns shelf contains 'YEAR(Order Date)' and the Rows shelf contains 'QUARTER(Order Date)' and 'MONTH(Order Date)'. The Marks card shows 'SUM(Sales)' with a green triangle icon. The visualization is a table with the following data:

| Quarter of ... | Month of O... | Order Date | | | |
|----------------|---------------|------------|-----------|-----------|-----------|
| | | 2011 | 2012 | 2013 | 2014 |
| Q1 | January | | | | |
| | February | -\$9,136 | -\$5,963 | \$4,325 | -\$24,420 |
| | March | \$50,880 | \$26,256 | \$28,319 | \$33,625 |
| Q2 | April | -\$27,396 | -\$4,272 | -\$11,938 | -\$13,797 |
| | May | -\$4,647 | -\$4,064 | \$17,442 | \$5,539 |
| | June | \$10,947 | -\$5,334 | -\$17,261 | \$2,609 |
| Q3 | July | -\$6,649 | \$3,968 | -\$990 | \$169 |
| | August | -\$6,037 | \$8,133 | -\$5,175 | \$13,088 |
| | September | \$53,868 | \$27,698 | \$39,643 | \$28,973 |
| Q4 | October | -\$50,324 | -\$33,191 | -\$16,445 | -\$12,695 |
| | November | \$47,175 | \$44,568 | \$25,729 | \$34,533 |
| | December | -\$9,083 | -\$1,053 | \$15,045 | -\$21,852 |

The 'Table Calculation' dialog box is open, showing 'Difference in Sales' as the calculation type. Under 'Compute Using', 'Table (across)' is selected. Under 'Specific Dimensions', 'Month of Order Date' and 'Quarter of Order Date' are checked. The 'At the level' dropdown is set to 'Deepest', 'Relative to' is 'Previous', and 'Sort order' is 'Specific Dimensions'. The 'Show calculation assistance' checkbox is checked.

At the level

The **At the level** option is only available when you select **Specific Dimensions** in the Table Calculations dialog box, and when more than one dimension is selected in the field immediately below the **Compute Using** options – that is, when more than one dimension is defined as an addressing field.

This option is not available when you're defining a table calculation with **Compute Using**, because those values establish partitions by position. But with **Specific Dimensions**, because the visual structure and the table calculation are not necessarily aligned, the **At the level** option is available to let you fine-tune your calculation.

Use this setting to set a break (that is, restart of the calculation) in the view, based on a particular dimension. How is this different from just using that dimension for partitioning? In fact, it is partitioning, but it's partitioning by position rather than by value, which is how partitioning is defined with the **Compute Using** options.

The choices available from the At the level drop-down list in the example above are:

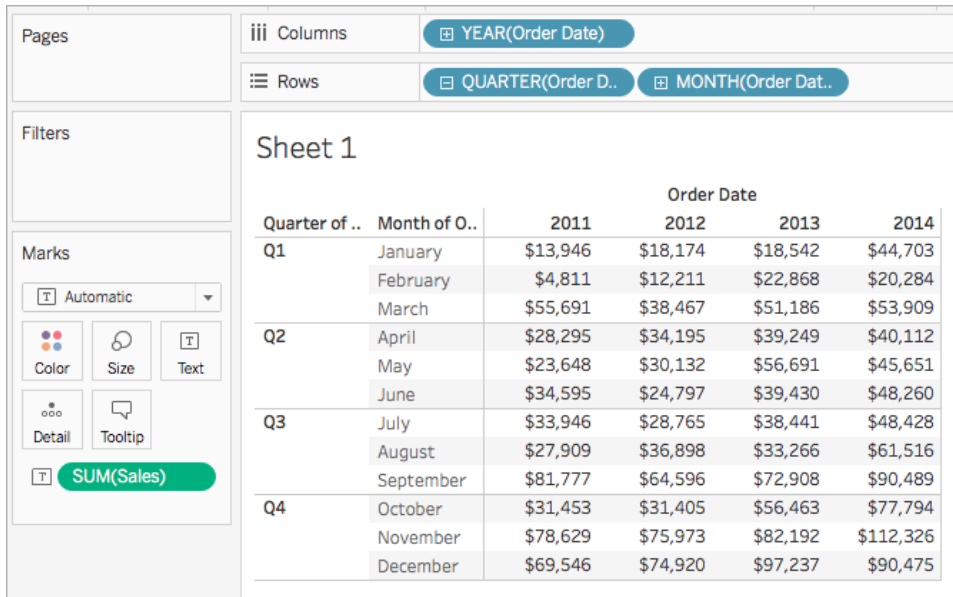

| | |
|------------------------------|--|
| Deepest | Specifies that the calculation should be performed at the level of finest granularity. This is the default option. |
| Quarter of Order Date | Specifies that the calculation should be performed at the quarter level. |
| Month of Order Date | Specifies that the calculation should be performed at the month level. |

Create a table calculation

To learn how to create a table calculation, follow along with the steps in the example below. To learn how to create quick table calculations, see [Quick Table Calculations on page 2387](#).

Step 1: Build the visualisation

1. Open Tableau and connect to the **Sample-Superstore** saved data source.
2. Navigate to a new worksheet.
3. From the **Data** pane, drag **Order Date** to the **Rows** shelf. The dimension updates to **YEAR (Order Date)**.
4. On the Rows shelf, right-click **YEAR(Order Date)** and select **Quarter**.
5. On the Rows shelf, click the **+** icon on **QUARTER(Order Date)**. **MONTH(Order Date)** is added to the shelf.
6. From the **Data** pane, under Dimensions, drag **Order Date** to the **Columns** shelf. The dimension updates to **YEAR(Order Date)** again.
7. From the **Data** pane, drag **Sales** to **Text** on the Marks card.

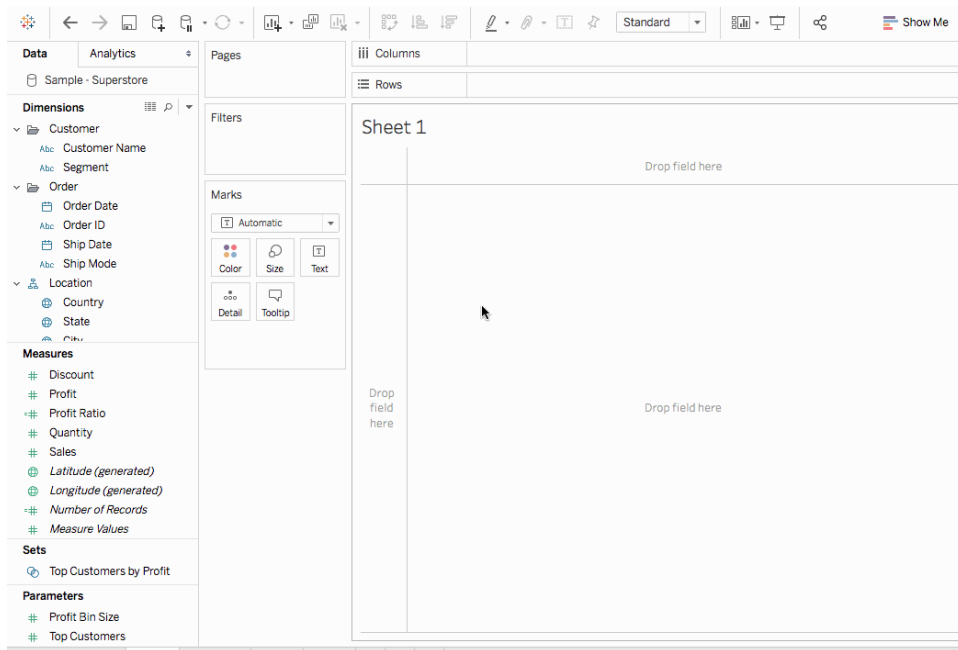

Step 2: Add the table calculation

1. On the Marks card, right-click SUM(Sales) and select **Add Table Calculation**.
2. In the Table Calculation dialog box that opens, do the following:
 - For **Calculation Type**: select **Difference From**.
For more information about the types of table calculations you can use in Tableau, and how you can configure them, see [Table Calculation Types on page 2366](#).
 - For **Compute Using**, select **Table (across)**. Note that as you select how to compute the calculation, the visualisation updates with visual indicators to guide you. For more information about these options, see [The basics: addressing and partitioning on page 2356](#) section.
 - When finished, click the X in the top corner of the Table Calculation dialog box to exit it.

The calculation is applied to the values in the visualisation.

Check your work!

Edit a table calculation

To edit a table calculation:

1. Right-click the measure in the view with the table calculation applied to it and select **Edit Table Calculation**.
2. In the Table Calculation dialog box that appears, make your changes.
3. When finished, click the X in the top corner of the Table Calculation dialog box to exit it.

Remove a table calculation

To remove a table calculation:

- Right-click the measure in the view with the table calculation applied to it and select **Clear Table Calculation**. The table calculation is removed from the measure and the visualisation updates with the original values.

Table Calculation Types

This article describes the types of table calculations available in Tableau and when to use them. It uses simple examples to demonstrate how each calculation transforms data in a table. For more information on how to create and configure table calculations, see [Create a table calculation on page 2363](#).

Difference From calculation

A **Difference From** table calculation computes the difference between the current value and another value in the table for each mark in the visualisation.

With a **Difference From**, **Percent Difference From**, or **Percent From** calculation, there are always two values to consider: the current value, and the value from which the difference should be calculated. In most cases, you want to calculate the difference between the current value and the previous value, as in the procedure above. But in some cases you may want something different.

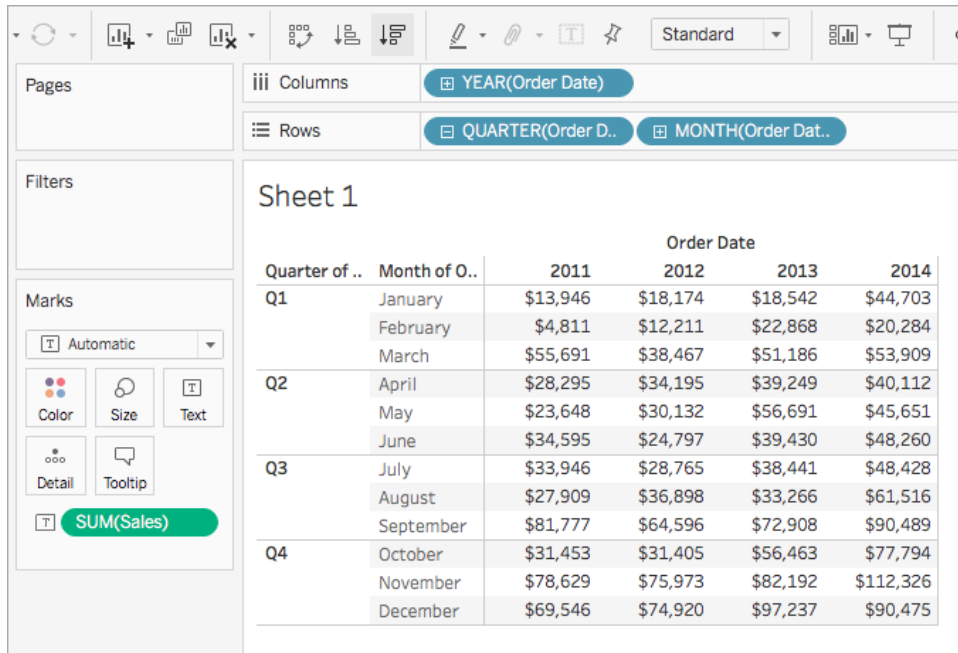

To specify from which value the difference should be calculated:

1. Right-click a measure in the view and select **Add Table Calculation**.
2. In the Table Calculation dialog box, for **Relative to**, select one of the following options:

| | |
|----------|---|
| Previous | Calculates the difference between the current value and the previous value in the partition. This is the default value. |
| Next | Calculates the difference between the current value and the next value in the partition. |
| First | Calculates the difference between the current value and the first value in the partition. |
| Last | Calculates the difference between the current value and the last value in the partition. |

Example

Consider the text table below. It shows the total sales per month for 2011, 2012, 2013 and 2014 for a large store chain.

You can use a Difference From table calculation to calculate how sales fluctuate (how much they go up or down) between the years for each month.

You can see that in January, there was a 368 USD difference between sales in 2012 and 2013, and a 26,161 USD difference between sales in 2013 and 2014.

Tip: When calculating year-over-year growth, the first year doesn't have a previous year to compare to, so the column is left blank. Hide the column that you don't want to show to keep the calculation intact. For details, see [Hide rows and columns on page 60](#).

Why? If you filtered out the first year to remove it from the view, it would also remove it from the calculation so the second year doesn't have a previous year to compare to and is left blank. Instead of filtering, hiding the column keeps the calculation intact.

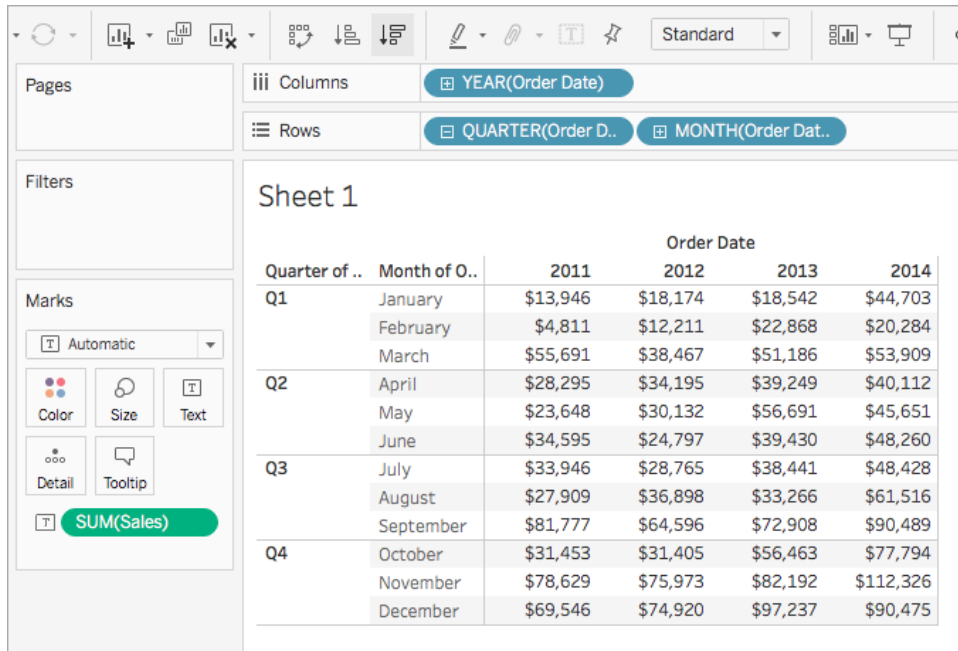

Moving calculation

For each mark in the view, a **Moving Calculation** table calculation (sometimes referred to as a *rolling* calculation) determines the value for a mark in the view by performing an aggregation (sum, average, minimum or maximum) across a specified number of values before and/or after the current value.

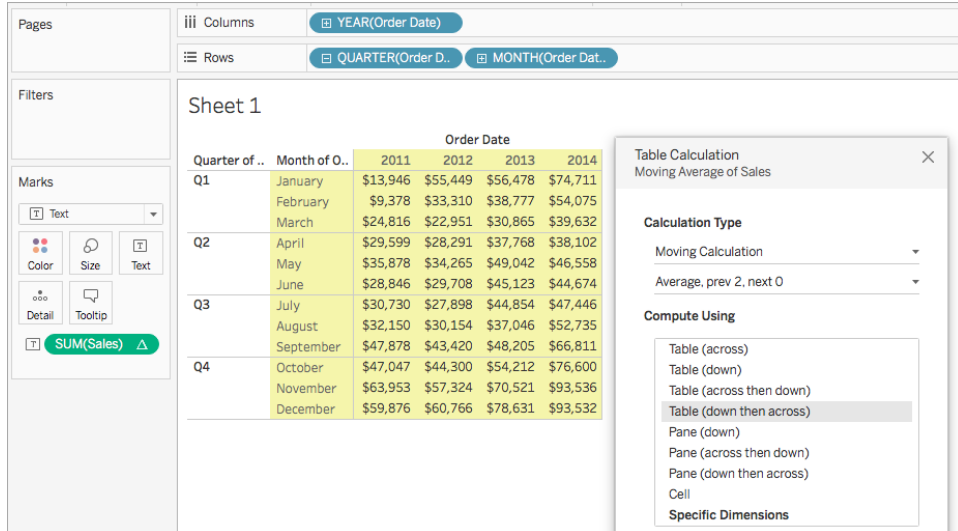

A moving calculation is typically used to smooth short-term fluctuations in your data so that you can see long-term trends. For example, with securities data there are so many fluctuations every day that it is hard to see the big picture through all the ups and downs. You can use a moving calculation to define a range of values to summarise using an aggregation of your choice.

Example

Consider the text table below. It shows the total sales per month for 2011, 2012, 2013 and 2014 for a large store chain.

You can use a Moving calculation to find out how sales totals are trending over time. To do this, you can transform each monthly total so that it averages the monthly total for it and the two previous months over time.

You can see the average sales over time. For example, the value listed for December 2011 is the average sales for October, November and December, 2011. The value listed for January, 2012 is the average sales for November and December, 2011, and January, 2012.

Add Secondary Calculation

With **Running Total** and **Moving Calculation** table calculations, you have the option to transform values twice to obtain the result you want – that is, to add a secondary table calculation on top of the primary table calculation. For example, you could add an initial table calculation to calculate the running total for sales per month within each individual year, and then a secondary calculation to calculate the year-over-year percent difference for each month from one year to the next.

For an example showing how to create a secondary calculation, see [Running Total calculation on page 2380](#).

Percent Difference From calculation

A **Percent Difference From** table calculation computes the difference between the current value and another value in the table as a percentage for each mark in the visualisation.

With a **Difference From**, **Percent Difference From**, or **Percent From** calculation, there are always two values to consider: the current value, and the value from which the difference should be calculated. In most cases, you want to calculate the difference between the current value and the previous value, as in the procedure above. But in some cases you may want something different.

To specify from which value the difference should be calculated:

1. Right-click a measure in the view and select **Add Table Calculation**.
2. In the Table Calculation dialog box, for **Relative to**, select one of the following options:

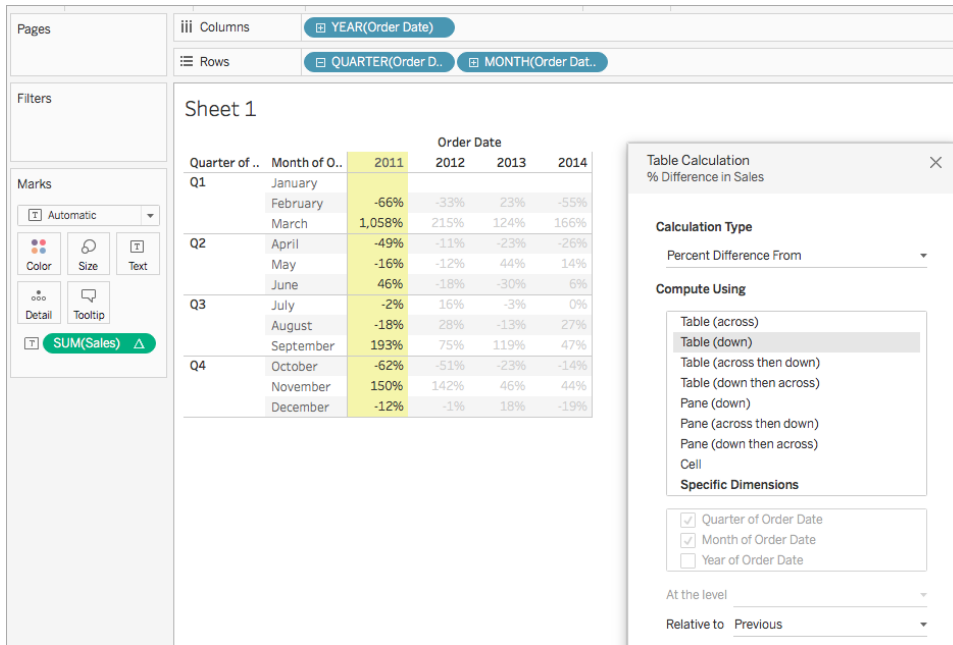

| | |
|----------|---|
| Previous | Calculates the difference between the current value and the previous value in the partition. This is the default value. |
| Next | Calculates the difference between the current value and the next value in the partition. |
| First | Calculates the difference between the current value and the first value in the partition. |
| Last | Calculates the difference between the current value and the last value in the partition. |

Example

Consider the text table below. It shows the total sales per month for 2011, 2012, 2013 and 2014 for a large store chain.

You can use a Percent Difference From table calculation to calculate how sales fluctuate (how much they go up or down) between the years for each month. Values are calculated as percentages.

You can see that between January and February, 2011, there was a -66% difference in sales, but between February and March, 2011, there was a huge improvement of 1,058% sales.

Percent From calculation

A **Percent From** table calculation computes a value as a percentage of some other value – typically, as a percentage of the previous value in the table – for each mark in the visualisation.

With a **Difference From**, **Percent Difference From**, or **Percent From** calculation, there are always two values to consider: the current value, and the value from which the difference should be calculated. In most cases, you want to calculate the difference between the current value and the previous value, as in the procedure above. But in some cases you may want something different.

To specify from which value the difference should be calculated:

1. Right-click a measure in the view and select **Add Table Calculation**.
2. In the Table Calculation dialog box, for **Relative to**, select one of the following options:

| | |
|----------|---|
| Previous | Calculates the difference between the current value and the previous value in the partition. This is the default value. |
| Next | Calculates the difference between the current value and the next value in the partition. |

| | |
|-------|---|
| First | Calculates the difference between the current value and the first value in the partition. |
| Last | Calculates the difference between the current value and the last value in the partition. |

Example

Consider the text table below. It shows the total sales per month for 2011, 2012, 2013 and 2014 for a large store chain.

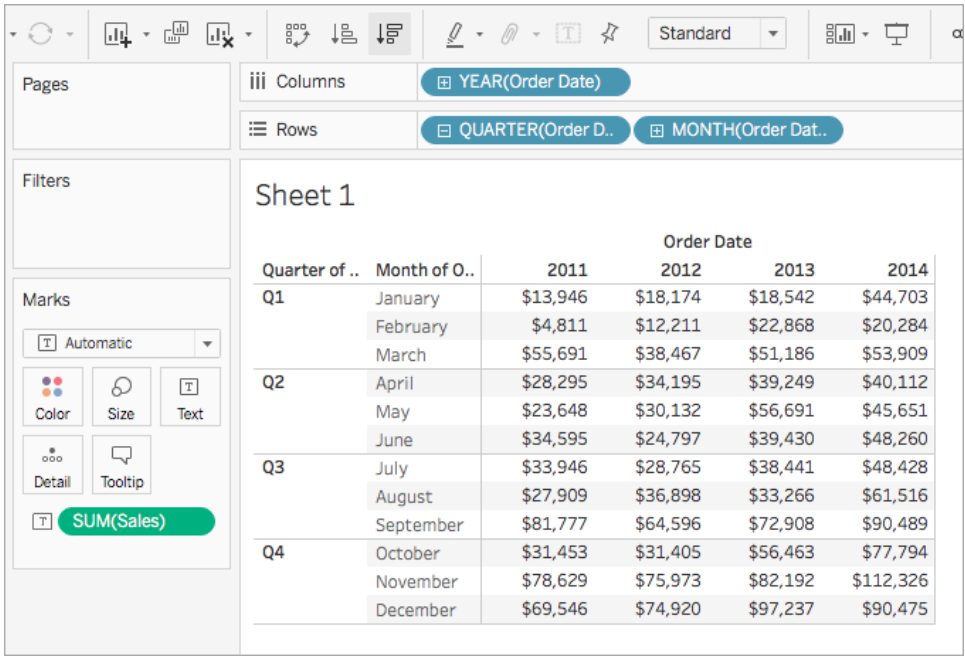

Tableau Desktop interface showing a table calculation. The Columns shelf contains YEAR(Order Date) and the Rows shelf contains QUARTER(Order Date) and MONTH(Order Date). The Marks shelf contains SUM(Sales). The resulting table shows sales data by quarter and month for 2011-2014.

| | | Order Date | | | |
|---------------|--------------|------------|----------|----------|-----------|
| Quarter of .. | Month of O.. | 2011 | 2012 | 2013 | 2014 |
| Q1 | January | \$13,946 | \$18,174 | \$18,542 | \$44,703 |
| | February | \$4,811 | \$12,211 | \$22,868 | \$20,284 |
| | March | \$55,691 | \$38,467 | \$51,186 | \$53,909 |
| Q2 | April | \$28,295 | \$34,195 | \$39,249 | \$40,112 |
| | May | \$23,648 | \$30,132 | \$56,691 | \$45,651 |
| | June | \$34,595 | \$24,797 | \$39,430 | \$48,260 |
| Q3 | July | \$33,946 | \$28,765 | \$38,441 | \$48,428 |
| | August | \$27,909 | \$36,898 | \$33,266 | \$61,516 |
| | September | \$81,777 | \$64,596 | \$72,908 | \$90,489 |
| Q4 | October | \$31,453 | \$31,405 | \$56,463 | \$77,794 |
| | November | \$78,629 | \$75,973 | \$82,192 | \$112,326 |
| | December | \$69,546 | \$74,920 | \$97,237 | \$90,475 |

You can use a Percent From table calculation to calculate the percentage of a previous value. For example, you can calculate what percentage of sales in January 2011, was made in February 2011.

You can see that February, 2011 made 34% of the sales made in January, 2011; March, 2011 made 1,158% of the sales made in February, and so on.

Percent of Total calculation

For each mark in the view, a **Percent of Total** table calculation computes a value as a percentage of all values in the current partition.

Example

Consider the text table below. It shows the total sales per month for 2011, 2012, 2013 and 2014 for a large store chain.

You can use a Percent of Total table calculation to calculate the percentage of total sales each month makes within a quarter. For example, you can see that January, 2011 makes up 18.73% of sales made in Q1.

Or you can calculate the percentage of total sales each month makes within a year. For example, you can see that January, 2011 makes up 2.88% of sales made in 2011.

Percentile calculation

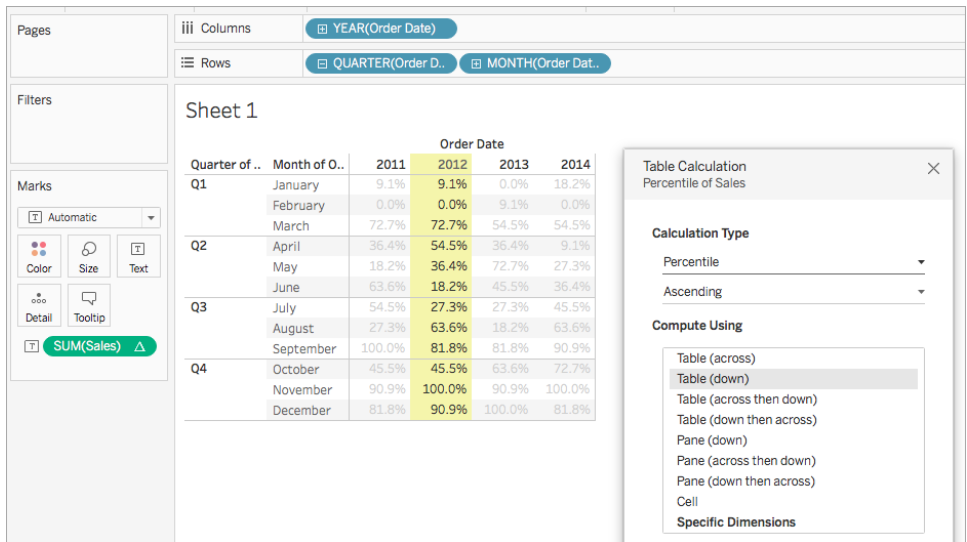

For each mark in the view, a **Percentile** table calculation computes a percentile rank for each value in a partition.

Example

Consider the text table below. It shows the total sales per month for 2011, 2012, 2013 and 2014 for a large store chain.

You can use a Percentile table calculation to rank the total sales for each month in a year as a percentage, rather than a whole number (for example, 1 through 10).

Since February made a very small amount of sales in 2012 compared to the overall total, it is ranked as 0.0% (or number 1 out of 12, since this example is Ascending, and therefore ranked from least to most). Sales in January, 2012 were a bit higher and were therefore ranked as 9.1% (or number 2 out of 12 months). Since November made the most sales in 2012, it is ranked as 100% (or number 12 out of 12).

Descending vs. Ascending

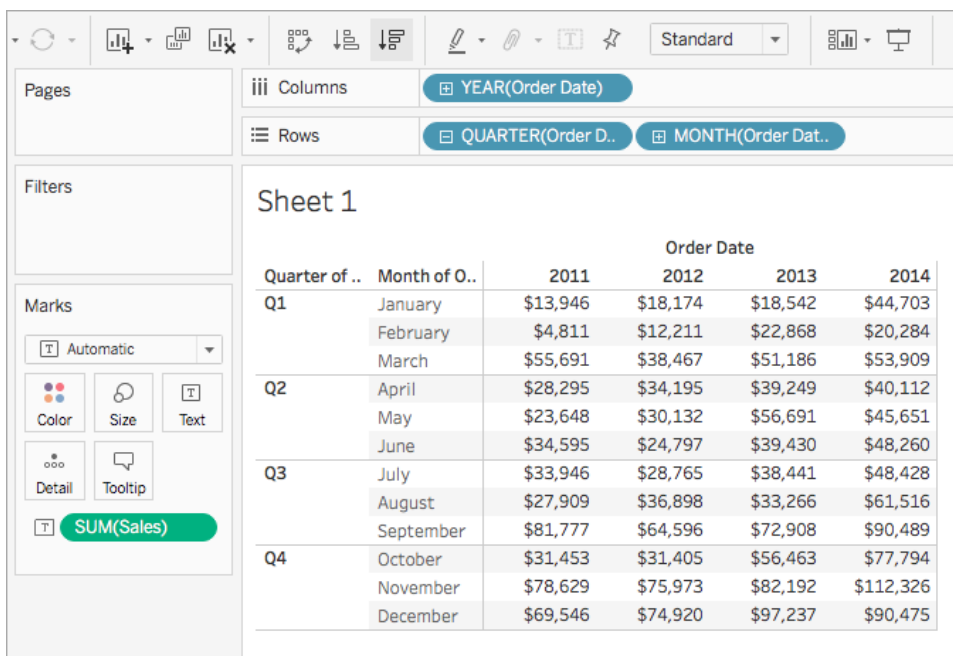

Ascending order ranks values from least to most. **Descending** order ranks values from most to least.

Rank calculation

For each mark in the view, a **Rank** table calculation computes a ranking for each value in a partition.

Example

Consider the text table below. It shows the total sales per month for 2011, 2012, 2013 and 2014 for a large store chain.

The screenshot shows the Tableau Desktop interface. The Columns shelf contains 'YEAR(Order Date)' and the Rows shelf contains 'QUARTER(Order Date)' and 'MONTH(Order Date)'. The Marks card is set to 'Automatic' with 'SUM(Sales)' as the calculation. The view displays a text table titled 'Sheet 1' with the following data:

| | | Order Date | | | |
|---------------|--------------|------------|----------|----------|-----------|
| Quarter of .. | Month of O.. | 2011 | 2012 | 2013 | 2014 |
| Q1 | January | \$13,946 | \$18,174 | \$18,542 | \$44,703 |
| | February | \$4,811 | \$12,211 | \$22,868 | \$20,284 |
| | March | \$55,691 | \$38,467 | \$51,186 | \$53,909 |
| Q2 | April | \$28,295 | \$34,195 | \$39,249 | \$40,112 |
| | May | \$23,648 | \$30,132 | \$56,691 | \$45,651 |
| | June | \$34,595 | \$24,797 | \$39,430 | \$48,260 |
| Q3 | July | \$33,946 | \$28,765 | \$38,441 | \$48,428 |
| | August | \$27,909 | \$36,898 | \$33,266 | \$61,516 |
| | September | \$81,777 | \$64,596 | \$72,908 | \$90,489 |
| Q4 | October | \$31,453 | \$31,405 | \$56,463 | \$77,794 |
| | November | \$78,629 | \$75,973 | \$82,192 | \$112,326 |
| | December | \$69,546 | \$74,920 | \$97,237 | \$90,475 |

You can use a Rank table calculation to calculate a ranking for each month in a year.

You can see that, since November made the most amount of sales in 2012, it is ranked as number 1 (because the rank is in descending order, meaning it is ordered from most to least). Since February made the least amount of sales in 2012, it is ranked number 12.

Descending vs. Ascending

Ascending order ranks values from least to most. **Descending** order ranks values from most to least. For Rank table calculation, the default value is **Descending**.

Rank Type

One issue with **Rank** calculations is that there may be more than one mark with the same value. What would happen, for example, if Tables in the Central region and Appliances in the South region both had sales of exactly \$36,729? Tableau lets you specify how to handle such cases by including an additional field in the Table Calculation dialog box when you set **Calculation Type** to **Rank**.

The choices are listed below. The number sequence at the beginning of each option show how each option would rank a hypothetical set of four values where two of the values are identical:

| Option | Result |
|--------------------------|---|
| Competition (1, 2, 2, 4) | Identical values are assigned an identical rank. The highest value is ranked 1 and then the next two, |

| | |
|-----------------------------------|---|
| | identical values, are both are ranked 2. The next value is then ranked 4. |
| Modified Competition (1, 3, 3, 4) | Identical values are assigned an identical rank. The highest value is ranked 1 and then the next two, identical values, are both are ranked 3. The next value is then ranked 4. |
| Dense (1, 2, 2, 3) | Duplicate values are all given the same rank, which is the next number in the ranking sequence. The next value after the duplicate values is computed as though the duplicate values were a single value. |
| Unique (1, 2, 3, 4) | Duplicate values are given unique rankings, according to the direction in which the ranking is being computed. |

Running Total calculation

For each mark in the view, a **Running Total** table calculation aggregates values cumulatively in a partition. It can do this by summing values, averaging values or replacing all values with either the lowest or highest actual value.

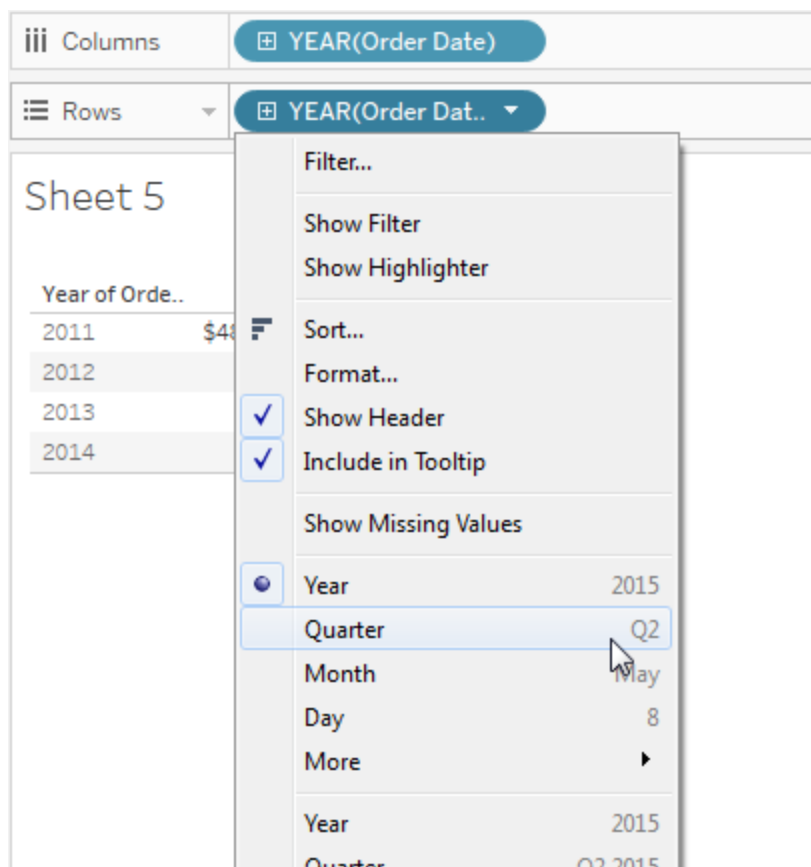

Suppose you are starting with the following text view, which shows sales totals broken out by year (from left to right) and by quarter and month (from top to bottom):

| | | Order Date | | | |
|----------------|---------------|------------|----------|----------|-----------|
| Quarter of O.. | Month of Or.. | 2011 | 2012 | 2013 | 2014 |
| Q1 | January | \$13,946 | \$18,174 | \$18,542 | \$44,703 |
| | February | \$4,811 | \$12,211 | \$22,868 | \$20,284 |
| | March | \$55,691 | \$38,467 | \$51,186 | \$53,909 |
| Q2 | April | \$28,295 | \$34,195 | \$39,249 | \$40,112 |
| | May | \$23,648 | \$30,132 | \$56,691 | \$45,651 |
| | June | \$34,595 | \$24,797 | \$39,430 | \$48,260 |
| Q3 | July | \$33,946 | \$28,765 | \$38,441 | \$48,428 |
| | August | \$27,909 | \$36,898 | \$33,266 | \$61,516 |
| | September | \$81,777 | \$64,596 | \$72,908 | \$90,489 |
| Q4 | October | \$31,453 | \$31,405 | \$56,463 | \$77,794 |
| | November | \$78,629 | \$75,973 | \$82,192 | \$112,326 |
| | December | \$69,546 | \$74,920 | \$97,237 | \$90,475 |

Instead of absolute sales values, you want to see a running total of sales for each year, such that each month's sales are added to all previous months' sales.

Create the Basic View

1. Connect to the **Sample - Superstore** data source.
2. Click and drag the **Order Date** field in the Data pane and drag it to the Columns shelf.
The default date level is YEAR (Order Date).
3. Click and drag **Order Date** again and drop it this time on the Rows shelf.
4. Click on the right side of the field to open the context menu. Then choose **Quarter**.

You will see two options named **Quarter**. Be sure to choose the first one.

The field should now read **QUARTER (Order Date)**.

Note: If you are creating the view on the web, the menu looks a bit different.

- Click and drag **Order Date** a third time and drop it on the Rows shelf to the right of **QUARTER (Order Date)**.
- Click on the right side of the field to open the context menu and this time choose **Month** (again, choose the first of two options named **Month**). The field should now read **MONTH (Order Date)**.
- Drag **Sales** from the Data pane and drop it on Text on the Marks card.

You now have the basic view, showing Sales by Order Date over a four-year period, by month, quarter and year.

Add a Running Total table calculation to the basic view

- Click the **SUM(Sales)** field on the Marks card and choose **Add table calculation**.
- In the Table Calculation dialog box, choose **Running Total** as the **Calculation Type**.
- Choose **Table (Down)** from the **Compute Using** list.

The highlighting in the view shows how this **Compute Using** value sets the scope of the calculation in the view:

| | | Order Date | | | |
|----------------|---------------|------------|-----------|-----------|-----------|
| Quarter of O.. | Month of Or.. | 2011 | 2012 | 2013 | 2014 |
| Q1 | January | \$13,946 | \$18,174 | \$18,542 | \$44,703 |
| | February | \$18,757 | \$30,385 | \$41,410 | \$64,987 |
| | March | \$74,448 | \$68,852 | \$92,596 | \$118,896 |
| Q2 | April | \$102,743 | \$103,047 | \$131,845 | \$159,008 |
| | May | \$126,391 | \$133,179 | \$188,536 | \$204,659 |
| | June | \$160,987 | \$157,976 | \$227,967 | \$252,919 |
| Q3 | July | \$194,933 | \$186,741 | \$266,407 | \$301,347 |
| | August | \$222,842 | \$223,640 | \$299,673 | \$362,863 |
| | September | \$304,620 | \$288,236 | \$372,581 | \$453,352 |
| Q4 | October | \$336,073 | \$319,640 | \$429,044 | \$531,146 |
| | November | \$414,702 | \$395,613 | \$511,236 | \$643,472 |
| | December | \$484,247 | \$470,533 | \$608,474 | \$733,947 |

Comparing the values in the original text view with the values in this view shows that the result is correct. The monthly values ascend steadily and the December value (484,247) is the same value you see if you show column grand totals (from the Analysis menu, select **Totals > Show column grand totals**).

4. Click the X in the upper-right corner of the Table Calculations dialog box to close it.

The Running Total doesn't have to be a sum

For a **Running Total** table calculation, Tableau can update values cumulatively in other ways than summing. Choose one of the options from the drop-down list just below the **Calculation Type** field:

| Option | Meaning |
|---------|---|
| Sum | Each value is added to the previous value. |
| Average | The running total averages the current and all previous values. |
| Minimum | All values are replaced with the lowest value in the original partition. |
| Maximum | All values are replaced with the highest value in the original partition. |

Restarting every option

The **Restarting every** option is only available when you select **Specific Dimensions** in the Table Calculations dialog box and when more than one dimension is selected in the field immediately below the **Compute Using** options – that is, when more than one dimension is defined as an addressing field.

This option is not available when you're defining a table calculation with **Compute Using**.

You can use this setting to set a break (that is, restart of the calculation) in the view, based on a particular dimension.

Restarting every can be useful in the following situations:

- With dates or other hierarchies, if you restart every month, as you bring in Year or Quarter, Tableau knows to partition automatically.

- With non-hierarchies, **Restarting every** affects the sorting. If you want to address on **Products** and partition by **State**, but you want the products sorted by **SUM(Sales)** within each state, you need to include **States** as an addressing field under Specific Dimensions, but then restart every state. Otherwise, the sort by **SUM(Sales)** would be based on each product's sum of sales across all states.

For example, if you take the result of the **Running Total** calculation you added above, you can see the effect of **Restarting every** by doing the following:

1. Click the **SUM (Sales)** field on the Marks card and choose **Edit table calculation**.
2. In the Table Calculation dialog box, choose **Specific Dimensions**.

Notice that two dimensions are now checked in the list box of dimensions: **Quarter of Order Date** and **Month of Order Date**. These are the addressing fields, and because more than one field is being used for addressing, Restarting every is now available.

The choices available from the At the level drop-down list are:

| | |
|------------------------------|--|
| None | Specifies that the calculation should be performed at the level of greatest granularity. This is the default option. This option does not change the view. |
| Quarter of Order Date | Specifies that the calculation should be performed at the quarter level. |

3. If you choose Quarter of Order Date, the view updates to show the effect of this change:

| Quarter of O.. | Month of Or.. | Order Date | | | |
|----------------|---------------|------------|-----------|-----------|-----------|
| | | 2011 | 2012 | 2013 | 2014 |
| Q1 | January | \$13,946 | \$18,174 | \$18,542 | \$44,703 |
| | February | \$18,757 | \$30,385 | \$41,410 | \$64,987 |
| | March | \$74,448 | \$68,852 | \$92,596 | \$118,896 |
| Q2 | April | \$28,295 | \$34,195 | \$39,249 | \$40,112 |
| | May | \$51,944 | \$64,327 | \$95,940 | \$85,764 |
| | June | \$86,539 | \$89,124 | \$135,370 | \$134,023 |
| Q3 | July | \$33,946 | \$28,765 | \$38,441 | \$48,428 |
| | August | \$61,856 | \$65,664 | \$71,706 | \$109,944 |
| | September | \$143,633 | \$130,260 | \$144,614 | \$200,433 |
| Q4 | October | \$31,453 | \$31,405 | \$56,463 | \$77,794 |
| | November | \$110,082 | \$107,377 | \$138,655 | \$190,120 |
| | December | \$179,628 | \$182,297 | \$235,893 | \$280,595 |

The calculation now restarts after every quarter. If you click out of the Table Calculations dialog box (to dismiss the highlighting) you can see this more clearly.

- Click the X in the upper-right corner of the Table Calculations dialog box to close it.

Add Secondary Calculation

With **Running Total** and **Moving Calculation** table calculations, you have the option to transform values twice to obtain the result you want – that is, to add a secondary table calculation on top of the primary table calculation. For example, you could add an initial table calculation to calculate the running total for sales per month within each individual year, and then a secondary calculation to calculate the year-over-year percent difference for each month from one year to the next.

To do this, first add the primary table calculation, as shown above. Then continue as follows:

- Click the **SUM (Sales)** field on the Marks card and select **Edit table calculation**.
- In the Table Calculation dialog box, click **Add Secondary Calculation**.

The Table Calculation dialog box expands to show a second panel:

Table Calculation
Difference in Running Sum of Sales

Primary Calculation Type
Running Total
Sum

Secondary Calculation Type
Difference From

Quick Table Calculations

Quick table calculations allow you to quickly apply a common table calculation to your visualisation using the most typical settings for that calculation type. This article demonstrates how to apply a quick table calculation to a visualisation using an example.

The following quick table calculations are available in Tableau for you to use:

- Running total
- Difference
- Percent difference
- Percent of total
- Rank
- Percentile
- Moving average
- YTD total
- Compound growth rate
- Year of year growth
- YTD growth

For more information about some of these, see [Table Calculation Types](#) on page 2366.

How does a quick table calculation differ from a table calculation?

Quick table calculations are table calculations that you can apply quickly to your visualisation in Tableau. They are applied to the visualisation with the most typical settings for the calculation type you choose so that you can continue on with your analysis. With traditional table calculations, you can apply the same settings, but you must apply them manually.

Apply a quick table calculation to the visualisation

Follow along with the steps below to learn how to apply a quick table calculation to a visualisation.

Step 1 Set up the visualisation

1. Open Tableau Desktop and connect to the **Sample-Superstore** data source, which comes with Tableau, and navigate to a new worksheet.
2. From the **Data** pane, drag **Order Date** to the **Columns** shelf.
3. Drag **State** to the **Rows** shelf.
4. Drag **Sales** to **Text** on the Marks Card.
5. Drag **Profit** to **Colour** on the Marks Card.

6. On the Marks card, click the Mark Type drop-down and select **Square**.

The visualisation updates to look like this:

Step 2 Apply the quick table calculation

1. On the Marks card, right-click **SUM(Profit)** and select **Quick Table Calculation > Moving Average**.

Note: You can only perform quick table calculations on measures in the view.

A delta symbol appears on the field to indicate that a quick table calculation is being applied to the field. The colours in the visualisation update to show the moving average of profit across the years.

Step 3(Optional) Customise the quick table calculation

1. On the Marks card, right-click **Sum(Profit)** and select **Edit Table Calculation**.
2. In the dialog box that opens, you can configure the following options:
 - The calculation type
 - How to aggregate the values
 - How to compute the calculation (how to address and partition the calculation)

For more information about these options, see [Table Calculation Types](#) on page 2366 and [The basics: addressing and partitioning](#) on page 2356

The visualisation updates as you make changes to the calculation. Highlighting and numbering are used to demonstrate how the calculation is being computed. For example, in the following image, the calculation is being computed across the table, for each State.

| State | Order Date | | | |
|----------------------|-----------------|-----------------|------------------|------------------|
| | 2014 | 2015 | 2016 | 2017 |
| Alabama | \$6,139 [1] | \$3,892 [2] | \$7,651 [3] | \$1,828 [4] |
| Arizona | \$8,295 [1] | \$9,611 [2] | \$6,242 [3] | \$11,134 [4] |
| Arkansas | \$6,303 [1] | \$444 [2] | \$2,224 [3] | \$2,708 [4] |
| California | \$91,304 [1] | \$88,444 [2] | \$131,552 [3] | \$146,388 [4] |
| Colorado | \$6,502 [1] | \$4,639 [2] | \$10,667 [3] | \$10,300 [4] |
| Connecticut | \$2,794 [1] | \$1,285 [2] | \$3,998 [3] | \$5,307 [4] |
| Delaware | \$4,786 [1] | \$6,190 [2] | \$2,720 [3] | \$13,755 [4] |
| District of Columbia | [1] | \$2,670 [2] | \$117 [3] | \$78 [4] |
| Florida | \$34,248 [1] | \$15,177 [2] | \$13,603 [3] | \$26,445 [4] |
| Georgia | \$4,540 [1] | \$11,338 [2] | \$14,058 [3] | \$19,160 [4] |
| Idaho | \$465 [1] | \$1,500 [2] | \$1,183 [3] | \$1,234 [4] |
| Illinois | \$16,203 [1] | \$18,578 [2] | \$21,034 [3] | \$24,352 [4] |
| Indiana | \$2,937 [1] | \$6,640 [2] | \$25,462 [3] | \$18,516 [4] |
| Iowa | \$1,191 [1] | \$1,713 [2] | \$959 [3] | \$716 [4] |

[Customise Table Calculations](#) below

Customise Table Calculations

You can always customise a table calculation by editing it in the Table Calculations dialog box, but there are other, more specialised ways to customise a table calculation.

Customising a Table Calculation Using Its Context Menu

Click any field in the view to see a context menu listing ways to customise the field. For a field in the view that has a table calculation, you can change the **Compute Using** option – that is, the option that determines the direction and scope of the calculation relative to the visual structure of the view. Do this by clicking the field and then choosing an option from the **Compute Using** list.

For **Difference From**, **Percent Difference From**, and **Percent From** table calculations, you can also specify a different field from which the difference should be computed. Do this by clicking the field and then choosing an option from the **Relative to** list. The options are **Previous**, **Next**, **First**, and **Last**.

Customising a Table Calculation Using the Calculation Editor

You can customise a table calculation by dragging it into the calculation editor:

The screenshot shows the Tableau interface. On the left, the Marks card has a green pill labeled 'SUM(Sales)' with a triangle icon. An arrow points from this pill to the calculation editor on the right. The calculation editor shows a text box labeled 'Calculation1' containing the formula: `WINDOW_AVG(SUM([Sales]), -2, 0)`. In the background, a table displays sales data by quarter and month.

| | Month | Q2 | Q3 | Q4 |
|----|-----------|-----------|-----------|-------------|
| Q2 | March | \$431,205 | \$319,390 | \$395,631 |
| | April | \$384,124 | \$287,534 | \$413,242 |
| | May | \$394,564 | \$343,181 | \$444,287 |
| Q3 | June | \$367,140 | \$431,925 | \$442,346 |
| | July | \$375,946 | \$441,334 | \$469,588 |
| | August | \$443,993 | \$423,132 | \$523,288 |
| Q4 | September | \$519,485 | \$534,675 | \$611,887 |
| | October | \$602,802 | \$671,275 | \$701,403 |
| | November | \$665,546 | \$902,301 | \$998,147 |
| | December | \$730,577 | \$872,136 | \$1,048,737 |

When you edit a table calculation in the calculation editor, you can click **Default Table Calculation** in the lower-right corner of the editor to open the calculation in the Table Calculation dialog box. This will allow you to create a new named calculated field that uses the same table calculation as the one you are basing the calculation on.

Nested Table Calculations

A nested table calculation can be one of two types of calculated fields:

- A calculated field that includes more than one calculated field with a table calculation (as in the example below), or
- A calculated field that itself has a table calculation and includes at least one calculated field with a table calculation.

With nested table calculations, you can set **Compute Using** configurations for individual calculations independently.

Here is a scenario you can try, using the Sample - Superstore data source that is included with Tableau Desktop, which results in a nested table calculation.

1. Drag **Sub-Category** to Columns and **Region** to Rows.
2. Create a calculated field, *1-nest*, with the definition `TOTAL (SUM ([Sales]))`.

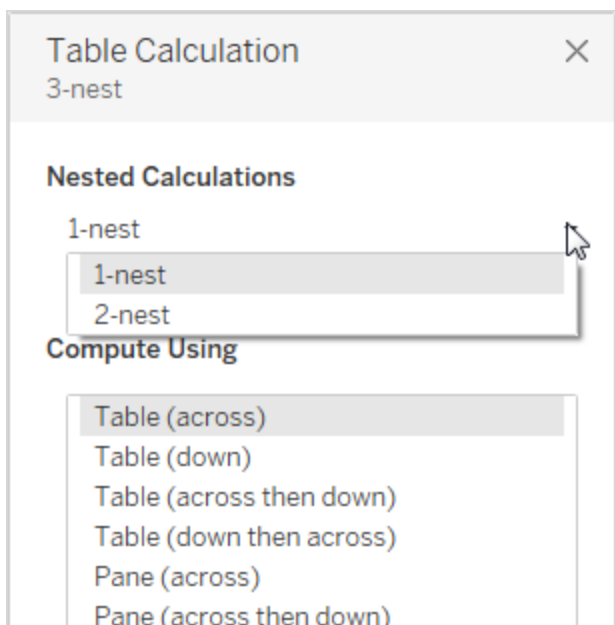

TOTAL is a table calculation function, so this calculated field automatically has a table calculation – when you use it in the view, the field will have the tell-tale table triangle, indicating a table calculation:

For information on table calculation functions, see [Table Calculation Functions on page 2137](#).

3. Create a second calculated field, *2-nest*, with the definition `TOTAL (SUM ([Profit]))`.
4. Create a third calculated field, *3-nest*, with the definition `[1-nest] + [2-nest]`.
5. Drag *3-nest* and drop it to the right of *Sub-Category* on Columns.
6. Click *3-nest* on Columns and choose **Edit Table Calculation**.

In the Table Calculations dialog box, you can now separately configure the underlying table calculations:

Create Level of Detail Expressions in Tableau

Level of Detail expressions (also known as LOD expressions) allow you to compute values at the data source level and the visualisation level. However, LOD expressions let you control the

granularity you want to compute. They can be performed at a more granular level (INCLUDE), a less granular level (EXCLUDE), or an entirely independent level (FIXED).

This article explains the types of LOD expressions you can use in Tableau, when to use them and how to format them.

How to create LOD expressions

Follow along with the steps to learn how to create and use an LOD expression in Tableau.

Step 1: Set up the Visualisation

1. Open Tableau Desktop and connect to the **Sample-Superstore** saved data source.
2. Navigate to a new worksheet.
3. From the **Data** pane, drag **Region** to the **Columns** Shelf.
4. From the **Data** pane, drag **Sales** to the **Rows** Shelf.

A bar chart showing the sum of sales for each region will appear.

Step 2: Create the LOD expression

Instead of the sum of all sales per region, you might want to also see the average sales per customer for each region. You can use an LOD expression to do this.

1. Select **Analysis > Create Calculated Field**.
2. In the Calculation editor that opens, do the following:
 - Name the calculation, Sales Per Customer.
 - Enter the following LOD expression:

```
{ INCLUDE [Customer Name] : SUM([Sales]) }
```

3. When finished, click **OK**.

The newly created LOD expression is added to the Data pane. To learn more about the types of LOD expressions you can use, see the [Types of LOD expressions on page 2403](#) section.

Step 3: Use the LOD expression in the visualisation

1. From the **Data** pane, drag **Sales per Customer** to the **Rows** shelf and place it to the left of SUM(Sales).
2. On the Rows shelf, right-click **Sales Per Customer** and select **Measure (Sum) > Average**.

You can now see both the sum of all sales and the average sales per customer for each region. For example, you can see that in the Central region, the sales totalled approximately \$500,000 with an average sale for each customer being approximately 800 USD.

Use a Quick LOD expression

You can create a FIXED LOD expression without needing to enter the full calculation into the calculation dialog.

There are two ways to create a quick LOD calculation.

1. In the **Data pane**, control-click drag the measure you want to aggregate onto the desired dimension. A new field appears as a FIXED LOD calculation.

The aggregation in the aggregate expression will come from the default aggregation on the measure. This is usually SUM. To change the aggregation or otherwise edit the LOD, right click on the new field and edit the calculation.

2. Or, in the **Data pane**, select the measure you want to aggregate and then control-click the dimension you want to aggregate on.

- Right-click on the selected fields and select **Create > LOD Calculation...**
- (Optional) Modify the LOD in the calculation editor.
- Select **OK** .

LOD expression syntax

A level of detail expression has the following structure:

```
{[FIXED | INCLUDE | EXCLUDE] <dimension declaration> : <aggregate expression>}
```

```
{ }
```

The entire level of detail expression is enclosed in curly brackets.

[FIXED | INCLUDE | EXCLUDE]

The first element after the opening curly bracket is one of the following scoping keywords:

FIXED

- FIXED level of detail expressions compute values using the specified dimensions without reference to the view level of detail – that is, regardless of other dimensions in the view.

- FIXED level of detail expressions ignore all the filters in the view other than context filters, data source filters and extract filters.

Example: { FIXED [Region] : SUM([Sales]) }

For more information about FIXED level of detail expressions, and for some example FIXED level of detail scenarios, see the [FIXED on page 2403](#) section.

INCLUDE

- INCLUDE level of detail expressions compute values using the specified dimensions in addition to whatever dimensions are in the view.
- INCLUDE level of detail expressions are most useful when including a dimension that isn't in the view.

Example: { INCLUDE [Customer Name] : SUM([Sales]) }

For more information about INCLUDE level of detail expressions, and for some example INCLUDE level of detail scenarios, see the [INCLUDE on page 2405](#) section.

EXCLUDE

- EXCLUDE level of detail expressions explicitly remove dimensions from the expression i.e. they subtract dimensions from the view level of detail.
- EXCLUDE level of detail expressions are most useful for eliminating a dimension in the view.

Example: { EXCLUDE [Region] : SUM([Sales]) }

For more information about EXCLUDE level of detail expressions, and for some example EXCLUDE level of detail scenarios, see the [EXCLUDE on page 2408](#) section.

Table-scoped

- For a table-scoped level of detail expression, no scoping keyword is required. For more information, see the [Table-Scoped on page 2410](#) section.

<dimension declaration>

Specifies one or more dimensions that set the scope of the aggregate expression, according to the keyword.

- `FIXED [Name]`

Use commas to separate multiple dimensions.

- `[Segment], [Category], [Region]`

You can use any expression that evaluates as dimension, including Date expressions.

- `{FIXED YEAR([Order Date]) : SUM(Sales)}` aggregates the sum of **Sales** at the Year level.
- `{INCLUDE DATETRUNC('day', [Order Date]) : AVG(Profit)}` aggregates the sum of **Sales** for **[Order Date]** truncated to the day date part. Because it's an INCLUDE expression, it also uses the dimensions in the view to aggregate the value.

Note: It's recommended that you drag fields into the calculation editor when creating dimension declarations, instead of typing them. For example, if you see **YEAR([Order Date])** on a shelf and then type that as the dimension declaration, it won't match the field on the shelf. But if you drag the field from the shelf into the expression, it becomes **DATEPART('year', [Order Date])**, and that matches the field on the shelf.

With calculations saved to the Data pane Tableau can't match the name of a calculation to its contents. For example:

- Create a calculation: **MyCalculation** = `YEAR([Order Date])`
- Create an EXCLUDE level of detail expression `{EXCLUDE YEAR([Order Date]) : SUM(Sales)}`

If you use both calculations in the view, **MyCalculation** isn't excluded. The LOD doesn't understand that `YEAR([Order Date])` is the same thing as **MyCalculation**.

Similarly, if the EXCLUDE expression specified **MyCalculation** (`{EXCLUDE MyCalculation : SUM(Sales)}`), then `YEAR([Order Date])` isn't excluded.

: (a colon)

A colon separates the dimension declaration from the aggregate expression.

<aggregate expression>

The aggregate expression is the calculation that is performed. For example, `SUM(Sales)` or `AVG(Discount)`. The results of the calculation in the aggregate expression depend on the dimension declaration and keyword.

The aggregate expression must be aggregated. The ATTR aggregation isn't supported, however. It doesn't have to be a simple aggregation, it can contain calculations, including other LOD expressions: `{FIXED [Question] : AVG(IF [Answer] = "Red" THEN 1 ELSE 0 END) }`

Table calculations aren't permitted in the aggregate expression.

Table-scoped LODs contain only the aggregate expression inside the braces, such as `{MIN(Grade) }`.

Types of LOD expressions

There are three types of LOD expressions you can create in Tableau:

- **FIXED** [below](#)
- **INCLUDE** [on page 2405](#)
- **EXCLUDE** [on page 2408](#)

You can also scope an LOD expression to the table. This is called a **Table-Scoped** [on page 2410](#) LOD expression.

FIXED

FIXED level of detail expressions compute a value using the specified dimensions, without reference to the dimensions in the view.

Example

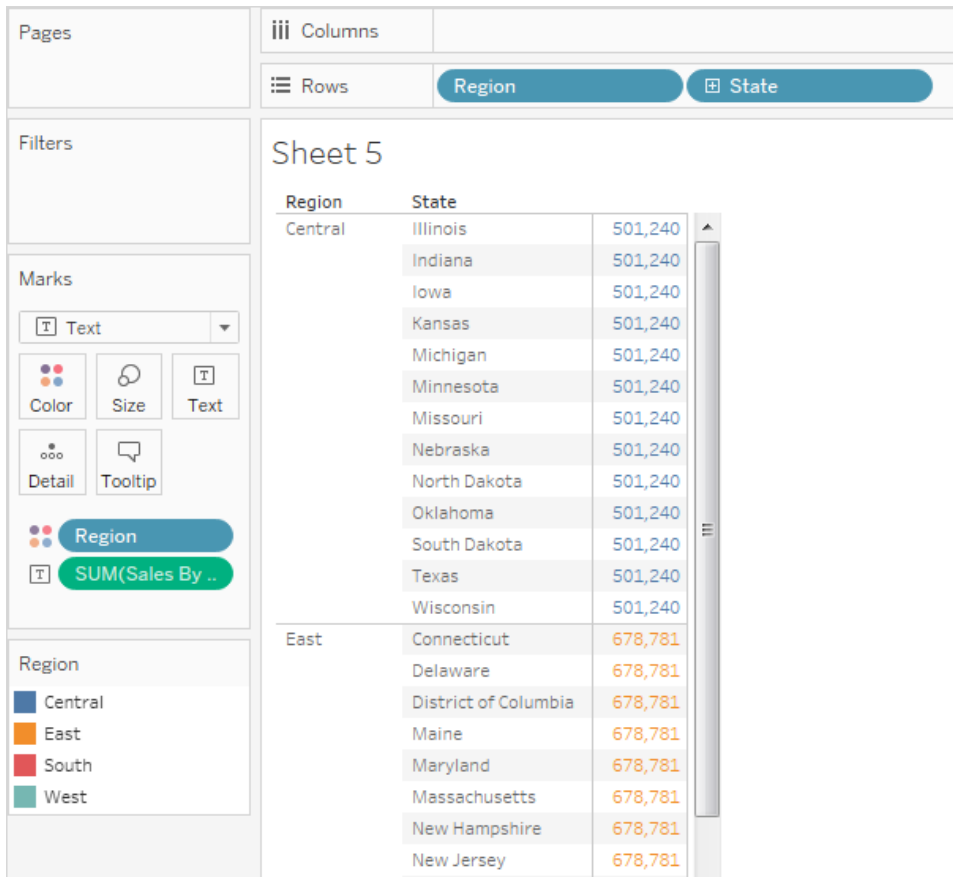

The following FIXED level of detail expression computes the sum of sales per region:

```
{FIXED [Region] : SUM([Sales])}
```

This level of detail expression, named **[Sales by Region]**, is then placed on Text to show total sales per region.

The view level of detail is **[Region]** and **[State]**. But FIXED level of detail expressions don't look at the dimensions in the view, only the dimensions specified in the calculation (here, **Region**).

Therefore, the values for the individual states in each region are identical. For more information, see [Aggregation and Level of Detail Expressions](#) on page 2415.

If the keyword had been **INCLUDE** instead of **FIXED**, the values would be different for each state. **INCLUDE** uses the dimension in the expression (**[Region]**) and any additional dimensions in the view (**[State]**) when evaluating the expression.

INCLUDE

INCLUDE level of detail expressions compute values using the specified dimensions in addition to whatever dimensions are in the view.

INCLUDE can be useful when you want to calculate at a fine level of detail in the database, but reaggregate at a coarser level of detail in your view. Fields based on INCLUDE level of detail expressions change as you add or remove dimensions from the view.

Example 1

This INCLUDE level of detail expression computes total sales per customer:

```
{ INCLUDE [Customer Name] : SUM([Sales]) }
```

With the LOD on the **Rows** shelf, aggregated as AVG, and **[Region]** on the **Columns** shelf, the view shows the average customer sales amount per region:

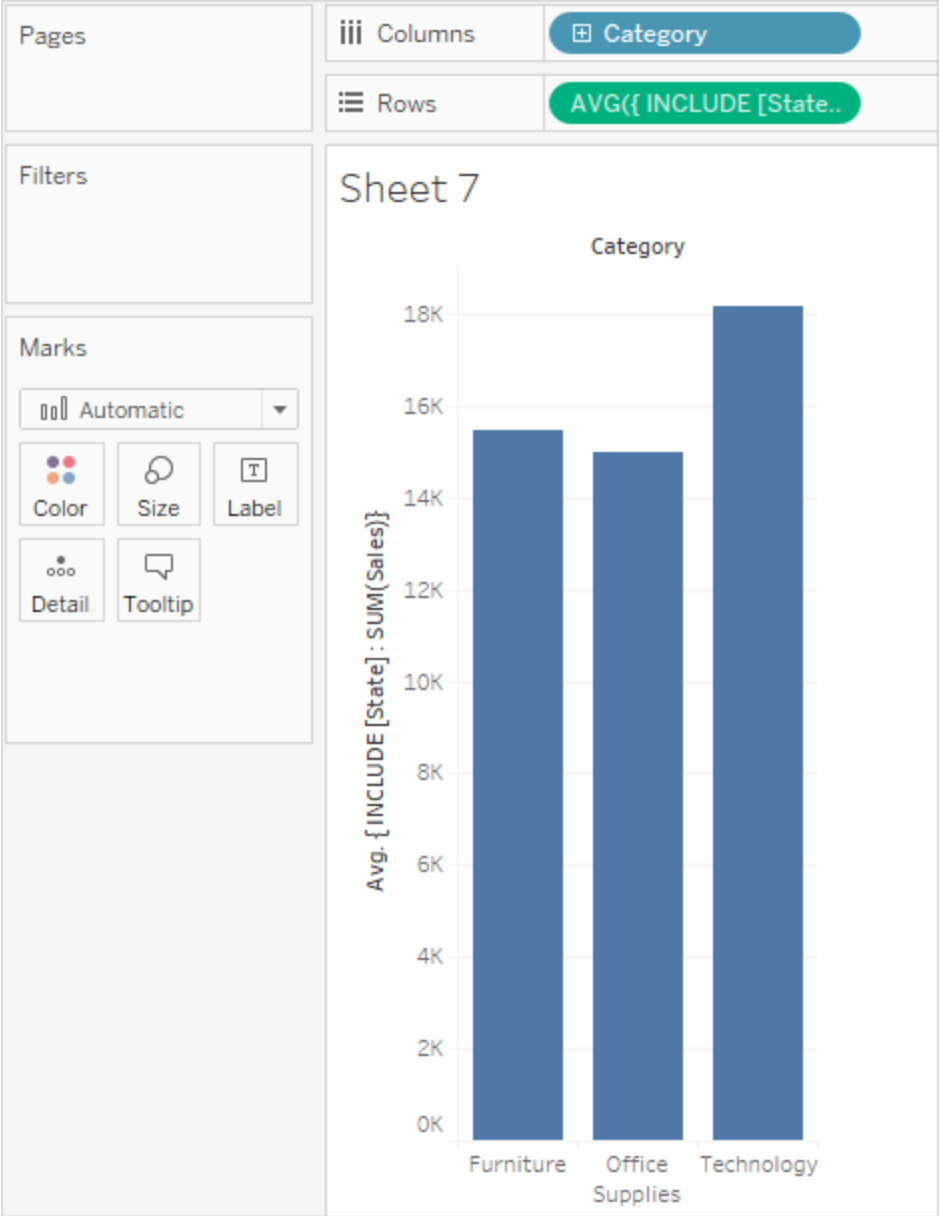

Example 2

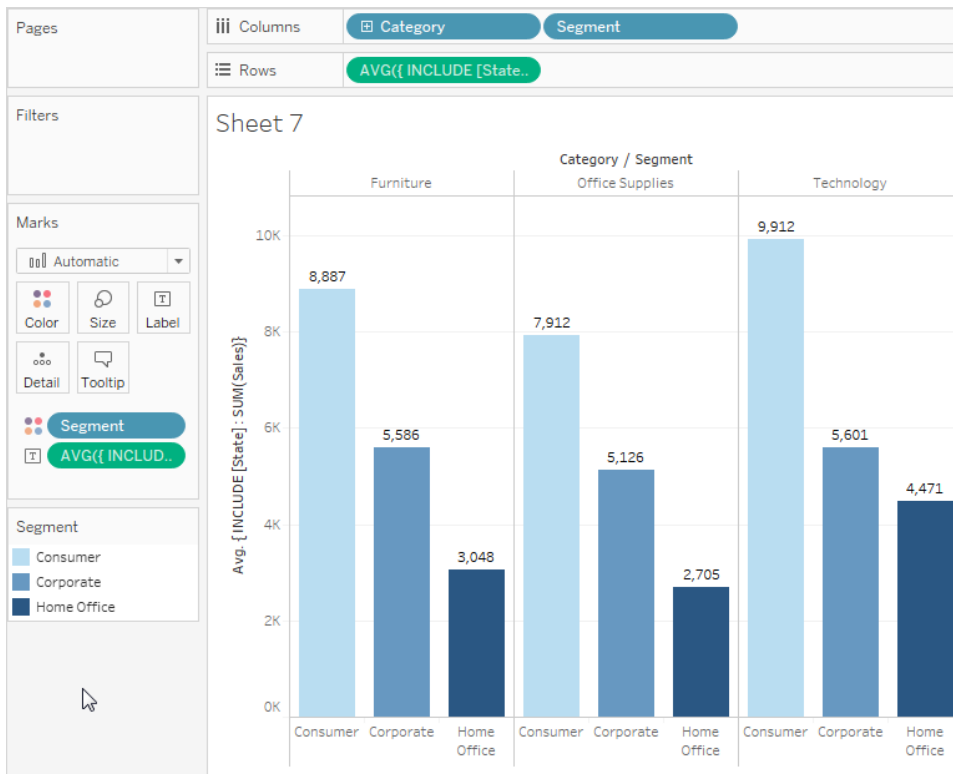

This INCLUDE level of detail expression calculates sum of sales on a per-state basis:

```
{ INCLUDE [State] : SUM(Sales) }
```

The calculation is placed on the Rows shelf and is aggregated as an average. The resulting visualisation averages the sum of sales by state across categories.

When **Segment** is added to the **Columns** shelf and the calculation is moved to **Label**, the LOD expression results update. Now you can see how the average sum of sales per state varies across categories and segments.

EXCLUDE

EXCLUDE level of detail expressions declare dimensions to omit from the view level of detail.

EXCLUDE is useful for 'percent of total' or 'difference from overall average' scenarios. They're comparable to Totals and Reference Lines.

EXCLUDE can't be used in row-level expressions (where there are no dimensions to omit). They can modify a view-level calculation or other LODs.

Example 1

The following EXCLUDE level of detail expression computes the average sales total per month then excludes the month.

1. First, create a field for Month/Year of Order Date.
 - Right-click "Order Date" in the **Data** pane and select Create > Create Custom Date.
 - From the Detail list, select "Month / Year". Leave the selection as discrete.

- Then, create an LOD expression named "average of sales by month":

```
{EXCLUDE [Order Date (Month / Year)] : AVG({FIXED [Order Date (Month / Year)] : SUM([Sales])})}
```

Notice that this is a nested level of detail expression – that is, a level of detail expression within another level of detail expression.

- The calculation can then be subtracted from the sum of sales per month with an ad-hoc calculation on the **Rows** shelf:

Rows $\sum([Sales]) - \sum([average\ of\ sales\ by\ month])$

- Put **Month([Order Date])** on the **Columns** shelf

The resulting view that shows the difference between actual sales per month and the average monthly sales for the entire four-year period:

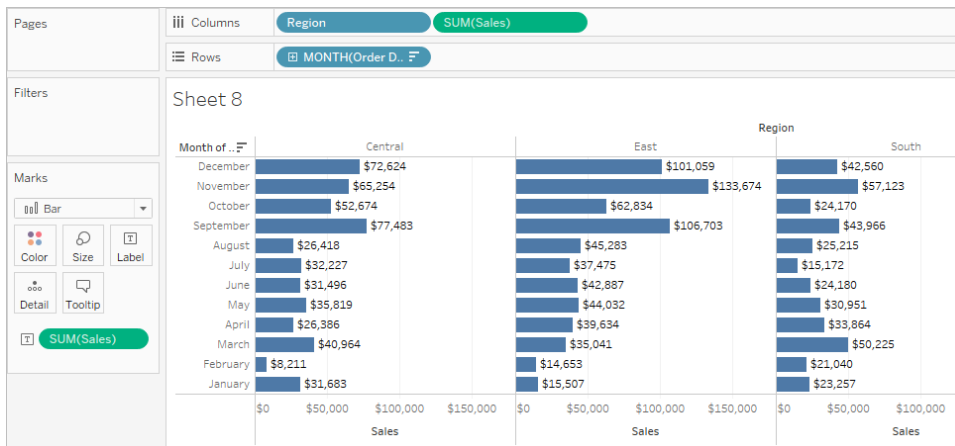

Example 2

Create a level of detail expression, named "ExcludeRegion", that excludes **[Region]** from the sum of **[Sales]**:

```
{EXCLUDE [Region] : SUM([Sales])}
```

Consider the following view, which breaks out the sum of sales by region and by month:

Putting **[ExcludeRegion]** on Colour shades the view to show total sales by month without the regional component:

Table-Scoped

It's possible to define a level of detail expression at the table level without using any of the scoping keywords. For example, the following expression returns the minimum (earliest) order date for the entire table:

```
{MIN([Order Date])}
```

This is equivalent to a FIXED level of detail expression with no dimension declaration:

```
{FIXED : MIN([Order Date])}
```

How Level of Detail Expressions Work in Tableau below

How Level of Detail Expressions Work in Tableau

This article explains how level of detail expressions are computed and how they function in Tableau. For more information about LOD expressions and how they work, see the [Understanding Level of Detail \(LOD\) Expressions](#) white paper on the Tableau website.

Row Level Expressions and View Level Expressions

In Tableau, expressions referencing **unaggregated** datasource columns are computed for each row in the underlying table. In this case, the dimensionality of the expression is *row level*. An example of a row-level expression is:

```
[Sales] / [Profit]
```

This calculation will be evaluated in each row of the database. For each row, the Sales value in that row will be divided by the Profit value in that row, producing a new column with the result of the multiplication (a profit ratio).

If you create a calculation with this definition, save it with the name **[ProfitRatio]**, and then drag it from the **Data** pane to a shelf, Tableau typically aggregates the calculated field for the view:

```
SUM([ProfitRatio])
```

By contrast, expressions referencing **aggregated** data source columns are computed at the dimensionality defined by the dimensions in the view. In this case, the dimensionality of the expression is view level. An example of a view-level expression is:

```
SUM(Sales) / SUM(Profit)
```

If you drag this calculation to a shelf (or type it directly on a shelf as an ad-hoc calculation), Tableau encloses it in an AGG function:

AGG(SUM(Sales) / SUM(Profit))

This is known as an aggregate calculation. For details, see [Aggregate Functions in Tableau on page 2107](#).

Dimension and set fields placed on any of the locations highlighted in the following image contribute to the view level of detail:

Before level of detail expressions were supported in Tableau, it was not possible to create calculations at a level of detail other than the view level. For example, if you attempted to save the following expression, Tableau displayed the error message: “Cannot mix aggregate and non-aggregate arguments with this function”:

```
[Sales] - AVG([Sales])
```

The user's intent, in this case, was to compare store sales for each individual store to the average of sales for all stores. This can now be accomplished with a level of detail expression:

```
[Sales] - {AVG([Sales])}
```

This is what is known as a table-scoped level of detail expression. See [Table-Scoped on page 2410](#)

Limitations for Level of Detail Expressions

The following limitations and constraints apply for level of detail expressions. Also see [Data Source Constraints for Level of Detail Expressions on page 2417](#).

- Level of detail expressions that reference floating-point measures can behave unreliably when used in a view that requires comparison of the values in the expression. For details, see [Understanding data types in calculations on page 2449](#).
- Level of detail expressions are not shown on the Data Source page. See [Data Source Page on page 23](#).
- When referencing a parameter in a dimensionality declaration, always use the parameter name, and not the parameter value.
- With data blending, the linking field from the primary data source must be in the view before you can use a level of detail expression from the secondary data source. See [Troubleshoot Data Blending on page 841](#).

In addition, some data sources have complexity limits. Tableau will not disable calculations for these databases, but query errors are a possibility if calculations become too complex.

Level of Detail Expressions Can Be Dimensions or Measures

When you save a level of detail expression, Tableau adds it to either the Dimensions or the Measures area in the Data pane.

FIXED level of detail expressions can result in measures or dimensions, depending on the underlying field in the aggregate expression. So `MIN([Date])` will be a dimension because `[Date]` is a dimension, and `{fixed Store : SUM([Sales])}` will be a measure because `[Sales]` is a measure. When a FIXED level of detail expression is saved as a measure you have the option of moving it to dimensions.

INCLUDE and EXCLUDE level of detail expressions are always measures.

Filters and Level of Detail Expressions

There are several different kinds of filters in Tableau. These are executed in the following order, from top to bottom.

The text on the right shows where level of detail expressions are evaluated in this sequence.

Extract Filters (in orange) are only relevant if you're creating a Tableau Extract from a data source. Table calculations filters (dark blue) are applied after calculations are executed and therefore hide marks without filtering out the underlying data used in the calculations.

If you're familiar with SQL, you can think of measure filters as equivalent to the HAVING clause in a query, and dimension filters as equivalent to the WHERE clause.

FIXED calculations are applied before dimension filters, so unless you promote the fields on your Filter shelf to **Use Context Filters** on page 1344, they will be ignored. For example, consider if you have the following calculation on one shelf in a view, along with **[State]** on a different shelf:

```
SUM([Sales]) / ATTR({FIXED : SUM([Sales])})
```

This calculation will give you the ratio of in-state sales to total sales.

If you then put **[State]** on the Filters shelf to hide some of the states, the filter will affect only the numerator in the calculation. Since the denominator is a FIXED level of detail expression, it will still divide the sales for the states still in the view against the total sales for all states – including the ones that have been filtered out of the view.

INCLUDE and EXCLUDE level of detail expressions are considered after Dimension filters. So if you want filters to apply to your FIXED level of detail expression but don't want to use Context Filters, consider rewriting them as INCLUDE or EXCLUDE expressions.

Aggregation and Level of Detail Expressions

The level of detail of the view determines the number of marks in your view. When you add a level of detail expression to the view, Tableau must reconcile two levels of detail – the one in the view, and the one in your expression.

The behaviour of a level of detail expression in the view varies depending on whether the expression's level of detail is coarser, finer or the same as the level of detail in the view. What do we mean by “coarser” or “finer” in this case?

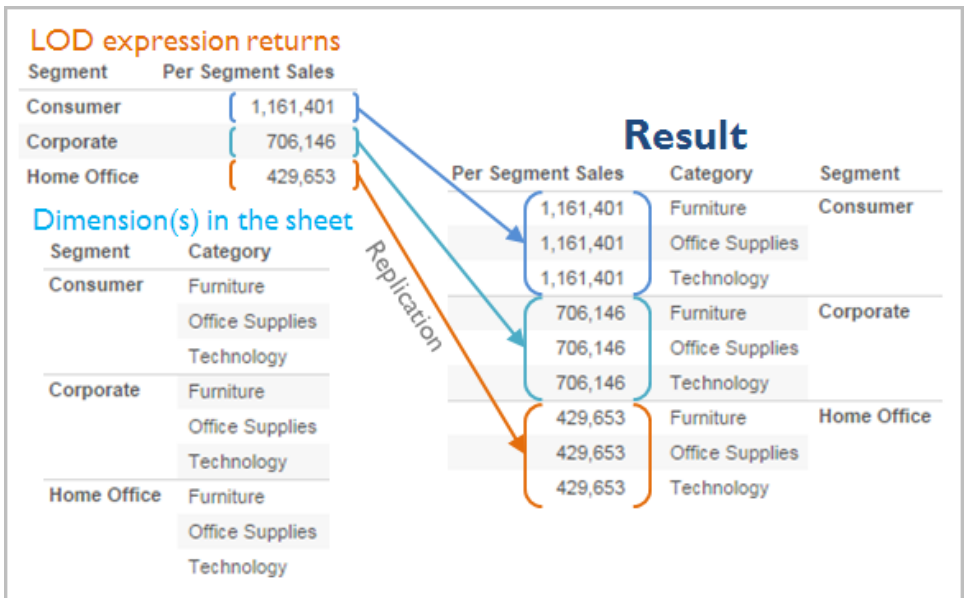

Level of Detail Expression is Coarser Than View Level of Detail

An expression has a coarser level of detail than the view when it references a subset of the dimensions in the view. For example, for a view that contained the dimensions **[Category]** and **[Segment]**, you could create a level of detail expression that uses only one of these dimensions:

```
{FIXED [Segment] : SUM([Sales])}
```

In this case, the expression has a coarser level of detail than the view. It bases its values on one dimension (**[Segment]**), whereas the view bases its view on two dimensions (**[Segment]** and **[Category]**).

The result is that using the level of detail expression in the view causes certain values to be replicated – that is, to appear multiple times.

Replicated values are useful for comparing specific values against average values within a category. For example the following calculation subtracts average sales for a customer from the average sales overall:

```
[Sales] - {FIXED [Customer Name] : AVG([Sales])}
```

When values are being replicated, changing the aggregation for the relevant field in the view (for example, from AVG to SUM) will not change the result of the aggregation.

Level of Detail Expression is Finer Than View Level of Detail

An expression has a finer level of detail than the view when it references a superset of the dimensions in the view. When you use such an expression in the view, Tableau will aggregate results up to the view level. For example, the following level of detail expression references two dimensions:

```
{FIXED [Segment], [Category] : SUM([Sales])}
```

When this expression is used in a view that has only [Segment] as its level of detail, the values must be aggregated. Here's what you would see if you dragged that expression to a shelf:

```
AVG([ {FIXED [Segment], [Category] : SUM([Sales]) } ])
```

An aggregation – in this case, average – is automatically assigned by Tableau. You can change the aggregation as needed.

Adding a Level of Detail Expression to the View

Whether a level of detail expression is aggregated or replicated in the view is determined by the expression type (FIXED, INCLUDE or EXCLUDE) and whether the expression's granularity is coarser or finer than the view's.

- INCLUDE level of detail expressions will have either the same level of detail as the view or a finer level of detail than the view. Therefore, values will never be replicated.
- FIXED level of detail expressions can have a finer level of detail than the view, a coarser level of detail or the same level of detail. The need to aggregate the results of a FIXED level of detail depends on what dimensions are in the view.
- EXCLUDE level of detail expressions always cause replicated values to appear in the view. When calculations including EXCLUDE level of detail expressions are placed on a shelf, Tableau defaults to the ATTR aggregation (as opposed to SUM or AVG) to indicate

that the expression is not actually being aggregated and that changing the aggregation will have no effect on the view.

Level of detail expressions are always automatically wrapped in an aggregate when they are added to a shelf in the view, unless they are used as dimensions. So, if you double-click on a shelf and type

```
{FIXED[Segment], [Category] : SUM([Sales])}
```

and then press Enter to commit the expression, what you now see on the shelf is

```
SUM({FIXED[Segment], [Category] : SUM([Sales])})
```

But if you double-click into the shelf to edit the expression, what you see in edit mode is the original expression.

If you wrap a level of detail expression in an aggregation when you create it, Tableau will use the aggregation you specified rather than assigning one when any calculation including that expression is placed on a shelf. When no aggregation is needed (because the level of detail of the expression is coarser than that of the view), the aggregation you specified is still shown when the expression is on a shelf, but it is ignored.

Data Source Constraints for Level of Detail Expressions

For some data sources, only more recent versions support level of detail expressions. Some data sources do not support level of detail expressions at all.

In addition, some data sources have complexity limits. Tableau will not disable calculations for these databases, but query errors are a possibility if calculations become too complex.

| Data Source | Support |
|---------------------------|---------------------------------------|
| Action Vectorwise | Not supported. |
| Amazon EMR Hadoop Hive | Supported for Hive 0.13 and later. |
| Amazon Redshift | Supported. |
| Aster Database | Supported for version 4.5 and later. |
| Cloudera Hadoop | Supported for Hive 0.13 and later. |
| Cloudera Impala | Supported for Impala 1.2.2 and later. |

| | |
|---|---|
| Cubes (multidimensional data sources) | Not supported. |
| DataStax Enterprise | Not supported. |
| EXASOL | Supported. |
| Firebird | Supported for version 2.0 and later. |
| Generic ODBC | Limited. Depends on the specific data source. |
| Google Big Query | Supported for standard SQL, not supported for legacy SQL. |
| Hortonworks Hadoop Hive | <p>Supported for Hive 0.13 and later.</p> <p>On version 1.1 of HIVE level of detail expressions that produce cross joins are not reliable.</p> <p>Cross join occur when there is no explicit field to join on. For example, for a level of detail expression <code>{fixed [Product Type] : sum (sales) }</code> when the view only contains one dimension [Ship Mode], Tableau creates a cross-join. A cross join produces rows which combine each row from the first table with each row from the second table.</p> |
| IBM BigInsights | Supported. |
| IBM DB2 | Supported for version 8.1 and later. |
| MarkLogic | Supported for version 7.0 and later. |
| Microsoft Access | Not supported. |
| Microsoft Jet-based connections (legacy connectors for Microsoft Excel, Microsoft Access, and text) | Not supported. |
| Microsoft SQL | SQL Server 2005 and later. |

Server

| | |
|-----------------------------|--------------------------------------|
| MySQL | Supported. |
| IBM PDA (Netezza) | Supported version 7.0 and later. |
| Oracle | Supported version 9i and later. |
| Action Matrix (ParAccel) | Supported version 3.1 and later. |
| Pivotal Greenplum | Supported for version 3.1 and later. |
| PostgreSQL | Supported version 7 and later. |
| Progress OpenEdge | Supported. |
| SAP HANA | Supported. |
| SAP Sybase ASE | Supported. |
| SAP Sybase IQ | Supported version 15.1 and later. |
| Spark SQL | Supported. |
| Splunk | Not supported. |
| Tableau Data Extract | Supported. |
| Teradata | Supported. |
| Vertica | Supported for version 6.1 and later. |

[Understanding Level of Detail \(LOD\) Expressions](#)

Table-Scoped Level of Detail Expressions

It is possible to define a level of detail expression at the table level without using any of the scoping keywords. For example, the following expression returns the minimum (earliest) order

date for the entire table:

```
{MIN([Order Date])}
```

This is equivalent to a FIXED level of detail expression with no dimension declaration:

```
{FIXED : MIN([Order Date])}
```

FIXED Level of Detail Expressions

FIXED level of detail expressions compute a value using the specified dimensions, without reference to the dimensions in the view.

The following examples can be recreated using the **Sample - Superstore** data source.

Example 1

The following view shows the interval between a customer's first purchase date and any subsequent purchase:

Step-by-Step

Here's how to build the view above, using the Sample - Superstore data source provided with Tableau Desktop.

1. Create two calculated fields: a FIXED level of detail expression, and a date subtraction.

| Name | Formula |
|----------------------------------|--|
| First Purchase Date | {FIXED [Customer Name] : MIN([Order Date])} |
| Days Since First Purchase | DATETRUNC('day', [Order Date])-DATETRUNC('day', [First Purchase Date]) |

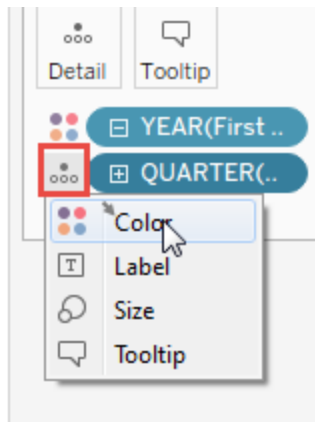

2. Drag **Days Since First Purchase** from the Measures area of the Data pane to the Dimensions area.

Because this calculated field contains a subtraction operation, the result is a number, and so Tableau assigns it to the measure category. But you will be using it as a dimension.

3. Drag **Days Since First Purchase** to Columns.
4. Click **Days Since First Purchase** on Columns and choose **Continuous**.
5. Drag **Sales** to Rows.
6. Change the aggregation for **Sales** on Rows from SUM to AVG.
7. Add a quick table calculation to **Sales** on Rows: Running Total.
8. Drag **First Purchase Date** to Colour.
9. Click the + in the **YEAR(First Purchase Date)** field on Colour to add the next level down in the date hierarchy: **QUARTER(First Purchase Date)**.

10. Tableau won't automatically put two fields on Colour, but you can make it happen by clicking the icon to the left of the **QUARTER(First Purchase Date)** field and choosing Colour:

11. Drag the Colour legend over to the left side of the view, below the Marks card.

Your view should now look like this:

The visualisation yields insights as you interact with it. Select individual quarters in the colour legend on the left to see how customers acquired in specific individual quarters continued to spend in subsequent quarters. Notice that customers acquired in the early going (2013) tend to spend at a higher rate, even allowing for the fact that they had more time to do so – thus, the blue lines (for 2013) are higher up on the x-axis than other lines. If you had used a standard date value on the y-axis, the view would have been easier to create, but the lines would not all start at the same coordinates and so it would be more difficult to compare acquisition rates.

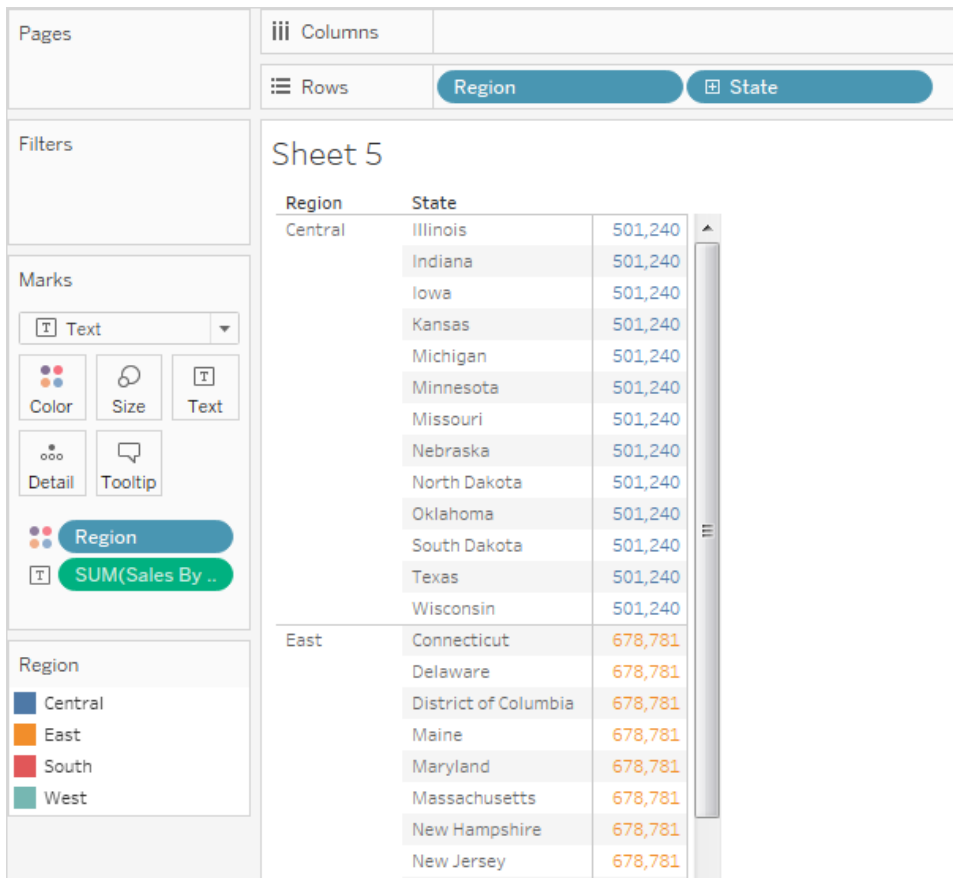

You can also drag either YEAR(First Purchase Date) or QUARTER(First Purchase Date) off colour to see seasonal or annual trends more clearly.

Example 2

The following FIXED level of detail expression computes the sum of sales per region:

```
{FIXED [Region] : SUM([Sales])}
```

This level of detail expression, named **[Sales by Region]**, is then placed on Text to show total sales per region:

The view level of detail is **[Region]** plus **[State]**, but because **FIXED** level of detail expressions do not consider the view level of detail, the calculation only uses the **[Region]** dimension, and so the values for the individual states in each region are identical. See [Level of Detail Expressions and Aggregation on page 2434](#) for an explanation of why this is so.

If the **INCLUDE** keyword had been used in the level of detail expression instead of **FIXED**, the values would be different for each state, because Tableau would add the dimension in the expression (**[Region]**) with any additional dimensions in the view (**[State]**) in determining values for the expression. The result would be:

INCLUDE Level of Detail Expressions

INCLUDE level of detail expressions compute values using the specified dimensions in addition to whatever dimensions are in the view.

INCLUDE level of detail expressions can be useful when you want to calculate at a fine level of detail in the database and then re-aggregate and show at a coarser level of detail in your view. Fields based on INCLUDE level of detail expressions will change as you add or remove dimensions from the view.

Example 1

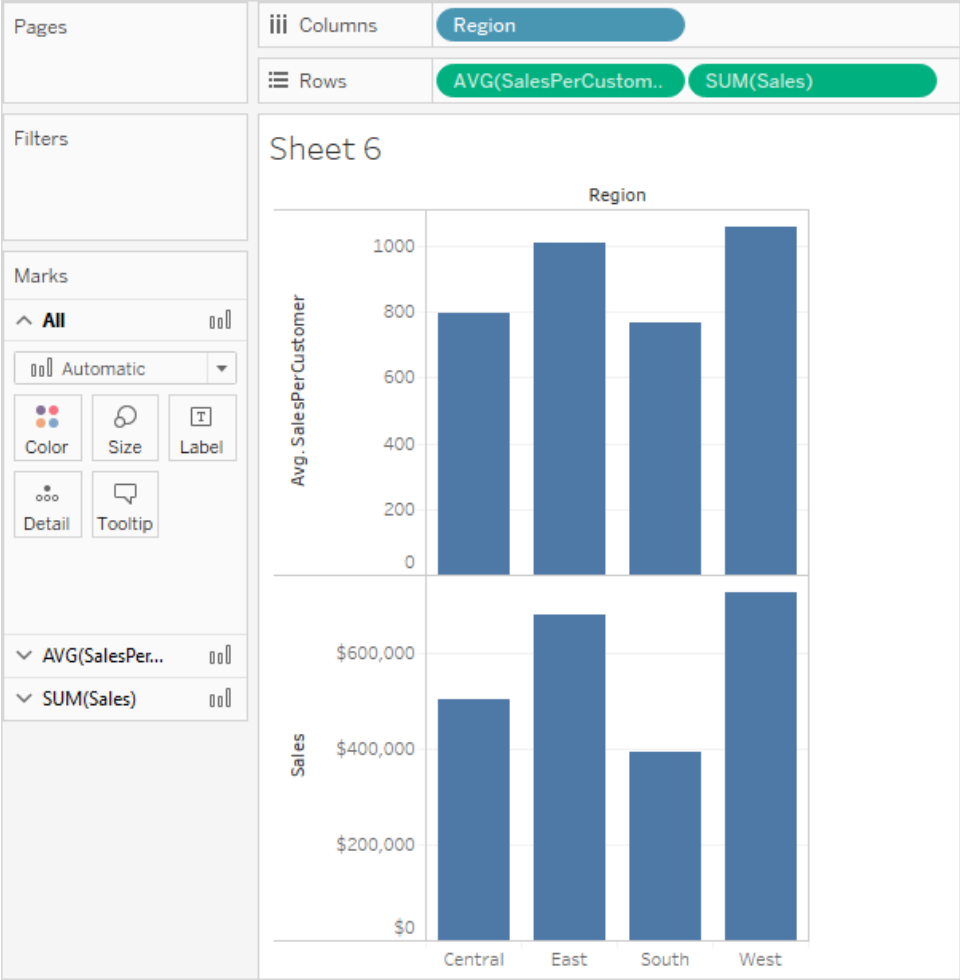

The following INCLUDE level of detail expression computes total sales per customer:

```
{ INCLUDE [Customer Name] : SUM([Sales]) }
```

When that calculation is placed on the **Rows** shelf, aggregated as AVG, and the **[Region]** dimension is placed on the **Columns** shelf, the view shows the average customer sales amount per region:

If the **[Sales]** measure is then dragged to the **Rows** shelf, the result illustrates the difference between the sum of sales (somewhere between \$390K and \$700K per region) and the average sales per customer (between \$750 and \$1100 per region):

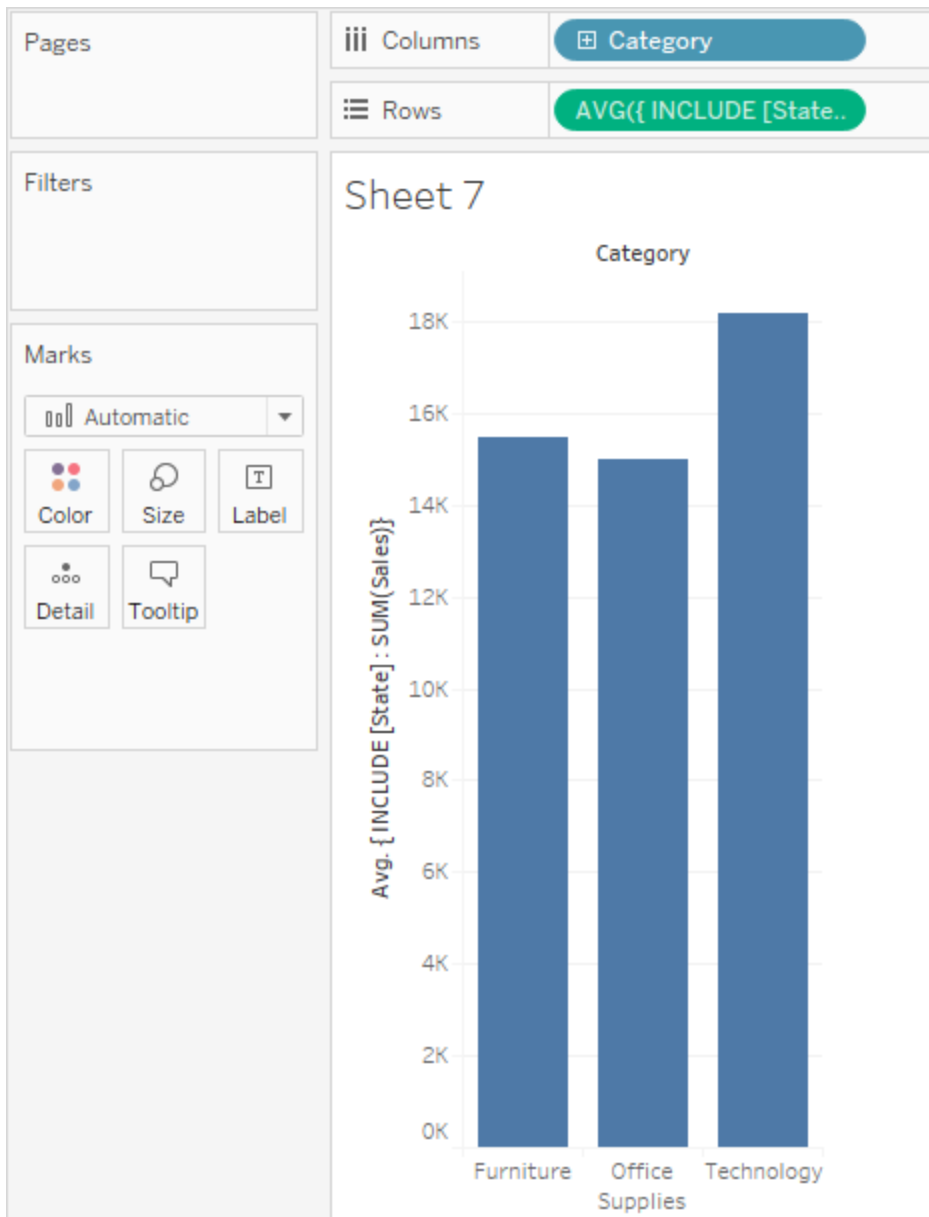

Example 2

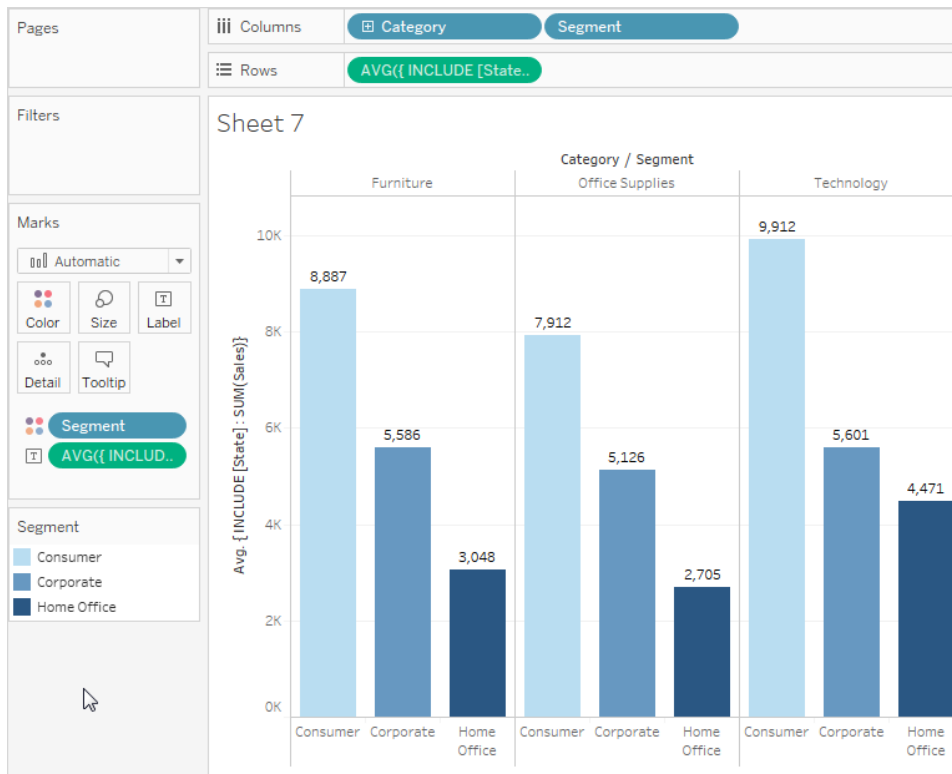

The following INCLUDE level of detail expression calculates sum of sales on a per-state basis:

```
{ INCLUDE [State] : SUM(Sales) }
```

Type the calculation directly on the **Rows** shelf, and then change the aggregation to AVG using the field's context menu. The resulting view averages the sum of sales by state across categories.

The view can be further enhanced by adding **[Segment]** to **Columns** and then copying the ad-hoc calculation from **Rows** to **Label** (using Ctrl+drag). In the image below we also dragged **Segment** to **Colour** and then edited the colours for aesthetic effect. Now we can see how the average sum of sales per state varies across categories and segments.

EXCLUDE Level of Detail Expressions

For foundational concepts about level of detail (LOD) expressions, see [Create Level of Detail Expressions in Tableau on page 2395](#) and [How Level of Detail Expressions Work in Tableau on page 2411](#).

Level of detail expressions are used to modify or control the level of detail (granularity) of a calculation. Most fields and calculations are tied to the granularity of the view or of the data source. LOD expressions allow you to set the granularity of a calculation explicitly.

- **FIXED** LOD expressions establish a specific dimension or dimensions for the rest of the calculation, such as returning the maximum blood pressure for each patient instead of the overall maximum in the data set by fixing the maximum to Patient ID.
- **INCLUDE** LOD expressions ensure that a dimension that isn't necessarily present in the view is considered in the calculation, such as looking at the average blood pressure for each patient including their sex, displayed in a view that doesn't contain sex information.
- **EXCLUDE** LOD expressions remove some of the detail from the view for the purposes of the calculation, such as looking at the average blood pressure for patients on a certain medication without considering individual patients, even if the view is by patient.

Note: Whenever a FIXED LOD is used, it will give the same result regardless of the visualisation. When an INCLUDE or EXCLUDE LOD is used, the value might change depending on the structure of the view. The INCLUDE keyword takes the context of the view and adds a dimension for the calculation to consider (and the EXCLUDE removes a dimension present in the view from the context of the calculation), so using the calculation in another context can offer different results.

Consider a view (A) built with patient ID, age and sex, and another view (B) with patient ID, age, and *weight*.

- A FIXED LOD expression will have the same value in both cases because the calculation ignores what is in the view and cares only about the dimension in the LOD expression.
- An INCLUDE LOD that includes *weight* will have a different value in each view, because it adds a dimension to view A but not to view B, which already had weight.
- An EXCLUDE LOD that excludes *weight* will have a different value in each view, because it removes a dimension from view B but doesn't change the context of view A, which already didn't have weight.

EXCLUDE

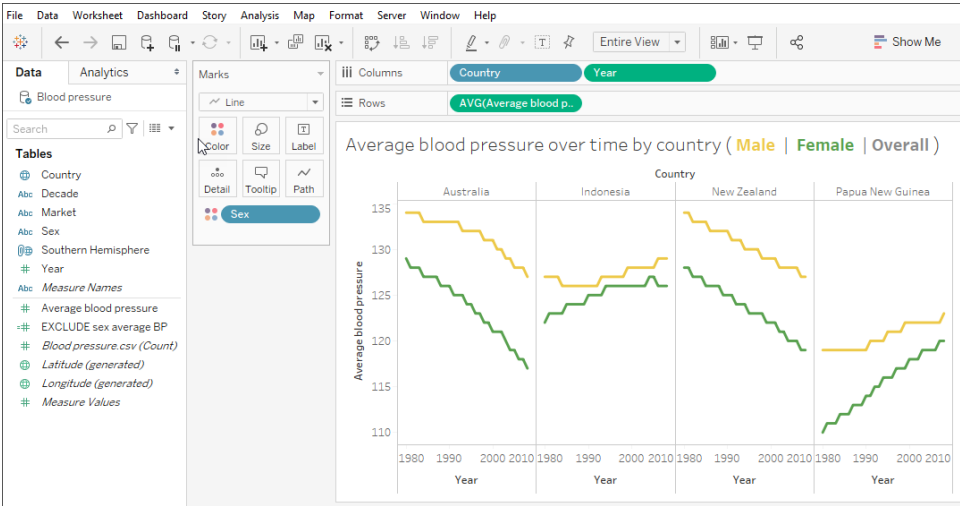

EXCLUDE level of detail expressions prevent the calculation from using one or more of the dimensions present in the view.

EXCLUDE level of detail expressions are useful for 'percent of total' or 'difference from overall average' scenarios. They are comparable to such features as Totals and Reference Lines.

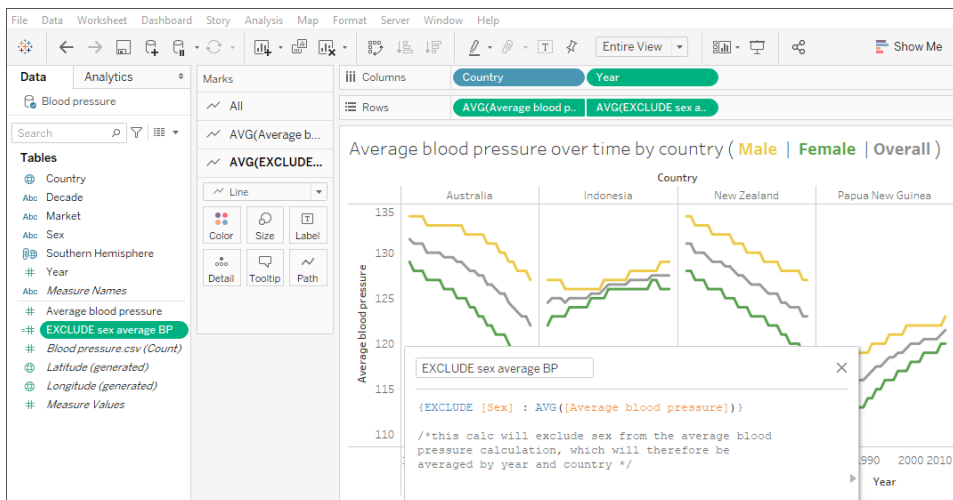

EXCLUDE level of detail expression cannot be used in row-level expressions (where there are no dimensions to omit), but can be used to modify either a view level calculation or anything in between (that is, you can use an EXCLUDE calculation to remove dimension from some other level of detail expression).

Example 1

The image below shows the change in average blood pressure over time for four countries, broken out by sex.

To see the average blood pressure for each country over time but without being split by male and female, use an EXCLUDE level of detail expression {EXCLUDE [Sex] : AVG[Average blood pressure]}. This is plotted as the grey line in the viz.

Bringing an average line out from the Analytics pane wouldn't work, because it would simply be a horizontal line for the average blood pressure per country, ignoring sex and year.

Note: This example takes the average of averages which is an incorrect analytical practice. It is done here purely for illustration purposes. No analysis should be made from this visualisation.

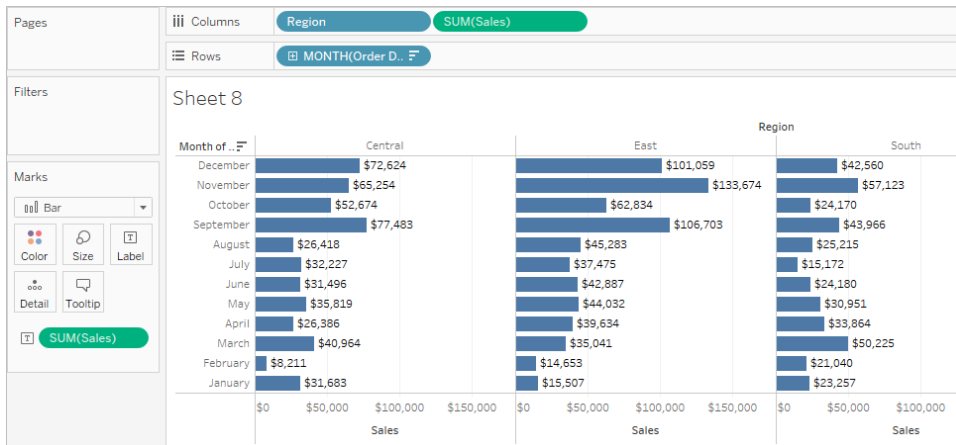

Example 2

The following level of detail expression excludes **[Region]** from a calculation of the sum of **[Sales]**:

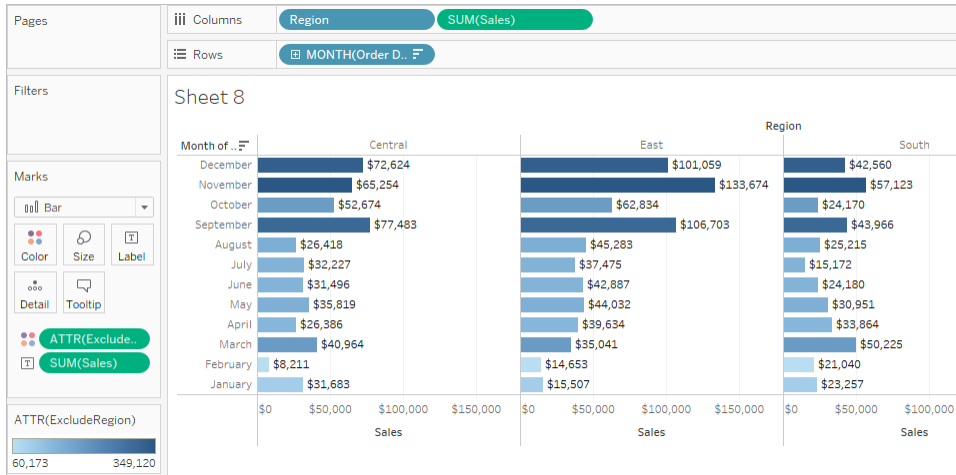

```
{EXCLUDE [Region]: SUM([Sales])}
```

The expression is saved as **[ExcludeRegion]**.

To illustrate how this expression might be useful, first consider the following view, which breaks down the sum of sales by region and by month:

Dropping **[ExcludeRegion]** on Colour shades the view to show total sales by month but without the regional component:

Example 3

The following EXCLUDE level of detail expression computes the average sales total per month and then excludes the month component:

```
{EXCLUDE [Order Date (Month / Year)] : AVG({FIXED [Order Date (Month / Year)] : SUM([Sales])})}
```

Notice that this is a nested level of detail expression – that is, a level of detail expression within another level of detail expression.

Saved as **[average of sales by month]**, the calculation can then be subtracted from the sum of sales per month by means of an ad-hoc calculation on the **Rows** shelf:

With **Month([Order Date])** on the **Columns** shelf, this creates a view that shows the difference between actual sales per month over a four-year period and the average monthly sales for the entire four-year period:

Level of Detail Expressions and Aggregation

The level of detail of the view determines the number of marks in your view. When you add a level of detail expression to the view, Tableau must reconcile two levels of detail – the one in the view, and the one in your expression.

The behaviour of a level of detail expression in the view varies depending on whether the expression's level of detail is coarser, finer or the same as the level of detail in the view. What do we mean by “coarser” or “finer” in this case?

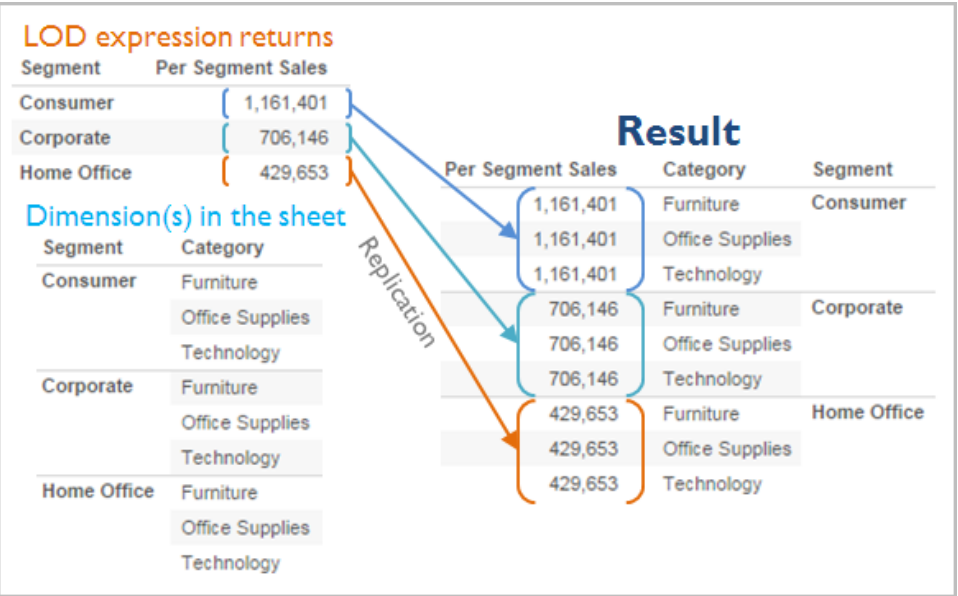

Level of Detail Expression is Coarser Than View Level of Detail

An expression has a coarser level of detail than the view when it references a subset of the dimensions in the view. For example, for a view that contained the dimensions **[Category]** and **[Segment]**, you could create a level of detail expression that uses only one of these dimensions:

```
{FIXED [Segment] : SUM([Sales])}
```

In this case, the expression has a coarser level of detail than the view. It bases its values on one dimension ([**Segment**]), whereas the view bases its view on two dimensions ([**Segment**] and [**Category**]).

The result is that using the level of detail expression in the view causes certain values to be replicated – that is, to appear multiple times.

Replicated values are useful for comparing specific values against average values within a category. For example the following calculation subtracts average sales for a customer from the average sales overall:

```
[Sales] - {FIXED [Customer Name] : AVG([Sales])}
```

When values are being replicated, changing the aggregation for the relevant field in the view (for example, from AVG to SUM) will not change the result of the aggregation.

Level of Detail Expression is Finer Than View Level of Detail

An expression has a finer level of detail than the view when it references a superset of the dimensions in the view. When you use such an expression in the view, Tableau will aggregate results up to the view level. For example, the following level of detail expression references two dimensions:

```
{FIXED [Segment], [Category] : SUM([Sales])}
```

When this expression is used in a view that has only [Segment] as its level of detail, the values must be aggregated. Here's what you would see if you dragged that expression to a shelf:

```
AVG([FIXED [Segment]], [Category] : SUM([Sales]))]
```

An aggregation – in this case, average – is automatically assigned by Tableau. You can change the aggregation as needed.

Adding a Level of Detail Expression to the View

Whether a level of detail expression is aggregated or replicated in the view is determined by the expression type (FIXED, INCLUDE or EXCLUDE) and whether the expression's granularity is coarser or finer than the view's.

- INCLUDE level of detail expressions will have either the same level of detail as the view or a finer level of detail than the view. Therefore, values will never be replicated.
- FIXED level of detail expressions can have a finer level of detail than the view, a coarser level of detail or the same level of detail. The need to aggregate the results of a FIXED level of detail depends on what dimensions are in the view.
- EXCLUDE level of detail expressions always cause replicated values to appear in the view. When calculations including EXCLUDE level of detail expressions are placed on a shelf, Tableau defaults to the ATTR aggregation (as opposed to SUM or AVG) to indicate that the expression is not actually being aggregated and that changing the aggregation will have no effect on the view.

Level of detail expressions are always automatically wrapped in an aggregate when they are added to a shelf in the view, unless they are used as dimensions. So, if you double-click on a shelf and type

```
{FIXED[Segment], [Category] : SUM([Sales])}
```

and then press Enter to commit the expression, what you now see on the shelf is

```
SUM({FIXED[Segment], [Category] : SUM([Sales])})
```

But if you double-click into the shelf to edit the expression, what you see in edit mode is the original expression.

If you wrap a level of detail expression in an aggregation when you create it, Tableau will use the aggregation you specified rather than assigning one when any calculation including that expression is placed on a shelf. When no aggregation is needed (because the level of detail of the expression is coarser than that of the view), the aggregation you specified is still shown when the expression is on a shelf, but it is ignored.

Filters and Level of Detail Expressions

There are several different kinds of filters in Tableau. These are executed in the following order, from top to bottom.

The text on the right shows where level of detail expressions are evaluated in this sequence.

Extract Filters (in orange) are only relevant if you're creating a Tableau Extract from a data source. Table calculations filters (dark blue) are applied after calculations are executed and therefore hide marks without filtering out the underlying data used in the calculations.

If you're familiar with SQL, you can think of measure filters as equivalent to the HAVING clause in a query, and dimension filters as equivalent to the WHERE clause.

FIXED calculations are applied before dimension filters, so unless you promote the fields on your Filter shelf to [Use Context Filters on page 1344](#), they will be ignored. For example, consider if you have the following calculation on one shelf in a view, along with **[State]** on a different shelf:

```
SUM([Sales]) / ATTR({FIXED : SUM([Sales])})
```

This calculation will give you the ratio of in-state sales to total sales.

If you then put **[State]** on the Filters shelf to hide some of the states, the filter will affect only the numerator in the calculation. Since the denominator is a FIXED level of detail expression, it will still divide the sales for the states still in the view against the total sales for all states – including the ones that have been filtered out of the view.

INCLUDE and EXCLUDE level of detail expressions are considered after Dimension filters. So if you want filters to apply to your FIXED level of detail expression but don't want to use Context Filters, consider rewriting them as INCLUDE or EXCLUDE expressions.

Data Source Constraints for Level of Detail Expressions

For some data sources, only more recent versions support level of detail expressions. Some data sources do not support level of detail expressions at all.

In addition, some data sources have complexity limits. Tableau will not disable calculations for these databases, but query errors are a possibility if calculations become too complex.

| Data Source | Support |
|---------------------------------------|--|
| Amazon EMR Hadoop Hive | Supported for Hive 0.13 and later. |
| Aster Database | Supported for version 4.5 and later. |
| Cloudera Hadoop | Supported for Hive 0.13 and later. |
| Cloudera Impala | Supported for Impala 1.2.2 and later. |
| Cubes (multidimensional data sources) | Not supported. |
| DataStax Enterprise | Not supported. |
| Firebird | Supported for version 2.0 and later. |
| Generic ODBC | Limited. Depends on the specific data source. |
| Google Big Query | Supported for standard SQL, not supported for legacy SQL. |
| Hortonworks Hadoop Hive | Supported for Hive 0.13 and later. On version 1.1 of HIVE level of detail expressions that produce cross joins are not reliable. Cross join occur when there is no explicit field to join on. For example, for a level of detail expression <code>{fixed [Product Type] : sum (sales)}</code> when the view only contains one dimension [Ship Mode] , |

Tableau creates a cross-join. A cross join produces rows which combine each row from the first table with each row from the second table.

| | |
|---|--------------------------------------|
| IBM DB2 | Supported for version 8.1 and later. |
| MarkLogic | Supported for version 7.0 and later. |
| Microsoft Access | Not supported. |
| Microsoft Jet-based connections (legacy connectors for Microsoft Excel, Microsoft Access, and text) | Not supported. |
| Microsoft SQL Server | SQL Server 2005 and later. |
| Mongo DB | Not supported. |
| IBM PDA (Netezza) | Supported version 7.0 and later. |
| Oracle | Supported version 9i and later. |
| Action Matrix (ParAccel) | Supported version 3.1 and later. |
| Pivotal Greenplum | Supported for version 3.1 and later. |
| PostgreSQL | Supported version 7 and later. |
| SAP Sybase IQ | Supported version 15.1 and later. |
| Splunk | Not supported. |
| Vertica | Supported for version 6.1 and later. |

Formatting Calculations in Tableau

This article describes how to create and format calculations in Tableau. It lists the basic components of calculations and explains the proper syntax for each.

Calculation building blocks

There are four basic components to calculations in Tableau:

- **Functions:** Statements used to transform the values or members in a field.
 - Functions require *arguments*, or specific pieces of information. Depending on the function, arguments can be fields, literals, parameters or nested functions.
- **Fields:** Dimensions or measures from your data source.
- **Operators:** Symbols that denote an operation.
- **Literal expressions:** Constant values that are hardcoded, such as "High" or 1,500.

Not all calculations need to contain all four components. Additionally, calculations can contain:

- **Parameters:** Placeholder variables that can be inserted into calculations to replace constant values. For more information on parameters, see [Create Parameters on page 1131](#).
- **Comments:** Notes about a calculation or its parts, not included in the computation of the calculation.

For more information about how to use and format each of these components in a calculation, see the following sections.

Example calculation explained

For example, consider the following calculation, which adds 14 days to a date ([Initial Visit]). A calculation like this could be useful for automatically finding the date for a two-week follow-up.

```
DATEADD('day', 14, [Initial Visit])
```

The components of this calculation can be broken down as:

- **Function:** DATEADD, which requires three arguments.
 - date_part ('day')
 - interval (14)
 - date ([Initial Visit]).
- **Field:** [Initial Visit]
- **Operators:** n/a
- **Literal expressions:**
 - String literal: 'day'
 - Numeric literal: 14

In this example, the hardcoded constant 14 could be replaced with a parameter, which would allow the user to select how many days out to look for a follow-up appointment.

`DATEADD('day', [How many days out?], [Initial Visit])`

At a glance: calculation syntax

| Components | Syntax | Example |
|----------------------------|--|--|
| Functions | See Tableau Functions (Alphabetical) on page 2291 or Tableau Functions (by Category) on page 2190 for examples of how to format all functions in Tableau. | <code>SUM(expression)</code> |
| Fields | A field in a calculation is often surrounded by brackets []. See Field syntax on page 2443 for more information. | <code>[Category]</code> |
| Operators | <code>+, -, *, /, %, ==, =, >, <, >=, <=, !=, <>, ^, AND, OR, NOT, ()</code> . See Operator syntax on page 2444 for information on the types of operators you can use in Tableau calculation and the order they are performed in a formula. | <code>[Price] * (1 - [discount])</code> |
| Literal expressions | Numeric literals are written as numbers. String literals are written with quotation marks. Date literals are written with the # symbol. Boolean literals are written as either true or false. Null literals are written as null. See Literal expression syntax on page 2447 for more information. | <code>1.3567</code> <code>"Unprofitable"</code> <code>#August 22, 2005#</code> <code>true</code> <code>Null</code> |
| Parameters | A parameter in a calculation is surrounded by brackets [], like a field. See Create Parameters on page 1131 for more information. | <code>[Bin Size]</code> |
| Comments | To enter a comment in a calculation, type two forward slashes //. See Add comments to a calculation on page 2449 for more information. | <code>SUM([Sales]) / SUM([Profit])</code> |

| | | |
|--|--|---|
| | Multi-line comments can be added by typing <code>/*</code> to start the comment and <code>*/</code> to end it. | <code>/*John's calculation To be used for profit ratio Do not edit*/</code> |
|--|--|---|

Calculation syntax in detail

See the following sections to learn more about the different components of Tableau calculations and how to format them to work in Tableau.

Function syntax

Functions are the main components of a calculation and can be used for various purposes.

Every function in Tableau requires a particular syntax. For example, the following calculation uses two functions, `LEN` and `LEFT`, as well as several logical operators (`IF`, `THEN`, `ELSE`, `END` and `>`).

```
IF LEN([Name]) > 5 THEN LEFT([Name], 5) ELSE [Name] END
```

- `LEN` takes a single argument, such as `LEN([Name])`, which returns the number of characters (that is, the length) for each value in the `Name` field.
- `LEFT` takes two arguments, a field and a number, such as `LEFT([Name], 5)`, which returns the first five characters from each value in the `Name` field starting from the left.
- The logical operators `IF`, `THEN`, `ELSE` and `END` work together to create a logical test.

This calculation evaluates the length of a name and, if it's more than five characters, returns only the first five. Otherwise, it returns the entire name.

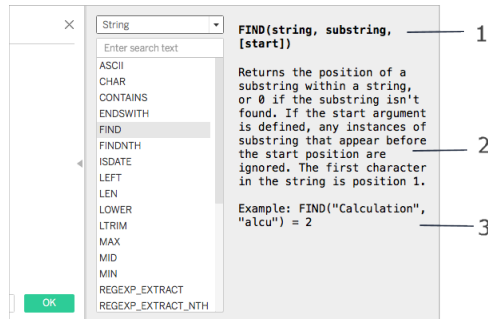

In the calculation editor, functions are coloured blue.

Use the calculation editor reference pane

You can look up how to use and format a particular function at any time. To open the list of functions in Tableau:

1. Select **Analysis > Create Calculated Field**.
2. In the Calculation Editor that opens, click the expand (triangle) icon located on the right edge of the editor.

A list of functions appears for you to browse. When you select a function from the list, the section on the far right updates with information about that function's required syntax (1), its description (2) and one or more examples (3).

Using multiple functions in a calculation

You can use more than one function in a calculation. For example:

```
ZN(SUM([Order Quantity])) - WINDOW_AVG(SUM([Order Quantity]))
```

There are three functions in the calculation: ZN, SUM and WINDOW_AVG. The ZN function and the WINDOW_AVG function are separated with the subtraction operator (-).

A function can also be part of another function (or nested), as is the case with the `ZN(SUM([Order Quantity]))` portion of the example above. In this case, the SUM of Order Quantity is computed before the ZN function because it is inside parentheses. For more information on why, see [Parentheses on page 2447](#).

Field syntax

Fields can be inserted into your calculations. Often, a function's syntax indicates where a field should be inserted into the calculation. For example: `SUM(expression)`.

Field names should be encompassed by brackets [] in a calculation when the field name contains a space or is not unique. For example, `[Sales Categories]`.

The type of function you use determines the type of field you use. For example, with the SUM function, you can insert a numerical field, but you cannot insert a date field. For more information, see [Understanding data types in calculations on page 2449](#).

The fields you choose to include in your calculations also depend on the purpose of calculation. For example, if you want to calculate profit ratio your calculation will use the Sales and Profit fields from your data source:

```
SUM([Sales])/SUM([Profit])
```

To add a field to a calculation, do one of the following:

- Drag it from the Data pane or the view and drop it in the calculation editor.
- In the Calculation Editor, type the field name. Note: The Calculation Editor attempts to auto-complete field names.

Fields are coloured orange in Tableau calculations.

Operator syntax

To create calculations, you need to understand the operators supported by Tableau. This section discusses the basic operators that are available and the order (precedence) in which they are performed.

Operators are coloured black in Tableau calculations.

+ (addition)

The + operator means addition when applied to numbers and concatenation when applied to strings. When applied to dates, it can be used to add a number of days to a date.

For example:

- `7 + 3`
- `Profit + Sales`
- `'abc' + 'def' = 'abcdef'`
- `#April 15, 2024# + 15 = #April 30, 2024#`

- (subtraction)

The - operator means subtraction when applied to numbers and negation if applied to an expression. When applied to dates, it can be used to subtract a number of days from a date. Hence, it can also be used to calculate the difference in days between two dates.

For example:

- $7 - 3$
- $\text{Profit} - \text{Sales}$
- $-(7+3) = -10$
- $\text{\#April 16, 2024\#} - 15 = \text{\#April 1, 2024\#}$
- $\text{\#April 15, 2024\#} - \text{\#April 8, 2024\#} = 7$

* (multiplication)

The * operator means numeric multiplication.

For example: $5 * 4 = 20$

/ (division)

The / operator means numeric division.

For example: $20 / 4 = 5$

% (modulo)

The % operator returns the remainder of a division operation. Modulo can only operate on integers.

For example: $9 \% 2 = 1$. (Because 2 goes into 9 four times with a remainder of 1.)

==, =, >, <, >=, <=, !=, <> (comparisons)

These are the basic comparison operators that can be used in expressions. Their meanings are as follows:

- $==$ or $=$ (equal to)
- $>$ (greater than)
- $<$ (less than)
- $>=$ (greater than or equal to)
- $<=$ (less than or equal to)
- $!=$ or $<>$ (not equal to)

Each operator compares two numbers, dates or strings and returns either TRUE, FALSE or NULL.

^ (power)

This symbol is equivalent to the POWER function. It raises a number to the specified power.

For example: $6^3 = 216$

AND

This is a logical operator. An expression or a boolean must appear on either side of it.

For example: `IIF(Profit =100 AND Sales =1000, "High", "Low")`

See **AND** in [Logical Functions on page 2090](#) for more information.

OR

This is a logical operator. An expression or a boolean must appear on either side of it.

For example: `IIF(Profit =100 OR Sales =1000, "High", "Low")`

See **OR** in [Logical Functions on page 2090](#) for more information.

NOT

This is a logical operator. It can be used to negate another boolean or an expression. For example,

`IIF(NOT(Sales = Profit), "Not Equal", "Equal")`

Other Operators

CASE, ELSE, ELSEIF, IF, THEN, WHEN and END are also operators used for [Logical Functions on page 2090](#).

Operator precedence

All operators in a calculation are evaluated in a specific order. For example, $2*1+2$ is equal to 4 and not equal to 6, because multiplication is performed before addition (the * operator is always evaluated before the + operator).

If two operators have the same precedence (such as addition and subtraction (+ or -)) they are evaluated from left to right in the calculation.

Parentheses can be used to change the order of precedence. See the [Parentheses](#) below section for more information.

| Precedence | Operator |
|------------|-----------------------------|
| 1 | – (negate) |
| 2 | ^ (power) |
| 3 | *, /, % |
| 4 | +, – |
| 5 | ==, =, >, <, >=, <=, !=, <> |
| 6 | NOT |
| 7 | AND |
| 8 | OR |

Parentheses

Parentheses can be used as needed to force an order of precedence. Operators that appear within parentheses are evaluated before those outside of parentheses, starting from the innermost parentheses and moving outward.

For example, $(1 + (2*2+1)*(3*6/3)) = 31$ because the operators within the innermost brackets are performed first. The calculation is calculated in the following order:

1. $(2*2+1) = 5$
2. $(3*6/3) = 6$
3. $(1+ 5*6) = 31$

Literal expression syntax

This section describes the proper syntax for using literal expressions in Tableau calculations. A literal expression signifies a constant value that is represented as is. When you are using functions you will sometimes want to use literal expressions to represent numbers, strings, dates and more.

For example, you may have a function where your input is a date. Rather than type "1 May 2005", which would be interpreted a string, you would type #1 May 2005#. This is equivalent to using a

date function to convert the argument from a string to a date (refer to [Date Functions on page 2067](#)).

You can use numeric, string, date, boolean and null literals in Tableau calculations. Each type, and how to format them, are described below.

Literal expressions are coloured black and grey in Tableau calculations.

Numeric Literals

A numeric literal is written as a number. For example, to input the number one as a numeric literal, enter `1`. If you want to input the number 0.25 as a numeric literal, enter `0.25`.

String Literals

A string literal can be written either using 'single quote' or "double quote".

If your string has a single or double quote within it, use the other option for the outermost string literals.

For example, to input the string `"cat"` as a string literal, type `'"cat"'`. For `'cat'`, type `"'cat'"`. If you want to type the string `She's my friend` as a string literal, use double quotes for the literals, as in `"She's my friend."`

Date Literals

Date literals are signified by the pound symbol (#). To input the date "22 August 2005" as a literal date, enter the ISO formatted date, `#2005-08-22#`.

Boolean Literals

Boolean literals are written as either true or false. To input "true" as a boolean literal, enter `true`.

Null Literals

Null literals are written as Null. To input "Null" as a Null literal, enter `Null`.

Add parameters to a calculation

Parameters are placeholder variables that can be inserted into calculations to replace constant values. When you use a parameter in a calculation, you can then expose a parameter control in a view or dashboard to allow users to dynamically change the value.

For details, see [Use a parameter on page 1135](#).

Parameters are coloured purple in Tableau calculations.

Add comments to a calculation

You can add comments to a calculation to make notes about it or its parts. Comments are not included in the computation of the calculation.

To add a comment to a calculation, type two forward slash (//) characters.

For example:

```
SUM([Sales])/SUM([Profit]) //My calculation
```

In this example, `//My calculation` is a comment.

A comment starts at the two forward slashes (//) and goes to the end of the line. To continue with your calculation, you must start a new line.

A multi-line comment can be written by starting the comment with a forward slash followed by an asterisk (*), and closed with an asterisk followed by a forward slash (*). For example:

```
SUM([Sales])/SUM([Profit])
/* This calculation is
used for profit ratio.
Do not edit */
```

Comments are coloured grey in Tableau calculations.

Understanding data types in calculations

If you create calculated fields, you need to know how to use and combine the different **data types** in calculations. Many functions that are available to you when you define a calculation only work when they are applied to specific data types.

For example, the `DATEPART()` function can accept only a date/datetime data type as an argument. You can enter `DATEPART('year', #2024-04-15#)` and expect a valid result: 2024. You cannot enter `DATEPART('year', "Tom Sawyer")` and expect a valid result. In fact, this example returns an error because "Tom Sawyer" is a string, not a date/datetime.

Note: Although Tableau attempts to fully validate all calculations, some data type errors cannot be found until the query is run against the database. These issues appear as error dialogs at the time of the query rather than in the calculation dialog box.

The data types supported by Tableau are described below. Refer to [Type Conversion on page 2084](#) to learn about converting from one data type to another.

String

A sequence of zero or more characters. For example, "Wisconsin", "ID-44400", and "Tom Sawyer" are all strings. Strings are recognised by single or double quotes. The quote character itself can be included in a string by repeating it. For example, 'O' 'Hanrahan'.

Date/Datetime

A date or a datetime. For example "January 23, 1972" or "January 23, 1972 12:32:00 AM". If you would like a date written in long-hand style to be interpreted as a date/datetime, place the # sign on either side of it. For instance, "January 23, 1972" is treated as a string data type but #January 23, 1972# is treated as a date/datetime data type.

Number

Numerical values in Tableau can be either *integers* or *floating-point numbers*.

With floating-point numbers, results of some aggregations may not always be exactly as expected. For example, you may find that the SUM function returns a value such as -1.42e-14 for a field of numbers that you know should sum to exactly 0. This happens because the Institute of Electrical and Electronics Engineers (IEEE) 754 floating-point standard requires that numbers be stored in binary format, which means that numbers are sometimes rounded at extremely fine levels of precision. You can eliminate this potential distraction by formatting the number to show fewer decimal places. For more information, see ROUND in [Number functions available in Tableau on page 2039](#).

Operations that test floating point values for equality can behave unpredictably for the same reason. Such comparisons can occur when using level of detail expressions as dimensions, in categorical filtering, creating ad-hoc groups, creating IN/OUT sets and with data blending.

Note: The largest signed 64-bit integer is 9,223,372,036,854,775,807. When connecting to a new data source, any column with data type set to **Number (whole)** can accommodate values up to this limit; for larger values, because **Number (whole)** does not use floating-points, Tableau displays "Null". When the data type is set to **Number (decimal)**, larger values can be accommodated.

Boolean

A field that contains the values TRUE or FALSE. An unknown value arises when the result of a comparison is unknown. For example, the expression 7 > Null yields unknown. Unknown

booleans are automatically converted to Null.

[Get Started with Calculations in Tableau](#) on page 2009

Best Practices for Creating Calculations in Tableau

This article describes several tips and guidelines for creating efficient calculations in Tableau. These guidelines are designed to help you optimise your workbook performance. For more information about all the ways you can improve workbook performance, see the [Optimise Workbook Performance](#) on page 3044 series.

General Rule: Avoid using a calculated field multiple times in another calculation

Referencing the same calculated field multiple times within another calculation will result in performance issues. If you use a calculated field within a calculation (also known as creating a Nested Calculation), try to reference it only once in the calculation.

Note that referencing a field (terminal field) multiple times in a calculation shouldn't degrade performance.

Example

Let's say you create a calculated field that uses a complicated multiple line calculation to find mentions, or Twitter handles, in tweets. The calculated field is titled, Twitter Handle. Each handle that is returned starts with the '@' sign (for example: @user).

For your analysis, you want to remove the '@' symbol.

To do so, you can use the following calculation to remove the first character from the string:

```
RIGHT([Twitter Handle], LEN([Twitter Handle]) -1)
```

This calculation is quite simple. However, since it references the Twitter Handle calculation twice, it performs that calculation twice for each record in your data source: once for the RIGHT function and again for the LEN function.

In order to avoid calculating the same calculation more than once, you can rewrite the calculation to one that uses the Twitter Handle calculation only once. In this example, you can use MID to accomplish the same goal:

```
MID([Twitter Handle], 2)
```

Tip 1: Convert multiple equality comparisons to a CASE expression or a group

Let's say you have the following calculation, which uses the calculated field, Person (calc), multiple times and employs a series of OR functions. This calculation, though a simple logical expression, will cause query performance issues because it performs the Person (calc) calculation at least ten times.

```
IF [Person (calc)] = 'Henry Wilson'
OR [Person (calc)] = 'Jane Johnson'
OR [Person (calc)] = 'Michelle Kim'
OR [Person (calc)] = 'Fred Suzuki'
OR [Person (calc)] = 'Alan Wang'
THEN 'Lead'
ELSEIF [Person (calc)] = 'Susan Nguyen'
OR [Person (calc)] = 'Laura Rodriguez'
OR [Person (calc)] = 'Ashley Garcia'
OR [Person (calc)] = 'Andrew Smith'
OR [Person (calc)] = 'Adam Davis'
THEN 'IC'
END
```

Instead of using an equality comparison, try the following solutions.

Solution 1

Use a CASE expression. For example:

```
CASE [Person (calc)]
WHEN 'Henry Wilson' THEN 'Lead'
WHEN 'Jane Johnson' THEN 'Lead'
WHEN 'Michelle Kim' THEN 'Lead'
WHEN 'Fred Suzuki' THEN 'Lead'
WHEN 'Alan Wang' THEN 'Lead'

WHEN 'Susan Nguyen' THEN 'IC'
WHEN 'Laura Rodriguez' THEN 'IC'
```

```

WHEN 'Ashley Garcia' THEN 'IC'
WHEN 'Andrew Smith' THEN 'IC'
WHEN 'Adam Davis' THEN 'IC'
END

```

In this example, the calculated field, Person (calc), is only referenced once. Therefore, it is only performed once. CASE expressions are also further optimised in the query pipeline, so you gain an additional performance benefit.

Solution 2

Create a group instead of a calculated field. For more information, see [Group Your Data on page 1087](#).

Tip 2: Convert multiple string calculations into a single REGEXP expression

Note: REGEXP calculations are available only when using Tableau data extracts or when connected to Text File, Hadoop Hive, Google BigQuery, PostgreSQL, Tableau Data Extract, Microsoft Excel, Salesforce, Vertica, Pivotal Greenplum, Teradata (version 14.1 and above), and Oracle data sources. For more information, see [Additional Functions on page 2184](#).

Example 1: CONTAINS

Let's say you have the following calculation, which uses the calculated field, Category (calc), multiple times. This calculation, though also a simple logical expression, will cause query performance issues because it performs the Category (calc) calculation multiple times.

```

IF CONTAINS([Segment (calc)], 'UNKNOWN')
OR CONTAINS([Segment (calc)], 'LEADER')
OR CONTAINS([Segment (calc)], 'ADVERTISING')
OR CONTAINS([Segment (calc)], 'CLOSED')
OR CONTAINS([Segment (calc)], 'COMPETITOR')
OR CONTAINS([Segment (calc)], 'REPEAT')
THEN 'UNKNOWN'
ELSE [Segment (calc)] END

```

You can use a REGEXP expression to get the same results without as much repetition.

Solution

```
IF REGEXP_MATCH([Segment (calc)],
'UNKNOWN|LEADER|ADVERTISING|CLOSED|COMPETITOR|REPEAT') THEN
'UNKNOWN'
ELSE [Segment (calc)] END
```

With string calculations that use a similar pattern, you can use the same REGEXP expression.

Example 2: STARTSWITH

```
IF STARTSWITH([Segment (calc)], 'UNKNOWN')
OR STARTSWITH([Segment (calc)], 'LEADER')
OR STARTSWITH([Segment (calc)], 'ADVERTISING')
OR STARTSWITH([Segment (calc)], 'CLOSED')
OR STARTSWITH([Segment (calc)], 'COMPETITOR')
OR STARTSWITH([Segment (calc)], 'REPEAT')
THEN 'UNKNOWN'
```

Solution

```
IF REGEXP_MATCH([Segment (calc)], '^
(UNKNOWN|LEADER|ADVERTISING|CLOSED|COMPETITOR|REPEAT)') THEN
'UNKNOWN'
ELSE [Segment (calc)] END
```

Note that the '^' symbol is used in this solution.

Example 3: ENDSWITH

```
IF ENDSWITH([Segment (calc)], 'UNKNOWN')
OR ENDSWITH([Segment (calc)], 'LEADER')
OR ENDSWITH([Segment (calc)], 'ADVERTISING')
OR ENDSWITH([Segment (calc)], 'CLOSED')
OR ENDSWITH([Segment (calc)], 'COMPETITOR')
OR ENDSWITH([Segment (calc)], 'REPEAT')
THEN 'UNKNOWN'
ELSE [Segment (calc)] END
```

Solution

```
IF REGEXP_MATCH([Segment (calc)], '
(UNKNOWN|LEADER|ADVERTISING|CLOSED|COMPETITOR|REPEAT)$') THEN
'UNKNOWN'
ELSE [Segment (calc)] END
```

Note that the '\$' symbol is used in this solution.

Tip 3: Manipulate strings with REGEXP instead of LEFT, MID, RIGHT, FIND, LEN

Regular expressions can be a very powerful tool. When doing complex string manipulation, consider using regular expressions. In a lot of cases, using a regular expression will result in a shorter and more efficient calculation. For more information about regular expressions, see the [Become a regex regular and wrangle imperfect data](#) post on the Tableau blog.

Example 1

Let's say you have the following calculation, which removes protocols from URLs. For example: "https://www.tableau.com" becomes "www.tableau.com".

```
IF (STARTSWITH([Server], "http://")) THEN
MID([Server], Len("http://") + 1)
ELSEIF(STARTSWITH([Server], "https://")) THEN
MID([Server], Len("https://") + 1)
ELSEIF(STARTSWITH([Server], "tcp:")) THEN
MID([Server], Len("tcp:") + 1)
ELSEIF(STARTSWITH([Server], "\\\")) THEN
```

```
MID([Server], Len("\\") + 1)
ELSE [Server]
END
```

Solution

You can simplify the calculation and improve performance by using a REGEXP_REPLACE function.

```
REGEXP_REPLACE([Server], "^(\http://|https://|tcp:|\\|\\|\\|\\|)", "")
```

Example 2

Let's say you have the following calculation, which returns the second part of an IPv4 address. For example: "172.16.0.1" becomes "16".

```
IF (FINDNTH([Server], ".", 2) > 0) THEN
MID([Server],
FIND([Server], ".") + 1,
FINDNTH([Server], ".", 2) - FINDNTH([Server], ".", 1) - 1
)
END
```

Solution

You can simplify the calculation and improve performance by using a REGEXP_EXTRACT function.

```
REGEXP_EXTRACT([Server], "\.([^\.]*)\.")
```

Tip 4: Do not use sets in calculations

If you are using sets in a calculation, consider replacing them with an alternative, but equivalent calculation.

Example

Let's say you have the following calculation, which uses the set, Top Customers (set).

```
IF ISNULL([Customer Name]) OR [Top customers (set)] THEN
[Segment] ELSE [Customer Name] END
```

Solution 1

If the set is simple, you can create a calculated field that returns the same result as the set. For example:

```
CASE [Customer Name]
WHEN 'Henry Wilson' THEN True
WHEN 'Jane Johnson' THEN True
WHEN 'Michelle Kim' THEN True
WHEN 'Fred Suzuki' THEN True
WHEN 'Alan Wang' THEN True
ELSE False
END
```

Note: Using the pattern WHEN TRUE ... ELSE is recommended in this situation to avoid performance issues due to the use of sets. It is not a recommended pattern in most scenarios.

Solution 2

If the set is more complex, consider creating a group that maps all the elements in the set to a given value or attribute, such as 'IN', and then modify the calculation to check for that value/attribute. For example:

```
IF ISNULL([Customer Name]) OR [Top Customers (group)]='IN' THEN
[Segment] ELSE [Customer Name] END
```

For more information, see [Group Your Data](#) on page 1087 and [Create Sets](#) on page 1101.

Tip 5: Do not use sets to group your data

Sets are meant to make comparisons on subsets of data. Groups are meant to combine related members in a field. Converting sets to groups, such as with the following example, is not recommended:

```
IF [Americas Set] THEN "Americas"  
ELSEIF [Africa Set] THEN "Africa"  
ELSEIF [Asia Set] THEN "Asia"  
ELSEIF [Europe Set] THEN "Europe"  
ELSEIF [Oceania Set] THEN "Oceania"  
ELSE "Unknown"  
END
```

This is not recommended for the following reasons:

- **Sets are not always exclusive.** Some members can appear in multiple sets. For example, Russia could be placed both in the Europe set and the Asia set.
- **Sets cannot always be translated to groups.** If the sets are defined by exclusion, conditions, or limits, it might be difficult or even impossible to create an equivalent group.

Solution

Group your data using the Group feature. For more information, see [Group Your Data on page 1087](#).

[Types of Calculations in Tableau on page 2017](#)

[Functions in Tableau on page 2039](#)

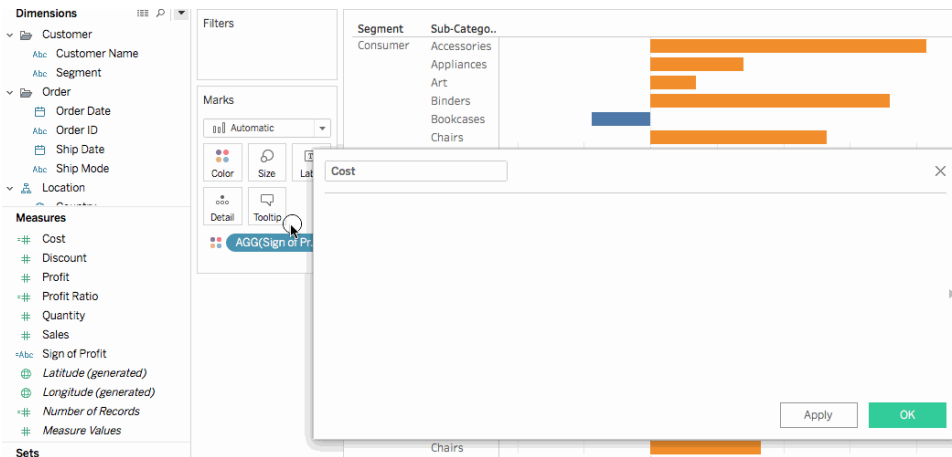

Tips for Working with Calculated Fields in Tableau

To help you become more efficient with creating and editing calculated fields in Tableau, this article lists several tips for working in the calculation editor.

Note: The GIFs in this topic show an older version of the UI. The **Data** pane no longer calls out Dimensions and Measures.

Drag and drop fields into the calculation editor

When creating fields in the calculation editor, you can drag existing fields from the Data pane into the editor at any time.

Drag and drop formulas from the calculation editor to the Data pane

When typing a calculation in the calculation editor, you can highlight all or part of the formula and drag it to the Data pane to create a new calculated field. You can then rename the field by typing a name. For more information, see [Ad-Hoc Calculations](#) on page 2462.

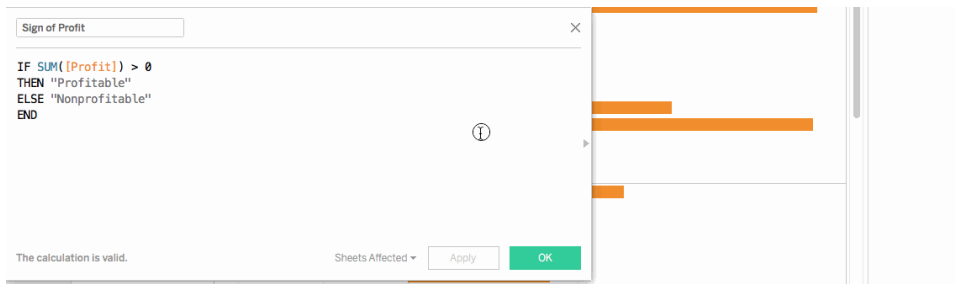

Use the functions reference in the calculation editor

When typing a calculation in the calculation editor, you can use the functions reference to browse all the functions available in Tableau.

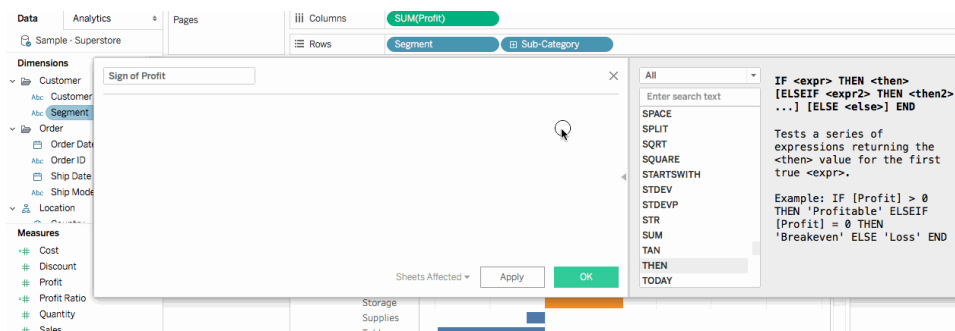

To open the functions reference:

In the calculation editor, click the triangle icon on the right-side of the editor.

To add a function from the reference to a formula:

In the function reference, double-click a function.

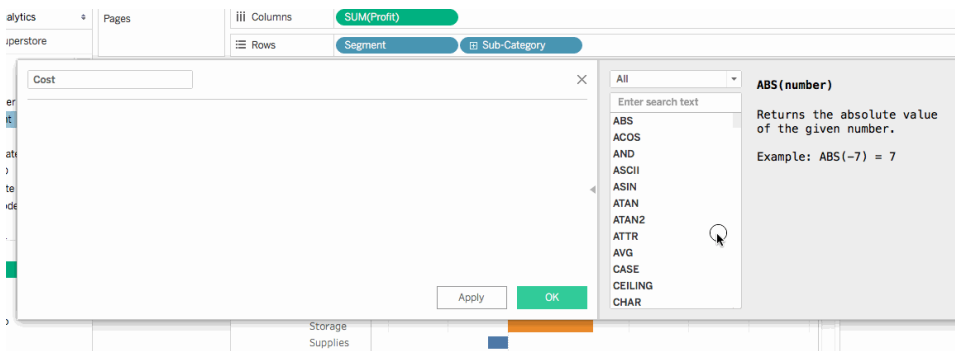

Take advantage of auto-complete for formulas

As you type a formula in the calculation editor, Tableau suggests options to complete items in your formula. Tableau suggests functions, fields in your data source, parameters, sets and bins that begin with or contain the string you type. The list of suggestions update as you type.

To add an item from auto-complete to a formula:

Press Enter on your keyboard to select the highlighted suggestion. You can use the up and down arrows on your keyboard to move between items in the auto-complete list.

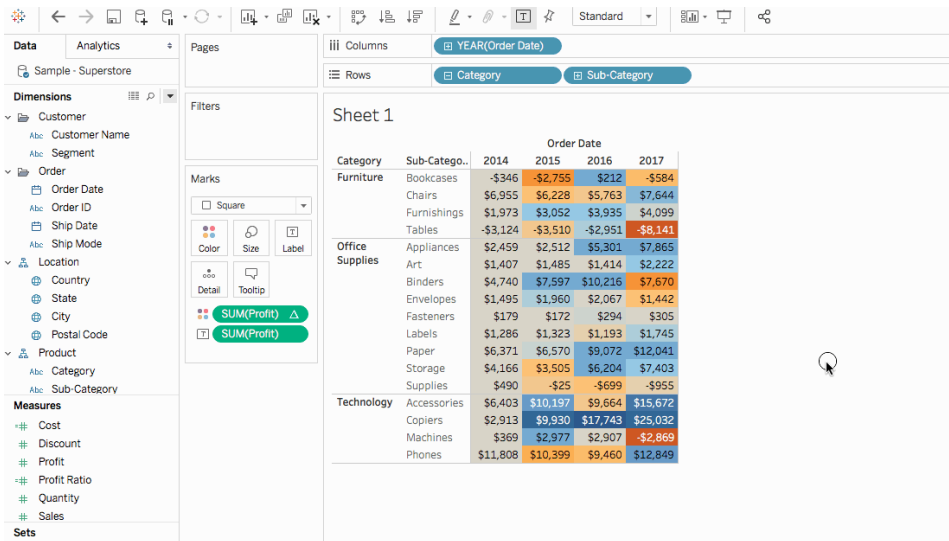

Drag table calculations into the calculation editor to edit them

When you create a table calculation, you can drag it into the calculation editor to review or make changes to the formula.

To edit a table calculation in the calculation editor:

1. In the **Analysis** menu, select **Create Calculated Field...**
2. From the worksheet, drag the table calculation into the calculation editor.
3. When finished, click **OK**.

Resize text in the calculation editor

You can adjust the size of the text in the calculation editor as you create or edit calculations.

To increase text size in the calculation editor:

Press the **CTRL** and **+** keys on your keyboard (**Command** + on a Mac)

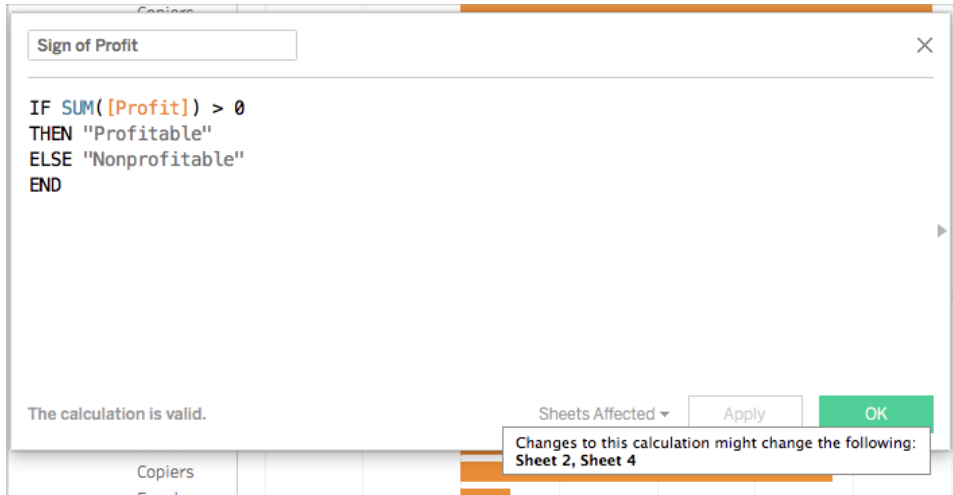

To decrease text size in the calculation editor:

Press the **CTRL** and **-** keys on your keyboard (**Command** - on a Mac).

Note: Text size persists until you close the editor. The next time you open the editor, text is at the default size.

See which sheets are using a calculated field

As you edit a calculated field, you can click **Sheets Affected** to see which other sheets are using the field. These sheets will also be updated when you commit your changes.

Format numbers and dates

Tip: Sometimes a calculation isn't needed, just some formatting.

There are times that a number or date value will be correct but it doesn't appear how you'd like. For example, a date displaying as 2027/02/02 instead of 2Feb27. This doesn't need a date calculation to fix. Instead, **format the date** to the visual presentation you desire.

Similarly, the results of the `ROUND()` function can sometimes display oddly due to details of the data source. To control how the results appear, **set the number format** to specify the number of decimal points.

Ad-Hoc Calculations

Ad-hoc calculations are calculations that you can create and update as you work with a field on a shelf in the view. Ad-hoc calculations are also known as type-in or in-line calculations.

Create an Ad-Hoc Calculation

Double-click on an existing field to start editing.

You can also double-click on an empty shelf or on an empty part of a shelf to create a new calculation.

Type to update the expression, or drag new fields into the expression from the **Data** pane or elsewhere in the view.

Press Enter, Tab, or click outside the expression to commit the expression, close the calculation, and update the view.

Press Ctrl+Enter (or Command+Enter on a Mac) to commit the expression and update the view without closing the calculation.

Ad-hoc calculations are supported on the **Rows**, **Columns**, **Marks**, and **Measure Values** shelves; they are not supported on the **Filters** or **Pages** shelves.

If you are working in Tableau Desktop, errors in ad-hoc calculations are underlined in red. Hover over the error to see a suggestion for resolving it.

Note: Ad-hoc calculations are not named and stored in the **Data** pane, but they are saved when you close the workbook. If you want to save an ad-hoc calculation for use in other workbook sheets, copy it to the **Data** pane. In Tableau Desktop (but not in the

browser) you will be prompted to name the calculation. Once you name an ad-hoc calculation, it is the same as any calculation you created with the calculation editor and is available on other sheets in the workbook. See [Get Started with Calculations in Tableau on page 2009](#)

Multi-Line Ad-Hoc Calculations

As you're typing an ad-hoc calculation, you can press Shift+Enter to start a new line. However, only the current line is ever visible in an ad-hoc calculation, so this can be confusing for anyone viewing or editing the calculation who has no way of knowing that it contains multiple lines.

The first line of a multi-line ad-hoc calculation can be a comment that serves as a title for the calculation. This is the only line that is visible on the shelf after the calculation is committed:

```
//City and State
```

```
[City] + ', ' + [State]
```

Ad-Hoc Calculations and Aggregation

If Tableau determines that the expression you enter is a measure (that is, returns a number), it automatically adds an aggregation to the expression when you commit the expression. For example, if you type `DATEDIFF('day', [Ship Date], [Order Date])` in an ad-hoc calculation and then press Enter, what you will see is the following:

```
SUM(DATEDIFF('day', [Ship Date], [Order Date]))
```

If you use a field that is already an aggregated field (for example, `SUM([Profit])`) in an ad-hoc calculation, the result is an aggregate calculation. For example, when you commit an ad-hoc calculation `SUM([Profit])/SUM([Sales])`, the result is:

```
AGG(SUM([Profit])/SUM([Sales]))
```

For more information on aggregate calculations, see [Aggregate Functions in Tableau on page 2107](#).

Ad-Hoc Calculations for Insight and Experimentation

Typically you create ad-hoc calculations on-the-fly to do things like

- Test a hunch
- Try a what-if scenario

- Debug a complex calculation

Managing Ad-Hoc Calculations

Use the following keystrokes to manage ad-hoc calculations.

- Double-click in an existing field on the **Rows**, **Columns**, **Marks**, or **Measure Values** shelf to open it as an ad-hoc calculation.
- Double-click elsewhere on any of these shelves to create a new ad-hoc calculation from scratch.
- Press Esc to cancel an ad-hoc calculation.
- Press Enter to commit an ad-hoc calculation, which updates the view and closes the ad-hoc calculation. Press Ctrl+Enter to commit the change and update the view without closing the ad-hoc calculation.
- If you are working in Tableau Desktop, and there is a field to the right of the current ad-hoc calculation on the same shelf, pressing Tab opens that field as an ad-hoc calculation. If there is no field to the right of the current ad-hoc calculation on the shelf, pressing Tab opens a new ad-hoc calculation. Shift+Tab has the same functionality, except it moves to the left.
- When you double-click a named field on a shelf to edit it, you are not changing the original named field.

In addition, the following rules govern the use of ad-hoc calculations.

- Only one ad-hoc calculation can be open at a time.
- If a field that has a geographic role or a fiscal year setting associated with it is added to an ad-hoc calculation, the ad-hoc calculation inherits that role or setting.
- The right-click context menu for an ad-hoc calculation supports the same options that would be available for any other field in the view of the same type, including the ability to change aggregation or format.
- Ad-hoc calculations are not available when you create groups, sets, hierarchies, or parameters.
- Ad-hoc calculations are valid for creating trend lines, forecasts, and reference lines, bands, and distributions.

Example - Spotlighting Using Calculations

Spotlighting is a technique for showing discrete thresholds based on the values of a measure. For instance, you might want to colour-code sales so that those over 10,000 appear green and those below 10,000 appear red. A spotlighting calculation is just a special case of a calculation that results in a discrete measure. A discrete measure is a calculation that is a dependent variable

(and therefore a measure), but which results in a discrete result (as opposed to a continuous result). Thus the name discrete measure. Here is an example:

The formula in this example defines a discrete measure named **Sales Spotlight**. Discrete measures always appear with a blue **abc** icon in the **Data** pane. **Sales Spotlight** is classified as a measure in Tableau because it is a function of another measure; it is discrete because it produces discrete values ("Good" and "Bad"). Here is an example of this categorical measure in use:

Pages: **Columns**: Segment **Rows**: Category Sub-Category

Filters:

Marks: Automatic Color Size Text Detail Tooltip

AGG(Sales Sp..) SUM(Sales)

AGG(Sales Spotlight)

Legend: Bad (Blue square), Good (Orange square)

Sheet 4

| | | Segment | | |
|-----------------|--------------|-----------|-----------|-------------|
| Category | Sub-Category | Consumer | Corporate | Home Office |
| Furniture | Bookcases | \$68,633 | \$34,006 | \$12,241 |
| | Chairs | \$172,863 | \$99,141 | \$56,445 |
| | Furnishings | \$49,620 | \$25,001 | \$17,084 |
| | Tables | \$99,934 | \$70,872 | \$36,160 |
| Office Supplies | Appliances | \$52,820 | \$36,589 | \$18,124 |
| | Art | \$14,252 | \$8,590 | \$4,276 |
| | Binders | \$118,161 | \$51,560 | \$33,691 |
| | Envelopes | \$7,771 | \$5,943 | \$2,763 |
| | Fasteners | \$1,681 | \$783 | \$560 |
| | Labels | \$6,709 | \$4,102 | \$1,675 |
| | Paper | \$36,324 | \$23,883 | \$18,272 |
| | Storage | \$100,492 | \$79,791 | \$43,560 |
| | Supplies | \$25,741 | \$19,435 | \$1,497 |
| Technology | Accessories | \$87,105 | \$48,191 | \$32,085 |
| | Copiers | \$69,819 | \$46,829 | \$32,880 |
| | Machines | \$79,543 | \$60,277 | \$49,419 |
| | Phones | \$169,933 | \$91,153 | \$68,921 |

Here, **Sales Spotlight** is on Colour in the Marks card. It appears with the **AGG** prefix because it is an aggregate calculation. Values above 10,000 and below 10,000 are assigned different colours.

Spot Trends

Reference Lines, Bands, Distributions and Boxes

You can add a reference line, band, distribution or box plot to identify a specific value, region or range on a continuous axis in a Tableau view. For example, if you are analysing the monthly sales for several products, you can include a reference line at the average sales mark so you can see how each product performed against the average.

Tableau lets you add as many reference lines, bands, distributions and box plots to a view as you require.

Types of Reference Lines, Bands, Distributions and Boxes

You can add reference lines, bands, distributions or (in Tableau Desktop but not on the web) box plots to any continuous axis in the view.

- **Reference Lines** - You can add a reference line at a constant or computed value on the axis. Computed values can be based on a specified field. You can also include confidence intervals with a reference line.

- **Reference Bands** - Reference bands shade an area behind the marks in the view between two constant or computed values on the axis.

- **Reference Distributions** - Reference distributions add a gradient of shading to indicate the distribution of values along the axis. Distribution can be defined by percentages, percentiles, quantiles (as in the following image) or standard deviation.

Reference distributions can also be used to create bullet charts. See [Add a Bullet Graph on page 2485](#) later in this article for specifics.

- **Box Plots** - Box plots (also known as box and whisker charts) are a standardised graphic for describing the distribution of values along an axis. Box plots show quartiles (also known as hinges) and whiskers. Tableau provides different box plot styles, and allows you to configure the location of the whiskers and other details.

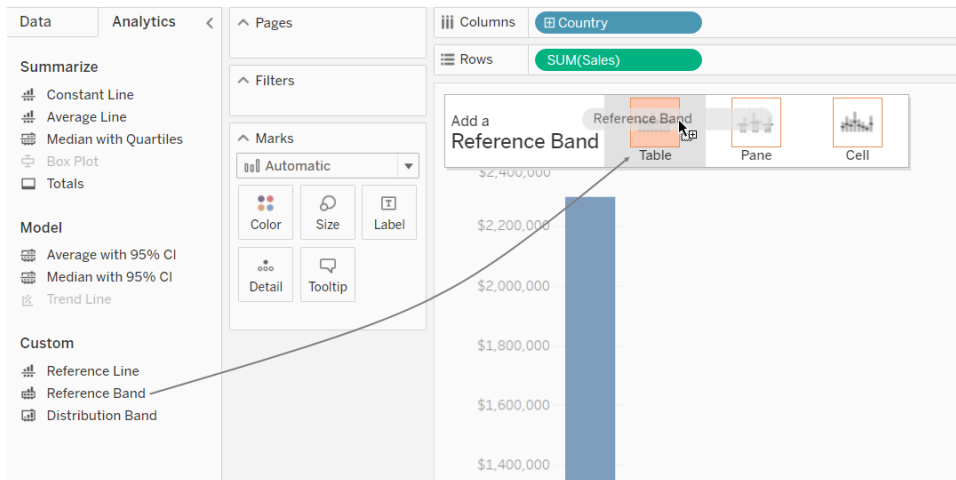

Add a Reference Line

You can add a reference line to any continuous axis in the view.

To add a reference line:

1. Drag **Reference Line** from the **Analytics** pane into the view. Tableau shows the possible destinations. The range of choices varies depending on the type of item and the current view.

In a simple case, the drop target area offers three options:

The view above is from a web editing session. In Tableau Desktop, the process is the same but the user interface looks a bit different. The terms **Table**, **Pane** and **Cell** define the scope for the item:

Adds a reference line to the entire table across all panes.

Adds a reference line on a per pane basis. Computed reference lines are recalculated for each pane in the view.

Adds a reference line within each cell. Computed reference lines are recalculated for each cell in the view.

For a more complicated view – for example, if the view contains a line chart with multiple or dual axes – Tableau shows you an expanded drop target area:

| | | | |
|-----------------------------|--|---|--|
| Add a Reference Line |  Table |  Pane |  Cell |
| SUM(Profit) | <input type="text"/> | <input type="text"/> | <input type="text"/> |
| SUM(Sales) | <input type="text"/> | <input type="text"/> | <input type="text"/> |

If you drop the item in one of the three larger boxes in the header (for example, the **Table** box), a separate reference line is added for each continuous field in the view:

But if you drop the item in any of the lower boxes that are aligned with a specific continuous field, the line is added on the corresponding axis, with the specified scope.

When you drop the line in the target area, Tableau displays a dialog box:

| | |
|--------------------------------|--------------------|
| Tableau Desktop version | Web version |
|--------------------------------|--------------------|

2. The **Line** option is already selected at the top of the dialog box.
3. Select a continuous field from the **Value** field to use as the basis for your reference line. You can also select a parameter.

You cannot select a continuous field that isn't currently in the view as the basis for your reference line. If you want to use such a continuous field, do the following:

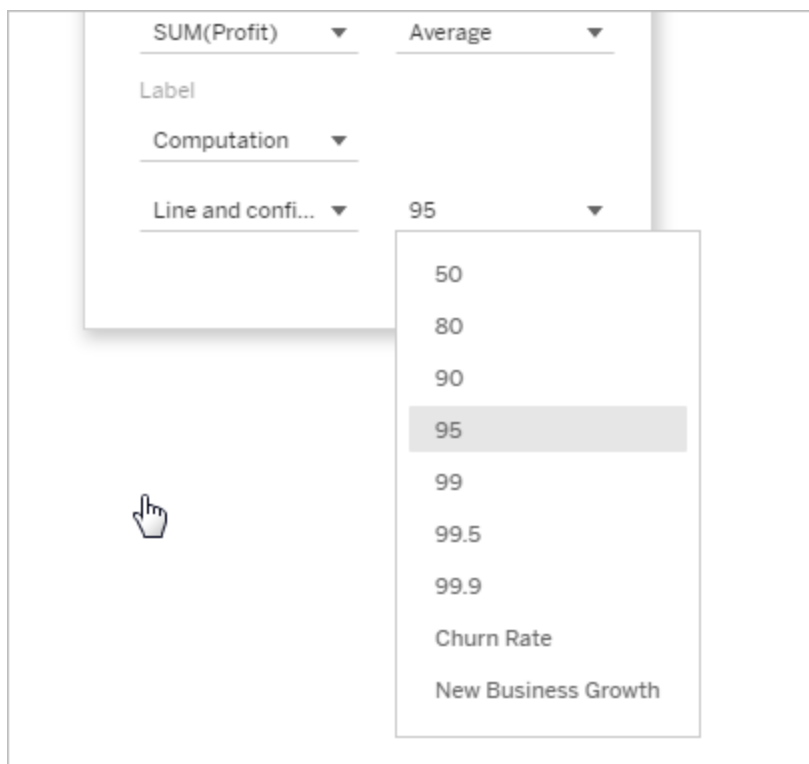

- a. Drag the continuous field from the Data pane to the Details target on the Marks card.
- b. Change the continuous field's aggregation if necessary.

This will not change the view, but it will allow you to use that continuous field as the basis for your reference band.

- c. Click on the reference line in the view and choose **Edit** to re-open the **Edit Line** dialog box.
4. Select an aggregation. The aggregations that are displayed depend on the continuous field you select:
 - **Total** - places a line at the aggregate of all the values in either the cell, pane or the entire view. This option is particularly useful when computing a weighted average rather than an average of averages. It is also useful when working with a calculation with a custom aggregation. The total is computed using the underlying data and behaves the same as selecting one of the totals option the Analysis menu.
 - **Sum** - places a line at the SUM of all the values in either the cell, pane or entire view.
 - **Constant** - places a line at the specified value on the axis.
 - **Minimum** - places a line at the minimum value.
 - **Maximum** - places a line at the maximum value.
 - **Average** - places a line at the average value along the axis.
 - **Median** - places a line at the median value.
5. Select how you want to label the line:
 - **None** – select this option to not show a label for the reference line.
 - **Value** – select this option to show a label corresponding to the line's value on the axis.
 - **Computation** – select this option to display the name of the continuous field that is the basis for your reference line and any computation that is performed.
 - **Custom** – select this option to build a custom label in the text box. You can use the menu to the right of the text box to insert values such as the computation or the value. You can also type text directly into the box, so you could create a value such as `<Field Name> = <Value>`.
6. Select how you want the tooltip to appear.
 - **None** – select this option to not show a tooltip for the reference line.
 - **Automatic** – select this option to show the default tooltip for the reference line.

- **Custom** – select this option to build a custom label in the tooltip. You can use the menu to the right of the text box to insert values such as the computation or the value. You can also type text directly into the box, so you could create a value such as `<Field Name> = <Value>`.
7. Specify whether to display the line with a confidence interval, just the line, or just the confidence interval.

Confidence interval distribution bands shade the region in which the population average will fall n of the time, where n is the value you select in the drop-down on the right. You can choose one of the listed numeric values or select a parameter:

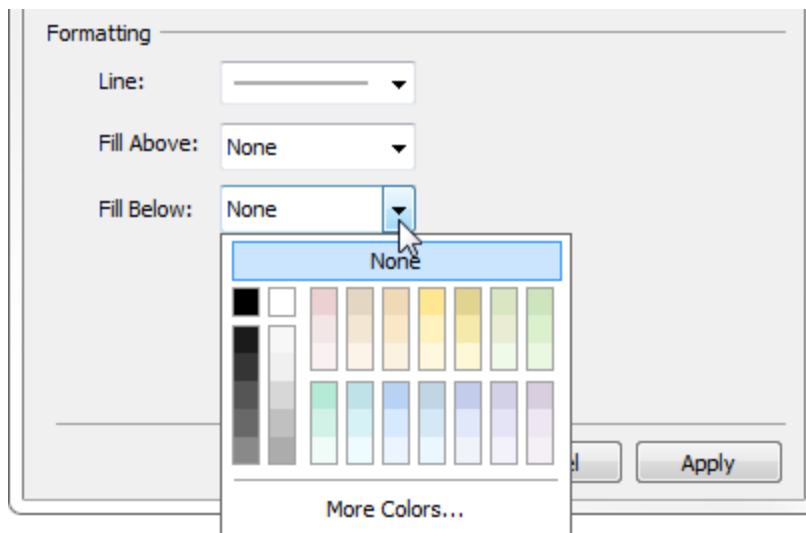

The higher the value you select, the wider the bands will be.

8. In Tableau Desktop, you can also specify formatting options for the line.

9. Optionally, add a fill colour above and below the line.

When you are displaying a line and a confidence interval, the shading will be darker within the confidence interval, and lighter beyond it:

When you are displaying a confidence interval without a line, the fill colours are disregarded, though your settings are retained and then applied if you decide later to show a line.

- Specify whether to **Show recalculated line for highlighted or selected data points**.
For more information, see [Compare marks data with recalculated lines](#) on page 1975.

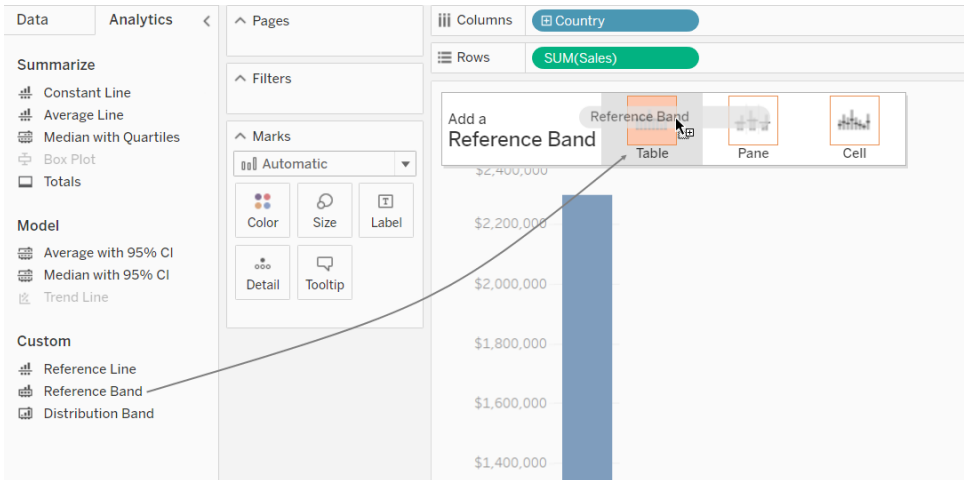

Add Reference Bands

Reference bands are shaded areas behind the marks in the view between two constant or computed values on the axis. You can add reference bands to any continuous axis in the view.

To add a reference band:

- Drag **Reference Band** from the **Analytics** pane into the view. Tableau shows the possible destinations. The range of choices varies depending on the type of item and the current view.

In a simple case, the drop target area would offer just three options:

The terms **Table**, **Pane** and **Cell** define the scope for the item:

Adds a reference line to the entire table across all panes.

Adds a reference line on a per pane basis. Computed reference lines are recalculated for each pane in the view.

Adds a reference line within each cell. Computed reference lines are recalculated for each cell in the view.

For a more complicated view – for example, if the view contains multiple or dual axes – Tableau shows you an expanded drop target area that looks like this:

| Add a Reference Band | Table | Pane | Cell |
|----------------------|----------------------|----------------------|----------------------|
| MONTH(Order Date) | <input type="text"/> | <input type="text"/> | <input type="text"/> |
| SUM(Sales) | <input type="text"/> | <input type="text"/> | <input type="text"/> |

If you drop the item in one of the three larger boxes in the header (for example, the **Table** box), a separate set of bands is added for each continuous field in the view:

But if you drop the item in any of the lower boxes aligned with a specific continuous field, the band is added on the corresponding axis, with the specified scope.

When you drop the band in the target area, Tableau displays a dialog box:

Tableau Desktop version

Web version

2. The **Band** area is already selected at the top of the dialog box.
3. Select two continuous fields to use as the basis for your reference band one in each **Value** field. You can also select a parameter from the drop-down lists. Do not select the same continuous field and aggregation in both areas.

You cannot select a continuous field that isn't currently in the view as the basis for your reference band. If you want to use such a continuous field, do the following:

- a. Drag the continuous field from the Data pane to the Details target on the Marks card.
 - b. Change the continuous field's aggregation if necessary.

This will not change the view, but it will allow you to use that continuous field as the basis for your reference band.
 - c. Click on the reference band in the view and choose **Edit** to re-open the **Edit Band** dialog box, and select the continuous field in the **Value (From)** area and one in the **Value (To)** area.
4. Select a computation for each value. The aggregations that are displayed depend on the continuous field you select:
- **Total** - extends the band to a value that is at the aggregate of all the values in either the cell, pane or the entire view. This option is particularly useful when computing a weighted average rather than an average of averages. It is also useful when working with a calculation with a custom aggregation. The total is computed using the underlying data and behaves the same as selecting one of the totals option the Analysis menu.
 - **Sum** - extends the band to a value that is at the SUM of all the values in either the cell, pane or entire view.
 - **Constant**- extends the band to a value that is at the specified value on the axis.
 - **Minimum** - extends the band to a value that is at the minimum value.
 - **Maximum** - extends the band to a value that is at the maximum value.
 - **Average** - extends the band to a value that is at the average value along the axis.
 - **Median**- extends the band to a value that is at the median value.
5. Select how you want to label the bands:
- **None** – select this option to not show a label for the reference band.
 - **Value** – select this option to show a label corresponding to the band's value on the axis.
 - **Computation** – select this option to display the name of the continuous field that is the basis for your reference band and any computation that is performed.

- **Custom** – select this option to build a custom label in the text box. You can use the menu to the right of the text box to insert values such as the computation or the value. You can also type text directly into the box, so you could create a value such as `<Field Name> = <Value>`.
6. Select how you want the tooltip to appear.
 - **None** – select this option to not show a tooltip for the reference band.
 - **Automatic** – select this option to show the default tooltip for the reference band.
 - **Custom** – select this option to build a custom label in the tooltip. You can use the menu to the right of the text box to insert values such as the computation or the value. You can also type text directly into the box, so you could create a value such as `<Field Name> = <Value>`.
 1. In Tableau Desktop, you can also specify formatting options for the bands. You can mark the two values with a line or select a shading colour for the band.

2. Specify whether to **Show recalculated line for highlighted or selected data points**.
 For more information, see [Compare marks data with recalculated lines on page 1975](#).

Add Reference Distributions

When you add a reference distribution, you specify one, two or more values. With one value, the result is a line; with two or more values the result is a set of one, two or more bands.

To add a reference distribution:

1. Drag **Distribution Band** from the **Analytics** pane into the view. Tableau shows the possible destinations. The range of choices varies depending on the type of item and the current view.
2. Select a scope for the distribution. The terms **Table**, **Pane** and **Cell** define the scope for the item:

3. Select the computation that will be used to create the distribution:

- **Percentages** - shades the interval between the specified percentage values. Use a comma to separate two or more percentage values (for example, 60, 80), and then specify which measure and aggregation to use for the percentages.

- **Percentiles** - shades intervals at the specified percentiles. Choose *Enter a value* from the **Value** drop-down list, and then enter two or more numerical values, delimited by commas (for example, 60, 80 or 25, 50, 75).
- **Quantiles** - breaks the view into the specified number of tiles using shading and lines. When you select this computation, you must also specify the number of tiles (from 3 to 10, inclusive). For example, if you select 3, Tableau calculates the

boundaries between the first, second and third terciles by calling the general quantile function and asking for the 33.33 and the 66.66 quantiles. It then shades the three terciles differently.

Tableau uses estimation type 7 in the R standard to compute quantiles and percentiles.

- **Standard Deviation** - places lines and shading to indicated the specified number of standard deviations above and below the mean. When you select this option you must specify the factor, which is the number of standard deviations and whether the computation is on a sample or the population.

4. Specify how you want to label the distribution bands:

- **None** – select this option to not show a label for the distribution bands.
- **Value** – select this option to show a label corresponding to each distribution band's value on the axis.
- **Computation** – select this option to display the name of the continuous field that is the basis for your distribution bands and any computation that is performed.
- **Custom** – select this option to build a custom label in the text box. You can use the menu to the right of the text box to insert values such as the computation or the value. You can also type text directly into the box, so you could create a value such as `<Field Name> = <Value>`.

5. Specify whether to **Show recalculated band for highlighted or selected data points**.

For more information, see [Compare marks data with recalculated lines on page 1975](#) in the Tableau Desktop online help.

Add a Bullet Graph

Reference distributions can also be used to create bullet graphs. A bullet graph is a variation of a bar graph developed to replace dashboard gauges and meters. The bullet graph is generally used to compare a primary measure to one or more other measures in the context of qualitative ranges of performance such as poor, satisfactory and good. You can create a bullet graph by adding a distribution to indicate the qualitative ranges of performance, and a line to indicate the target. The following procedure uses Show Me to make this process easier.

1. Select one or more dimensions, and two measures in the **Data** pane. The bullet graph will compare measure values. For example, budget vs. actual; actual vs. target; etc. Select multiple fields in the **Data** pane by holding down the Ctrl key as you click fields. If you are

using the Superstore sample workbook, you can select the fields show below:

2. Click the **Show Me** button in the toolbar.

3. Select **Bullet Graph** in the Show Me pane.

Tableau adds a reference distribution that is defined at 60% and 80% of the Average of the measure on Detail. It also adds a reference line that marks the Average of that same measure. The other measure is placed on the Rows shelf.

You can edit either of these to change its definition. For example, you may want to add 100% to the set of distribution band values, or draw a line at a constant value. Click on the outer edge or a distribution band, or on the line, and choose **Edit**.

Add a Box Plot

In Tableau Desktop, but not on the web, you can add box plots to a continuous axis.

Use box plots, also known as box-and-whisker plots, to show the distribution of values along an axis.

Boxes indicate the middle 50 percent of the data (that is, the middle two quartiles of the data's distribution). You can configure lines, called *whiskers*, to display all points within 1.5 times the interquartile range (in other words, all points within 1.5 times the width of the adjoining box), or all points at the maximum extent of the data, as shown in the following image:

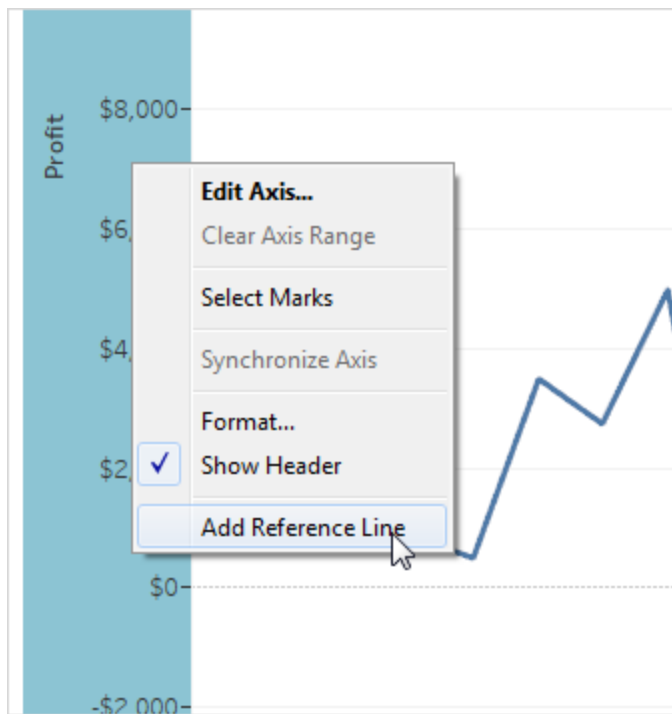

Boxplots are also available from the Show Me pane when you have at least one measure in the view:

For information on Show Me, see [Use Show Me to Start a View](#) on page 1237

To add a box plot:

1. Right-click (Control-click on a Mac) on a quantitative axis and select **Add Reference Line**.

2. In the Add Reference Line, Band or Box dialog box, select **Box Plot**.

3. Under Plot Options, specify placement for the whiskers:
 - **Data within 1.5 times the IQR** - places whiskers at a location that is 1.5 times the interquartile range – that is, 1.5 times further out than the width of the adjoining box. This is also known as a schematic box plot.
 - **Maximum extent of the data** - places whiskers at the farthest data point (mark) in the distribution. This is also known as a skeletal box plot.
4. Specify whether to **Hide underlying marks (except outliers)** – that is, whether to hide all marks except those beyond the whiskers.
5. Configure the appearance of the plot by selecting a **Style**, **Fill**, **Border** and **Whiskers**.

Box Plot Alternatives: Show Me Vs. Add Reference Line, Band or Box

The difference between adding a box plot using Show Me and adding a box plot using Add Reference Line is that with Show Me, the box plot is your visualisation, whereas with Add

Reference Line, Band or Box, you are adding a box plot to an existing visualisation. For example, you could create the following view by first selecting a circle view in Show Me, and then adding a box plot from Add Reference Line:

Edit Existing Reference Lines, Bands and Distributions

You can edit existing lines, bands or distributions. To do this, click on a line or on the outer edge of a band and choose **Edit** to reopen the edit dialog box for that object.

Remove Reference Lines, Bands or Distributions

To remove a reference line, band or distribution, click on a line or on the outer edge of a band and choose **Remove**. You can also drag a line or band off the view.

Add Trend Lines to a Visualisation

You can show trend lines in a visualisation to highlight trends in your data. You can publish a view that contains trend lines, and you add trend lines to a view as you edit it on the web.

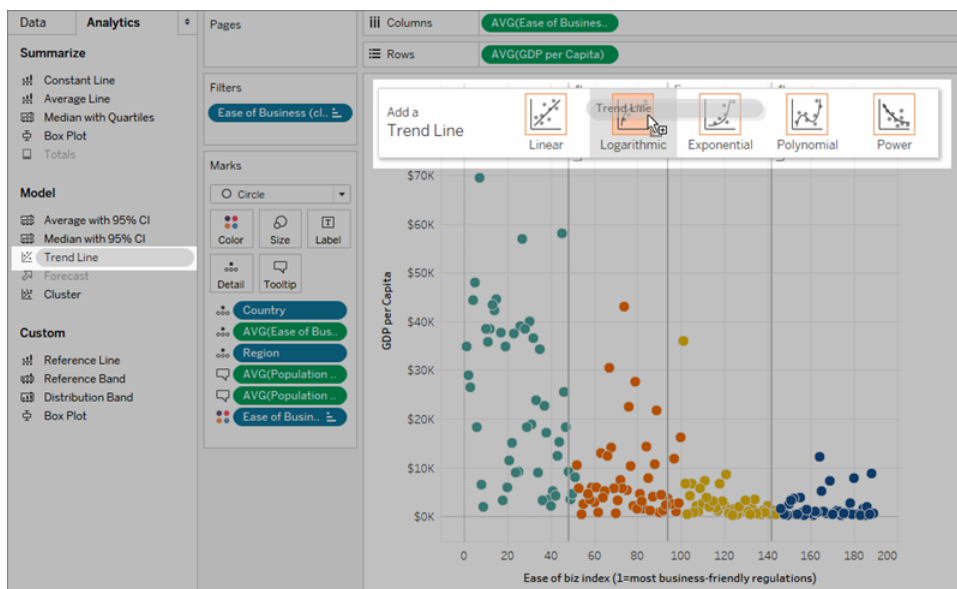

When you add trend lines to a view, you can specify how you want them to look and behave.

Add trend lines to a view

To add a trend line to a visualisation:

1. Select the Analytics pane.
2. From the Analytics pane, drag **Trend Line** into the view, and then drop it on the Linear, Logarithmic, Exponential, Polynomial or Power model types.

For more information on each of these model types, see [Trend Line Model Types on page 2500](#).

About adding trend lines (and when you can't add them)

To add trend lines to a view, both axes must contain a field that can be interpreted as a number. For example, you cannot add a trend line to a view that has the Product **Category** dimension, which contains strings, on the **Columns** shelf and the **Profit** measure on the **Rows** shelf. However, you can add a trend line to a view of sales over time because both sales and time can be interpreted as numeric values.

For multidimensional data sources, the date hierarchies actually contain strings rather than numbers. Therefore, trend lines are not allowed. Additionally, the 'm/d/yy' and 'mmmm yyyy' date formats on all data sources do not allow trend lines.

If you have trend lines turned on and you modify the view in a way where trend lines are not allowed, the trend lines do not show. When you change the view back to a state that allows trend lines, they reappear.

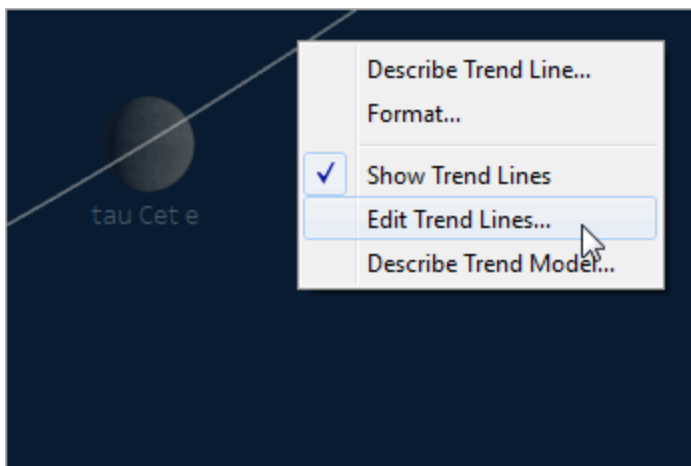

Tableau automatically stacks bar marks in many cases. However, trend lines cannot be turned on for stacked bars. You can turn off stacked marks by clearing the **Analysis > Stack Marks** option.

Edit a trend line

Once you add a trend line to the visualisation, you can edit it to fit your analysis.

To edit a trend line:

In Tableau Desktop: Right-click a trend line in the visualisation, and select **Edit Trend Lines**.

In web editing mode:

1. In the visualisation, click the trend line, and then hover your cursor over it.
2. In the tooltip that appears, select **Edit** to open the **Trend Line Options** dialog box.

Note: To edit a trend line in Tableau Cloud or Tableau Server, you must have web editing permissions.

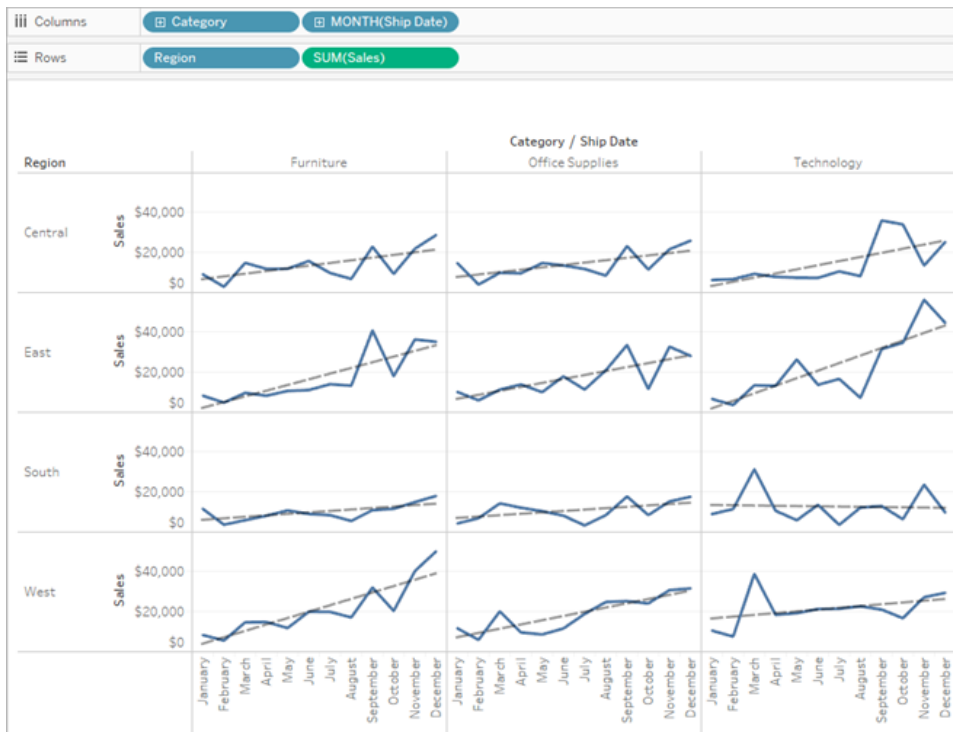

You can configure the following options in the Trend Line Options dialog box:

- Select a model type. For more information, see [Trend Line Model Types](#) on page 2500.
- Select which fields to use as factors in the trend line model. For more information, see [Choose which fields to use as factors in the trend line model](#) below.
- Decide whether to exclude colour, using the **Allow a trend line per colour** option. When you have colour encodings in your view, you can use this option to add a single trend line that models all of the data, ignoring the colour encoding.
- Decide whether to **Show Confidence Bands**. Tableau confidence bands show upper and lower 95% confidence lines by default when you add trend lines. Confidence lines are not supported for Exponential models.
- Select whether to **Force the y-intercept to zero**. This option is useful when you know that you want your trend line to begin at zero. This option is available only when both the **Rows** shelf and the **Columns** shelf contain a continuous field, as with a scatterplot.
- Decide whether to **show recalculated lines** when you select or highlight data in the visualisation.

Choose which fields to use as factors in the trend line model

For trend models that are considering multiple fields, you can eliminate specific fields as factors in the trend line model.

Often you will want to remove factors because you want the trend line model to be based on the entire row in the table rather than broken up by the members or values of a field. Consider the following example. The view below shows the monthly sales for various products categories, broken down by region.

You can see that a separate model is created for each region.

Now remove **Region** as a factor in the model by deselecting it in the Trend Lines Options dialog box.

You can see that the trend line model within a category is now the same across all regions. This allows you to compare actual sales against a trend line that is the same for all regions.

Remove Trend Lines

To remove a trend line from a visualisation, drag it off of the visualisation area. You can also click a trend line and select **Remove**.

To remove all trend lines from the view, select **Analysis > Trend Lines > Show Trend Lines**.

Note: In Tableau Desktop, trend line options are retained so that if you choose **Show Trend Lines** again from the Analysis menu, the options are as you last set them. However, if you close the workbook with trend lines turned off, trend line options revert to defaults.

See a description of a trend line or trend line model

After you add trend lines, you can display statistics on the trend line. For example, you can see the formula as well as r-squared and p values. For more information on the model types and terms used in the descriptions, see the [Trend Line Model Terms on page 2502](#) and [Trend Line Model Types on page 2500](#) sections.

To see a description of a trend line:

- Hover over any part of a trend line to see its description.

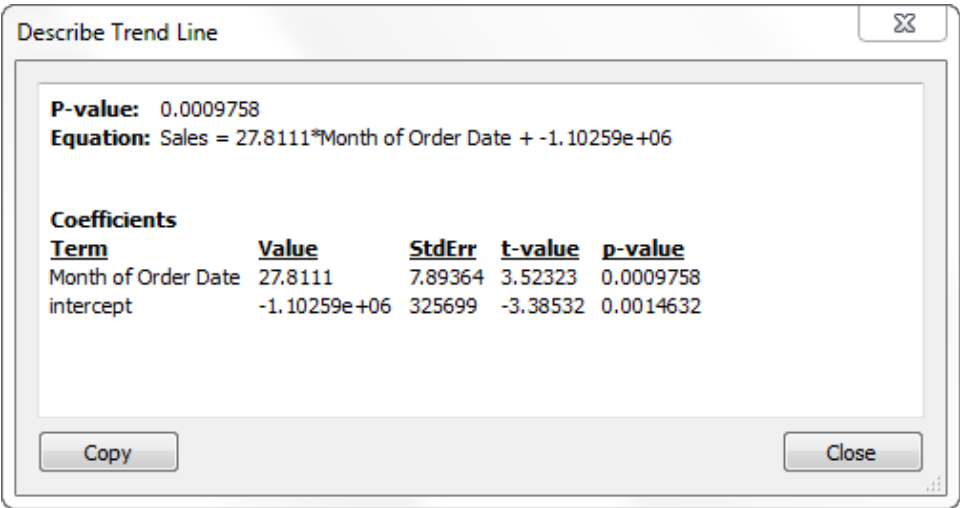

Tableau Desktop only

- Right-click the trend line in the visualisation , and then select **Describe Trend Line**.

To view a full description of the model being used in the current view:

- Right-click a trend line in the visualisation, and then select **Describe Trend Model**.

Trend Line Model Types

These model types are available for trend lines: [Linear](#) below, [Logarithmic](#) below, [Exponential](#) on the facing page, [Power](#) on the facing page and [Polynomial](#) on the facing page.

In the following formulas, X represents the explanatory variable, and Y the response variable.

Linear

With the linear model type the formula is:

$$Y = b_0 + b_1 * X$$

where b_1 is the slope and b_0 is the intercept of the line.

Logarithmic

With the logarithmic model type, the formula is:

$$Y = b_0 + b_1 * \ln(X)$$

Because a logarithm is not defined for number less than zero, any marks for which the explanatory variable is negative are filtered before estimation of the model. Avoid using a model that discards some data unless you know that the data being filtered out is invalid. The trend line description reports how many marks were filtered before model estimation.

Exponential

With the exponential model type, the formula is:

$$Y = \exp(b_0) * \exp(b_1 * X)$$

With an exponential model, the response variable is transformed by the natural log before estimation of the model so the marks plotted in your view are found by plugging in various explanatory values to find values of $\ln(Y)$.

$$\ln(Y) = b_0 + b_1 * X$$

These values are then exponentiated to plot the trend line. What you see is the exponential model in the following form:

$$Y = b_2 * \exp(b_1 * X)$$

Where b_2 is the value of $\exp(b_0)$. Because a logarithm is not defined for numbers less than zero, any marks for which the response variable is negative are filtered before model estimation.

Power

With the power model type, the formula is:

$$Y = b_0 * X^{b_1}$$

With a power model, both variables are transformed by the natural log before estimation of the model resulting in this formula:

$$\ln(Y) = \ln(b_0) + b_1 * \ln(X)$$

These values are then exponentiated to plot the trend line.

Because a logarithm is not defined for numbers less than zero, any marks for which the response variable or explanatory variable is negative are filtered before model estimation.

Polynomial

With the polynomial model type, the response variable is transformed into a polynomial series of the specified degree. The formula is:

$$Y = b_0 + b_1 * X + b_2 * X^2 + \dots$$

With a polynomial model type, you must also select a **Degree** between 2 and 8. The higher polynomial degrees exaggerate the differences between the values of your data. If your data increases very rapidly, the lower order terms may have almost no variation compared to the higher order terms, rendering the model impossible to estimate accurately. Also, more complicated higher order polynomial models require more data to estimate. Check the model

description of the individual trends line for a red warning message indicating that an accurate model of this type is not possible.

Trend Line Model Terms

When you view the description for a trend line model, there are several values listed. This section discusses what each of these values means.

Model formula

This is the formula for the full trend line model. The formula reflects whether you have specified to exclude factors from the model.

Number of modelled observations

The number of rows used in the view.

Number of filtered observations

The number of observations excluded from the model.

Model degrees of freedom

The number of parameters needed to completely specify the model. Linear, logarithmic and exponential trends have model degrees of freedom of 2. Polynomial trends have model degrees of freedom of 1 plus the degree of the polynomial. For example a cubic trend has model degrees of freedom of 4, since we need parameters for the cubed, squared, linear and constant terms.

Residual degrees of freedom (DF)

For a fixed model, this value is defined as the number of observations minus the number of parameters estimated in the model.

SSE (sum squared error)

The errors are the difference between the observed value and the value predicted by the model. In the Analysis of Variance table, this column is actually the difference between the SSE of the simpler model in that particular row and the full model, which uses all the factors. This SSE also corresponds to the sum of the differences squared of the predicted values from the smaller model and the full model.

MSE (mean squared error)

The term MSE refers to 'mean squared error' which is the SSE quantity divided by its corresponding degrees of freedom.

R-Squared

R-squared is a measure of how well the data fits the linear model. It is the ratio of the variance of the model's error, or unexplained variance, to the total variance of the data.

When the y-intercept is determined by the model, R-squared is derived using the following equation:

$$1 - \frac{\sum_{i=1}^n (y_i - \hat{y}_i)^2}{\sum_{i=1}^n (y_i - \bar{y})^2}$$

When the y-intercept is forced to 0, R-squared is derived using this equation instead:

$$1 - \frac{\sum_{i=1}^n (y_i - \hat{y}_i)^2}{\sum_{i=1}^n y_i^2}$$

In the latter case, the equation will not necessarily match Excel. This is because R-squared is not well defined in this case, and Tableau's behaviour matches that of R instead of that of Excel.

Note: The R-Squared value for a linear trend line model is equivalent to the square of the result from the CORR function. See [Tableau Functions \(Alphabetical\)](#) on page 2291 for syntax and examples for CORR.

Standard error

The square root of the MSE of the full model. An estimate of the standard deviation (variability) of the 'random errors' in the model formula.

p-value (significance)

The probability that an F random variable with the above degrees of freedom exceeds the observed F in this row of the Analysis of Variance table.

Analysis of Variance

This table, also known as the ANOVA table, lists information for each factor in the trend line model. The values are a comparison of the model without the factor in question to the entire model, which includes all factors.

Individual trend lines

This table provides information about each trend line in the view. Looking at the list you can see which, if any, are the most statistically significant. This table also lists coefficient statistics for each trend line. A row describes each coefficient in each trend line model. For example, a linear model with an intercept requires two rows for each trend line. In the Line column, the p-value and the DF for each line span all the coefficient rows. The DF column under the shows the residual degrees of freedom available during the estimation of each line.

Terms

The name of the independent term.

Value

The estimated value of the coefficient for the independent term.

StdErr

A measure of the spread of the sampling distribution of the coefficient estimate. This error shrinks as the quality and quantity of the information used in the estimate grows.

t-value

The statistic used to test the null hypothesis that the true value of the coefficient is zero.

p-value

The probability of observing a t-value that large or larger in magnitude if the true value of the coefficient is zero. So, a p-value of .05 gives us 95% confidence that the true value is not zero.

Assess Trend Line Significance

To see relevant information for any trend line in the view, hover the cursor over it:

The first line in the tooltip shows the equation used to compute a value of **Profit** from a value of **Year of Order Date**.

The second line, the R-Squared value, shows the ratio of variance in the data, as explained by the model, to the total variance in the data. For more details, see [Trend Line Model Terms on page 2502](#).

The third line, the P-value, reports the probability that the equation in the first line was a result of random chance. The smaller the p-value, the more significant the model is. A p-value of 0.05 or less is often considered sufficient.

Entire Model Significance

Once you've added a trend line to a view, you typically want to know the goodness of fit of the model, which is a measure of the quality of the model's predictions. In addition, you may be interested in the significance of each factor contributing to the model. To view these numbers, open the Describe Trend Model dialog box, right-click (Control-click on a Mac) in the view and select **Trend Lines >Describe Trend Model**.

When you are testing significance, you are concerned with the p-values. The smaller the p-value, the more significant the model or factor is. It is possible to have a model that has statistical significance but which contains an individual trend line or a term of an individual trend line that does not contribute to the overall significance.

Under Trend Lines Model, look for the line that shows the p-value (significance) of the model: The smaller the p-value, the less likely it is that the difference in the unexplained variance between models with and without the relevant measure or measures was a result of random chance.

Describe Trend Model

Trend Lines Model

A linear trend model is computed for sum of Sales given Ship Date Month. The model may be significant at $p \leq 0.05$. The factor Category may be significant at $p=0.05$.

Model formula: Category*(Month of Ship Date + intercept)

Number of modeled observations: 204

Number of filtered observations: 0

Model degrees of freedom: 34

Residual degrees of freedom (DF): 170

SSE (sum squared error): 6.32245e+011

MSE (mean squared error): 3.71909e+009

R-Squared: 0.850309

Standard error: 60984.4

p-value (significance): < 0.0001

Analysis of Variance:

| Field | DF | SSE | MSE | F | p-value |
|----------|----|--------------|-------------|---------|----------|
| Category | 32 | 3.08378e+012 | 9.6368e+010 | 25.9117 | < 0.0001 |

Individual trend lines:

| Panels | | Line | Coefficients | | | | | |
|--------|--------------------------------|-----------|--------------|--------------------|---------|---------|----------|-----------|
| Row | Column | p-value | DF | Term | Value | StdErr | t-value | p-value |
| Sales | Appliances | 0.0221712 | 10 | Month of Ship Date | 11355.9 | 4200.11 | 2.70372 | 0.0221712 |
| | | | | intercept | 52856.9 | 30912 | 1.70992 | 0.118073 |
| Sales | Binders and Binder Accessories | 0.0048827 | 10 | Month of Ship Date | 21028.2 | 5848.16 | 3.5957 | 0.0048827 |
| | | | | intercept | 38108.4 | 43041.3 | 0.885391 | 0.396736 |
| Sales | Bookcases | 0.0582459 | 10 | Month of Ship Date | 12823 | 5998.1 | 2.13785 | 0.0582459 |

This p-value for a model compares the fit of the entire model to the fit of a model composed solely of the grand mean (the average of data in the data view). That is, it assesses the explanatory power of the quantitative term $f(x)$ in the model formula, which can be linear, polynomial, exponential or logarithmic with the factors fixed. It is common to assess significance using the '95% confidence' rule. Thus, as noted above, a p-value of 0.05 or less is considered good.

Significance of Categorical Factors

In the Analysis of Variance table, sometimes referred to as the ANOVA table, each field that is used as a factor in the model is listed. For each field, among other values, you can see the p-value. In this case, the p-value indicates how much that field adds to the significance of the entire model. The smaller the p-value, the less likely it is that the difference in the unexplained variance between models with and without the field was a result of random chance. The values displayed for each field are derived by comparing the entire model to a model that does not include the field in question.

The following image shows the Analysis of Variance table for a view of quarterly sales for the past two years of three different product categories.

| Analysis of Variance: | | | | | |
|-----------------------|-----|--------------|--------------|---------|----------|
| Field | DF | SSE | MSE | F | p-value |
| Category | 160 | 1.65811e+012 | 1.03632e+010 | 20.9732 | < 0.0001 |
| Region | 136 | 2.64345e+012 | 1.94371e+010 | 39.3372 | < 0.0001 |

As you can see, the p-values for **Category** and **Region** are both quite small. Both of these factors are statistically significant in this model.

For information on specific trend line terms, see [Trend Line Model Terms on page 2502](#).

For ANOVA models, trend lines are defined by the mathematical formula:

$$Y = \text{factor 1} * \text{factor 2} * \dots \text{factorN} * f(x) + e$$

The term Y is called the *response variable* and corresponds to the value you are trying to predict. The term x is the *explanatory variable*, and e (epsilon) is random error. The factors in the expression correspond to the categorical fields in the view. In addition, each factor is represented as a matrix. The $*$ is a particular kind of matrix multiplication operator that takes two matrices with the same number of rows and returns a new matrix with the same number of rows. That means that in the expression `factor 1 * factor 2`, all combinations of the members of factor 1 and factor 2 are introduced. For example, if factor 1 and factor 2 both have three members, then a total of nine variables are introduced into the model formula by this operator.

Trend Line Assumptions

The p-values reported in Tableau trend lines depend on some assumptions about the data.

The first assumption is that, whenever a test is performed, the model for the mean is (at least approximately) correct.

The second assumption is that the 'random errors' referred to in the model formula (see [Trend Line Model Types on page 2500](#)) are independent across different observations, and that they all have the same distribution. This constraint would be violated if the response variable had much more variability around the true trend line in one category than in another.

Assumptions Required to Compute Trend Lines

The Assumptions required to compute (using Ordinary Least Squares) each individual trend line are:

- Your model is an accurate functional simplification of the true data generating process (for example, no linear model for a log linear relationship).

- Your errors average to zero and are uncorrelated with your independent variable (for example, no error measuring the independent variable).
- Your errors have constant variance and are not correlated with each other (for example, no increase in error spread as your independent variable increases).
- Explanatory variables are not exact linear functions of each other (perfect multicollinearity).

Commonly Asked Questions About Trend Lines

This section describes some commonly asked questions regarding trend lines in Tableau.

How do I change the confidence level used in the model?

Tableau does not enforce a confidence level. It simply reports the significance of the whole model, or of a specific field, by showing the p-value. The p-value will measure the probability of obtaining the same trend result without taking the dimensions into account. For example, a trend of sales per time p-value of 0.05 means that there is 5% chance that the same value could be obtained without taking the time into consideration.

What does it mean if the p-value for the model is significant but the p-value for the specific field in the Analysis of Variance table is not significant?

The p-value in the Analysis of Variance table indicates whether the field adds or detracts from the significance of the entire model. The smaller the p-value, the less likely it is that the difference in the unexplained variance between models with and without the field was a result of random chance. The values displayed for each field are derived by comparing the entire model to a model that does not include the field in question. So, for the situation where the p-value for the model is significant but the p-value for the specific field is not, you know that the model is statistically significant, but you cannot be confident that the specific field in question adds anything to it. Consider whether you might not be better off removing the factor from the model.

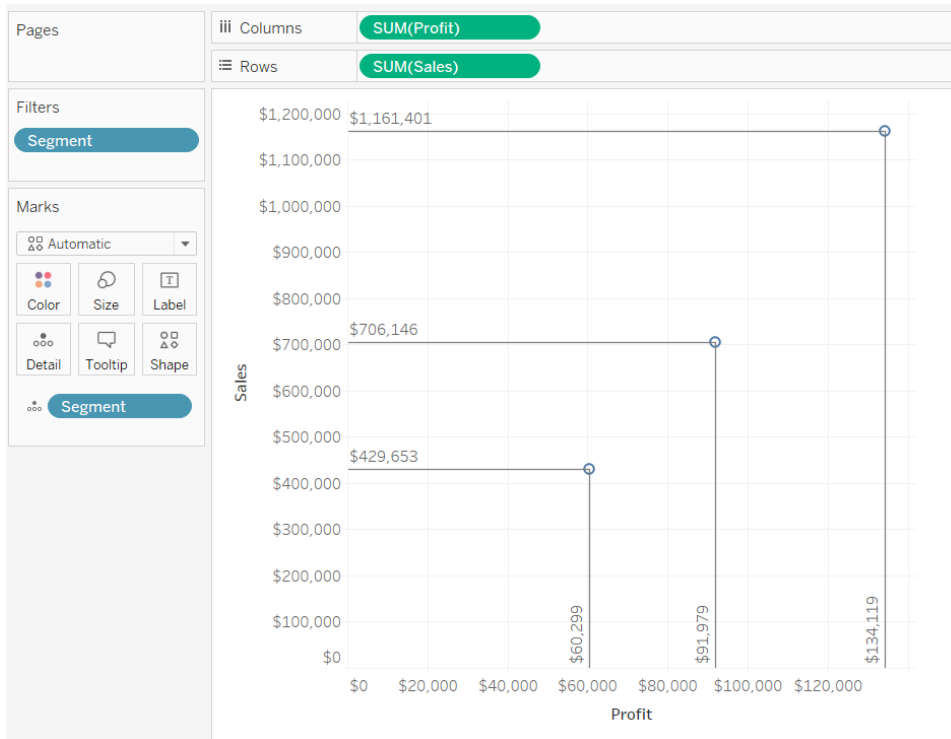

What does it mean if the p-value for the specific field in the Analysis of Variance table is significant but the p-value for the model is not significant?

This could happen in a case when there is no 'trend' within each pane. For example, the lines are flat, but the mean varies across a given factor.

Drop Lines

Use drop lines to distinguish marks and call out their position in the view. For example, in a view that is dense with scatter marks, you can turn on drop lines to show the position of a particular

data point. When you add drop lines, a line is extended from the marks to one of the axes. You can show drop lines all the time or only when a mark is selected.

Note: Drop lines do not display when you publish a view to Tableau Server or Tableau Cloud.

To add drop lines to the view, right-click (control-click on Mac) the pane and select **Drop Lines > Show Drop Lines**.

By default, drop lines are set to only show when the mark is selected. You can change this setting and specify other options in the Drop Lines dialog box.

Right-click (Control-click on Mac) the pane and select **Drop Lines > Edit Drop Lines** to open the Drop Lines dialog box.

In the Drop Lines dialog box select an axis to draw the line to, whether to always show the drop lines, and whether to show labels.

Find Clusters in Data

Cluster analysis partitions marks in the view into clusters, where the marks within each cluster are more similar to one another than they are to marks in other clusters.

For an example that demonstrates the process of creating clusters with sample data, see [Example: Create clusters using World Economic Indicators data on page 2526](#).

Create clusters

To find clusters in a view in Tableau, follow these steps.

1. Create a view.
2. Drag **Cluster** from the **Analytics** pane into the view, and drop it on in the target area in the view:

You can also double-click **Cluster** to find clusters in the view.

When you drop or double-click **Cluster**:

- Tableau creates a **Clusters** group on **Colour**, and colours the marks in your view by cluster. If there is already a field on **Colour**, Tableau moves that field to **Detail** and replaces it on **Colour** with the clustering results.

Tableau assigns each mark in the view to one of the clusters. In some cases, marks that do not fit well into a cluster are assigned to a 'Not Clustered' cluster.

- Tableau displays the Clusters dialog box, where you can customise the cluster.

3. Customise the cluster results by doing either of the following in the Clusters dialog box.
 - Drag new fields from the **Data** pane into the Variables area of the Clusters dialog box. You can also drag fields out of the Variables area to remove them.

When you add variables, measures are aggregated using the default aggregation for the field; dimensions are aggregated using ATTR, which is the standard way that Tableau aggregates dimensions.

To change the aggregation for a variable, right-click it.

- Specify the number of clusters (between 2 and 50). If you do not specify a value, Tableau will automatically create up to 25 clusters.
4. When you finish customising the cluster results, click the X in the upper-right corner of the Clusters dialog box to close it:

Note: You can move the cluster field from Colour to another shelf in the view. However, you cannot move the cluster field from the **Filters** shelf to the **Data** pane.

To rename the resulting clusters, you must first save the cluster as a group. For details, see [Create a group from cluster results on page 2516](#) and [Edit clusters](#) below.

Clustering constraints

Clustering is available in Tableau Desktop but is not available for authoring on the web (Tableau Server, Tableau Cloud). Clustering is also not available when any of the following conditions apply:

- When you are using a cube (multidimensional) data source.
- When there is a blended dimension in the view.
- When there are no fields that can be used as variables (inputs) for clustering in the view.
- When there are no dimensions present in an aggregated view.

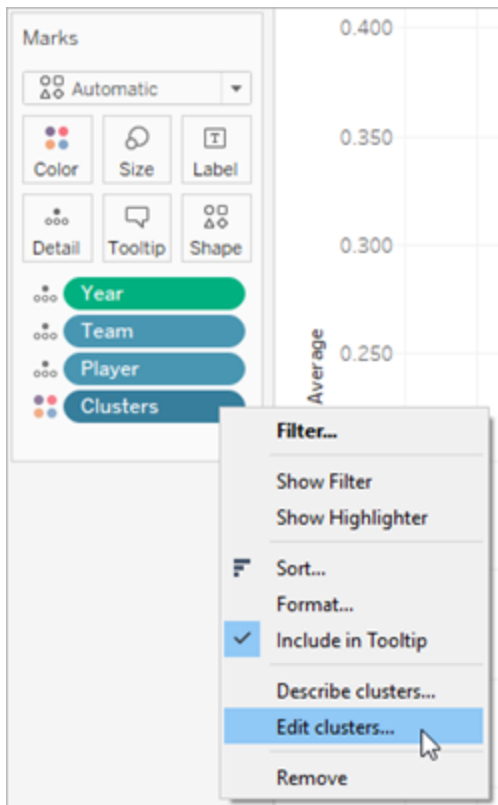

When any of those conditions apply, you will not be able to drag **Clusters** from the Analytics pane to the view.

In addition, the following field types cannot be used as variables (inputs) for clustering:

- Table calculations
- Blended calculations
- Ad-hoc calculations
- Generated latitude/longitude values
- Groups
- Sets
- Bins
- Parameters
- Dates
- Measure Names/Measure Values

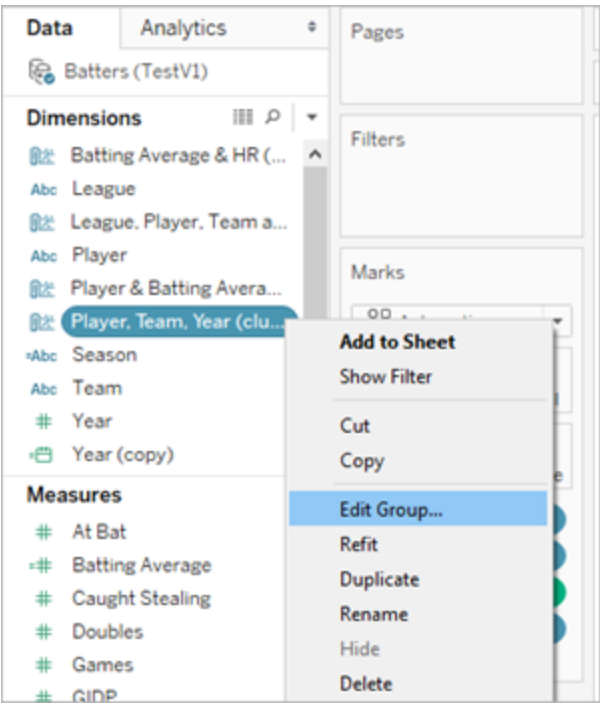

Edit clusters

To edit an existing cluster, right-click (Control-click on a Mac) a **Clusters** field on **Colour** and select **Edit clusters**.

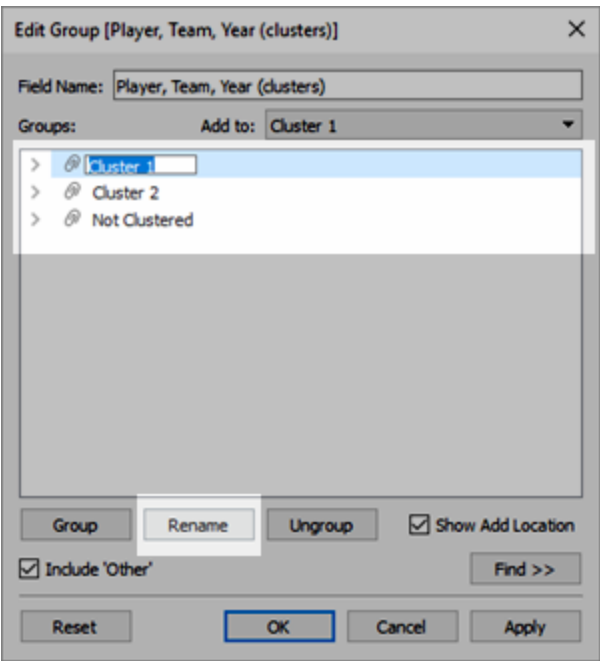

To change the names used for each cluster, you will first need to drag the Clusters field to the **Data** pane and save it as a group. For details, see [Create a group from cluster results](#) on [page 2516](#).

Right-click the cluster group and select **Edit Group** to make changes to each cluster.

Select a cluster group in the list of Groups and click **Rename** to change the name.

Create a group from cluster results

If you drag a cluster to the **Data** pane, it becomes a group dimension in which the individual members (Cluster 1, Cluster 2, etc.) contain the marks that the cluster algorithm has determined are more similar to each other than they are to other marks.

After you drag a cluster group to the **Data** pane, you can use it in other worksheets.

Drag **Clusters** from the **Marks** card to the **Data** pane to create a Tableau group:

After you create a group from clusters, the group and the original clusters are separate and distinct. Editing the clusters does not affect the group, and editing the group does not affect the cluster results. The group has the same characteristics as any other Tableau group. It is part of the data source. Unlike the original clusters, you can use the group in other worksheets in the workbook. So if you rename the saved cluster group, that renaming is not applied to the original

clustering in the view. See [Correct Data Errors or Combine Dimension Members by Grouping Your Data](#) on page 1099.

Constraints on saving clusters as groups

You will not be able to save Clusters to the **Data** pane under any of the following circumstances:

- When the measures in the view are disaggregated and the measures you are using as clustering variables are not the same as the measures in the view. For details, see [How to Disaggregate Data](#) on page 180.
- When the Clusters you want to save are on the **Filters** shelf.
- When **Measure Names** or **Measure Values** is in the view.
- When there is a blended dimension in the view.

Refit saved clusters

When you save a Clusters field as a group, it is saved with its analytic model. You can use your cluster groups in other worksheets and workbooks, however, they don't automatically refresh.

In this example, a saved cluster group and its analytic model has been applied to a different worksheet. As a result, some of the marks are not included in the clustering yet (indicated by grey marks).

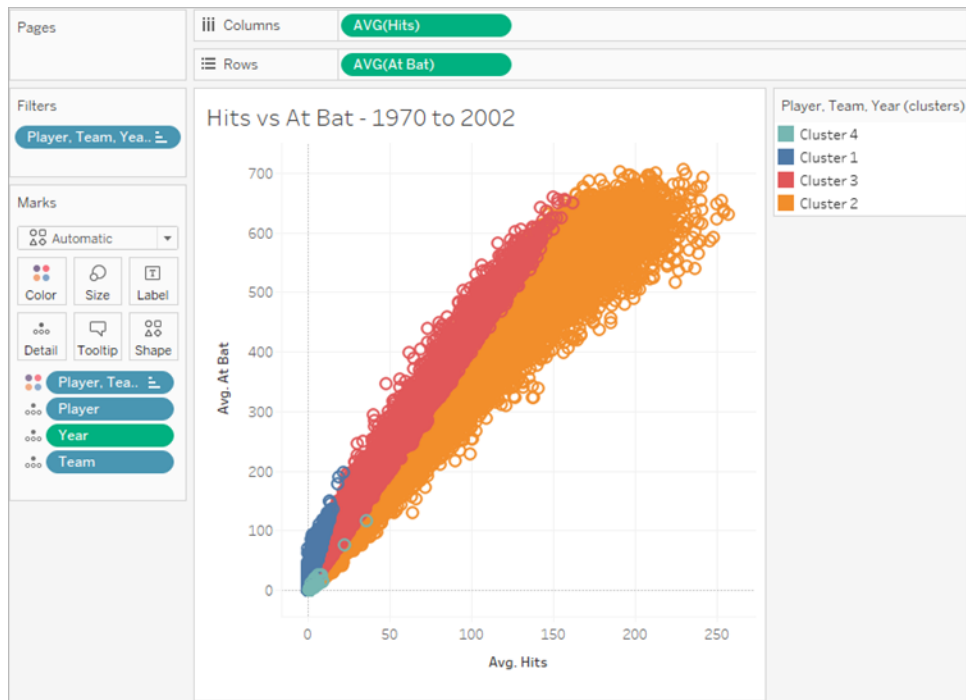

If the underlying data changes, you can use the **Refit** option to refresh and recompute the data for a saved clusters group.

To refit a saved cluster

- Right-click a clusters group in the Data pane, and then click **Refit**.

Here's an example of updated clustering after refitting the saved cluster:

When you refit saved clusters, new clusters will be created and existing aliases for each cluster group category will be replaced with new, generic cluster aliases. Be aware that refitting saved clusters may alter your visualisations that use existing clusters and aliases.

How clustering works

Cluster analysis partitions the marks in the view into clusters, where the marks within each cluster are more similar to one another than they are to marks in other clusters. Tableau distinguishes clusters using colour.

Note: For additional insight into how clustering works in Tableau, see the blog post [Understanding Clustering in Tableau 10](#).

The clustering algorithm

Tableau uses the k-means algorithm for clustering. For a given number of clusters k , the algorithm partitions the data into k clusters. Each cluster has a centre (centroid) that is the mean value of all the points in that cluster. K-means locates centres through an iterative procedure that minimises distances between individual points in a cluster and the cluster centre. In Tableau, you can specify a desired number of clusters, or have Tableau test different values of k and suggest

an optimal number of clusters (see [Criteria used to determine the optimal number of clusters on page 2522](#)).

K-means requires an initial specification of cluster centres. Starting with one cluster, the method chooses a variable whose mean is used as a threshold for splitting the data in two. The centroids of these two parts are then used to initialise k-means to optimise the membership of the two clusters. Next, one of the two clusters is chosen for splitting and a variable within that cluster is chosen whose mean is used as a threshold for splitting that cluster in two. K-means is then used to partition the data into three clusters, initialised with the centroids of the two parts of the split cluster and the centroid of the remaining cluster. This process is repeated until a set number of clusters is reached.

Tableau uses Lloyd's algorithm with squared Euclidean distances to compute the k-means clustering for each k . Combined with the splitting procedure to determine the initial centres for each $k > 1$, the resulting clustering is deterministic, with the result dependent only on the number of clusters.

The algorithm starts by picking initial cluster centres:

It then partitions the marks by assigning each to its nearest centre:

Then it refines the results by computing new centres for each partition by averaging all the points assigned to the same cluster:

It then reviews the assignment of marks to clusters and reassigns any marks that are now closer to a different centre than before.

The clusters are redefined and marks are reassigned iteratively until no more changes are occurring.

Note: Due to underlying differences in the technologies, there may be slight differences between clusters created on x64 or arm64 CPUs for the same data.

Criteria used to determine the optimal number of clusters

Tableau uses the Calinski-Harabasz criterion to assess cluster quality. The Calinski-Harabasz criterion is defined as

$$\frac{SS_B}{SS_W} \times \frac{(N-k)}{(k-1)}$$

where SS_B is the overall between-cluster variance, SS_W the overall within-cluster variance, k the number of clusters and N the number of observations.

The greater the value of this ratio, the more cohesive the clusters (low within-cluster variance) and the more distinct/separate the individual clusters (high between-cluster variance).

Since the Calinski-Harabasz index is not defined for $k=1$, it cannot be used to detect one-cluster cases.

If a user does not specify the number of clusters, Tableau picks the number of clusters corresponding to the first local maximum of the Calinski-Harabasz index. By default, k-means will be run for up to 25 clusters if the first local maximum of the index is not reached for a smaller value of k . You can set a maximum value of 50 clusters.

Note: If a categorical variable (that is, a dimension) has more than 25 unique values, then Tableau will disregard that variable when computing clusters.

What values get assigned to the 'Not Clustered' category?

When there are null values for a measure, Tableau assigns values for rows with null to a **Not Clustered** category. Categorical variables (that is, dimensions) that return * for ATTR (meaning

that all values are not identical) are also not clustered.

Scaling

Tableau scales values automatically so that columns having a larger range of magnitudes don't dominate the results. For example, an analyst could be using inflation and GDP as input variables for clustering, but because GDP values are in trillions of dollars, this could cause the inflation values to be almost completely disregarded in the computation. Tableau uses a scaling method called *min-max normalisation*, in which the values of each variable is mapped to a value between 0 and 1 by subtracting its minimum and dividing by its range.

Information on statistics models used for clusters

The Describe Clusters dialog box provides information about the models that Tableau computed for clustering. You can use these statistics to assess the quality of the clustering.

When the view includes clustering, you can open the Describe Clusters dialog box by right-clicking **Clusters** on the **Marks** card (Control-clicking on a Mac) and choosing **Describe Clusters**. The information in the Describe Clusters dialog box is read-only, though you can click **Copy to Clipboard** and then paste the screen contents into a writeable document.

Describe Clusters - Summary Tab

The Summary tab identifies the inputs that were used to generate the clusters and provides some statistics that characterise the clusters.

Inputs for Clustering

Variables

Identifies the fields Tableau uses to compute clusters. These are the fields listed in the Variables box in the Clusters dialog box.

Level of Detail

Identifies the fields that are contributing to the view's level of detail – that is, the fields that determine the level of aggregation. For details, see [How dimensions affect the level of detail in the view on page 150](#).

Scaling

Identifies the scaling method used for pre-processing. Normalised is currently the only scaling method Tableau uses. The formula for this method, also known as min-max normalisation, is $(x - \min(x)) / (\max(x) - \min(x))$.

Summary Diagnostics

Number of Clusters

The number of individual clusters in the clustering.

Number of Points

The number of marks in the view.

Between-group sum of squares

A metric quantifying the separation between clusters as a sum of squared distances between each cluster's centre (average value), weighted by the number of data points assigned to the cluster, and the centre of the data set. The larger the value, the better the separation between clusters.

Within-group sum of squares

A metric quantifying the cohesion of clusters as a sum of squared distances between the centre of each cluster and the individual marks in the cluster. The smaller the value, the more cohesive the clusters.

Total sum of squares

Totals the between-group sum of squares and the within-group sum of squares. The ratio $(\text{between-group sum of squares})/(\text{total sum of squares})$ gives the proportion of variance explained by the model. Values are between 0 and 1; larger values typically indicate a better model. However, you can increase this ratio just by increasing the number of clusters, so it could be misleading if you compare a five-cluster model with a three-cluster model using just this value.

Cluster Statistics

For each cluster in the clustering, the following information is provided.

Items

The number of marks within the cluster.

Centres

The average value within each cluster (shown for numeric items).

Most Common

The most common value within each cluster (only shown for categorical items).

Describe Clusters - Models Tab

Analysis of variance (ANOVA) is a collection of statistical models and associated procedures useful for analysing variation within and between observations that have been partitioned into groups or clusters. In this case, analysis of variance is computed per variable, and the resulting analysis of variance table can be used to determine which variables are most effective for distinguishing clusters.

Relevant analysis of variance statistics for clustering include:

F-statistic

The F-statistic for one-way, or single-factor, ANOVA is the fraction of variance explained by a variable. It is the ratio of the between-group variance to the total variance.

The larger the F-statistic, the better the corresponding variable is distinguishing between clusters.

p-value

The p-value is the probability that the F-distribution of all possible values of the F-statistic takes on a value greater than the actual F-statistic for a variable. If the p-value falls below a specified significance level, then the null hypothesis (that the individual elements of the variable are random samples from a single population) can be rejected. The degrees of freedom for this F-distribution are $(k - 1, N - k)$, where k is the number of clusters and N is the number of items (rows) clustered.

The lower the p-value, the more the expected values of the elements of the corresponding variable differ among clusters.

Model Sum of Squares and Degrees of Freedom

The Model Sum of Squares is the ratio of the between-group sum of squares to the model degrees of freedom. The between group sum of squares is a measure of the variation between cluster means. If the cluster means are close to each other (and therefore close to the overall mean), this value will be small. The model has $k-1$ degrees of freedom, where k is the number of clusters.

Error Sum of Squares and Degrees of Freedom

The Error Sum of Squares is the ratio of within-group sum of squares to the error degrees of freedom. The within-group sum-of-squares measures the variation between observations within

each cluster. The error has $N-k$ degrees of freedom, where N is the total number of observations (rows) clustered and k is the number of clusters.

The Error Sum of Squares can be thought of as the overall Mean Square Error, assuming that each cluster centre represents the 'truth' for each cluster.

Example: Create clusters using World Economic Indicators data

The Tableau clustering feature partitions marks in the view into clusters, where the marks within each cluster are more similar to one another than they are to marks in other clusters. This example shows how a researcher might use clustering to find an optimal set of marks (in this case, countries/regions) in a data source.

The objective

As life expectancy increases around the world, and as older people remain more active, senior tourism can be a lucrative market for companies that know how to find and appeal to potential customers. The World Indicators sample data set that comes with Tableau contains the kind of data that might help companies identify the countries or regions where there are enough of the right kind of customers.

Finding the right countries/regions

Here is an example of how Tableau clustering could help such a company identify the countries/regions where a senior tourism business could succeed. Imagine you are the analyst. Here is how you might proceed.

1. Open the **World Indicators** sample data source in Tableau Desktop.
2. Double-click **Country/Region** in the **Data** pane.

Tableau automatically creates a map view, with a mark in each country/region.

3. On the **Marks** card, change the mark type to **Map**:

You should now see a map projection where all countries/regions are filled with a solid colour:

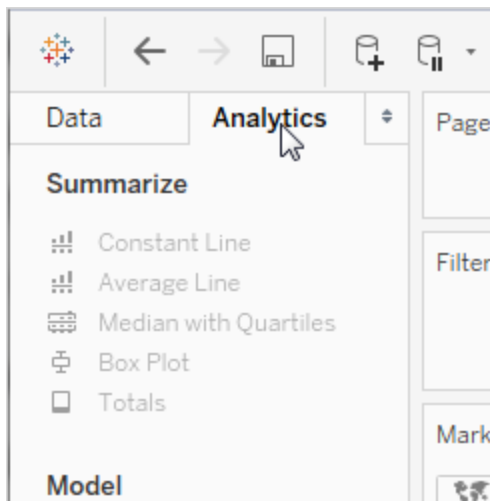

4. The next step is to identify the fields that you will use as variables for clustering. Here are the fields you choose:

| Field | Reason for inclusion |
|---|--|
| Life Expectancy Female and Life Expectancy Male | Where people are living longer, there are more likely to be people who are interested in traveling later in life. |
| Population Urban | It is easier to market services in areas with greater population density. |
| Population 65+ | The target population is older residents with the time and funds to travel. |
| TourismPerCapita | <p>This is a measure that you must create as a named calculated field. The formula is:</p> $\text{SUM}([\text{Tourism Outbound}]) / \text{SUM}([\text{Population Total}])$ |

Tourism Outbound aggregates the money (in US dollars) that residents of a country/region spend annually on international travel. But this total must be divided by the population of each country/region to determine the average amount each resident spends on international travel.

There is no guarantee that these are the ideal fields to choose, or that these fields will produce cluster results that are clear and unambiguous. Clustering is an iterative process – experimentation leads to discovery which leads, in turn, to more experimentation.

5. Drag these five fields from the **Data** pane to **Detail** on the **Marks** card.
6. Click to open the **Analytics** pane:

7. Drag **Cluster** from the **Analytics** pane and drop it in the view:

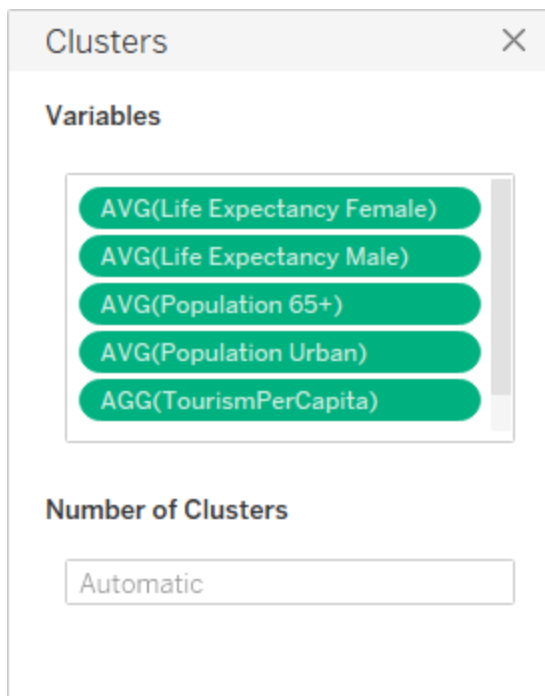

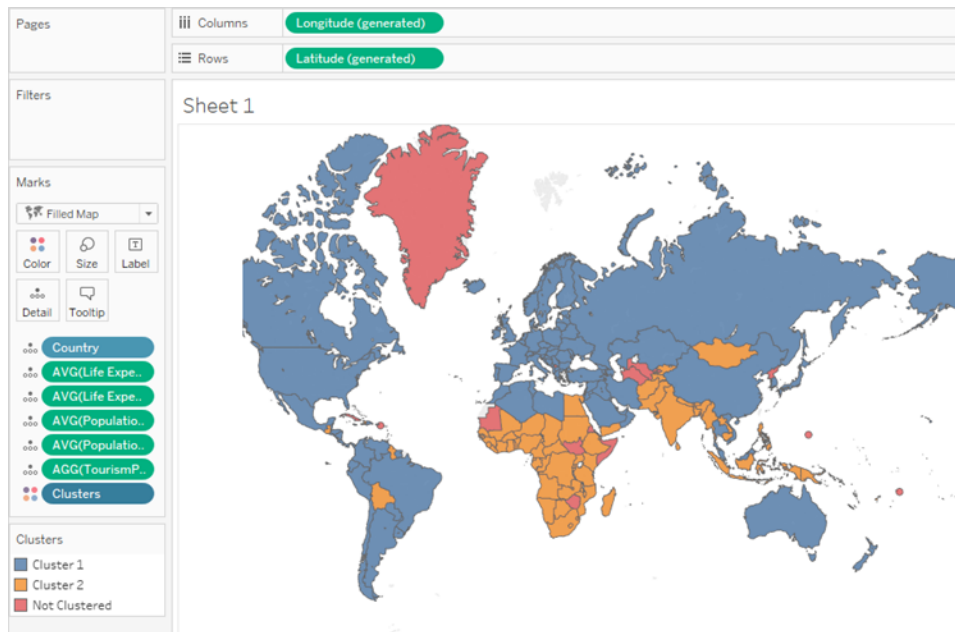

Tableau displays the Clusters dialog box and adds the measures in the view to the list of variables:

It also updates the view by adding clusters to **Colour**. In this case, Tableau finds two distinct clusters, and is unable to assign certain countries/regions (coloured reddish-pink) to either cluster:

Note: See [How clustering works](#) on page 2519 for details on data that Tableau assigns to 'Not clustered'.

8. You decide that two clusters isn't enough – you don't have the resources to set up shop in half the countries/regions in the world. So you type 4 in the **Number of Clusters** field in the Clusters dialog box.

The map becomes more interesting:

But how do these clusters relate to the variables you have chosen? Which one correlates best with the factors that support senior tourism? It's time to look at the statistics behind the clusters.

9. Close the Clusters dialog box by clicking the X in its upper-right corner:

10. Click the **Clusters** field on the **Marks** card and choose **Describe Clusters**.

The table at the bottom of the **Models** tab in the Describe Clusters dialog box shows the average value for each variable in each cluster:

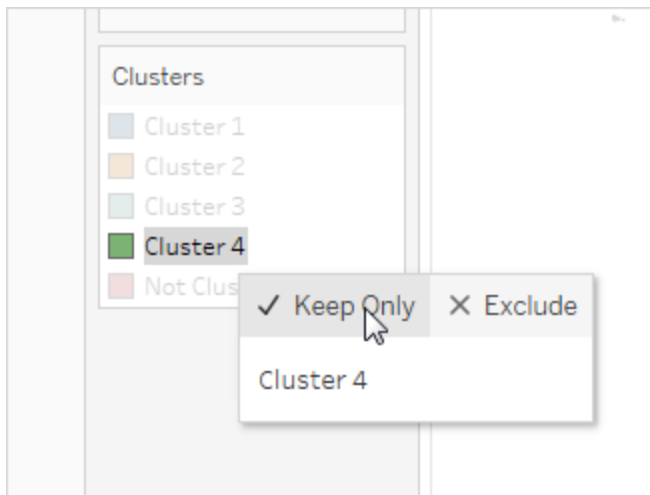

| Clusters | Number of Items | Centers | | | | |
|---------------|-----------------|-----------------------------|---------------------------|---------------------|-----------------------|------------------|
| | | Avg. Life Expectancy Female | Avg. Life Expectancy Male | Avg. Population 65+ | Avg. Population Urban | TourismPerCapita |
| Cluster 1 | 69 | 74.216 | 69.003 | 0.054943 | 0.5325 | 197.12 |
| Cluster 2 | 52 | 56.75 | 54.429 | 0.031889 | 0.33127 | 20.775 |
| Cluster 3 | 29 | 79.164 | 71.706 | 0.15493 | 0.65532 | 320.92 |
| Cluster 4 | 30 | 81.287 | 76.355 | 0.11606 | 0.87123 | 1360.4 |
| Not Clustered | 28 | | | | | |

Cluster 4 has the highest life expectancy (both male and female), the highest concentration of urban population, and the highest expenditure for international tourism: \$1360.40 per capita. The only variable for which Cluster 4 does not have the highest

value is **Population 65+**, where Cluster 3 has the advantage: 0.15493 (just under 16%) to 0.11606 (just over 11%) in Cluster 4.

The clustering algorithm does not know whether you are looking for the maximum value for these variables, the minimum value, or something in the middle – it just looks for correlation. But you know that higher values for these variables is the signal you're looking for, and Cluster 4 is the best choice.

11. You could attempt to pick out the Cluster 4 countries/regions from the map, but there is an easier way. Close the **Describe Clusters** dialog box and then click **Cluster 4** on the Colour legend and choose **Keep Only**.

12. Choose Text Table from ShowMe.

You now see a list of the countries/regions in Cluster 4:

| Clusters | Country | |
|-----------|----------------------|-----|
| Cluster 4 | Argentina | Abc |
| | Australia | Abc |
| | Bahamas, The | Abc |
| | Belgium | Abc |
| | Canada | Abc |
| | Chile | Abc |
| | Curacao | Abc |
| | Cyprus | Abc |
| | Denmark | Abc |
| | Hong Kong SAR, China | Abc |
| | Iceland | Abc |
| | Ireland | Abc |
| | Israel | Abc |
| | Korea, Rep. | Abc |
| | Kuwait | Abc |
| | Lebanon | Abc |
| | Luxembourg | Abc |
| | Macao SAR, China | Abc |
| | Malta | Abc |
| | Netherlands | Abc |
| | New Zealand | Abc |
| | Norway | Abc |
| | Puerto Rico | Abc |
| | Qatar | Abc |
| | Singapore | Abc |
| | Sweden | Abc |
| | Switzerland | Abc |
| | United Kingdom | Abc |
| | United States | Abc |
| | Uruguay | Abc |

This list is not the end of the process. You might try clustering again with a somewhat different set of variables and maybe a different number of clusters, or you might add some countries/regions to the list and remove others, based on other factors. For example, if your tours are mostly to tropical locales, you might remove countries/regions like Curacao and the Bahamas from the list, because tropical tours might not appeal to residents of those countries/regions.

Another option is to filter your data before you re-cluster, to only show countries/regions with populations above a certain threshold, or to target countries/regions in a particular geographical area.

Forecasting

You can add a forecast to a view when there is at least one date dimension and one measure in the view. If you're interested in predictive modelling, also available in Tableau, see [How Predictive Modelling Functions Work in Tableau on page 2561](#).

To turn forecasting on, right-click (control-click on Mac) on the visualisation and choose **Forecast >Show Forecast**, or choose **Analysis >Forecast >Show Forecast**.

When no date dimension is present, you can add a forecast if there is a dimension field in the view that has integer values. For details, see [Forecasting When No Date is in the View on page 2546](#).

You can forecast quantitative time-series data using exponential smoothing models in Tableau Desktop. With exponential smoothing, recent observations are given relatively more weight than older observations. These models capture the evolving trend or seasonality of your data and extrapolate them into the future. Forecasting is fully automatic, yet configurable. Many forecast results can become fields in your visualisations.

When a forecast is showing, future values for the measure are shown next to the actual values.

Forecasting Constraints

Forecasting is not supported for Multidimensional data sources. In Tableau Desktop, multidimensional data sources are supported only in Windows.

You can publish a view that contains a forecast, and see the forecast when you view or edit the view on the web, but you cannot modify or add a forecast when you are editing a view on the web.

In addition, you cannot add a forecast to a view if it contains any of the following:

- Table calculations
- Disaggregated measures
- Percent calculations
- Grand Totals or Subtotals
- Date values with aggregation set to Exact Date

How Forecasting Works in Tableau

Forecasting in Tableau uses a technique known as exponential smoothing. Forecast algorithms try to find a regular pattern in measures that can be continued into the future. If you're interested in predictive modelling, also available in Tableau, see [How Predictive Modelling Functions Work in Tableau on page 2561](#).

You typically add a forecast to a view that contains a date field and at least one measure. However, in the absence of a date, Tableau can create a forecast for a view that contains a dimension with integer values in addition to at least one measure.

For details on creating a forecast, see [Create a Forecast on page 2542](#). For details on forecasting using an integer dimension, see [Forecasting When No Date is in the View on page 2546](#).

Overview

All forecast algorithms are simple models of a real-world data generating process (DGP). For a high quality forecast, a simple pattern in the DGP must match the pattern described by the model reasonably well. Quality metrics measure how well the model matches the DGP. If the quality is low, the precision measured by the confidence bands is not important because it measures the precision of an inaccurate estimate.

Tableau automatically selects the best of up to eight models, the best being the one that generates the highest quality forecast. The smoothing parameters of each model are optimised before Tableau assesses forecast quality. The optimisation method is global. Therefore, choosing locally optimal smoothing parameters that are not also globally optimal is not impossible. However, initial value parameters are selected according to best practices but are not further optimised. So it is possible for initial value parameters to be less than optimal. The eight models available in Tableau are among those described at the following location on the OTexts web site: [A taxonomy of exponential smoothing methods](#).

When there is not enough data in the visualisation, Tableau automatically tries to forecast at a finer temporal granularity, and then aggregates the forecast back to the granularity of the visualisation. Tableau provides prediction bands which may be simulated or calculated from a closed form equation. All models with a multiplicative component or with aggregated forecasts have simulated bands, while all other models use the closed form equations.

Exponential Smoothing and Trend

Exponential smoothing models iteratively forecast future values of a regular time series of values from weighted averages of past values of the series. The simplest model, *Simple*

Exponential Smoothing, computes the next level or smoothed value from a weighted average of the last actual value and the last level value. The method is exponential because the value of each level is influenced by every preceding actual value to an exponentially decreasing degree – more recent values are given greater weight.

Exponential smoothing models with trend or seasonal components are effective when the measure to be forecast exhibits trend or seasonality over the period of time on which the forecast is based. *Trend* is a tendency in the data to increase or decrease over time. *Seasonality* is a repeating, predictable variation in value, such as an annual fluctuation in temperature relative to the season.

In general, the more data points you have in your time series, the better the resulting forecast will be. Having enough data is particularly important if you want to model seasonality, because the model is more complicated and requires more proof in the form of data to achieve a reasonable level of precision. On the other hand, if you forecast using data generated by two or more different DGPs, you will get a lower quality forecast because a model can only match one.

Seasonality

Tableau tests for a seasonal cycle with the length most typical for the time aggregation of the time series for which the forecast is estimated. So if you aggregate by months, Tableau will look for a 12-month cycle; if you aggregate by quarters, Tableau will search for a four-quarter cycle; and if you aggregate by days, Tableau will search for weekly seasonality. Therefore, if there is a six-month cycle in your monthly time series, Tableau will probably find a 12-month pattern that contains two similar sub-patterns. However, if there is a seven-month cycle in your monthly time series, Tableau will probably find no cycle at all. Luckily, seven-month cycles are uncommon.

Tableau can use either of two methods for deriving season length. The original temporal method uses the natural season length of the temporal granularity (TG) of the view. Temporal granularity means the finest unit of time expressed by the view. For example, if the view contains either a continuous green date truncated to month or discrete blue year and month date parts, the temporal granularity of the view is month. The new non-temporal method, introduced with Tableau 9.3, uses periodic regression to check season lengths from 2 to 60 for candidate lengths.

Tableau automatically selects the most appropriate method for a given view. When Tableau is using a date to order the measures in a view, if the temporal granularity is quarterly, monthly, weekly, daily or hourly, the season lengths are almost certainly 4, 12, 13, 7 or 24, respectively. So only the length natural to the TG is used to construct the five seasonal exponential smoothing models supported by Tableau. The AIC of the five seasonal models and the three non-seasonal models are compared and the lowest returned. (For an explanation of the AIC metric, see Forecast Descriptions.)

When Tableau is using an integer dimension for forecasting, the second method is used. In this case there is no temporal granularity (TG), so potential season lengths must be derived from the data.

The second method is also used if the temporal granularity is yearly. Yearly series rarely have seasonality, but, if they do, it must also be derived from the data.

The second method is also used for views with temporal granularity of minute or second. If such series have seasonality, the season lengths are likely 60. However, when measuring a regular real world process, the process may have a regular repetition which does not correspond to the clock. So, for minutes and seconds, Tableau also checks for a length different from 60 in the data. This does not mean that Tableau can model two different season lengths at the same time. Rather, ten seasonal models are estimated, five with a season length of 60 and another five with the season length derived from the data. Whichever of the ten seasonal models or three non-seasonal models has the lowest AIC, that model is used to compute the forecast.

For series ordered by year, minute or second, a single season length from the data is tested if the pattern is fairly clear. For integer ordered series, up to nine somewhat less clear potential season lengths are estimated for all five seasonal models, and the model with the lowest AIC is returned. If there are no likely season length candidates, only the non-seasonal models are estimated.

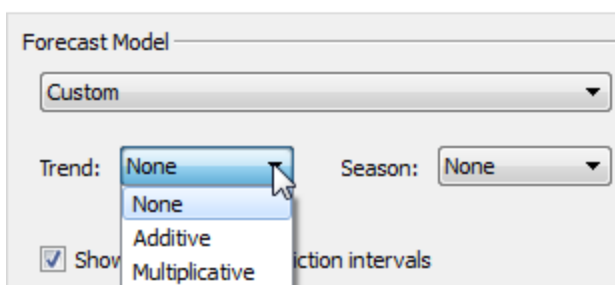

Since all selection is automatic when Tableau is deriving potential season lengths from the data, the default Model Type of 'Automatic' in the Forecast Options Dialog Model Type menu does not change. Selecting 'Automatic without seasonality' improves performance by eliminating all season length searching and estimation of seasonal models.

The heuristic that Tableau uses to decide when to use season lengths derived from the data depends on the distribution of errors for the periodic regression of each candidate season length. Since the assembly of season length candidates by periodic regression usually produces one or two clear winning lengths if seasonality actually exists in the data, the return of a single candidate indicates likely seasonality. In this case, Tableau estimates seasonal models with this candidate for year, minute and second granularity. The return of less than the maximum of ten candidates indicates possible seasonality. In this case, Tableau estimates seasonal models with all returned candidates for integer ordered views. The return of the maximum number of candidates indicates that errors for most length are similar. Therefore, the existence of any seasonality is unlikely. In this case, Tableau estimates only non-seasonal models for an integer-ordered or yearly ordered series, and only the seasonal models with a natural season length for other temporally ordered views.

For Model Type 'Automatic' in integer-, year-, minute- and second-ordered views, candidate season lengths are always derived from the data whether or not they are used. Since model estimation is much more time consuming than periodic regression, the performance impact should be moderate.

Model Types

In the Forecast Options dialog box, you can choose the model type Tableau users for forecasting. The **Automatic** setting is typically optimal for most views. If you choose **Custom**, then you can specify the trend and season characteristics independently, choosing either **None**, **Additive** or **Multiplicative**:

An additive model is one in which the contributions of the model components are summed, whereas a multiplicative model is one in which at least some component contributions are multiplied. Multiplicative models can significantly improve forecast quality for data where the trend or seasonality is affected by the level (magnitude) of the data:

Keep in mind that you do not need to create a custom model to generate a forecast that is multiplicative: the **Automatic** setting can determine if a multiplicative forecast is appropriate for your data. However, a multiplicative model cannot be computed when the measure to be forecast has one or more values that are less than or equal to zero.

Forecasting with Time

When you are forecasting with a date, there can be only one base date in the view. Part dates are supported, but all parts must refer to the same underlying field. Dates can be on **Rows**, **Columns** or **Marks** (with the exception of the Tooltip target).

Tableau supports three types of dates, two of which can be used for forecasting:

- Truncated dates reference a particular point in history with specific temporal granularity, such as February 2017. They are usually continuous, with a green background in the view. Truncated dates are valid for forecasting.
- Date parts refer to a particular member of a temporal measure such as February. Each date part is represented by a different, usually discrete field (with a blue background). Forecasting requires at least a Year date part. Specifically, it can use any of the following sets of date parts for forecasting:
 - *Year*
 - *Year + quarter*
 - *Year + month*
 - *Year + quarter + month*
 - *Year + week*
 - *Custom: Month/Year, Month/Day/Year*

Other date parts, such as *Quarter* or *Quarter + month*, are not valid for forecasting. See [Convert Fields between Discrete and Continuous on page 1077](#) for more details about different date types.

- Exact dates refer to a particular point in history with maximum temporal granularity such as 1 February 2012 at 14:23:45.0. Exact dates are invalid for forecasting.

It is also possible to forecast without a date. See [Forecasting When No Date is in the View on page 2546](#).

Granularity and Trimming

When you create a forecast, you select a date dimension that specifies a unit of time at which date values are to be measured. Tableau dates support a range of such time units, including Year, Quarter, Month and Day. The unit you choose for the date value is known as the *granularity* of the date.

The data in your measure typically does not align precisely with your unit of granularity. You might set your date value to quarters, but your actual data may terminate in the middle of a quarter – for example, at the end of November. This can cause a problem because the value for this fractional quarter is treated by the forecasting model as a full quarter, which will typically have a lower value than a full quarter would. If the forecasting model is allowed to consider this data, the resulting forecast will be inaccurate. The solution is to trim the data, such that the trailing periods that could mislead the forecast are ignored. Use the Ignore Last option in the Forecast Options dialog box to remove – or *trim* – such partial periods. The default is to trim one period.

Getting More Data

Tableau requires at least five data points in the time series to estimate a trend, and enough data points for at least two seasons or one season plus five periods to estimate seasonality. For example, at least nine data points are required to estimate a model with a four quarter seasonal cycle ($4 + 5$), and at least 24 to estimate a model with a twelve month seasonal cycle ($2 * 12$).

If you turn on forecasting for a view that does not have enough data points to support a good forecast, Tableau can sometimes retrieve enough data points to produce a valid forecast by querying the datasource for a finer level of granularity:

- If your view contains fewer than nine years of data, by default, Tableau will query the data source for quarterly data, estimate a quarterly forecast and aggregate to a yearly forecast to display in your view. If there are still not enough data points, Tableau will estimate a monthly forecast and return the aggregated yearly forecast to your view.
- If your view contains fewer than nine quarters of data, by default Tableau will estimate a monthly forecast and return the aggregated quarterly forecast results to your view.
- If your view contains fewer than nine weeks of data, by default, Tableau will estimate a daily forecast and return the aggregated weekly forecast results to your view.
- If your view contains fewer than nine days of data, by default, Tableau will estimate an hourly forecast and return the aggregated daily forecast results to your view.
- If your view contains fewer than nine hours of data, by default, Tableau will estimate a minutely forecast and return the aggregated hourly forecast results to your view.
- If your view contains fewer than nine minutes of data, by default, Tableau will estimate a secondly forecast and return the aggregated minutely forecast results to your view.

These adjustments happen behind the scene and require no configuration. Tableau does not change the appearance of your visualisation, and does not actually change your date value.

However, the summary of the forecast time period in the Describe Forecast and Forecast Options dialog will reflect the actual granularity used.

Tableau can only get more data when the aggregation for the measure you are forecasting is SUM or COUNT. See [Data Aggregation in Tableau on page 171](#) for information on available aggregation types and information on how to change the aggregation type.

Create a Forecast

To create a forecast, your view must be using at least one date dimension and one measure.

To turn forecasting on, right-click (control-click on Mac) on the visualisation and choose **Forecast >Show Forecast**, or choose **Analysis >Forecast >Show Forecast**.

Each of the following examples indicate the structure that supports creating a forecast.

- The field you want to forecast is on the **Rows** shelf and a continuous date field is on the **Columns** shelf.
- The field you want to forecast is on the **Columns** shelf and a continuous date field is on the **Rows** shelf.
- The field you want to forecast on either the **Rows** or **Columns** shelf, and discrete dates are on either the **Rows** or **Columns** shelf. At least one of the included date levels must be Year.
- The field you want to forecast is on the Marks card, and a continuous date or discrete date set is on **Rows**, **Columns** or **Marks**.

Note: You can also create a forecast when no date dimension is present if there is a dimension in the view that has integer values. See [Forecasting When No Date is in the View on page 2546](#).

With forecasting on, Tableau visualises estimated future values of the measure, in addition to actual historical values. The estimated values are shown by default in a lighter shade of the colour used for the historical data:

Prediction Intervals

The shaded area in the image above shows the 95% prediction interval for the forecast. That is, the model has determined that there is a 95% likelihood that the value of sales will be within the shaded area for the forecast period. You can configure the confidence level percentile for the prediction bands, and whether prediction bands are included in the forecast, using the **Show prediction intervals** setting in the Forecast Options dialog box:

Clear the tick box if you do not want to display prediction bands in forecasts. To set the prediction interval, select one of the values or enter a custom value. The lower the percentile you set for the confidence level, the narrower the prediction bands will be.

How your prediction intervals are displayed depends on the mark type of your forecasted marks:

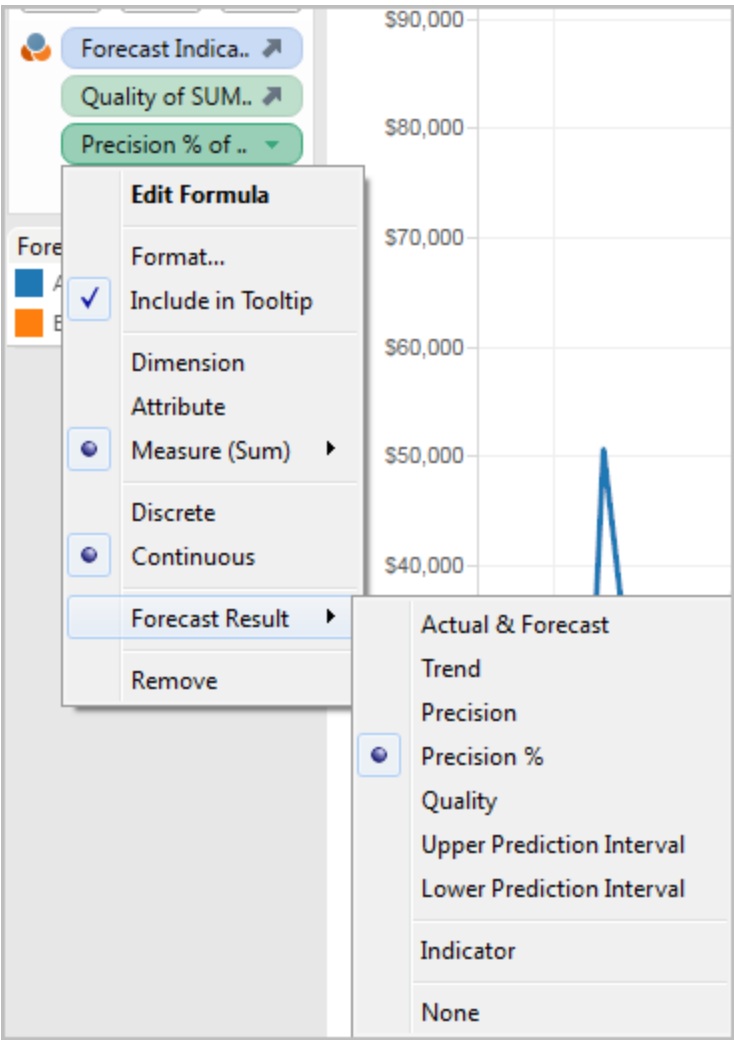

| Forecast mark type | Prediction intervals displayed using |
|-----------------------------------|--------------------------------------|
| Line | Bands |
| Shape, square, circle, bar or pie | Whiskers |

In the following example, forecast data is indicated by lighter shaded circles, and the prediction intervals are indicated by lines ending in whiskers:

Enhancing Forecasts

For each forecast value, consider verifying the quality or precision of your forecast by dragging another instance of the forecast measure from the **Data** pane to the Detail shelf on the Marks card and then after right-clicking the field to open the content menu, choosing one of the available options:

For descriptions of these options, see [Forecast Field Results](#) on the next page.

You can repeat the process to add additional result types for each forecast value. See "Changing the Forecast Result" type in [Forecast Field Results](#) on the next page for information on changing the result type.

By adding such result types to the Details shelf, you add information about the forecast to tooltips for all marks that are based on forecasted data.

| | |
|-----------------------|-------------------|
| Forecast Indicator: | Estimate |
| Month of Ship Date: | April 2015 |
| Precision % of Sales: | ±38.00% |
| Quality of Sales: | 64 |
| Sales: | \$54,753 |

Forecasting When No Date is in the View

If a valid date is not in the view, Tableau will look for a dimension in the view that has integer values. If it finds such a dimension it will use that to forecast additional values for measures in the view. As with a date, when an integer dimension is selected to order the measures to be forecast, it is no longer used to partition the data. If there is more than one such integer dimension, Tableau will go in this order:

- An integer dimension on the Columns shelf. If there is more than one such dimension, it will use the first one (farthest to the left on the shelf).
- An integer dimension on the Rows shelf.
- An integer dimension on the Pages shelf.
- An integer dimension on the Marks card.

When Tableau is using an integer dimension to forecast, the Forecast Option and Forecast Description dialog boxes will automatically specify that forecasting is aggregating by periods:

Forecast Field Results

Tableau provides several types of forecast results. To view these result types in the view, right-click (control-click on Mac) on the measure field, choose **Forecast Result**, and then choose one

of the options.

The options are:

- **Actual & Forecast** – Show the actual data extended by forecasted data.
- **Trend** – Show the forecast value with the seasonal component removed.
- **Precision** – Show the prediction interval distance from the forecast value for the configured confidence level.
- **Precision %** – Show precision as a percentage of the forecast value.
- **Quality** – Show the quality of the forecast, on a scale of 0 (worst) to 100 (best). This metric is scaled MASE, based on the MASE (Mean Absolute Scaled Error) of the forecast, which is the ratio of forecast error to the errors of a naïve forecast which assumes that the value of the current period will be the same as the value of the next period. The actual equation used for quality is:

$$100 * \text{MAX}(1 - \text{MASE}, 0)$$

The quality for a naïve forecast would be 0. The advantage of the MASE metric over the more common MAPE is that MASE is defined for time series which contain zero, whereas MAPE is not. In addition, MASE weights errors equally while MAPE weights positive and/or extreme errors more heavily.

- **Upper Prediction Interval** – Shows 90, 95 or 99 confidence level above the forecast value (that is, if the confidence level is 90, the true future value will be above the upper prediction interval 10% of the time), assuming a high-quality model. The confidence level percentage is controlled by the **Prediction Interval** setting in the Forecast Options dialog box. See [Configure Forecast Options on the next page](#).
- **Lower Prediction Interval** – Shows 90, 95, or 99 confidence level below the forecast value. The actual interval is controlled by the **Prediction Interval** setting in the Forecast Options dialog box.
- **Indicator** – Show the string **Actual** for rows that were already on the worksheet when forecasting was inactive and **Estimate** for rows that were added when forecasting was activated.
- **None** – Do not show forecast data for this measure.

Forecast description information is also included in the worksheet description. See [Get Details About Fields and Sheets in a Workbook on page 2007](#).

Forecasting a New Measure

When you add a new measure to a visualisation that already has forecasting enabled, Tableau attempts to forecast future values.

Changing the Forecast Result Type

To change the forecast result type for a measure, right-click (control-click on Mac) on the measure field, select **Forecast Result**, and then choose a result type.

Configure Forecast Options

Use the Forecast Options dialog box to configure forecast options, including:

- The length of the forecast
- The range and temporal aggregation of source data from which to generate the forecast
- The forecast model
- Prediction intervals

When forecasting is enabled, you can open the Forecast Options dialog box by choosing **Analysis > Forecast > Forecast Options**.

Forecast Length

The **Forecast Length** section determines how far into the future the forecast extends. Select one of the following:

- **Automatic:** Tableau determines the forecast length based on the data.
- **Exactly:** Extends the forecast for the specified number of units.
- **Until:** Extends the forecast to the specified point in the future.

Source Data

Use the **Source Data** section to specify.

- **Aggregate by:** Specifies the temporal granularity of the time series. With the default value (**Automatic**), Tableau chooses the best granularity for estimation. This will typically match the temporal granularity of the visualisation (that is, the date dimension that the forecast is based on). However, it is sometimes possible and desirable to estimate the forecast model at a finer granularity than the visualisation when the time series in the visualisation is too short to allow estimation.

Note: When you are using an integer dimension instead of a date dimension for forecasting, the Aggregate by value is always Periods. See [Forecasting When No Date is in the View on page 2546](#).

- **Ignore last:** Specifies the number of periods at the end of the actual data that should be ignored in estimating the forecast model. Forecast data is used instead of actual data for these time periods. Use this feature to trim off unreliable or partial trailing periods which could mislead the forecast. When the estimation granularity specified in the **Source Data** section is finer than in the visualisation, the trimmed periods are estimation periods. As a result, the trailing actual visualisation period may become a forecast period, which is an aggregate of both actual and forecast periods of estimation granularity. In contrast, null

values are not filled with zeros and must be filtered to allow forecast.

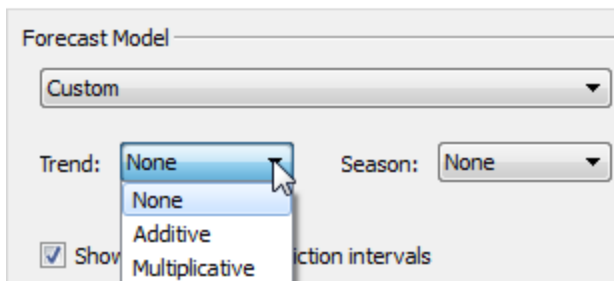

- **Fill in missing values with zeros:** If there are missing values in the measure you are attempting to forecast, you can specify that Tableau fill in these missing values with zero.

Forecast Model

The **Forecast Model** section specifies how the forecast model is to be produced.

Use the drop down to specify whether Tableau selects what it determines to be the best of all models (**Automatic**), the best of those with no seasonal component (**Automatic without seasonality**), or the model you specify (**Custom**).

When you choose the **Custom** option, two new fields appear in the Forecast Options dialog box, which you use to specify the trend and season characteristics for your model:

The choices are the same for both fields:

- **None:** When you select **None** for Trend, the model does not assess the data for trend. When you select **None** for Season, the model does not assess the data for seasonality.
- **Additive:** An additive model is one in which the combined effect of several independent factors is the sum of the isolated effects of each factor. You can assess the data in your view for additive trend, additive seasonality, or both.
- **Multiplicative :** A multiplicative model is one in which the combined effect of several independent factors is the product of the isolated effects of each factor. You can assess the data in your view for multiplicative trend, multiplicative seasonality, or both.

If there is more than one time series in your visualisation, the Custom option forces them all to be forecast using the same custom model. Constraining the models in this way usually results in lower quality models than would be produced by automatic model selection.

Constraints on Multiplicative Models

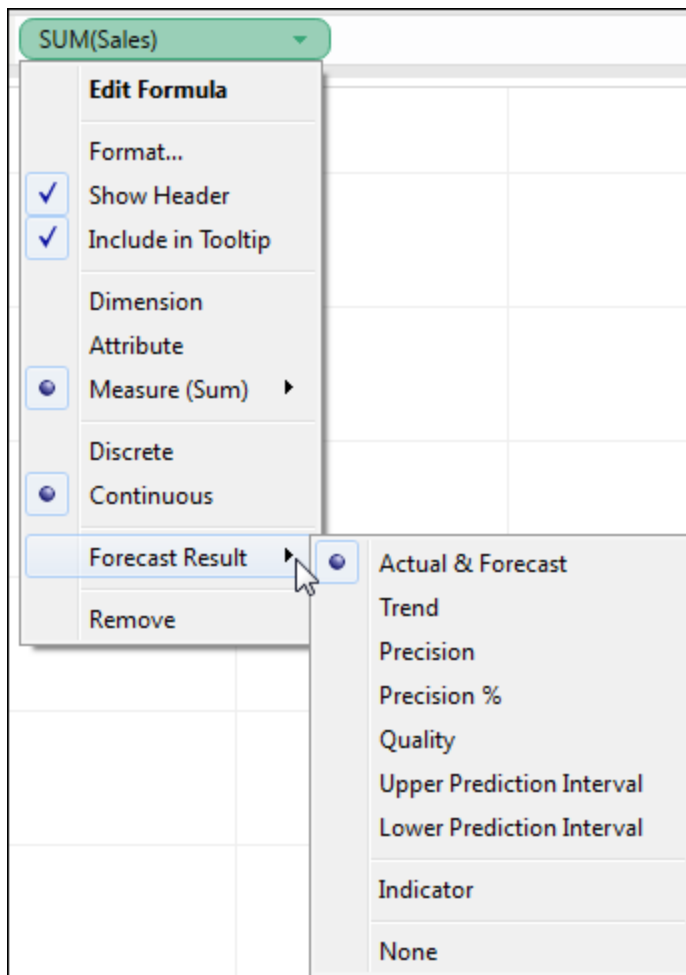

- You cannot use a multiplicative model when the measure to be forecast has one or more values that are less than or equal to zero, or even when some of the data points are too close to zero, relative to other data points.
- You cannot specify a model with multiplicative trend and additive season because the result may be numerically unstable.

Prediction Interval

You can set the prediction interval to 90, 95, or 99 percent, or enter a custom value. This value is used in two locations:

- In the prediction bands displayed with a forecast.
- For the prediction interval options (**Upper Prediction Interval** and **Lower Prediction**

Interval) that are available as forecast result types for a measure in the view:

Forecast Summary

The text box at the bottom of the Forecast Options dialog box provides a description of the current forecast. The forecast summary updates whenever you change any of the forecast options above. If there is a problem with the forecast, the text box provides an error message that may help you resolve the issue. See [Resolving Forecasting Errors on page 2558](#).

Forecast Descriptions

The **Describe Forecast** dialog box describes the forecast models that Tableau computed for your visualisation.

When forecasting is enabled, you can open this dialog by selecting **Analysis > Forecast > Describe Forecast**.

The information in the Describe Forecast dialog box is read-only, though you can click **Copy to Clipboard** and then paste the screen contents into a document.

The **Describe Forecast** dialog box has two tabs: a **Summary** tab and a **Models** tab.

Describe Forecast - Summary Tab

The **Summary** tab describes the forecast models Tableau has created, as well as the general patterns Tableau discovered in the data.

Options Used To Create Forecasts

This section summarises the options Tableau used to create forecasts. These options were either selected automatically by Tableau or specified in the Forecast Options dialog box.

- **Time series** – The continuous date field used to define the time series. In some cases this value might not actually be a date. See [Forecasting When No Date is in the View on page 2546](#).
- **Measures** – The measures for which values are estimated.
- **Forecast forward** – The length and date range of the forecast.
- **Forecast based on** – The date range of the actual data used to create the forecast.
- **Ignore last** – The number of periods at the end of the actual data that are disregarded--forecast data is displayed for these periods. This value is determined by the **Ignore Last** option in the Forecast Options dialog box.
- **Seasonal pattern** – The length of the seasonal cycle that Tableau found in the data, or None if no seasonal cycle was found in any forecast.

Forecast Summary Tables

For each measure that is forecasted, a summary table is displayed describing the forecast. If the view is broken into multiple panes using dimensions, a column is inserted into each table that identifies the dimensions. The fields in summary forecast tables are:

- **Initial** – The value and prediction interval of the first forecast period.
- **Change From Initial** – The difference between the first and the last forecast estimate points. The interval for those two points is shown in the column header. When values are shown as percentages, this field shows the percentage change from the first forecast period.

- **Seasonal Effect** – These fields are displayed for models identified as having seasonality—that is, a repeating pattern of variation over time. They show the high and low value of the seasonal component of the last full seasonal cycle in the combined time series of actual and forecast values. The seasonal component expresses the deviation from the trend and so varies around zero and sums to zero over the course of a season.
- **Contribution** – The extent to which Trend and Seasonality contribute to the forecast. These values are always expressed as percentages and add up to 100%.
- **Quality** – Indicates how well the forecast fits the actual data. Possible values are GOOD, OK, and POOR. A naïve forecast is defined as a forecast that estimates that the value of the next period will be identical to the value of the current period. Quality is expressed relative to a naïve forecast, such that OK means the forecast is likely to have less error than a naïve forecast, GOOD means that the forecast has less than half as much error, and POOR means that the forecast has more error.

Describe Forecast - Models Tab

The **Models** tab provides more exhaustive statistics and smoothing coefficient values for the Holt-Winters exponential smoothing models underlying the forecasts. For each measure that is forecasted, a table is displayed describing the forecast models Tableau created for the measure. If the view is broken into multiple panes using dimensions, a column is inserted into each table that identifies the dimensions. The table is organised into the following sections:

Model

Specifies whether the components **Level**, **Trend**, or **Season** are part of the model used to generate the forecast. The value for each component is one of the following:

- **None** – The component is not present in the model.
- **Additive** – The component is present and is added to the other components to create the overall forecast value.
- **Multiplicative** – The component is present and is multiplied by the other components to create the overall forecast value.

Quality Metrics

This set of values provides statistical information about the quality of the model.

| Value | Definition |
|-------|------------|
|-------|------------|

| | |
|--|---|
| RMSE: Root mean squared error | $\sqrt{\left(\frac{1}{n}\right) \sum e(t)^2}$ |
| MAE: Mean absolute error | $\frac{1}{n} \sum e(t) $ |
| <p>MASE: Mean absolute scaled error.</p> <p>MASE measures the magnitude of the error compared to the magnitude of the error of a naive one-step ahead forecast as a ratio. A naive forecast assumes that whatever the value is today will be same value tomorrow. So, a MASE of 0.5 means that your forecast is likely to have half as much error as a naive forecast, which is better than a MASE of 1.0, which is no better than a naive forecast. Since this is a normalised statistic that is defined for all values and weighs errors evenly, it is an excellent metric for comparing the quality of different forecast methods.</p> <p>The advantage of MASE over the more common MAPE metric is that MASE is defined for time series that contain zero, whereas MAPE is not. Also, MASE weights errors equally, whereas MAPE weights positive and/or extreme errors more heavily.</p> | $\frac{\frac{1}{n} \sum e(t) }{\frac{1}{(n-1)} \sum \frac{n}{2} \left Y(t) - Y(t-1) \right }$ |
| <p>MAPE: Mean absolute percentage error.</p> <p>MAPE measures the magnitude of the error compared to the magnitude of your data, as a percentage. So, a MAPE of 20% is better than a MAPE of 60%. Errors are the differences between the response values, which the model estimates, and the actual response values for each</p> | $100 \frac{1}{n} \sum \left \frac{e(t)}{A(t)} \right $ |

explanatory value in your data. Since this is a normalised statistic, it can be used to compare the quality of different models computed in Tableau. However, it is unreliable for some comparisons because it weights some kinds of error more heavily than others. Also, it is undefined for data with values of zero.

AIC: Akaike information criterion.

AIC is a model quality measure, developed by Hirotugu Akaike, that penalises complex models to prevent overfitting. In this definition, k is the number of estimated parameters, including initial states, and SSE is the sum of the squared errors.

$$n * \log(SSE/n) + 2 * (k + 1)$$

In the preceding definitions, the variables are as follow:

| Variable | Meaning |
|----------|--|
| t | Index of a period in a time series. |
| n | Time series length. |
| m | Number of periods in a season/cycle. |
| A(t) | Actual value of the time series at period t. |
| F(t) | Fitted or forecast value at period t. |

Residuals are: $e(t) = F(t) - A(t)$

Smoothing Coefficients

Depending on the rate of evolution in the level, trend, or seasonal components of the data, smoothing coefficients are optimised to weight more recent data values over older ones, such that within-sample one-step-ahead forecast errors are minimised. Alpha is the level smoothing coefficient, beta the trend smoothing coefficient, and gamma the seasonal smoothing coefficient. The closer a smoothing coefficient is to 1.00, the less smoothing is performed, allowing for rapid component changes and heavy reliance on recent data. The closer a

smoothing coefficient is to 0.00, the more smoothing is performed, allowing for gradual component changes and less reliance on recent data.

Troubleshooting Forecasting

This topic discusses some issues that may arise as you use forecasting in Tableau.

Null Forecasts

A null forecast results when you are using forecasting and modify the view in a manner that is incompatible with forecasting. The most obvious indication that you have a null forecast is that no forecast data is displayed in your view and the text No Forecast is displayed. Hover the cursor over this message to see why Tableau is unable to create a forecast:

Another indication is that the **Forecast Indicator** field on the Marks card shows Actual values, but no Estimate values:

To diagnose a null forecast, open the Describe Forecast dialog box from the Analysis menu (**Analysis > Forecast > Describe Forecast**) to see the error message. Then see [Resolving Forecasting Errors on the next page](#) for a suggested resolution.

Tableau also displays the error message in the Forecast Options dialog box (**Analysis > Forecast > Forecast Options**).

Because a forecast cannot be computed for a time series with null date values in the middle, actions that filter data, either explicitly or implicitly can trigger a null forecast. The **Keep Only** and

Exclude commands on tooltips are examples of actions that can filter data implicitly – in some cases, these commands are removed when a forecast is shown. For example, if you have a time series of sales for each quarter from 2008 until 2012 and you exclude the Sales value for the second quarter of 2010, you will get a Null forecast because the time series is irregular. If, instead, you exclude the first quarter of 2008, you have shortened the time series but it remains regular. So, a valid forecast is still possible.

Resolving Forecasting Errors

If Tableau is unable to provide a forecast for your view, the problem can often be resolved by changing the Date value in the view (see [Change Date Levels on page 1161](#)).

Forecasting errors can result when the aggregation level of the time series (months, weeks, etc.) is either too fine or too coarse for the data to be forecast. This can lead to the "too much data" or "too little data" errors described below. Date aggregation can trigger a "too many Nulls" scenario when forecasting attempts to extract more data from the measure than is possible. For example, if the underlying granularity of the sales data is months but you aggregate by weeks, the result may be a significant number of Null values.

Other problems arise when the view's aggregation and the aggregation specified for the forecast (using the **Aggregate by** field in the Forecast Options dialog box) are not compatible. Tableau can create a forecast when the forecast aggregation is a finer level of detail than the view's aggregation, but not when it is at a coarser level of detail; even when it is finer, the two values are only compatible if there is a strict hierarchy that Tableau can use (for example, quarters can be evenly divided into three months, but months can't be evenly divided into weeks). Avoid these scenarios by setting **Aggregate by** to Automatic.

The following list shows errors that can be result from invalid forecasts in Tableau, and provides advice on how to resolve them.

| Error message | Suggestion for Resolution |
|---|--|
| A continuous date cannot be derived from the date fields in the view. | <p>Forecasting requires a date field that can be interpreted continuously. If the date field is not explicitly continuous, then one of the included date levels must be Year.</p> <p>This error is returned if there are no dates in the view, or if the dates in the view don't constitute a full hierarchy (for example, the date includes Year and Day, but not Month), or if they constitute a hierarchy that is not supported (for example, Year, Week, Day).</p> |

| | |
|---|--|
| The time series is too short to forecast. | <p>Expand the time series in your view to include more date values.</p> <p>This error is returned if there are fewer than four data points after trimming off unreliable or partial trailing periods which could mislead the forecast.</p> |
| A forecast cannot be computed for a time series with Null date values. | Eliminate any Null values from the date field or fields in the view, either by filtering the date field or by using a less detailed date granularity (for example, by switching from months to quarters). |
| A forecast cannot be computed when the view contains multiple distinct date fields. | This error is returned if there are multiple date fields in the view. For example, if both Order Date and Ship Date are in the same view, forecasting is not supported. |
| The selected 'Aggregate by' value in Forecast Options is not compatible with the visualisation. | <p>The date in the view must be compatible with the value of Aggregate by in the Forecast Options dialog box. For example, if Aggregate by is set to Weeks and the date in the view is set to Months, this error occurs.</p> <p>Change one of the dates so that the two are compatible, or set Aggregate by to Automatic.</p> |
| A forecast cannot be computed because there are too many missing values. | <p>This error is returned if more than 40% of the data in a pane is missing.</p> <p>Selecting Fill in missing values with zeros in the Forecast Options dialog box will not resolve this error. Aggregate your data to a higher level of detail by removing dimensions or changing the date level, for example from 'weeks' to 'months'.</p> <p>Otherwise, you must modify the source data or use data from a different source.</p> |
| There is no measure to forecast. | This error is returned if no measure that can be forecast is present in the view. Forecast measures must be on the Rows or Columns shelf, or on the Marks card. |
| The measure to forecast | Some measures cannot be interpreted numerically and there- |

| | |
|--|--|
| must be a number. | fore cannot be forecast. |
| A forecast cannot be computed for a dimension. | The value to be forecast must be a measure, and not a dimension. |
| There is too much data to compute a forecast. | Forecasting is not possible when the result set from the query is too large. The limit is about 10,000 rows. To fix the forecast, aggregate the time series value at a higher level (for example, Month instead of Week) or filter the data. |
| A forecast cannot be computed because the data is divided into too many rows, columns, or colours. | Simplify the view to resolve the error by filtering or removing some of the dimensions. |
| A forecast cannot be computed because the view contains table calculations. | Create a version of the view that does not contain table calculations. |
| A forecast cannot be computed because there is a measure on the Filters shelf. | Remove the measure from the Filters shelf. |
| A forecast cannot be computed because Aggregate Measures is not selected. | Aggregate Measures is an option on the Analysis menu. See Data Aggregation in Tableau on page 171 and How to Disaggregate Data on page 180. |
| A forecast cannot be computed because the view contains percent calculations. | Percentage of is an option on the Analysis menu. See Calculate Percentages in Tableau on page 2677. |
| A forecast cannot be computed because Grand Totals or Subtotals is enabled. | These options are controlled from the Totals command in the Analysis menu. See Show Totals in a Visualisation on page 1361. |
| A multiplicative model cannot be computed because the measure to be forecast | You have created a custom model with Trend or Seasonality set to Multiplicative . Change this value, or set the Forecast Model to Automatic . |

| | |
|--|---|
| has one or more values that are less than or equal to zero. | |
| A model with multiplicative trend and additive season is not allowed because it is numerically unstable. | You have created a custom model configured as described in the error message. Change the settings for the custom model, or set the Forecast Model to Automatic . |
| A seasonal model cannot be computed because the time series is too short. | Expand the time series in your view to include more date values. |
| The selected multiplicative model cannot be computed because some of the data is too close to zero relative to the rest of the data. | You have created a custom model configured as described in the error message. Change the settings for the custom model, or set the Forecast Model to Automatic . |

Predictive Modelling

Predictive modelling functions in Tableau use linear regression to build predictive models and generate predictions about your data. Two [table calculations](#), MODEL_PERCENTILE and MODEL_QUANTILE, can generate predictions and surface relationships within your data. These can be used to identify outliers, estimate values for sparse or missing data, and predict values for future time periods.

This section provides all the documentation you need to get started with predictive modelling functions in Tableau.

How Predictive Modelling Functions Work in Tableau

You can already add [trend lines](#) and [forecasts](#) to a visualisation, but now you can go beyond this, using the power of a statistical engine to build a model that understands how your data is distributed around such a trend line, or line of best fit. Previously, users had to integrate Tableau with R and Python in order to perform advanced statistical calculations and visualise them in Tableau. Now, you can use the predictive modelling functions to make predictions from your data by including them in a table calculation. For more information about table calculations, see [Transform Values with Table Calculations](#).

With these predictive modelling functions, you can select targets and predictors by updating the variables and visualising multiple models with different combinations of predictors. The data can be filtered, aggregated and transformed at any level of detail, and the model – and thus the prediction – will automatically recalculate to match your data.

For a detailed example that shows how to create prediction calculations using these functions, see [Example – Explore Female Life Expectancy with Predictive Modelling Functions on page 2591](#).

Predictive modelling functions available in Tableau

MODEL_PERCENTILE

| | |
|------------|---|
| Syntax | <code>MODEL_PERCENTILE (model_specification (optional), target_expression, predictor_expression(s))</code> |
| Definition | Returns the probability (between 0 and 1) of the expected value being less than or equal to the observed mark, defined by the target expression and other predictors. This is the Posterior Predictive Distribution Function, also known as the Cumulative Distribution Function (CDF). |
| Example | <code>MODEL_PERCENTILE (SUM([Sales]),COUNT([Orders]))</code> |

MODEL_QUANTILE

| | |
|------------|---|
| Syntax | <code>MODEL_QUANTILE (model_specification (optional), quantile, target_expression, predictor_expression(s))</code> |
| Definition | Returns a target numeric value within the probable range defined by the target expression and other predictors, at a specified quantile. This is the Posterior Predictive Quantile. |
| Example | <code>MODEL_QUANTILE(0.5, SUM([Sales]), COUNT([Orders]))</code> |

The power of predictive modelling functions

Let's look at an example using salary data, starting with MODEL_QUANTILE.

In the example below, MODEL_QUANTILE has been used to display the 10th percentile and the 90th percentile of the expected distribution for the same data set. Based on the existing data and using a linear regression model, the statistical engine has determined that there is a 90% probability that the maximum salary for each tenure will be below the green line, and a 10% probability that the minimum salary for each tenure will be below the blue line.

In other words, with the quantile set at 0.9, the model predicts all salaries will fall at or below the green line 90% of the time. The blue line is set at .1 or 10%, so only 10% of salaries will fall at or below the blue line, with the inverse of that (90%) above the blue line.

Effectively, this gives us a band that we can predict 80% of potentially generated future points or unobserved data will fall inside.

Next, let's see how `MODEL_PERCENTILE`, the inverse of `MODEL_QUANTILE`, can help us understand the data further.

You can identify the outliers of the data set by using the `MODEL_PERCENTILE` function. `MODEL_PERCENTILE` tells you, as a percentile, where the observed mark falls within a range of probable values for each mark. If the percentile is very close to 0.5, the value observed is very close to the median value predicted. If the percentile is close to 0 or 1, the value observed is at the lower or upper boundaries of the model range and is relatively unexpected.

Below, we have applied `MODEL_PERCENTILE` as colour to the salary visualisation in the top half of the image, to help us understand which values are most expected.

Syntax of predictive modelling functions in detail

What is MODEL_QUANTILE?

MODEL_QUANTILE calculates the posterior predictive quantile, or the expected value at a specified quantile.

- **Quantile:** The first argument is a number between 0 and 1, indicating what quantile should be predicted. For example, 0.5 specifies that the median will be predicted.
- **Target expression:** The second argument is the measure to predict or 'target'.
- **Predictor expression(s):** The third argument is the predictor used to make the prediction. Predictors can be dimensions, measures or both.

The result is a number within the probable range.

You can use MODEL_QUANTILE to generate a confidence interval, missing values such as future dates, or to generate categories that don't exist in your underlying data set.

What is MODEL_PERCENTILE?

MODEL_PERCENTILE calculates the posterior predictive distribution function, also known as the Cumulative Distribution Function (CDF). This calculates the quantile of a particular value between 0 and 1, the inverse of MODEL_QUANTILE.

- **Target expression:** The first argument is the measure to target, identifying which values to assess.
- **Predictor expression(s):** The second argument is the predictor used to make the prediction.
- Additional arguments are optional and are included to control the prediction.

Notice that the calculation syntax is similar, with MODEL_QUANTILE having the extra argument of a defined quantile.

The result is the probability of the expected value being less than or equal to the observed value expressed in the mark.

You can use MODEL_PERCENTILE to surface correlations and relationships within your database. If MODEL_PERCENTILE returns a value close to 0.5, the observed mark is near the median of the range of predicted values, given the other predictors that you've selected. If MODEL_PERCENTILE returns a value close to 0 or to 1, the observed mark is near the lower or upper range of what the model expects, given the other predictors that you've selected.

Note: Dimensions used as predictors can be *ordered* or *unordered*. An ordered dimension is any dimension whose values can be sequenced, such as MONTH. An unordered dimension is any

dimension whose values don't have an inherent sequence, such as gender or colour. This distinction matters when using Gaussian process regression. For more information on this model and others, see [Choosing a Predictive Model on page 2569](#).

For advanced users, there are two other optional arguments you can include to control the prediction. For more information, see [Regularisation and Augmentation in Predictive Modelling on page 2613](#).

What's being computed?

The input used to build the model is a matrix where each mark is a row, and the columns are the target expression and predictor expressions evaluated for each mark. Whatever row is specified on the viz is what defines the row for the data set being computed by the statistical engine.

Let's look at the example below, where rows (and thus marks) are defined by job titles, and columns are the target expression MEDIAN([Annual Rt]). These are followed by the optional additional predictors MEDIAN([Tenure in Months (Measure)]) and ATTR([Department Generic (group)]).

| Jobtitle | Actual Median Annual Rt | Median Tenure in Months (Measure) | Department |
|------------------------------|-------------------------|-----------------------------------|-----------------|
| 911 Lead Operator | 60,425 | 287 | Fire Department |
| 911 Operator | 53,134 | 141 | Fire Department |
| 911 Operator Supervisor | 66,537 | 423 | Fire Department |
| Account Executive | 60,700 | 35 | M-R |
| Account Executive Supervisor | 73,900 | 70 | M-R |
| Accountant I | 52,268 | 75 | * |
| Accountant II | 61,451 | 102 | * |
| Accountant Supervisor | 71,300 | 225 | * |
| Accounting Assistant I | 32,003 | 113 | * |
| Accounting Assistant II | 34,011 | 61 | * |
| Accounting Assistant III | 46,758 | 206 | * |
| Accounting Asst II | 32,271 | 58 | M-R |
| Accounting Asst III | 41,810 | 60 | M-R |
| Accounting Manager | 88,100 | 123 | * |
| Accounting Systems Admin | 68,136 | 137 | Finance |

Note: Several job titles have an asterisk listed under Department. This is because those job titles exist in several departments, but Tableau treats all of them as though they are in the same department. In addition, the statistical engine doesn't consider the number of records, and treats each mark as equally likely. This is because Tableau can't perform table calculations on unaggregated data, and can't aggregate the results of table calculations. For more information on aggregation, see [Data Aggregation in Tableau](#).

For more information on the data used to build a model and generate predictions, see [Compute Using and Data Partitioning in Predictive Modelling on page 2582](#).

What models are supported?

Predictive modelling functions support linear regression, regularised linear regression and Gaussian process regression. These models support different use cases and prediction types, as well as having different limitations. For more information, see [Choosing a Predictive Model on page 2569](#).

Choosing your predictors

A predictor can be any field in your data source – measure or dimension – including calculated fields.

Note: If using a dimension as a predictor, you must use a ATTR wrapper (e.g. ATTR([State]) rather than just [State]). This is because dimensions will generally only work if they are in the level of detail in the visualisation either directly, or above it in a hierarchy.

For example, suppose you have a data set that includes the fields [City], [State] and [Region], where multiple [City] records exist within a [State], and multiple [State] records within a [Region].

In a visualisation that uses [State] as a mark, the predictor ATTR([State]) or ATTR([Region]) will both work as predictors. However, the predictor ATTR([City]) will revert to *, as multiple cities exist within a visualised state and so cannot be used as predictors. In other words, including a predictor that's at a lower level of detail than the viz adds no value to the predictions. In most cases, a predictor at a lower level of detail than the viz will evaluate to * and so will all be treated identically.

However, if the same data set is used to generate a viz that uses [City] as a mark, ATTR([City]), ATTR([State]) and ATTR([Region]) can all be used successfully as predictors. For more information about the use of ATTR functions, see [When to Use the Attribute \(ATTR\) Function](#).

Dimensions and measures do not need to be visualised (in the view or viz) in order to be included as predictors. For more detailed guidance, see [Choosing Predictors on page 2571](#).

Recommendations

Prediction calculations are best used as follows:

- To predict values for individual records, where each mark in your viz represents a discrete entity such as a product, sale, person, etc., rather than aggregated data. This is because Tableau regards each mark as equally likely, even if one mark is made up of 100 records and the other marks are made up of one record each. The statistical engine does not weigh marks based on the number of records that make it up.
- To predict values for aggregated target expressions using SUM and COUNT.

Note: MODEL_QUANTILE and MODEL_PERCENTILE aren't recommended to predict values for aggregated target_expressions using AVG, MEDIAN, MIN and MAX.

Limitations

- You must use a calculated field to extend a time series into the future. For more information, see [Predicting the Future](#).
- Predictors should be at the same or higher level of detail than the view. That is, if your view aggregates by state, you should use state or region as a predictor, but not city. For more information, see [Choosing Predictors on page 2571](#).

When will prediction calculations break?

Regardless of the model you're using, you must have at least three data points within each partition for the model to return a response.

If you have specified Gaussian process regression as your model, it can be used in predictive calculations with one **ordered** dimensional predictor and any number of **unordered** dimensional predictors. Measures aren't supported as predictors in Gaussian process regression calculations, but can be used in linear and regularised linear regression calculations. For more information on model selection, see [Choosing a Predictive Model on the facing page](#).

If your calculation used ATTR[State] as a predictor and your viz also included State as a mark but no other field at a lower level of detail, such as City, then you would return an error. To prevent this, simply ensure there is not a one-to-one relationship between marks and predictor categories.

For more information on these and other prediction problems, see [Resolve Errors in Predictive Modelling Functions](#).

FAQ

What about marks in multiple predictor-groups?

If a row is aggregated from data that exists within multiple predictor-groups, the value of the ATTR function is a special value of multiple values. For instance, all cities that exist in multiple states will have the same predicted value (unless there are other predictors that are distinct). When selecting your predictors, it's best to use predictors that are at the same level of detail as the viz or higher. Again, for more information on ATTR functions, see [When to Use the Attribute \(ATTR\) Function](#).

What if ATTR Aggregation returns a * value?

* is treated as a distinct value. If ATTR returns * for all marks, then you, in essence, have a predictor with a constant value, which will be ignored. This is the same as not including that predictor at all.

If ATTR returns * for some but not all marks, then it will be treated as a category where all the * values are considered to be the same. This scenario is identical to the above scenario, in which marks exist in multiple predictor-groups.

What about the 'Compute Using' table calculation menu options?

This functions identically to Compute Using in other table calculations. For more information, see [Compute Using and Data Partitioning in Predictive Modelling on page 2582](#).

Why am I getting an error?

There are several reasons why you might be encountering an error when using predictive modelling functions. For detailed troubleshooting steps, see [Resolve Errors in Predictive Modelling Functions](#).

Choosing a Predictive Model

Predictive modelling functions support linear regression, regularised linear regression and Gaussian process regression. These models support different use cases and prediction types, as well as having different limitations.

Supported models

Linear regression

Linear regression (also known as ordinary least squares regression, or OLS) is best used when there are one or more predictors that have a linear relationship between the prediction and the prediction target, they aren't affected by the same underlying conditions, and they don't represent two instances of the same data (for example, sales expressed in both dollars and euros). Linear regression is the default model for predictive modelling functions in Tableau; if you don't specify a model, linear regression will be used. You can explicitly specify this model by including **"model=linear"** as the first argument in your table calculation.

Example:

```
MODEL_QUANTILE (
  "model=linear",
  0.5,
  SUM([Sales]),
  ATTR(DATETRUNC('month', ([Order Date])))
)
```

Regularised linear regression

Regularised linear regression is best used when there's an approximate linear relationship between two or more independent variables – also known as **multicollinearity**. This is frequently observed in real-world data sets. To use this model instead of the default linear regression, include **"model=rl"** as the first argument in your table calculation.

Example:

```
MODEL_QUANTILE (
  "model=rl",
  0.5,
  SUM([Sales]),
  ATTR(DATETRUNC('month', ([Order Date])))
)
```

Gaussian process regression

Gaussian process regression is best used when generating predictions across a continuous domain, such as time or space, or when there is a nonlinear relationship between the variable and the prediction target. Gaussian process regression in Tableau must have a single **ordered** dimension as a predictor but may include multiple **unordered** dimensions as predictors. Note that measures can't be used as predictors in Gaussian process regression in Tableau. To use this model instead of the default linear regression, include **"model=gp"** as the first argument in your table calculation.

Note: An *ordered* dimension is any dimension whose values can be sequenced, such as MONTH. An *unordered* dimension is any dimension whose values don't have an inherent sequence, such as gender or colour.

Example:

```
MODEL_PERCENTILE (
  "model=gp",
  AVG([Days to Ship Actual]),
  ATTR(DATETRUNC('month', ([Order Date])))
)
```

As a simple heuristic, you can use the below criteria for selecting your model:

- **Linear regression (default):** Use when you have only one predictor which has a linear relationship with your target metric.
- **Regularised linear regression:** Use when you have multiple predictors, especially when those predictors have a linear relationship to the target metric and those predictors are likely affected by similar underlying relationships or trends.
- **Gaussian process regression:** Use when you have time or space predictors, or when you're using predictors that might not have a linear relationship with the target metric.

Choosing Predictors

When creating prediction calculations using the [predictive modelling functions](#) in Tableau, you'll need to choose predictors. As a reminder, a predictor is an input variable whose value is used to predict an outcome variable, also known as the target or response. Often, you'll be working with data you have extensive domain knowledge of and will already have a good sense of which fields are strongly correlated with your prediction target, and would make good predictors. However, it's still a good idea to take the time to evaluate your predictors and ensure that you're choosing them wisely. You will *always* want to include at least one predictor, and usually more than one.

First, select your target. This sounds obvious, but making sure that you're selecting your predictors *based on what you want to predict* is a critical first step. For example, the fields that are most correlated with female life expectancy might be very different from the fields most correlated with male life expectancy. Similarly, the fields most correlated with sales could be very different from the fields most correlated with profit.

Another thing to keep in mind is that by default, the predictive modelling functions use [linear regression](#) as the underlying statistical model. With this model, the most correlated predictors are those that have a linear relationship with the target. For information on using another supported model, see [Choosing a Predictive Model](#) on page 2569.

To better understand how to choose the best predictors for the questions you're aiming to answer, let's look at female life expectancy data. To follow along, download the following workbook from Tableau Public: [Choosing Predictors for Your Predictions](#).

Measures as predictors

When using a measure as a predictor, you can evaluate its correlation with your target using Tableau. One way is to build a [scatter plot](#). Below, we compare a country's median female life expectancy with a variety of other measures.

For some measures, like **Infant Mortality** and **Birth Rate**, there's a clear negative correlation with **Female Life Expectancy**, as seen in the negative slope of the scatter plot. For others, it's less clear. However, one thing that we can clearly see is an L-shaped distribution for **Median GDP**, **Median Mobile Phone Usage** and **Median Health Exp/Capita**. This L-shaped distribution often indicates that using a [log transformation](#) can help you analyse your data more accurately. Another clue is if all a column's values are positive. In Tableau, you can use a log transformation by editing the pill and wrapping the expression in a [LOG function](#):

This takes us from the L-shaped distribution – where it's hard to differentiate between the extremes of the scale – to a more even distribution less compressed by the extremes of the scale.

Repeating this with the other L-shaped distributions gives us the following:

Coefficient of determination, or R-squared value

The closer the marks are to lying on a straight line, the higher the correlation between the two measures. To help evaluate the correlation, you can add **trend lines**. From the **Analytics** pane, drag **Trend Line** into the view and drop it on **Linear**. Hovering your cursor over the trend line will tell you the **R-squared** value, or coefficient of determination, which indicates how much of the dependent variable (the target) is explained by the independent variable (the predictor). Predictors with R-squared values closer to 1 are better than predictors with R-squared values closer to 0.

Looking at our scatter plots, we can see that the best predictor for median female life expectancy is median infant mortality, which has an R-squared value of 0.87:

Other good predictors are **Median Birth Rate** (R-squared=0.76) and the log transformation of **Median Health Expenditure/Capita** (R-squared=0.56).

Note: The slope of the line does *not* clearly show you which predictors have the highest R-squared value. Since the scale of the x-axis is determined by the range of the specific variable selected, the slope of the line is greatly affected by the specific variables used.

In the below image, we've visualised **Median Female Life Expectancy** against **Median Female Life Expectancy**, with the resulting viz being a perfectly straight line on a 45° angle: as expected, there is a perfect correlation between the value on the x-axis and the value on the y-axis, with an R-squared value of 1:

However, as shown below, even though LOG(MEDIAN([GDP])) has a steeper sloped trend line than the others, it has a low R-squared score of only 0.169. This is due to the scale of the x-axis for that pane:

Furthermore, let's take a look at how a few marks can significantly affect the slope of a trend line. Zooming in on the scatter plot for **Median Business Tax Rate** we can see that the majority of the marks have a tax rate between 0 and about 1, with six countries having much higher rates, between 2 and 3. The R-squared value for all marks is 0.0879:

However, let's see what happens if we remove that cluster of six marks:

The trend line goes nearly flat, and the R-squared value drops to 0.0006 – indicating that there's essentially no correlation between **Median Business Tax Rate** and **Median Female Life Expectancy**. As you visualise your data and use good statistical methods to select your predictors, it's important to carefully consider whether there are any outliers or other data characteristics that could affect your conclusions.

Note: For more examples of how summary statistics might not give you the full picture, read up on [Anscombe's quartet](#).

Dimensions as predictors

When using dimensions as predictors, you can use a similar procedure to determine correlation. However, you may find that there's a significant discrepancy between different dimensions in their level of relationship to the target. For example, when subdividing by **Region**, one region may be a very good predictor for the target, but another region may have significantly less correlation. This doesn't mean that you shouldn't use that dimension as a predictor, but you may want to consider whether using additional measures or dimensions will help improve your model, and in turn, your predictions.

Since we've determined the best predictors for our data set are **Median Infant Mortality**, **Median Birth Rate**, and the log transformation of **Median Health Expenditure/Capita**, let's limit the viz to these three variables:

Next, let's partition the data by adding **Region** to Colour on the Marks card and see what happens to the viz:

Comparing R-squared values across predictors

Let's see how the R-squared values compare for each of the **Region** trend lines for each predictor:

| Region | Median Infant Mortality Rate | Median Birth Rate | LOG(Median(Health Exp/Capita)) |
|--------------|------------------------------|-------------------|--------------------------------|
| Africa | 0.659 | 0.407 | 0.131 |
| Asia | 0.813 | 0.701 | 0.618 |
| Europe | 0.547 | 0.036 | 0.755 |
| Middle East | 0.859 | 0.491 | 0.459 |
| Oceania | 0.756 | 0.747 | 0.656 |
| The Americas | 0.797 | 0.396 | 0.528 |

In the table above, the lowest R-squared value for each predictor is highlighted in red, and the second-lowest is in yellow.

Europe has the lowest R-squared values for Median Infant Mortality and Median Birth Rate and Africa has the lowest R-squared value for the log transformation of Median Health Expenditure/Capita (highlighted in red). Africa also has lower R-squared values for both Median Infant Mortality Rate and Median Birth Rate.

Adding a dimension can provide your model with more information, and adding more information can improve the quality of your prediction. However, within a given subdivision (a Region, in this case), the prediction quality could either improve or decline. In some cases, you may want to build an individual model for each subdivision based on the measures that are the best predictors for that specific group.

In this case, Infant Mortality has a reasonably strong correlation with Female Life Expectancy for all regions, although it's somewhat weaker in Africa and Europe; Median Birth Rate is a good predictor for Oceania and Asia, but has almost no correlation with Female Life Expectancy in Europe, and the log transformation of Median Health Expenditure is a reasonable predictor for all regions except Africa. We can expect that the model built with all four predictors (Infant Mortality, Birth Rate, Log(Health Expenditure) and Region) will have the least accurate predictions for countries in Europe and Africa; we may want to do some deeper dives into the data to see if there are additional or alternative predictors we could use to build models that are better fits for Europe and Africa.

Building your predictive modelling function

Now that we've found good predictors, we can build and apply a predictive modelling function to see it in action.

1. Open the **Analysis** menu at the top, and then select **Create Calculated Field**.
2. In the Calculation Editor, name the calculation, do the following:
 - Name the calculation: **Quantile_LifeExpFemale_HealthExpend,BirthRate,Mortality,Region**
 - Enter the following formula:

```
MODEL_QUANTILE(0.5,MEDIAN([Life Expectancy Female]),
LOG(MEDIAN([Health Exp/Capita])),
MEDIAN([Birth Rate]),
```

```
MEDIAN([Infant Mortality Rate]),
ATTR([Region]))
```

This calculation will return the median value (0.5) of the range of modelled median female life expectancies, based on the predictors we selected: **Health Expenditure, Birth Rate, Infant Mortality** and **Region**.

Next, let's build a scatter plot that shows both the *actual* median female life expectancy and the *predicted* median female life expectancy:

Great! The predictions are pretty much in line with the actual values for each region.

But let's do another pass to figure out where the predictions are furthest off the mark. Create another calculation called **Residual_LifeExpFemale_HealthExpend,BirthRate,Mortality,Region**, as follows:

```
MEDIAN([Life Expectancy Female]) - [Quantile_LifeExpFemale_
HealthExpend,BirthRate,Mortality,Region]
```

This residual calculation will return the difference between the *predicted* median and the *actual* median, helping us see the countries where there's the biggest discrepancy between the actual and predicted median female life expectancy.

Next, let's apply this residual calculation to **Colour**:

You can see in the above viz that most countries, across most regions, have low discrepancies between predictions and actual values. Africa is the region with the largest number of countries with significant discrepancies, but let's do one more round to see what kind of differences we're looking at.

You can see that the differences range between -17 and +9, so let's divide the viz into groups where there's less than ± 3 years difference, less than ± 5 years difference, less than ± 10 years difference and more than ± 10 years difference.

Create one more calculation, called **Grouped_Residual_LifeExpFemale_HealthExpend,BirthRate,Mortality,Region**, as follows:

```
IF [Residual_LifeExpFemale_HealthExpend,BirthRate,Mortality,Region] <= 3
AND [Residual_LifeExpFemale_HealthExpend,BirthRate,Mortality,Region] >= -3
THEN "±3"
ELSEIF [Residual_LifeExpFemale_HealthExpend,BirthRate,Mortality,Region] <= 5
AND [Residual_LifeExpFemale_HealthExpend,BirthRate,Mortality,Region] >= -5
THEN "±5"
ELSEIF [Residual_LifeExpFemale_HealthExpend,BirthRate,Mortality,Region] <= 10
AND [Residual_LifeExpFemale_HealthExpend,BirthRate,Mortality,Region] >= -10
THEN "±10"
ELSE
"> ±10"
END
```

Again, let's add the calculation to **Colour**:

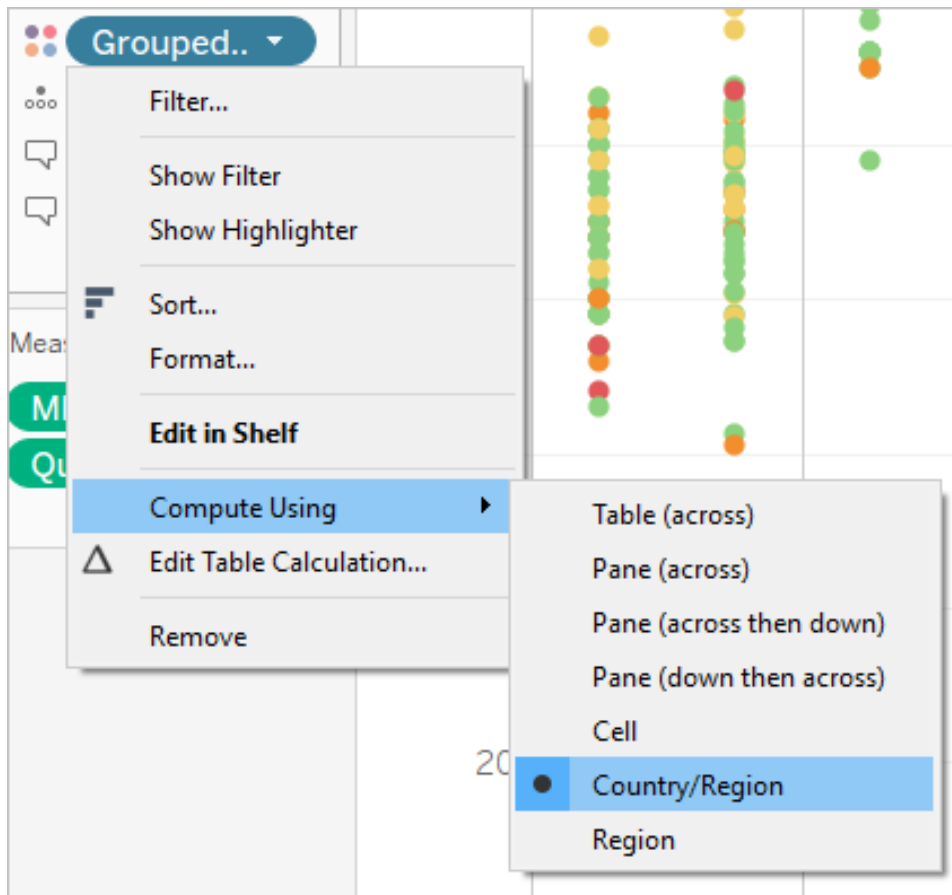

Notice that the vast majority of predictions are incorrect by less than 3 years, and that only a small handful are off by more than 10 years. Overall, pretty good!

This means that using this model would allow us to accurately identify those countries with median female life expectancies that are outliers, or to provide the modelled female life expectancy for a country where this data was missing.

Compute Using and Data Partitioning in Predictive Modelling

You make predictions from your data by including the **predictive modelling functions**, `MODEL_QUANTILE` or `MODEL_PERCENTILE`, in a table calculation.

Remember that all table calculations must have a **Compute Using** direction specified. For an overview of how different addressing and partitioning dimensions can affect your results, see [Transform Values with Table Calculations](#) on page 2355.

Note: When you add a table calculation, you must use all dimensions in the level of detail either for partitioning (scoping) or for addressing (direction). The dimensions that define how to group the calculation (the scope of data it is performed on) are called partitioning fields. The table calculation is performed separately within each partition. The remaining dimensions, upon which the table calculation is performed, are called addressing fields, and determine the direction of the calculation. For more details, see [The basics: addressing and partitioning](#).

In predictive modelling functions, the **Compute Using** option is used to partition (scope) the data set that will be used to build the predictive model.

Predictive modelling functions *do not* have a concept of addressing (direction), since the model returns a distinct result for each mark based on the predictors selected. That is, unlike **Running Total**, where the addressing dimension determines the order in which fields are added and results are returned, predictive modelling functions are inherently non-sequential. They calculate results using a model from the data defined by the function's target and predictors, at the level of detail specified by the visualisation. Within that data, there's no concept of sequencing unless an ordered predictor, such as a date dimension, is used.

Additionally, the level of detail of the visualisation is always used when defining the data used to build the model. All table calculations operate at the same level of detail as the viz itself, and predictive modelling functions are no exception.

Recommendations for predictive modelling functions

It's recommended you select a specific dimension to partition on when using predictive modelling functions. Since you may have multiple prediction calculations in a single viz or dashboard, selecting a specific partitioning dimension ensures that you're building models using the same underlying data set for each individual function, and so comparing results from like models.

When working with predictive modelling functions in Tableau, it's critical to ensure that you maintain consistency across the different instantiations, both in different iterations of your model (e.g. as you select different predictors), and in different vizzes. Using the directional Compute Using options opens up the possibility that a small change in your visualised data will significantly affect the data being used to build the model, thus affecting its validity and its consistency across different vizzes.

Choosing dimensions

The following examples use the **Sample - Superstore** data source, which is included with Tableau Desktop.

When choosing a dimension, remember that Tableau will build a predictive model *across* that dimension. That is, if you select **Order Date** as your partitioning dimension, Tableau will use data *within* any other established partition, but *along* values of **Order Date**.

The image below shows the data that is used to build the model highlighted in yellow, and the model output highlighted in orange. In this case, since there aren't any predictors, all responses are identical within a given **Sub-Category**; selecting optimal predictors will help you generate more meaningful results. For more information on optimal predictors, see [Choosing Predictors on page 2571](#).

| Order Date | | Order Date / Month of Order Date | | | | | | | | | | | |
|-----------------|--------------|----------------------------------|---------------|------------|------------|----------|-----------|--|---------------|------------|------------|----------|-----------|
| Category | Sub-Category | Sales | | | | | | MODEL_QUANTILE nopred along Order Date | | | | | |
| | | Q1 | | | Q2 | | | Q1 | | | Q2 | | |
| | | January 2016 | February 2016 | March 2016 | April 2016 | May 2016 | June 2016 | January 2016 | February 2016 | March 2016 | April 2016 | May 2016 | June 2016 |
| Furniture | Bookcases | \$1,010 | | \$1,706 | \$308 | \$641 | \$760 | \$885 | \$885 | \$885 | \$885 | \$885 | \$885 |
| | Chairs | \$4,188 | \$190 | \$5,713 | \$3,211 | \$3,675 | \$6,456 | \$3,906 | \$3,906 | \$3,906 | \$3,906 | \$3,906 | \$3,906 |
| | Furnishings | \$712 | \$393 | \$480 | \$984 | \$780 | \$433 | \$630 | \$630 | \$630 | \$630 | \$630 | \$630 |
| | Tables | \$333 | \$1,256 | \$6,674 | \$3,442 | \$1,817 | \$5,558 | \$3,180 | \$3,180 | \$3,180 | \$3,180 | \$3,180 | \$3,180 |
| Office Supplies | Appliances | \$313 | \$90 | \$503 | \$533 | \$919 | \$2,275 | \$772 | \$772 | \$772 | \$772 | \$772 | \$772 |
| | Art | \$177 | \$74 | \$413 | \$568 | \$288 | \$686 | \$368 | \$368 | \$368 | \$368 | \$368 | \$368 |
| | Binders | \$815 | \$339 | \$1,526 | \$986 | \$4,372 | \$4,276 | \$2,052 | \$2,052 | \$2,052 | \$2,052 | \$2,052 | \$2,052 |

Similarly, if **Sub-Category** had been selected as a partitioning dimension, Tableau would use the data *within* a given month but *along* multiple subcategories, as below. If the data is further subdivided into panes, the pane boundaries would be respected when building a model.

| Sub-Category | | Order Date / Month of Order Date | | | | | | | | | | | |
|-----------------|--------------|----------------------------------|---------------|------------|------------|----------|-----------|--|---------------|------------|------------|----------|-----------|
| Category | Sub-Category | Sales | | | | | | MODEL_QUANTILE nopred along Sub-Category | | | | | |
| | | Q1 | | | Q2 | | | Q1 | | | Q2 | | |
| | | January 2016 | February 2016 | March 2016 | April 2016 | May 2016 | June 2016 | January 2016 | February 2016 | March 2016 | April 2016 | May 2016 | June 2016 |
| Furniture | Bookcases | \$1,010 | | \$1,706 | \$308 | \$641 | \$760 | \$1,561 | \$613 | \$3,643 | \$1,986 | \$1,728 | \$3,302 |
| | Chairs | \$4,188 | \$190 | \$5,713 | \$3,211 | \$3,675 | \$6,456 | \$1,561 | \$613 | \$3,643 | \$1,986 | \$1,728 | \$3,302 |
| | Furnishings | \$712 | \$393 | \$480 | \$984 | \$780 | \$433 | \$1,561 | \$613 | \$3,643 | \$1,986 | \$1,728 | \$3,302 |

| Office Supplies | Appliances | \$313 | \$90 | \$503 | \$533 | \$919 | \$2,275 | \$606 | \$134 | \$956 | \$1,239 | \$793 | \$1,439 |
| | Art | \$177 | \$74 | \$413 | \$568 | \$288 | \$686 | \$606 | \$134 | \$956 | \$1,239 | \$793 | \$1,439 |

A note on partitioning

Note that partitioning your data visually has significant effects on the data that's used to build a model and generate your predictions. Adding a higher level of detail (for example, including both **State** and **City** on a single shelf) will partition your data by the higher LOD. This is true regardless of the order in which the pills are placed on the shelf. For instance, these will return identical predictions:

Adding a pill that modifies the level of detail will partition your data if it's added to either the Rows or Columns shelf, or to Colour, Size, Label, Detail or Shape on the Marks card. Adding a pill at a different level of detail to Tooltip will *not* partition your data.

In the below example, the model is automatically partitioning by **Category** since the **Category** and **Sub-Category** pills are both on Rows. The prediction calculation is being computed across **Sub-Category** within the boundaries of the higher-level pill, **Category**.

| Sub-Category | | Order Date / Month of Order Date | | | | | | | | | | | |
|-----------------|--------------|----------------------------------|---------------|------------|------------|----------|-----------|--|---------------|------------|------------|----------|-----------|
| Category | Sub-Category | Sales | | | | | | MODEL_QUANTILE nopred along Sub-Category | | | | | |
| | | Q1 | | | Q2 | | | Q1 | | | Q2 | | |
| | | January 2016 | February 2016 | March 2016 | April 2016 | May 2016 | June 2016 | January 2016 | February 2016 | March 2016 | April 2016 | May 2016 | June 2016 |
| Furniture | Bookcases | \$1,010 | | \$1,706 | \$308 | \$641 | \$760 | \$1,561 | \$613 | \$3,643 | \$1,986 | \$1,728 | \$3,302 |
| | Chairs | \$4,188 | \$190 | \$5,713 | \$3,211 | \$3,675 | \$6,456 | \$1,561 | \$613 | \$3,643 | \$1,986 | \$1,728 | \$3,302 |
| | Furnishings | \$712 | \$393 | \$480 | \$984 | \$780 | \$433 | \$1,561 | \$613 | \$3,643 | \$1,986 | \$1,728 | \$3,302 |
| | Tables | \$333 | \$1,256 | \$6,674 | \$3,442 | \$1,817 | \$5,558 | \$1,561 | \$613 | \$3,643 | \$1,986 | \$1,728 | \$3,302 |
| Office Supplies | Appliances | \$313 | \$90 | \$503 | \$533 | \$919 | \$2,275 | \$606 | \$134 | \$956 | \$1,239 | \$793 | \$1,439 |
| | Art | \$177 | \$74 | \$413 | \$568 | \$288 | \$686 | \$606 | \$134 | \$956 | \$1,239 | \$793 | \$1,439 |

This has implications for how your predictors are applied. Let's look at the example below. In this case, we have three MODEL_QUANTILE table calculations being applied:

| Predict_Sales_City | Predict_Sales_State | Predict_Sales_Region |
|--|---|--|
| MODEL_QUANTILE (0.5, sum([Sales]), ATTR([City])) | MODEL_QUANTILE (0.5, sum([Sales]), ATTR([State])) | MODEL_QUANTILE (0.5, sum([Sales]), ATTR([Region])) |

For all three, we've selected **Compute Using > City**. Let's take a look at some cities in North Carolina:

| Region | State | City | Sales | Predict_Sales_City along City | Predict_Sales_State along City | Predict_Sales_Region along City |
|--------|----------------|------------------|----------|----------------------------------|-----------------------------------|------------------------------------|
| South | North Carolina | Asheville | \$1,475 | 2,926 | 2,926 | 2,926 |
| | | Burlington | \$12,681 | 2,926 | 2,926 | 2,926 |
| | | Cary | \$505 | 2,926 | 2,926 | 2,926 |
| | | Chapel Hill | \$14 | 2,926 | 2,926 | 2,926 |
| | | Charlotte | \$13,693 | 2,926 | 2,926 | 2,926 |
| | | Concord | \$5,112 | 2,926 | 2,926 | 2,926 |
| | | Durham | \$880 | 2,926 | 2,926 | 2,926 |
| | | Fayetteville | \$3,183 | 2,926 | 2,926 | 2,926 |
| | | Gastonia | \$895 | 2,926 | 2,926 | 2,926 |
| | | Goldsboro | \$35 | 2,926 | 2,926 | 2,926 |
| | | Greensboro | \$2,407 | 2,926 | 2,926 | 2,926 |
| | | Greenville | \$2,118 | 2,926 | 2,926 | 2,926 |
| | | Hickory | \$41 | 2,926 | 2,926 | 2,926 |
| | | Jacksonville | \$5,580 | 2,926 | 2,926 | 2,926 |
| | | Monroe | \$1,213 | 2,926 | 2,926 | 2,926 |
| | | Raleigh | \$4,508 | 2,926 | 2,926 | 2,926 |
| | | Thomasville | \$151 | 2,926 | 2,926 | 2,926 |
| | | Wilmington | \$743 | 2,926 | 2,926 | 2,926 |
| | | Wilson | \$369 | 2,926 | 2,926 | 2,926 |
| | South Carolina | Columbia | \$6,168 | 1,414 | 1,414 | 1,414 |
| | | Florence | \$1,065 | 1,414 | 1,414 | 1,414 |
| | | Mount Pleasant | \$546 | 1,414 | 1,414 | 1,414 |
| | | North Charleston | \$284 | 1,414 | 1,414 | 1,414 |
| | | Rock Hill | \$12 | 1,414 | 1,414 | 1,414 |
| | Tennessee | Summerville | \$407 | 1,414 | 1,414 | 1,414 |
| | | Bartlett | \$89 | 2,044 | 2,044 | 2,044 |
| | | Bristol | \$437 | 2,044 | 2,044 | 2,044 |
| | | Chattanooga | \$989 | 2,044 | 2,044 | 2,044 |
| | | Clarksville | \$2,218 | 2,044 | 2,044 | 2,044 |
| | | Columbia | \$5,163 | 2,044 | 2,044 | 2,044 |
| | | Franklin | \$948 | 2,044 | 2,044 | 2,044 |

Notice that the results from all three calculations are identical within a given state, despite using different predictors.

If we remove **Region** from the Rows shelf, nothing happens to our results – they're still all identical within a given state:

| State | City | Sales | Predict_Sales_City along City | Predict_Sales_State along City | Predict_Sales_Region along City |
|----------------|---------------|----------|----------------------------------|-----------------------------------|------------------------------------|
| North Carolina | Asheville | \$1,475 | 2,926 | 2,926 | 2,926 |
| | Burlington | \$12,681 | 2,926 | 2,926 | 2,926 |
| | Cary | \$505 | 2,926 | 2,926 | 2,926 |
| | Chapel Hill | \$14 | 2,926 | 2,926 | 2,926 |
| | Charlotte | \$13,693 | 2,926 | 2,926 | 2,926 |
| | Concord | \$5,112 | 2,926 | 2,926 | 2,926 |
| | Durham | \$880 | 2,926 | 2,926 | 2,926 |
| | Fayetteville | \$3,183 | 2,926 | 2,926 | 2,926 |
| | Gastonia | \$895 | 2,926 | 2,926 | 2,926 |
| | Goldsboro | \$35 | 2,926 | 2,926 | 2,926 |
| | Greensboro | \$2,407 | 2,926 | 2,926 | 2,926 |
| | Greenville | \$2,118 | 2,926 | 2,926 | 2,926 |
| | Hickory | \$41 | 2,926 | 2,926 | 2,926 |
| | Jacksonville | \$5,580 | 2,926 | 2,926 | 2,926 |
| | Monroe | \$1,213 | 2,926 | 2,926 | 2,926 |
| | Raleigh | \$4,508 | 2,926 | 2,926 | 2,926 |
| | Thomasville | \$151 | 2,926 | 2,926 | 2,926 |
| | Wilmington | \$743 | 2,926 | 2,926 | 2,926 |
| | Wilson | \$369 | 2,926 | 2,926 | 2,926 |
| North Dakota | Fargo | \$920 | | | |
| Ohio | Akron | \$2,730 | 3,261 | 3,261 | 3,261 |
| | Bowling Green | \$1,866 | 3,261 | 3,261 | 3,261 |
| | Cincinnati | \$1,612 | 3,261 | 3,261 | 3,261 |
| | Cleveland | \$6,346 | 3,261 | 3,261 | 3,261 |
| | Columbus | \$15,901 | 3,261 | 3,261 | 3,261 |

But when we remove **State** from the Rows shelf, we see different results for each calculation:

| City | Sales | Predict_Sales_City along City | Predict_Sales_State along City | Predict_Sales_Region along City |
|-----------------|----------|----------------------------------|-----------------------------------|------------------------------------|
| Burbank | \$3,247 | 4,326 | 6,260 | 4,667 |
| Burlington | \$21,668 | 4,326 | 9,366 | 9,647 |
| Caldwell | \$456 | 4,326 | 875 | 4,667 |
| Camarillo | \$1,468 | 4,326 | 6,260 | 4,667 |
| Cambridge | \$502 | 4,326 | 1,038 | 6,574 |
| Canton | \$818 | 4,326 | 3,507 | 2,528 |
| Carlsbad | \$419 | 4,326 | 683 | 4,667 |
| Carol Stream | \$1,306 | 4,326 | 2,926 | 2,528 |
| Carrollton | \$2,201 | 4,326 | 3,102 | 2,528 |
| Cary | \$505 | 4,326 | 2,084 | 2,465 |
| Cedar Hill | \$122 | 4,326 | 3,102 | 2,528 |
| Cedar Rapids | \$278 | 4,326 | 431 | 2,528 |
| Champaign | \$152 | 4,326 | 2,926 | 2,528 |
| Chandler | \$1,077 | 4,326 | 2,828 | 4,667 |
| Chapel Hill | \$14 | 4,326 | 2,084 | 2,465 |
| Charlotte | \$13,693 | 4,326 | 2,084 | 2,465 |
| Charlottesville | \$103 | 4,326 | 3,607 | 2,465 |

What's going on?

In the first example, **Region** and **State** on the Rows shelf are partitioning the cities. Therefore, the models for **Predict_Sales_City**, **Predict_Sales_State**, and **Predict_Sales_Region** are receiving the same data and generating the same predictions.

Since we've already visually partitioned the data within **State** and **Region**, none of our predictors add any value to the model and have no impact on the results:

| Region | State | City | Sales | Predict_Sales_City along City | Predict_Sales_State along City | Predict_Sales_Region along City |
|--------|----------------|------------------|----------|----------------------------------|-----------------------------------|------------------------------------|
| South | North Carolina | Asheville | \$1,475 | 2,926 | 2,926 | 2,926 |
| | | Burlington | \$12,681 | 2,926 | 2,926 | 2,926 |
| | | Cary | \$505 | 2,926 | 2,926 | 2,926 |
| | | Chapel Hill | \$14 | 2,926 | 2,926 | 2,926 |
| | | Charlotte | \$13,693 | 2,926 | 2,926 | 2,926 |
| | | Concord | \$5,112 | 2,926 | 2,926 | 2,926 |
| | | Durham | \$880 | 2,926 | 2,926 | 2,926 |
| | | Fayetteville | \$3,183 | 2,926 | 2,926 | 2,926 |
| | | Gastonia | \$895 | 2,926 | 2,926 | 2,926 |
| | | Goldsboro | \$35 | 2,926 | 2,926 | 2,926 |
| | | Greensboro | \$2,407 | 2,926 | 2,926 | 2,926 |
| | | Greenville | \$2,118 | 2,926 | 2,926 | 2,926 |
| | | Hickory | \$41 | 2,926 | 2,926 | 2,926 |
| | | Jacksonville | \$5,580 | 2,926 | 2,926 | 2,926 |
| | | Monroe | \$1,213 | 2,926 | 2,926 | 2,926 |
| | | Raleigh | \$4,508 | 2,926 | 2,926 | 2,926 |
| | | Thomasville | \$151 | 2,926 | 2,926 | 2,926 |
| | | Wilmington | \$743 | 2,926 | 2,926 | 2,926 |
| | | Wilson | \$369 | 2,926 | 2,926 | 2,926 |
| | South Carolina | Columbia | \$6,168 | 1,414 | 1,414 | 1,414 |
| | | Florence | \$1,065 | 1,414 | 1,414 | 1,414 |
| | | Mount Pleasant | \$546 | 1,414 | 1,414 | 1,414 |
| | | North Charleston | \$284 | 1,414 | 1,414 | 1,414 |
| | | Rock Hill | \$12 | 1,414 | 1,414 | 1,414 |
| | | Summerville | \$407 | 1,414 | 1,414 | 1,414 |
| | Tennessee | Bartlett | \$89 | 2,044 | 2,044 | 2,044 |
| | | Bristol | \$437 | 2,044 | 2,044 | 2,044 |
| | | Chattanooga | \$989 | 2,044 | 2,044 | 2,044 |
| | | Clarksville | \$2,218 | 2,044 | 2,044 | 2,044 |
| | | Columbia | \$5,163 | 2,044 | 2,044 | 2,044 |
| | | Franklin | \$948 | 2,044 | 2,044 | 2,044 |

When we remove **Region** from the Rows shelf, we're still partitioning by **State** – so there's no change to the data used to build the model. Again, since we've already visually partitioned the data within **State**, none of our predictors add any value to the model or have any impact on results:

| State | City | Sales | Predict_Sales_City along City | Predict_Sales_State along City | Predict_Sales_Region along City |
|----------------|---------------|----------|----------------------------------|-----------------------------------|------------------------------------|
| North Carolina | Asheville | \$1,475 | 2,926 | 2,926 | 2,926 |
| | Burlington | \$12,681 | 2,926 | 2,926 | 2,926 |
| | Cary | \$505 | 2,926 | 2,926 | 2,926 |
| | Chapel Hill | \$14 | 2,926 | 2,926 | 2,926 |
| | Charlotte | \$13,693 | 2,926 | 2,926 | 2,926 |
| | Concord | \$5,112 | 2,926 | 2,926 | 2,926 |
| | Durham | \$880 | 2,926 | 2,926 | 2,926 |
| | Fayetteville | \$3,183 | 2,926 | 2,926 | 2,926 |
| | Gastonia | \$895 | 2,926 | 2,926 | 2,926 |
| | Goldsboro | \$35 | 2,926 | 2,926 | 2,926 |
| | Greensboro | \$2,407 | 2,926 | 2,926 | 2,926 |
| | Greenville | \$2,118 | 2,926 | 2,926 | 2,926 |
| | Hickory | \$41 | 2,926 | 2,926 | 2,926 |
| | Jacksonville | \$5,580 | 2,926 | 2,926 | 2,926 |
| | Monroe | \$1,213 | 2,926 | 2,926 | 2,926 |
| | Raleigh | \$4,508 | 2,926 | 2,926 | 2,926 |
| | Thomasville | \$151 | 2,926 | 2,926 | 2,926 |
| | Wilmington | \$743 | 2,926 | 2,926 | 2,926 |
| | Wilson | \$369 | 2,926 | 2,926 | 2,926 |
| North Dakota | Fargo | \$920 | | | |
| Ohio | Akron | \$2,730 | 3,261 | 3,261 | 3,261 |
| | Bowling Green | \$1,866 | 3,261 | 3,261 | 3,261 |
| | Cincinnati | \$1,612 | 3,261 | 3,261 | 3,261 |
| | Cleveland | \$6,346 | 3,261 | 3,261 | 3,261 |
| | Columbus | \$15,901 | 3,261 | 3,261 | 3,261 |

However, when we remove **State**, the data is de-partitioned and we see different predictions for each calculation. Let's take a closer look at what's happening there:

| City | Sales | Predict_Sales_City along City | Predict_Sales_State along City | Predict_Sales_Region along City |
|-----------------|----------|----------------------------------|-----------------------------------|------------------------------------|
| Burbank | \$3,247 | 4,326 | 6,260 | 4,667 |
| Burlington | \$21,668 | 4,326 | 9,366 | 9,647 |
| Caldwell | \$456 | 4,326 | 875 | 4,667 |
| Camarillo | \$1,468 | 4,326 | 6,260 | 4,667 |
| Cambridge | \$502 | 4,326 | 1,038 | 6,574 |
| Canton | \$818 | 4,326 | 3,507 | 2,528 |
| Carlsbad | \$419 | 4,326 | 683 | 4,667 |
| Carol Stream | \$1,306 | 4,326 | 2,926 | 2,528 |
| Carrollton | \$2,201 | 4,326 | 3,102 | 2,528 |
| Cary | \$505 | 4,326 | 2,084 | 2,465 |
| Cedar Hill | \$122 | 4,326 | 3,102 | 2,528 |
| Cedar Rapids | \$278 | 4,326 | 431 | 2,528 |
| Champaign | \$152 | 4,326 | 2,926 | 2,528 |
| Chandler | \$1,077 | 4,326 | 2,828 | 4,667 |
| Chapel Hill | \$14 | 4,326 | 2,084 | 2,465 |
| Charlotte | \$13,693 | 4,326 | 2,084 | 2,465 |
| Charlottesville | \$103 | 4,326 | 3,607 | 2,465 |

For **Predict_Sales_City**, we're using **ATTR([City])** as a predictor. Since this is at the same level of detail as the viz, it adds no value and is disregarded. We are aggregating **Sales** for all cities, passing them to the statistical engine and computing the predicted sales. Since no other predictors are included, we see the same result for each city; if we had included one or more measures, we'd see variation in the results.

| City | Sales | Predict_Sales_City along City | Predict_Sales_State along City | Predict_Sales_Region along City |
|-----------------|----------|----------------------------------|-----------------------------------|------------------------------------|
| Burbank | \$3,247 | 4,326 | 6,260 | 4,667 |
| Burlington | \$21,668 | 4,326 | 9,366 | 9,647 |
| Caldwell | \$456 | 4,326 | 875 | 4,667 |
| Camarillo | \$1,468 | 4,326 | 6,260 | 4,667 |
| Cambridge | \$502 | 4,326 | 1,038 | 6,574 |
| Canton | \$818 | 4,326 | 3,507 | 2,528 |
| Carlsbad | \$419 | 4,326 | 683 | 4,667 |
| Carol Stream | \$1,306 | 4,326 | 2,926 | 2,528 |
| Carrollton | \$2,201 | 4,326 | 3,102 | 2,528 |
| Cary | \$505 | 4,326 | 2,084 | 2,465 |
| Cedar Hill | \$122 | 4,326 | 3,102 | 2,528 |
| Cedar Rapids | \$278 | 4,326 | 431 | 2,528 |
| Champaign | \$152 | 4,326 | 2,926 | 2,528 |
| Chandler | \$1,077 | 4,326 | 2,828 | 4,667 |
| Chapel Hill | \$14 | 4,326 | 2,084 | 2,465 |
| Charlotte | \$13,693 | 4,326 | 2,084 | 2,465 |
| Charlottesville | \$103 | 4,326 | 3,607 | 2,465 |

For **Predict_Sales_State**, we're using ATTR([State]) as a predictor. The *predictor* is partitioning all the **City** data by **State**. We expect to see identical results *within* a state, but different results for *each* state.

But notice that isn't quite what we get. The cities of Cary, Chapel Hill and Charlotte all have identical predictions of \$2,084, as we expect. Burlington, however, shows us a different prediction of \$9,366:

| City | Sales | Predict_Sales_City along City | Predict_Sales_State along City | Predict_Sales_Region along City |
|-----------------|----------|----------------------------------|-----------------------------------|------------------------------------|
| Burbank | \$3,247 | 4,326 | 6,260 | 4,667 |
| Burlington | \$21,668 | 4,326 | 9,366 | 9,647 |
| Caldwell | \$456 | 4,326 | 875 | 4,667 |
| Camarillo | \$1,468 | 4,326 | 6,260 | 4,667 |
| Cambridge | \$502 | 4,326 | 1,038 | 6,574 |
| Canton | \$818 | 4,326 | 3,507 | 2,528 |
| Carlsbad | \$419 | 4,326 | 683 | 4,667 |
| Carol Stream | \$1,306 | 4,326 | 2,926 | 2,528 |
| Carrollton | \$2,201 | 4,326 | 3,102 | 2,528 |
| Cary | \$505 | 4,326 | 2,084 | 2,465 |
| Cedar Hill | \$122 | 4,326 | 3,102 | 2,528 |
| Cedar Rapids | \$278 | 4,326 | 431 | 2,528 |
| Champaign | \$152 | 4,326 | 2,926 | 2,528 |
| Chandler | \$1,077 | 4,326 | 2,828 | 4,667 |
| Chapel Hill | \$14 | 4,326 | 2,084 | 2,465 |
| Charlotte | \$13,693 | 4,326 | 2,084 | 2,465 |
| Charlottesville | \$103 | 4,326 | 3,607 | 2,465 |

That's because a city named "Burlington" exists within multiple states (Iowa, North Carolina and Vermont). Therefore, **State** resolves to *, meaning 'more than one value'. All marks where **State** resolves to * are evaluated together, so any other city that also exists in multiple states would also have a prediction of \$9,366.

For **Predict_Sales_Region**, we're using ATTR([Region]) as a predictor. The *predictor* is partitioning all the **City** data by **Region**. You expect to see identical results *within* a region, but different results for *each* region:

| City | Sales | Predict_Sales_City along City | Predict_Sales_State along City | Predict_Sales_Region along City |
|-----------------|----------|----------------------------------|-----------------------------------|------------------------------------|
| Burbank | \$3,247 | 4,326 | 6,260 | 4,667 |
| Burlington | \$21,668 | 4,326 | 9,366 | 9,647 |
| Caldwell | \$456 | 4,326 | 875 | 4,667 |
| Camarillo | \$1,468 | 4,326 | 6,260 | 4,667 |
| Cambridge | \$502 | 4,326 | 1,038 | 6,574 |
| Canton | \$818 | 4,326 | 3,507 | 2,528 |
| Carlsbad | \$419 | 4,326 | 683 | 4,667 |
| Carol Stream | \$1,306 | 4,326 | 2,926 | 2,528 |
| Carrollton | \$2,201 | 4,326 | 3,102 | 2,528 |
| Cary | \$505 | 4,326 | 2,084 | 2,465 |
| Cedar Hill | \$122 | 4,326 | 3,102 | 2,528 |
| Cedar Rapids | \$278 | 4,326 | 431 | 2,528 |
| Champaign | \$152 | 4,326 | 2,926 | 2,528 |
| Chandler | \$1,077 | 4,326 | 2,828 | 4,667 |
| Chapel Hill | \$14 | 4,326 | 2,084 | 2,465 |
| Charlotte | \$13,693 | 4,326 | 2,084 | 2,465 |
| Charlottesville | \$103 | 4,326 | 3,607 | 2,465 |
| Chattanooga | \$989 | 4,326 | 2,115 | 2,465 |
| Chesapeake | \$5,997 | 4,326 | 3,607 | 2,465 |
| Chester | \$1,968 | 4,326 | 16,471 | 6,574 |
| Cheyenne | \$1,603 | 4,326 | 1,603 | 4,667 |
| Chicago | \$48,540 | 4,326 | 2,926 | 2,528 |

Again, since Burlington exists within multiple regions (Central, East and South), **Region** resolves to *. Burlington's predictions will match only those cities that also exist within multiple regions.

As you can see, it's very important to ensure that any dimensional predictors are correctly aligned with both your visualisation's level of detail and your partitioning. Subdividing your visualisation by any dimension could have unintended effects on your predictions.

Example - Explore Female Life Expectancy with Predictive Modelling Functions

This example uses the World Indicators saved data source, which comes with Tableau. We'll use the MODEL_QUANTILE and MODEL_PERCENTILE **predictive modelling functions** to explore the relationships between health spending per capita, female life expectancy, birth rate.

Let's start with a visualisation that compares each country's health spending with its female life expectancy. To follow along and access the pre-built views and dashboards, or to view the solution, download the following workbook from Tableau Public: **Predictive Modelling of Female Life Expectancy**.

Using MODEL_PERCENTILE

First we'll evaluate the life expectancy and health expenditures for all visible marks. This will allow Tableau to build a model from those marks and return the percentile for each within the model.

Step 1: Create the prediction calculation

If you also have Tableau Server or Tableau Cloud and you want to do your authoring on the web instead of in Tableau Desktop, publish the workbook to your Tableau server, click **Workbooks**, select the workbook, then under Actions, choose **Edit Workbook**.

Once you open the workbook, you'll see that it has several sheets. You'll be using those sheets to build your views.

1. In the starter workbook, click the **Percentile Starter** sheet.
2. Open the **Analysis** menu at the top, and then select **Create Calculated Field**.
3. In the Calculation Editor, do the following:

- Name the calculation: **Percentile Expectancy vs Spending**

Note: If you're following along in the starter workbook, you'll see different names for the calculations used throughout this example. This is so that you'll be able to name the fields as described here, without creating duplicates. Your solution may have different names, but the visualisations should look the same.

- Enter the following formula:

```
MODEL_PERCENTILE(AVG([Life Expectancy Female]), LOG(MEDIAN
([Health Exp/Capita])))
```

This calculation uses average life expectancy as the target expression, and median health expenditure as the predictor. In this case, we used a logarithmic transformation on the health spending axis, as well as for the predictor.

Note: Because this data set skews toward very large values, we transformed our data using a **logarithmic scale**, which is useful when analysing data with a few values that are much higher than the rest, and will make it easier to identify trends and relationships in our data set.

4. Click **OK**.

The prediction calculation is now added as a calculated field in the Data pane.

Step 2: Add the prediction calculation to the view

In the viz above, you can see each country's health spending against its female life expectancy, filtered to 2012.

Now, let's add the MODEL_PERCENTILE calculation to the view and see what insights we can gain.

1. Drag **Percentile Expectancy vs Spending** to Colour on the Marks card.
2. Click the drop-down arrow on the pill and select **Compute Using > Country/Region**.
3. Click **Colour** on the Marks card, and then click **Edit Colours**.
 - Under Palette, select **Orange-Blue Diverging**.
 - Select the **Stepped Colour** tick box.
 - Select the **Reversed** tick box.
4. Click **OK**.

You can see the distribution of countries where health expectancy is both higher and lower than expected based on the level of spending. Notice that generally, the dark red marks indicate that life expectancy is high relative to healthcare spending, dark blue means that life expectancy is low relative to healthcare spending, and grey means that life expectancy is close to what the model expects, based on the level of healthcare spending.

Step 3: Group the results by colour

To simplify analysis, let's use the prediction calculation within a new calculation to group the results. We'll build groups so that marks above the 90th percentile and below the 10th percentile are grouped together, marks in the 80th–90th percentile range and 10th–20th percentile range are grouped together, and so on. We'll also highlight marks with a null value and address those later using the other predictive modelling function, `MODEL_QUANTILE`.

1. In the Calculation Editor, do the following:
 - Name the calculation: **Percentile by Colour.**
 - Enter the following formula:

```
IF
ISNULL([Percentile Expectancy vs Spending])
THEN "Null"
ELSEIF [Percentile Expectancy vs Spending] >=0.9 OR
[Percentile Expectancy vs Spending] <=0.1
THEN "<10th & >90th percentile"
ELSEIF [Percentile Expectancy vs Spending] >=0.8 OR
[Percentile Expectancy vs Spending] <=0.2
THEN "<20th & >80th percentile"
ELSEIF [Percentile Expectancy vs Spending] >=0.7 OR
[Percentile Expectancy vs Spending] <=0.3
THEN "<30th & >70th percentile"
ELSEIF [Percentile Expectancy vs Spending] >=0.6 OR
[Percentile Expectancy vs Spending] <=0.4
THEN "<40th & >60th percentile"
ELSE "50th percentile +/-10"
END
```

2. Add the new calculation to **Colour** on the Marks card.
3. Click the drop-down arrow on the pill and select **Compute Using > Country/Region**.
4. Click Colour on the Marks card, and then click **Edit Colours**.
 - Adjust the colours to better see the trend. In this case, let's use the **Traffic Light** colour palette, and use grey for Nulls.
5. Click **OK**.

Looking at the orange mark in the corner, notice that the US spends \$8,895 per female for a life expectancy of 81 years. Moving along the X-axis to the left, you can see that other countries spend less and have the same life expectancy.

The model evaluates the strength of the relationship at each point, where the US is close to the upper end of the model's expected range.

Step 4: Compare life expectancy with birth rate

Next, let's look at a viz that compares female life expectancy with birth rate. Notice that there is a negative correlation between birth rates and female life expectancy; however, this does not mean that higher birth rates cause lower female life expectancy. There are likely additional factors that affect both birth rates and female life expectancy that are not visible in this view of the data. But let's add the model and see where the model expects female life expectancy to be higher or lower given health expenditures.

1. On the **Birth Rate** sheet, add the **Percentile by Colour** prediction calculation to **Colour** on the Marks card to bring it into the view.
2. Click the drop-down arrow on the pill and select **Compute Using > Country/Region**.
3. Click **Colour** on the Marks card, and click **Edit Colours**. Edit the colours as before, using the **Traffic Light** palette and grey for Null.
4. Click **OK**.

Now the data is much more distributed. The red band in the lower right corner is where life expectancy is lowest but the birth rate is highest, and healthcare spending relative to life expectancy is low. Singling out the two red marks in the top left quadrant, which pertain to Albania and Armenia, you'll notice that both countries have high female life expectancy, lower birth rates and low health expenditures.

As you can see, we were able to use MODEL_PERCENTILE to identify that these two countries are outliers: Even though they both had relatively low healthcare spending, they still have relatively high life expectancies, placed in the context of birth rate.

Now, let's see how you can use the other predictive modelling function, `MODEL_QUANTILE`, to continue your analysis.

Using `MODEL_QUANTILE`

`MODEL_QUANTILE` is used to generate numeric predictions, given a target percentile, target expression and predictors. It's the inverse of `MODEL_PERCENTILE`.

Recall that we have several null values in our results, meaning that some countries don't have health expenditure data. We'll use `MODEL_QUANTILE` to estimate those missing values.

Step 1: Create the prediction calculations

We've been working with this calculation:

```
MODEL_PERCENTILE(AVG([Life Expectancy Female]), LOG(MEDIAN([Health
Exp/Capita])))
```

First, we want to invert this function in order to get a prediction for healthcare expenditure based on female life expectancy.

1. In the starter workbook, click the **Quantile Starter** sheet.
2. Open the **Analysis** menu at the top, and then select **Create Calculated Field**.
3. In the Calculation Editor, do the following:
 - Name the calculation: **Quantile of Life Expectancy vs Spending**
 - Enter the following formula:

```
POWER(10, MODEL_QUANTILE(0.5, LOG(MEDIAN([Health
Exp/Capita])), AVG([Life Expectancy Female]))))
```

Let's break this calculation down to better understand it:

- We start with **MODEL_QUANTILE**, where the first argument is 0.5, specifying what percentile to predict.
- The target expression is median health expenditure per capita.
- The predictor is average female life expectancy.
- In addition, we wrapped the function inside a **POWER** function to convert the log-transformed target expression back into dollars.

4. Click **OK**.

The prediction calculation is now added as a calculated field in the Data pane.

Step 2: Add the prediction calculation to the view

1. Drag **Quantile of Life Expectancy vs Spending** to Tooltip on the Marks card.
2. Click the drop-down arrow on the pill and select **Compute Using > Country/Region**.
3. Click **Tooltip** on the Marks card and add a row for the **MODEL_QUANTILE** prediction:
 - Name the tooltip row: **Predicted Health Spend from Female Life Expectancy:**
 - Click **Insert** and select the calculation to ensure the tooltip will dynamically show the mark's unique prediction as you interact with the viz.
4. Click **OK**.

Right now our **MODEL_QUANTILE** calculation only has one predictor: female life expectancy. Notice as you move from left to right, viewing the tooltip for marks with the same life expectancy, that each one has the same predicted health spend. Indonesia's predicted health spend from life expectancy is \$336, but so is Fiji's, Egypt's and other countries that have the same female life expectancy.

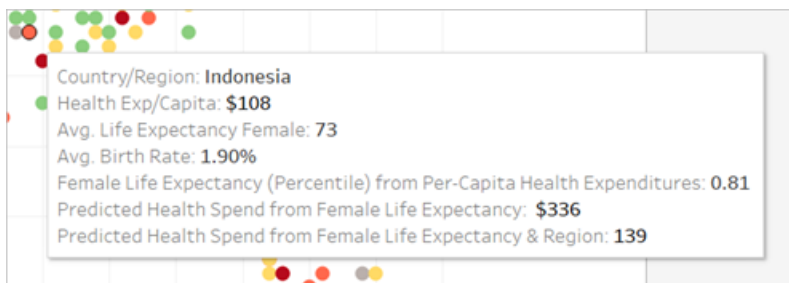

This is because the model provides the same estimated expenditure for each mark. Since we're only using one predictor (female life expectancy), the model returns the same results for all marks where the predictor has the same value. You can add more nuance to the model by adding predictors.

Step 3: Add a prediction with a second predictor

As you build your predictions, you should consider which fields will be good predictors for your target values and include them in your calculations. You can combine any number of dimensions and measures. For example, we could add GDP, population and other fields as predictors to improve our predictions. In this case, let's add **Region**.

1. In the Calculation Editor, do the following:
 - Name the calculation: **Quantile Spend vs Expectancy & Region**
 - Enter the following formula, which is the same as the previous calculation, but adds **Region** as a predictor:

```
POWER(10, MODEL_QUANTILE(0.5, LOG(MEDIAN([Health Exp/Capita])), AVG([Life Expectancy Female]), ATTR([Region])))
```
2. Click **OK**.
3. Next, add the new calculation to Tooltip on the Marks card.
4. Click **Tooltip**, and add another line to describe the new prediction, such as **Predicted Health Spend from Female Life Expectancy & Region:**.

Now the tooltip shows both predictions.

Step 4: Compare actual values to predicted values

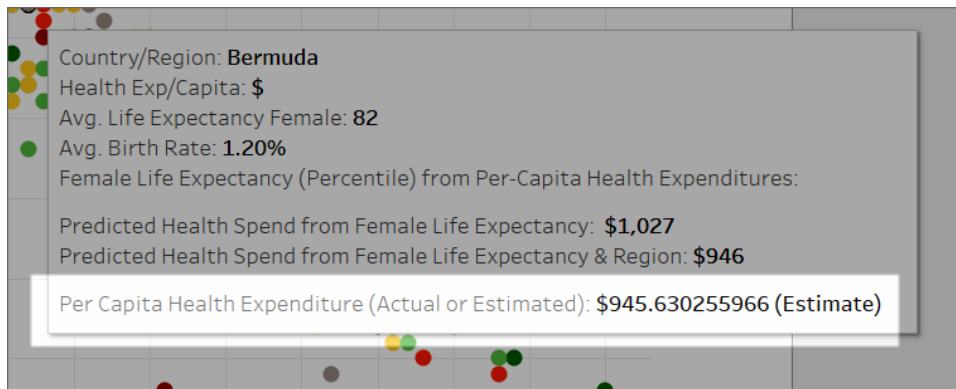

As a final step in your analysis, you can also build prediction calculations that combine actual and predicted values. In our example, let's show the actual health expenditures where available and

the estimated expenditures where unavailable.

1. In the Calculation Editor, do the following:
 - Name the calculation: **Health Spend Actual vs Prediction Value**
 - Enter the following formula, which will return the numeric value of the prediction:

```
ROUND(IFNULL(AVG([Health Exp/Capita]),[Quantile_HE/Cap_
LEF,Region]),0)
```
2. Click **OK**.
3. Create another calculation as follows:
 - Name the calculation: **Health Spend Actual vs Prediction Tag**
 - Enter the following formula, which will act as a label for the above calculation:

```
STR(IF ISNULL(AVG([Health Exp/Capita])) THEN "(Estimate)"
ELSE "(Actual)" END)
```
4. Click **OK**.
5. Next, add both calculations to **Tooltip** on the Marks card.
6. Click **Tooltip**, and add another line to describe the new calculations:
 - **Per Capita Health Expenditure (Actual or Estimated):**
 - Insert the new calculations, one after the other.
7. Click **OK**.

Now, as you interact with the viz, you can see each country's per capita health spending, or view an estimate if the actual value was missing (null) from the data.

Just like that, you can use predictive modelling functions in Tableau to gain insights into your data.

Predictive Modelling Functions in Time Series Visualisations

This document describes the steps required to extend a time axis into the future, so that you can make predictions for future dates using predictive modelling functions.

To see how, follow along with the below example.

Step 1: Create a visualisation

1. In Tableau Desktop, connect to the **Sample - Superstore** saved data source, which comes with Tableau.
2. Navigate to the **Sheet 1** worksheet.
3. From the Data pane, drag the **Order Date** dimension to the Columns shelf.
4. Open the measure's context menu to change its list level to Month and Year:

5. Drag **Profit** to the Rows shelf.

Step 2: Create a prediction calculation

1. Click to open the **Analysis** menu at the top, and then select **Create Calculated Field**.
2. In the Calculation Editor, do the following:
 - Name the calculation: **Quantile Predict Median Profit**.
 - Enter the following formula:

```
MODEL_QUANTILE(0.5, SUM([Profit]),ATTR(DATETRUNC
('month', [Order Date])))
```

The `MODEL_QUANTILE` function takes a given quantile and predicts values based on the predictors you input. In this case, the quantile = 0.5, which predicts the median. We

want to predict profit, so the target expression is `SUM([Profit])`. And since we want to base the prediction on past performance, we need to include date as a predictor.

Note: With Predictive Modelling functions, you cannot mix aggregate and non-aggregate arguments. Since the target expression must be an aggregate, so must the predictor. In this case, we used `ATTR(DATETRUNC('month', [Order Date]))`. For more information about the use of ATTR functions, see [When to Use the Attribute \(ATTR\) Function](#).

3. When finished, click **OK**.

The prediction calculation is now added as a calculated field in the Data pane.

Step 3: Add the prediction calculation to the view

1. Drag the prediction calculation to the Rows shelf, to the right of `SUM(Profit)`.
2. Right-click (Control-click on Mac) the measure and select **Dual Axis**.
3. To align the two axes in a dual axes chart to use the same scale, right-click (Control-click on Mac) the secondary axis, in this case **Quantile Predict Median Profit**, and select **Synchronise Axis**. This aligns the scale of the two axes.

Step 4: Extend the date range and densify the data

The final step is to extend the horizontal axis into the future so that you can add marks beyond the current date range.

1. To do this, open the context menu of the MONTH(Order Date) pill, and select **Extend Date Range**.
2. In the Extend Date Range dialog, let's extend the axis by 16 months:

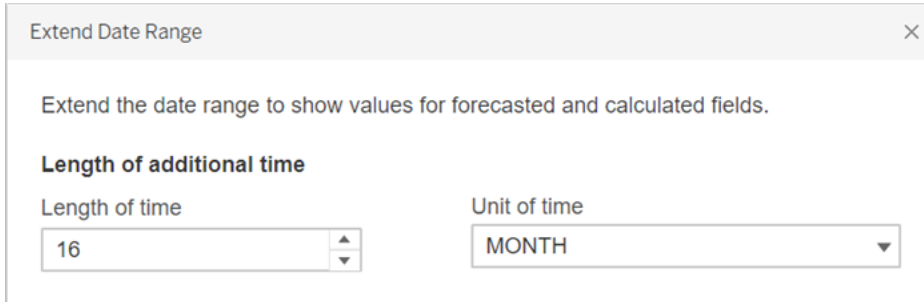

Tableau has automatically updated the view by extending the horizontal axis and includes predictions on these future dates:

Notice that the blue **Profit** line doesn't extend to the end of the graph. However, the orange line representing the prediction calculation, **Quantile Predict Median Profit**, does extend to the end of the graph. Computing the predicted profit on future dates is an example of data densification, which occurs when Tableau creates additional marks in the view to compensate for **missing values**. Data is not added to the underlying data source; marks are simply generated and added to the view.

Note: When you extend a date range into the future, Tableau automatically enables the **Infer Properties from Missing Values** option in the **Analysis** menu. This ensures that your prediction calculation will work on the missing values. For more details on this menu option, see [Predictive Modelling with Generated Marks](#) below.

For more information on data densification, see this [data densification post](#) from [Data Plus Science](#).

Predictive Modelling with Generated Marks

If you've been using Tableau for a while, you may have heard of the phrase "data densification." This refers to a process in which marks are generated by Tableau and added to the view, even

though those marks aren't supported by records in the underlying data source. This might be done to extend a date axis, or if you're working with [predictive modelling functions](#), to show predictions.

Watch a video: For an in-depth discussion on densifying data, check out this presentation from TC19: [You Did What to Your Data? A Deep Dive into Imputing and Densifying Data](#).

Learn more: See this blog post on [data densification](#) from [Data Plus Science](#).

Calculate predictions on missing values

For example, you might want to add predictions for future dates. By default, [missing values](#) in Tableau aren't shown, but you can generate these marks as follows:

1. Right-click (control-click on Mac) the date or bin header.
2. Select **Show Missing Values**.

But this isn't enough to let you make predictions on those generated marks. If you tried to perform a calculation on them (whether that's a prediction calculation or not), Tableau would return **null values**. This is expected, since those marks are based on missing values that don't exist.

To make predictions on those missing values, open the **Analysis** menu at the top, and then select **Infer Properties from Missing Values**.

Note: The default setting is that **Infer Properties from Missing Values** is turned off, even when **Show Missing Values** is turned on. Any field or axis that can be expanded using **Show Missing Values** can have this setting applied.

Example of predictions on generated marks

Now let's explore this behaviour further. We'll compare three different illustrations showing how the **Show Missing Values** and **Infer Properties from Missing Values** settings can affect your visualisation, depending on whether one or both are turned on or off. To follow along, download the following workbook from Tableau Public: [Predictions on Missing Values](#).

We've included predictions using `ATTR(DAY([Order Date]))` as a predictor. This isn't the best predictor for the data (and yields inadequate predictions), but for the purposes of this article, it's a good illustration of **Infer Properties from Missing Values**.

Each viz includes the same four measures on the Rows shelf, as outlined below:

- Row 1: `SUM([Profit])`
- Row 2: `RUNNING_SUM(SUM([Profit]))`
- Row 3: `ATTR(DAY([Order Date]))`
- Row 4: `MODEL_QUANTILE(0.5, SUM([Profit]), ATTR(DAY([Order Date])))`

Illustration 1

In the above image, both **Show Missing Values** and **Infer Properties from Missing Values** are turned off, which are the default settings in Tableau.

You would see the same viz if **Infer Properties from Missing Values** was turned on and **Show Missing Values** was turned off. This is because **Infer Properties from Missing Values** depends on **Show Missing Values** being turned on.

Illustration 2

In the above image, **Show Missing Values** is turned on and **Infer Properties from Missing Values** is turned off. The default setting is that **Infer Properties from Missing Values** is turned off, even when **Show Missing Values** is turned on.

Note that in this situation, we do not compute a value for ATTR on DAY([Order Date]) for the missing values (Row 3). We do generate a prediction for the densified dates, but they are identical for all missing dates, since we're not able to infer the actual ATTR(DAY([Order Date])) as shown in Row 3. Effectively, those marks are being computed as if DAY([Order Date]) is null.

Illustration 3

In this image, both **Show Missing Values** and **Infer Properties from Missing Values** are turned on, illustrating the **Infer Properties from Missing Values** setting in action.

As you can see, since we're able to infer the `ATTR(DAY([Order Date]))` (Row 3), we're able to use it in predictions in Row 4, returning a nice smooth curve of predictions.

Regularisation and Augmentation in Predictive Modelling

Many people who use Tableau may not use **predictive modelling**, let alone look for ways to improve a predictive model's fit and prediction quality. This article is for advanced users who are interested in this area of data science.

In addition to the default arguments such as target expression (the measure to predict) and predictor expression (the measure and/or dimensions used to make the prediction), you can add two more arguments to fine-tune your predictions: *lambda*, a regularisation parameter, and *augmentation*. This involves adding the new arguments to the **syntax** of your calculation.

Which models work with regularisation and augmentation?

As a reminder, predictive modelling functions in Tableau support three models: linear regression (also known as ordinary least squares regression, or OLS), regularised linear regression (or ridge regression) and Gaussian process regression. If you're using linear or ridge regression, then augmentation allows you to increase the ability of your models to pick up non-linear patterns. If

you're using ridge regression, then the regularisation parameter is a scalar you can use to adjust the regularisation effect on your model.

Regularisation and augmentation are not applicable to [Gaussian process regression](#).

Before discussing regularisation and augmentation further, let's review these two models:

Linear regression is best used when there are one or more predictors that have a linear relationship between the prediction and the prediction target, they aren't affected by the same underlying conditions, and they don't represent two instances of the same data (for example, sales expressed in both dollars and euros).

Regularised linear regression is used to improve stability, reduce the impact of collinearity, and improve computational efficiency and generalisation. In Tableau, L2 regularisation is used. For more information on L2 regularisation, see this lesson on [Ridge Regression](#).

What is regularisation?

Ridge regression is a specific kind of regularised linear regression. Regularisation imposes a penalty on the size of the model's coefficients. The strength of the regularisation is controlled by [lambda](#), a scalar used to fine-tune the overall impact of regularisation. The higher the value, the heavier the penalty (i.e. the greater the regularisation).

Ridge regression addresses some of the problems of linear regression:

- It removes pathologies introduced by multicollinearity among predictors.
- If the least-square problem is ill-conditioned, such as if the number of data points is less than the number of features, then lambda will select a unique solution.
- It provides a way of improving the generalisation of the linear model.

By default, ridge regression in Tableau has **lambda=0.5** because this value works well in many cases. To change the lambda value, simply edit the table calculation (examples below).

What is augmentation?

Augmentation in MODEL_QUANTILE and MODEL_PERCENTILE is a simple example of [data augmentation](#): predictors are expanded to higher order polynomials. In Tableau, there are a couple types of polynomial augmentations built in to the predictive modeling functions.

- For **ordered dimensions**, [Legendre polynomials](#) up to order 3 allow the linear model to pick up quadratic and cubic relations between the augmented predictor and response.
- For **measures**, 2nd degree [Hermite polynomials](#) allow the linear model to pick up quadratic relations between the augmented predictor and response.

In linear regression, only ordered dimensions are augmented by default with **augmentation=on**; in ridge regression where **model=rl**, only measures are augmented by default. To override the setting and disable augmentation for each predictor in your calculation, use **augmentation=off**; no higher order polynomials will be added.

Turning off augmentations is advantageous when the data set is very small because the augmentations could overfit any noise present in the original data, and also because the resulting relationship is simpler and more intuitive.

Note: Augmentation is turned on/off on a per-predictor basis (i.e. within the predictor argument of your calculation). Lambda (and model) are applied at the higher level (outside any predictor expressions).

Configuring lambda and augmentation in your calculation

Now that you know about the regularisation parameter (or lambda) and data augmentation, let's see them in the context of a prediction calculation:

```
MODEL_QUANTILE("model=rl, lambda=0.05", 0.5, SUM([Profit]),
"augmentation=off", SUM([Sales]))
```

Below is a table that quickly summarises if changing the augmentation and lambda from the default affects the linear models:

| | Augmentation | Lambda |
|-------------------|--------------|----------------|
| Ridge regression | Yes | Yes |
| Linear regression | Yes | Not applicable |

Considerations for regularisation and augmentation

- If you have the wrong model for your data, then changing the regularisation parameter or augmentation isn't likely to produce significantly better results. Consider reviewing if the data types are correct (measures vs dimensions). If the underlying data is a time series, for instance, consider using **Gaussian process regression** instead, by changing the model in your table calculation with **model=gp**.
- Because OLS is not regularised, there is no lambda value that can be changed.
- If your data set is extremely small and you have dimensions (especially high cardinality dimensions), then consider using ridge regression by adding model=rl to your table

calculation.

- All things being equal (for the same data set, given augmentation is on or off), a low lambda may improve fit, but hurt generalisation (cause overfitting).
- Conversely, a high lambda may push the fit to be a constant model, with no dependence on any of the predictor. This will reduce the model capacity (cause underfitting).

Example 1

This example shows the relationship between average cholesterol and heart disease in males and females, where males are represented by square marks and females are represented by circles.

In the first visualisation, the blue marks indicate the prediction target and the orange marks are the modelled values. You can see that the data is very noisy, and that with augmentation turned on and a small lambda value of 0.01, we see unrealistic heart disease rates greater than 1. There is far too steep of a dependence, probably due to all the outliers in the noisy data.

`MODEL_QUANTILE("model=rl, lambda=0.01", 0.5, AVG([Target]), ATTR([Sex]), "augmentation=on", AVG([Chol]))`

In the next visualisation, we compare the prediction target with a different model, with augmentation turned off and a lambda value off 10. Notice that this model is more realistic, and no marks exceed a disease rate of 1.

```
MODEL_QUANTILE("model=rl, lambda=10", 0.5, AVG([Target]), ATTR([Sex]), "augmentation=off", AVG([Chol]))
```

Example 2

Next, let's look at another real-world example using ridership data for Boston's Bluebikes (formerly Hubway) bike sharing system. In this case, linear regression works well. Compare the following visualisations, aggregated to quarters of 2017:

```
MODEL_QUANTILE('model=rl, lambda=0.05', 0.5, sum([Trip.Duration]), AVG([Temp]))
```

`MODEL_QUANTILE('model=rl, lambda=0.05', 0.5, AVG([Speed]), AVG([Temp]))`

Neither is prone to overfitting much, so the dependence on lambda is weak for a small lambda.

Now look at this last visualisation:

`MODEL_QUANTILE('model=rl, lambda=2', 0.5, sum([Trip.Duration]), AVG([Temp]))`

Notice that as lambda increases, the fit flattens to no slope (that is, becomes over-regularised or “underfit”).

Resolve Errors in Predictive Modelling Functions

When using **predictive modelling functions** in Tableau, you may encounter errors when trying to add the calculations to a viz. Often, this is due to the combination of predictors and visualised elements, leading to a mathematically invalid computation.

Generally, the first thing to try is to double check your **Compute Using** dimension. Next, verify there isn't a mismatch between the level of detail specified in your predictors and the level of detail in the view. Also verify that your predictors provide relevant data to the model, given the current visualisation.

In this article, we describe several common issues in detail, and the ways in which you can address them.

Errors with predictive modelling functions are usually caused by one or more of the following issues, depending on the model used.

General errors

- [Invalid Compute Using dimension](#) below
- [Dimension predictors conflict with level of detail visualised](#) on the next page
- [Multiple predictors conflict with each other](#) on page 2621
- [There's not enough data to build a model](#) on page 2621
- [A successful model couldn't be constructed from the data provided](#) on page 2621

Gaussian process regression errors

- [Gaussian process regression requires exactly one ordered dimension predictor](#) on page 2622
- [Gaussian process regression only supports dimensions as predictors](#) on page 2623
- [There's no training data for one or more prediction targets](#) on page 2624
- [There are more than 5,000 marks](#) on page 2624

Invalid Compute Using dimension

When visualising a predictive modelling function, a Compute Using dimension must be specified. It's recommended that you select a specific dimension (such as **Region** or **Category**) rather than a directional dimension (such as **Table Across Then Down** or **Pane Across**).

Since you may have multiple predictive modelling functions included in a viz or dashboard, selecting a specific partitioning dimension will help ensure you're building models using the same underlying data set for each individual function – in other words, comparing results from like to like models.

For more information on addressing and partitioning, see [Transform Values with Table Calculations](#) on page 2355.

When working with predictive modelling functions, you must ensure you maintain consistency across the different instantiations, both in different iterations of your model (e.g. as you select different predictors), and in different vizzes. Using the directional Compute Using dimensions opens up the possibility that a trivial change in your visualised data will significantly affect the data being used to build the model, thus affecting its validity and consistency across different vizzes.

You may see **null values** if no Compute Using dimension has been specified, or if an invalid Compute Using dimension has been selected.

Invalid Compute Using dimensions include:

- Cell: This dimension will always result in a single data point being used to build a model and will not be successful.
- A higher-level nested dimension (e.g. if **Region** and **State** are both visualised on an axis, where marks are generated for **State** but grouped by **Region**.) If **Region** is selected as the partitioning dimension, it will return null values, since there are no marks formalised for **Region** in this view.

*In the above viz, valid Compute Using dimensions are **State** and **Category**. Partitioning the data by **State** or by **Category** yields multiple valid marks that can be used to build a model.*

***Region**, while listed as a Compute Using option, doesn't generate any marks on this view's level of detail, and can't be used to partition the data.*

For more information, see [Compute Using and Data Partitioning in Predictive Modelling on page 2582](#).

Dimension predictors conflict with level of detail visualised

Dimension predictors must be at the same level of detail being visualised or *higher*. That is, if you're visualising data by **State**, you can use **State**, **Region** or **Country** as predictors, but using **City** as a predictor will cause an error. Since multiple cities exist within a state, this predictor will resolve to * for all marks and won't return meaningful information; as such, Tableau ignores it.

Each dimensional predictor must be enclosed within an **ATTR function**, for example:

```
MODEL_PERCENTILE(SUM([Sales]), ATTR([State]), ATTR([Category]))
```

Multiple predictors conflict with each other

Each predictor used within a given predictive modelling function must provide independent information to the calculation. If two predictors are selected that are exactly equivalent, scaled versions or inverses of each other, the predictive modelling function will return an error when it's visualised.

For example, a data set that tracks weather conditions over time might have two fields: **IsRain** and **IsClear**. These two fields are inverses of each other; that is, **IsClear** = True when **IsRain** = False, and vice versa. Including both **IsClear** and **IsRain** as predictors on a single predictive modelling function will return an error.

The above is true for both measures and dimensions as predictors.

In both cases, the error can be resolved by modifying your predictors to remove the highly correlated predictors. For more information, see [Choosing Predictors on page 2571](#).

There's not enough data to build a model

There must be at least three marks within a partition to allow predictive modelling functions to build a model and generate predictions. If there are two or fewer marks in the data set defined by the viewed data and the Compute Using dimension, then the predictive modelling function will return null results.

To resolve this issue, revise your level of detail, your data filtering parameters or your Compute Using dimension, so that each partition has more than two marks.

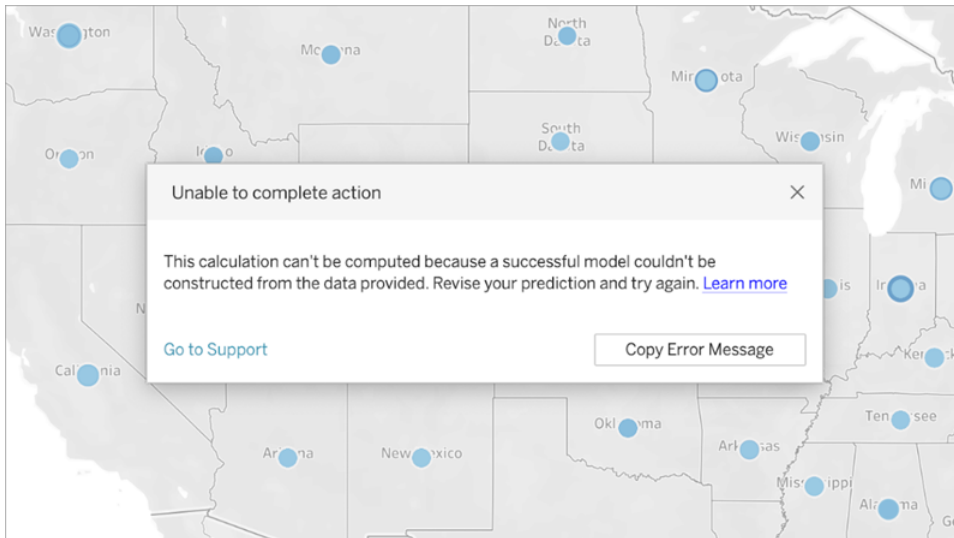

A successful model couldn't be constructed from the data provided

This error appears if there's a conflict between the predictor(s) selected, the visualised level of detail and/or the selected Compute Using dimension, such that it is impossible to use the predictors to build a rational model.

For example, let's look at this MODEL_QUANTILE calculation:

```
MODEL_QUANTILE(0.5, MEDIAN([Profit]), ATTR(MONTH([Order Date])))
```

Applying this calculation to a viz where each mark represents a **State** value will return the below error:

Since **Order Date** is not used to visualise or segment the data, the predictive modelling function can't use the predictor specified to build a model.

To resolve this:

- Update your visualisation to include the predictor as a dimension.
- Update your function to remove the non-viable predictor.

It's worth noting that this error reflects a mismatch between the visualisation and the table calculation's specific predictors. This same calculation would work without issue if applied to a visualisation that included **Order Date** as a dimension.

Gaussian process regression requires exactly one ordered dimension predictor

To use Gaussian process regression, you must include exactly one ordered dimension as a predictor. You can include additional *unordered* dimensions as predictors. Measures can't be used as predictors with Gaussian process regression.

If you encounter this error, add an ordered dimension predictor to your table calculation, remove the excess ordered dimension predictor, or specify that one of the ordered dimensions should be treated as an unordered dimension.

As Gaussian process regression is best used on time-series data, this will usually take the form of a time-based predictor such as `ATTR(DATETRUNC('month',[Order Date]))`. Any **date_part** can be used in the `DATETRUNC` expression, but the `date_part` must be at the same or higher level of detail as the viz. That is, if the viz uses `WEEK([Order Date])` as the level of aggregation,

the `date_part` must be 'week','month','quarter', etc.; it can't be 'dayofyear', 'day', 'weekday', 'hour', etc.

Note that because `ATTR(MONTH([Date]))` returns string values, it will not function as an ordered dimensional predictor unless it is manually specified. This is done by including **"ordered"** immediately before the predictor, as below:

```
MODEL_PERCENTILE (
  "model=gp",
  SUM([Sales]),
  "ordered",ATTR(MONTH([Order Date]))
)
```

If you want to include multiple time dimensions in your predictors, you must specify which ones you wish to use as unordered dimensions. This can be done by including **"unordered"** directly before that dimension, as below:

```
MODEL_PERCENTILE (
  "model=gp",
  SUM([Sales]),
  ATTR(DATETRUNC('month',[Order Date]))
  "unordered",ATTR(DATETRUNC('year',[Order Date]))
)
```

Attempting to use the above calculation without specifying **"unordered"** in front of `ATTR(DATETRUNC('year',[Order Date]))` will return an error.

Additionally, the addressing direction (or 'Compute Using') for Gaussian process regression must be set to the same field as the ordered dimension predictor.

Only one addressing direction (or 'Compute Using') can be selected for all models.

Gaussian process regression only supports dimensions as predictors

You can't use any measures as predictors in Gaussian process calculations. Remove the measure predictor.

This limitation only applies to predictive modelling functions that specify Gaussian process regression. Linear regression (or OLS, the default) and regularised linear regression functions both support measures as predictors.

There's no training data for one or more prediction targets

Gaussian process regression requires that each data partition has at least n data points in order to build a predictive model and return predictions. If you encounter this error, revise your predictions.

There are more than 5,000 marks

Gaussian process regressions are only supported on vizs with fewer than 5,000 marks. To resolve this issue, update your level of detail to decrease the number of marks, or select a different statistical model.

Integrate Einstein Discovery Predictions in Tableau

Reveal dynamic predictions from Einstein Discovery in your Tableau views and dashboards. In Tableau 2021.1 and later, you can access the power of Einstein Discovery predictions in these ways:

- Connect to the [Einstein Discovery analytics extension](#) to interact with Einstein Discovery-powered predictive models from Tableau.
- Embed predictions in a Tableau workbook by pasting generated [table calculation scripts from Einstein Discovery](#) into calculated fields in Tableau.
- Give users dynamic, on-demand predictions based on their Tableau data using the [Einstein Discovery dashboard extension](#).
- In Tableau Prep, [add Einstein Discovery prediction steps to flows](#) to enrich your flow output with predictions and, optionally, improvements and top factors.

Note: For an introduction to Einstein Discovery in Tableau, see the [Einstein Discovery in Tableau](#) page and [demo](#) on [tableau.com](#).

What is Einstein Discovery?

Einstein Discovery is an analytics tool that augments your data analysis with the power of artificial intelligence using machine learning models and comprehensive statistical analysis. Einstein Discovery quickly sifts through millions of rows of data to find important correlations, predict outcomes and suggest ways to improve those predicted outcomes.

For more information about Einstein Discovery, see [Gain Insight with Einstein Discovery](#) trail in [Trailhead](#).

Note: Einstein Discovery in Tableau is powered by salesforce.com. Consult your agreement with salesforce.com for applicable terms.

Requirements for access

To configure and use Einstein Discovery predictions in Tableau, you and anyone who will be viewing predictions in a Tableau workbook will need certain licences, access and permissions in Salesforce and Tableau.

Salesforce Requirements

Tableau integration with Einstein Discovery is supported in Tableau version 21.1 or later. Integration requires:

| requirement | description |
|--------------------------------|---|
| Salesforce licence | <p>One of the following licences:</p> <ul style="list-style-type: none"> • Einstein Discovery in Tableau licence • Tableau CRM Plus licence • Einstein Predictions licence <p>These licences are available for an extra cost.</p> |
| Salesforce user account | <p>Account that is configured to access Einstein Discovery.</p> <p>If you use the Einstein Discovery in Tableau licence, your user account must have the View Einstein Discovery Recommendations Via Connect API system permission assigned to it.</p> <p>If you use either the Tableau CRM Plus licence or Einstein Predictions licence:</p> <ul style="list-style-type: none"> • To get predictions using already deployed Einstein Discovery predictions, the account must have the View Einstein Discovery Recommendations system permission assigned to it. • To build, deploy and manage predictions in Einstein Discovery, the account must have the Manage Einstein Discovery permission assigned to it. |

| requirement | description |
|-------------------------------|---|
| | To configure user accounts, see Set Up Einstein Discovery in Salesforce help. |
| Administrator settings | <p>Salesforce administrators will need to:</p> <ul style="list-style-type: none"> • Analytics Extension: Configure Salesforce to create a connected app for Tableau Server (basic). Required for Tableau Server only. • Dashboard Extension: Add the Tableau Server or Tableau Cloud website domain to the Salesforce Cross-Origin Resource Sharing (CORS) allowlist. |

Tableau Requirements

| requirement | description |
|--|--|
| Tableau licence and permissions | <p>Authors who need to configure the Einstein Discovery dashboard extension will need a Creator or Explorer licence and permissions that allow them to edit and save workbooks.</p> <p>Creators, Explorers and Viewers will need to be signed in to the Salesforce org account to access predictions in the Einstein Discovery dashboard extension in Tableau.</p> |
| Tableau user account | In Tableau Cloud and Tableau Server, users can save Salesforce user account credentials along with their Tableau user account. |
| Administrator settings | <p>Tableau Server administrators will need to configure Tableau Server for OAuth (enables access to predictions from Tableau). For more information, see Configure Einstein Discovery Integration in Tableau Server help.</p> <p>To let users see predictions in published table calculations, Tableau Server administrators need to enable analytics extensions for the site. Analytics extension support for Einstein Discovery predictions

Einstein Discovery in Tableau brings trusted, intuitive predictions and improvements from Einstein Discovery to every Tableau user across your organisation. Workbook authors can build and share visualisations and dashboards that dynamically integrate predictions from predictive models deployed in Salesforce [Einstein Discovery](#).

Authors set up the Einstein Discovery analytics extension for use in a workbook, and then can embed Einstein Discovery-powered predictions directly in Tableau using calculated fields.

Access Einstein Discovery predictions in Tableau calculated fields

With Tableau connected to the Einstein Discovery analytics extension, you can embed predictions directly in calculated fields. In Salesforce, use Model Manager to auto-generate a Tableau table calculation script, and then paste that script into a calculated field for use in a Tableau workbook. The table calculation script accesses predictive models deployed in Salesforce by calling the prediction ID and passing the data required for the model.

You can create prediction-enhanced visualisations in Tableau Desktop, Tableau Cloud or Tableau Server, or publish them to the web.

For more details, see [Einstein Discovery on page 2650](#) in [Pass Expressions with Analytics Extensions on page 2643](#).

Einstein Discovery dashboard extension in Tableau

Integrate on-demand, interpretable predictions from Einstein Discovery in Tableau dashboards. Authors create worksheets and the dashboard, and then configure the Einstein Discovery dashboard extension to use a selected Einstein Discovery prediction definition, which uses source data available in the dashboard to derive predictions. Dashboard viewers and users can click different marks in the Tableau visualisation to explore predictions.

For more information, see [Explore Predictions in Tableau with the Einstein Discovery Dashboard Extension](#) below.

Explore Predictions in Tableau with the Einstein Discovery Dashboard Extension

Use the Einstein Discovery dashboard extension to surface real-time predictions in Tableau. The dashboard extension generates predictions interactively, on-demand, using an Einstein Discovery predictive model on source data in your Tableau workbook.

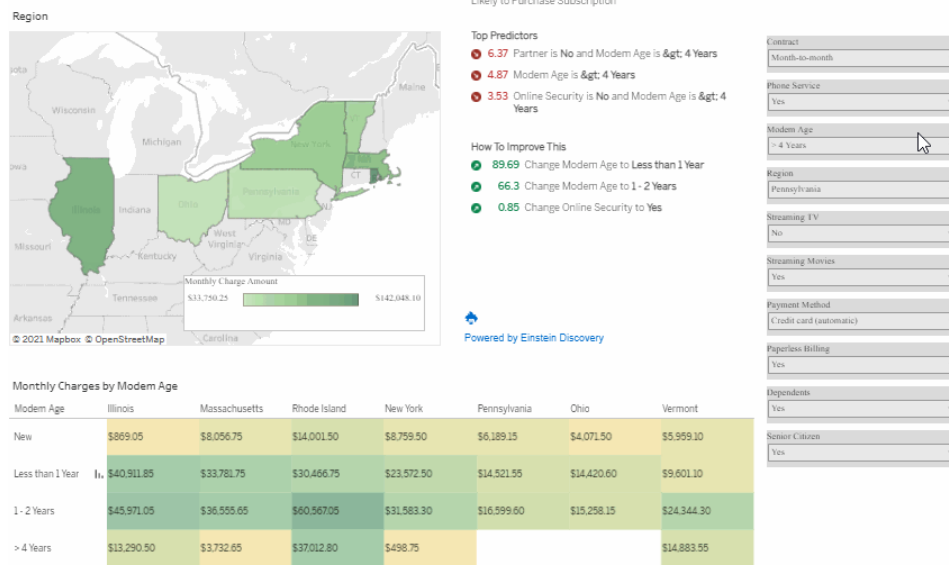

Click marks in the dashboard to see dynamic predictions, key drivers and possible ways to improve predictions based on an Einstein Discovery predictive model

Dashboard authors can configure the dashboard extension to run predictions on aggregated data in a worksheet, as demonstrated in the image above, or use parameters to let dashboard users explore "what-if" scenarios based on a single set of input values.

For information on how to add the Einstein Discovery dashboard extension, see [Add and configure the Einstein Discovery dashboard extension](#) on page 2632 in this topic. Also see [Requirements for access](#) on page 2625.

Predicted likelihood to purchase subscription

Select inputs in parameters to see how those values might affect predictions

For more information about Einstein Discovery, see [Introduction to Einstein Discovery](#), and [Enhanced Analytics with Einstein Discovery](#) in Salesforce help. You can also expand your knowledge with the [Gain Insight with Einstein Discovery](#) trail in [Trailhead](#).

Note: Einstein Discovery in Tableau is powered by [salesforce.com](#). Consult your agreement with [salesforce.com](#) for applicable terms.

Use the Einstein Discovery dashboard extension

To explore predictions in a dashboard that uses the Einstein Discovery dashboard extension, select different marks or parameter values in the view. Predictions update based on the data in your selection.

You might need to sign into the Salesforce org account that has access to the prediction definition used by the dashboard extension.

In Tableau Desktop, you will need to sign in to your Salesforce account every time you use the Einstein Discovery dashboard extension. If Salesforce signs you out of your session automatically, you may need to reload the dashboard extension (click the drop-down arrow on the Extension object and then select **Reload**).

In Tableau Cloud and Tableau Server, you should need to sign in only once if your credentials are being saved with your Tableau account settings.

For related information, see [Use Dashboard Extensions](#) in Tableau help.

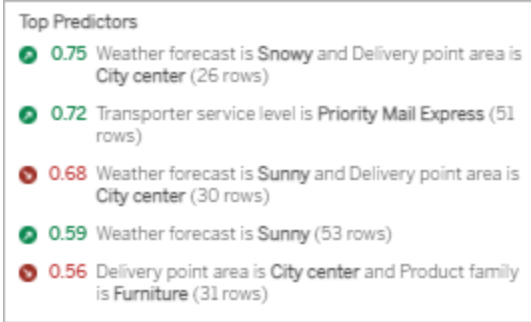

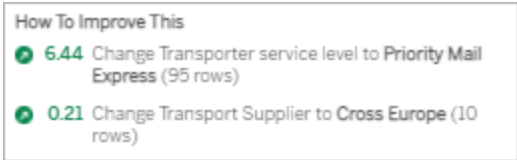

How to read Einstein Discovery predictions

The dashboard extension has three sections:

- **Prediction** – The predicted outcome
- **Top Predictors**: Conditions that affect the predicted outcome
- **How To Improve This**: Suggested actions to take to improve the predicted outcome

| Section | Description | Example |
|---|---|--|
| <p>Prediction</p> <p>The prediction reflects the goal of the use case.</p> | <p>The goal is to either maximise or minimise the outcome. For example, your goal can be to minimise shipping time or to maximise the average sales revenue per shipment.</p> | <div><div>74%</div><div>Likelihood of On-time Delivery</div><div>165 selected rows</div></div> |

| Section | Description | Example |
|--|--|---|
| <p>Top Predictors</p> <p>Conditions that most significantly affect the predicted outcome, in decreasing order of magnitude.</p> | <p>A condition is a data value associated with a field.</p> <p>A predictor consists of one or two conditions. If two conditions are shown, they are joined by <i>and</i> to represent the intersection of those conditions.</p> <p>Green (arrow up) indicates that the predictor improves the predicted outcome.</p> <p>Red (arrow down) indicates that the predictor worsens the predicted outcome.</p> |  <p>Top Predictors</p> <ul style="list-style-type: none"> 0.75 Weather forecast is Snowy and Delivery point area is City center (26 rows) 0.72 Transporter service level is Priority Mail Express (51 rows) 0.68 Weather forecast is Sunny and Delivery point area is City center (30 rows) 0.59 Weather forecast is Sunny (53 rows) 0.56 Delivery point area is City center and Product family is Furniture (31 rows) |
| <p>How To Improve This</p> <p>Suggested actions the user can take to improve the predicted outcome.</p> | <p>Improvements are associated with factors over which users can possibly control, such as the shipping method or a subscriber's membership level.</p> |  <p>How To Improve This</p> <ul style="list-style-type: none"> 6.44 Change Transporter service level to Priority Mail Express (95 rows) 0.21 Change Transport Supplier to Cross Europe (10 rows) |

Add and configure the Einstein Discovery dashboard extension

To configure and use the Einstein Discovery dashboard extension in Tableau, you will need:

- Access to a Salesforce org and Tableau Desktop, Tableau Server or Tableau Cloud.
- An Einstein Discovery prediction definition that is deployed in Salesforce.
- Source data in Tableau with fields that match the model fields required by the Einstein Discovery prediction definition.
- A worksheet in Tableau that contains the source data for the prediction.
- Additional worksheets that can be used as filters in the dashboard.
- The Einstein Discovery dashboard extension in a dashboard.

To configure and use Einstein Discovery predictions in Tableau, you and anyone who will be viewing predictions in a Tableau workbook will need certain licences, access and permissions in Salesforce and Tableau. For more information, see [Requirements for access on page 2625](#).

Prepare the model and the workbook

1. Build and deploy the Einstein Discovery prediction definition that you want to use. You can also use a prediction definition that someone else has built and deployed. For more information, see [Build, Deploy and Manage Models](#) in Salesforce help.
2. Create a Tableau workbook that uses a data source with fields that can be mapped to all model fields required by the Einstein Discovery prediction definition.
3. Create a worksheet that contains the source data for the dashboard extension.

This source data must include all of the fields required by the Einstein Discovery prediction definition to predict an outcome. Also, the source data must match the granularity that the Einstein Discovery prediction definition expects. For example, if the prediction definition expects sales per individual order, then your Tableau data must include fields at the level of detail of individual orders.

- **Worksheets** support predictions for multiple rows of data (bulk predictions). The worksheet can contain the necessary fields in the Rows or Columns shelves, or on Marks card properties. The worksheet will not be visible in the dashboard; a simple view will suffice. For example, you could create a text table.

Or a basic bar chart.

The worksheet used as source data for the model cannot exceed 50,000 rows of data. Fields in the view can't be Measure Names or Measure Values.

- **Parameters** support single-row predictions. To set up the worksheet, show the parameters in the view. You don't need to add fields to the view for this worksheet. For example:

4. Create one or more worksheets with visualisations that you can set to **Use as Filter** in the dashboard.

The visualisation can use a subset of the fields used by the model. Clicking marks in these views in the dashboard will refresh the predictions in the dashboard extension.

5. Create the dashboard. In the **Objects** section, click **Floating**. From the **Sheets** section, drag the source data worksheet to the canvas. Resize and hide that sheet so users won't see it in the dashboard. Also drag one or more sheets to the canvas to serve as filters in the dashboard.

In the Sheet object menu, set at least one worksheet with a visualisation to **Use as Filter**.

Configure the extension

1. From the **Objects** section, select **Floating** and then drag the **Extension** object to the dashboard canvas. In the Tableau Exchange, select **Einstein Discovery**.

Sign in to your Salesforce account. After you sign in, a web page opens asking if you want to allow your Salesforce account to access Tableau. Click **Allow** to continue, and then close the resulting tab in your browser.

On Tableau Desktop, you will need to sign in to your Salesforce account every time you use the Einstein Discovery dashboard extension. If Salesforce signs you out of your session automatically, you may need to reload the dashboard extension (click the drop-down arrow on the Extension object and then select **Reload**). This time-out setting is configurable. For more information, see [Edit Session Settings in Profiles](#) in Salesforce help.

In Tableau Cloud and Tableau Server, you should need to sign in only once if your credentials are being saved with your Tableau account settings.

2. Configure the dashboard extension.

For **Prediction Definition**, click *Search Predictions* and then select the name of a prediction model deployed in Salesforce.

Select **Worksheet** or **Parameters** to be the source data for the predictions. Worksheet provides predictions based on a selected mark with aggregated values. Parameters supports interactive, “what if” predictive analysis on a single set of input values.

For **Worksheet**, click **Select an Option**, and then select the name of the worksheet with the source data. For **Parameters**, no other setting is needed.

Select the prediction definition

Prediction Definition (Required)

Maximize On Time Delivery X

Where is the data to use for making predictions?

☒ Worksheet

☒ Show prediction warnings ⓘ

Back Done

Prediction Label: Click the field and type a label that represents the outcome that you

are predicting, for example, *Likelihood of On Time Delivery*. The deployed model name is displayed by default.

Prediction Score Unit: Type a symbol or text that indicates the unit for the prediction score. For example, %. If the unit should be displayed before the score, select **Unit precedes score**. For example, a currency symbol (such as \$) would precede a currency amount.

Aggregation: Specify how you want to aggregate the selected records (**Average**, **Median** or **Sum**) in the source data worksheet. Tableau aggregates your selected data into a single set of values, which it submits to the Einstein Discovery prediction definition as input. The granularity must match the granularity expected for the model.

Top predictors: Specify whether to display top predictors that impact the prediction. You can also specify the number of top predictors displayed, and whether the impact values are displayed next to each predictor.

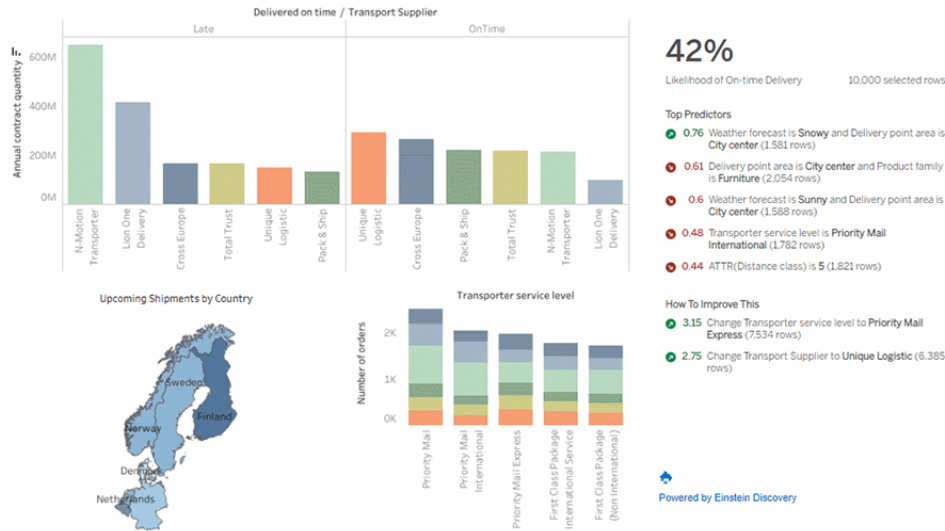

Top improvements: Specify whether to display information on ways to improve the probability of the predicted outcome. You can also specify the number of improvements displayed, and whether the impact values are displayed next to each improvement. For **Improvement threshold percentage**, specify a percentage number (0-99) to display improvements only if they improve the prediction by that percentage.

Show prediction warnings: Specify whether to show warnings about the predictive model, such as missing values in required fields or out-of-bounds values.

Consider showing everything to start with and then fine tuning what you end up sharing with your dashboard audience.

5. Click **Done**. Tableau submits the data immediately to the target Einstein Discovery prediction definition, and then displays the result.
6. In the dashboard, make sure at least one worksheet is set to **Use as Filter**. Every worksheet in the dashboard that is set to **Use as Filter** will drive the extension to update the predictions based on the current selection.

Test your dashboard by clicking and selecting different marks and areas in the dashboard (or by selecting different parameter values) to see what outcome Einstein Discovery predicts for that subset of the data.

Save the workbook in Tableau Cloud or Tableau Server. Or, publish the dashboard from Tableau Desktop to your Tableau Cloud or Tableau Server site to share it with more people. Explorers and Viewers with access to the same Salesforce org and an Einstein Discovery in Tableau licence, a Tableau CRM Plus licence, or an Einstein Predictions licence will be able to use the extension.

Troubleshoot field mapping

If a field you are expecting to use is not in the list of available fields, you might need to check the data type for the field in Tableau.

Einstein Discovery and Tableau do not always recognise dimensions, measures and data types in the same way, so you might have to change the data type and role (dimension or measure) in the Data pane of the worksheet to match how Einstein Discovery interprets the field.

1. Close the **Extension: Einstein Discovery** window.
2. Go to the source data worksheet. In the Data pane, change the data type and role of a problematic field in Tableau to match the Einstein Discovery field data type and role in the mapping settings. After you change the data type or role, you will need to replace incorrect fields in the view with the updated fields from the Data pane.
3. In the dashboard, click the drop-down menu for the extension, and then select **Configure**. Proceed to the field mapping settings and select the fields from the list.
4. If you still don't see the fields you expect in the list, go back to the source data worksheet. Remove the fields that are missing for mapping from the Marks card, or the Rows, or Columns shelves.

Next, drag the missing fields from the Data pane to Tooltip on the Marks card.

5. Repeat Step 3 to select the fields for mapping.

Pass Expressions with Analytics Extensions

Beginning with version 2021.2, you can create multiple analytics extensions connections for any site. Versions prior to 2021.2 are limited to a single analytics extension for any site.

After you create a connection to an analytic extension, you can communicate with your external service through calculated fields. Each calculated field uses the [SCRIPT functions for expressions on page 2645](#), operating as a table calculation.

Configure an analytics extension

Tableau allows connections to analytics extensions via a set of SCRIPT functions. Before you can pass any SCRIPT functions to your analytics extension, you need to configure your connection to the service.

1. In Tableau Desktop, click the **Help** menu, and then select **Settings and Performance > Manage Analytics Extension Connection**. Select the analytics extension you want to connect to. **MATLAB** connections are managed by the Analytics Extension API.

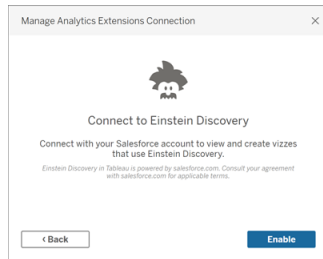

2. Select and configure your analytics service.

If you are using **Einstein Discovery**, select Enable. Your default browser will open, allowing you to authorise the connection to Salesforce. After connecting, go to the [Einstein Discovery on page 2650](#) section of

For all other services (Tabpy, Matlab and RServe), the following dialog will appear.

this help topic to continue.

3. Enter or select a server name using a domain or an IP address.

If your server is using SSL encryption, select the **Require SSL** option. Tableau will read certificates installed in the operating system key store to establish the secured connection.

Note: Tableau only supports **PEM** encoded certificates when connecting to **TabPy** or **RServe**.

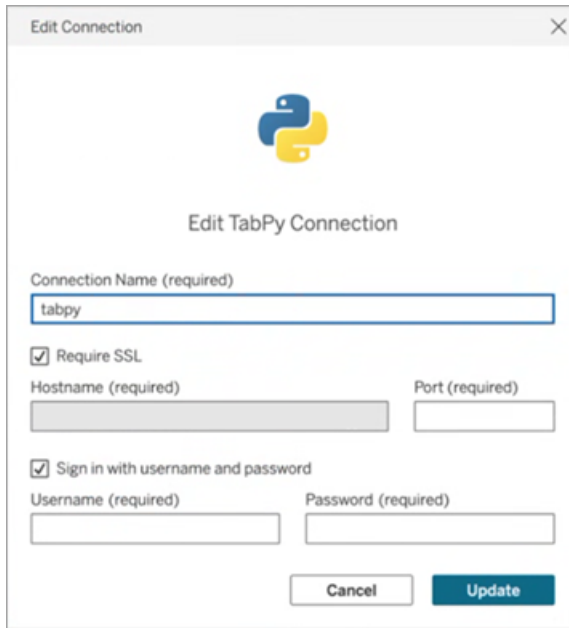

4. Specify a port.
 - Port 6311 is the default port for plaintext RServe servers.
 - Port 4912 is the default port for SSL-encrypted RServe servers.
 - Port 9004 is the default port for TabPy.
5. Click **Test Connection**.
6. Click **Save**.

If no connection can be established, an error message is displayed. Click **Show Details** in the message to see any diagnostic information returned by the server.

Configure Analytics Extensions in Web Authoring

When using Tableau Cloud web authoring, select **Analysis > Analytics Extension > Manage Connection....**

Select which type of connection you want to make, then fill in the required connection information.

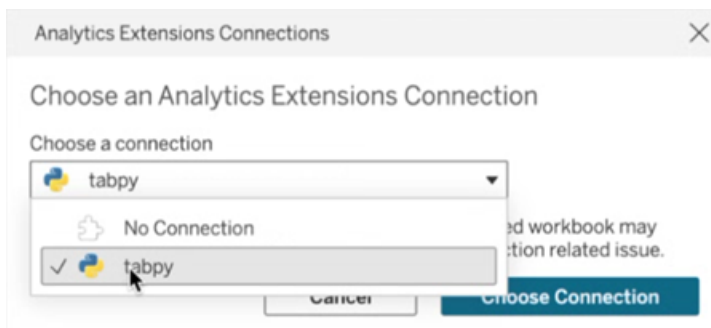

The "Edit Connection" dialog box for TabPy. It features the Python logo at the top. Below it, the title "Edit TabPy Connection" is centered. The form includes a "Connection Name (required)" field with "tabpy" entered. There are two checkboxes: "Require SSL" (checked) and "Sign in with username and password" (checked). Below these are fields for "Hostname (required)", "Port (required)", "Username (required)", and "Password (required)". At the bottom are "Cancel" and "Update" buttons.

- For Tableau Server, see "Configure Connection with Analytics Extension" ([Windows](#) | [Linux](#)).

Use Analytics Extensions in Web Authoring

To use an analytics extension, select **Analysis > Analytics Extension > Custom Functions Explorer...** then choose the analytics extension you want to use for the workbook. Only one analytics extension can be used per workbook.

The "Analytics Extensions Connections" dialog box. It has the title "Choose an Analytics Extensions Connection". Below it is a section "Choose a connection" with a dropdown menu showing "tabpy". Below the dropdown is a list of connections: "No Connection" and "tabpy" (which is selected with a checkmark). At the bottom are "Cancel" and "Choose Connection" buttons. A partial message on the right says "ed workbook may" and "tion related issue."

SCRIPT functions for expressions

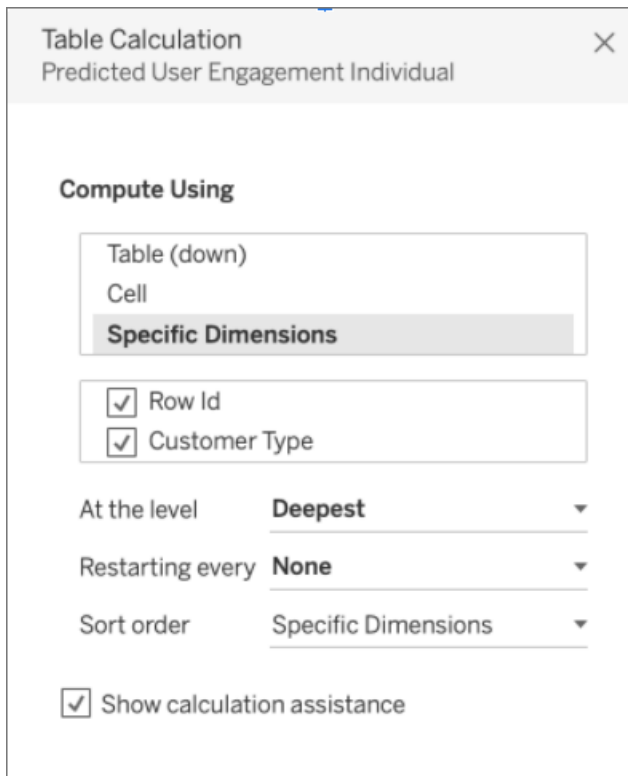

A series of four SCRIPT functions are available for passing expressions to analytics extensions and obtaining a result. The functions are:

- `SCRIPT_BOOL`
- `SCRIPT_INT`
- `SCRIPT_REAL`
- `SCRIPT_STR`

See [SCRIPT_ functions on page 2147](#) for details and examples.

Because connecting to an analytics extension involves some network overhead, it is often most efficient to pass data all at once rather than as individual row values whenever possible. For example if you set addressing to **Cell** (for example, by clicking the field in the view and choosing **Compute Along > Cell**), Tableau will make a separate call per row (created by each mark in the visualisation) to the analytics extension. Depending on the size of the data, this can result in a very large number of individual calls.

The easiest way to ensure efficient calls are made to the analytics extension is to navigate to **Edit Table Calculation** and select **Specific Dimensions** then check the box next to each dimension to put that dimension on addressing. This will generate a single analytics extension call for the entire visualisation. Any dimension left unticked will be partitioned on, generating a separate call for each member in the visualisation. If there are many marks in the visualisation, it may be advantageous to select **Pause Auto Updates** while selecting dimensions to prevent frequent runs of the calculation before it is properly computed.

Directly query external analytics models

A series of four functions can directly query a deployed model in your analytics extension. This can keep you from having to write lengthy calculations into a script function. Collectively, these are known as the `MODEL_EXTENSION` functions, and just like the above-mentioned Script functions, there are four iterations:

- `MODEL_EXTENSION_BOOL`
- `MODEL_EXTENSION_INT`
- `MODEL_EXTENSION_REAL`
- `MODEL_EXTENSION_STR`

The four functions differ only by what values they return. A `MODEL_EXTENSION_BOOL` function returns a Boolean value, for example. In order to use the `MODEL_EXTENSION` functions, you need to have a deployed model in your external analytics service, and the external analytics service must allow for direct queries of that model.

Note: Currently, only **TabPy** models support `MODEL_EXTENSION` functions.

Parts of the MODEL_EXTENSION function

- A.** The model you are invoking. The model name must match the deployed model.
- B.** The model's inputs. Talk to your administrator to learn what inputs are expected by the model you are using.
- C.** The values passed from Tableau to the model.

See [Table Calculation Functions on page 2137](#) for details and examples.

Because these SCRIPT functions are table calculations, addressing and partitioning concepts apply. (For an explanation of these concepts, see [The basics: addressing and partitioning on page 2356](#).) Tableau makes one call to an the analytics extension per partition. This means that for each dimension the calculation is partitioning on, one call will be made for every member of that dimension present in the visualisation. For this reason, it is recommended to put dimensions on addressing unless partitioning is necessary.

TabPy

Python is a widely used high-level programming language for general-purpose programming. By sending Python commands to an analytics extension, you can do things like predicting customer churn or running sentiment analysis.

Tableau Python Server (TabPy) is part of Tableau's expanding range of extensibility options. To install TabPy, visit this [GitHub page](#). To read more about the possibilities of Python in Tableau, see [Building advanced-analytics applications with TabPy](#).

Custom Functions Explorer for deployed models

Deployed models can contain schema information that includes a description, the type of arguments they take, what their output is and similar documentation. The Custom Function Explorer can read that schema and provide point-in-time documentation for those using the model.

For example, a deployed model `translateToEnglish` may look like this:

```
"translateToEnglish": {
  "description": "Translates a given input to English",
  "type": "model",
  "version": 2,
  "dependencies": [],
  "target": null,
  "creation_time": 1726765000,
  "last_modified_time": 1726777904,
  "schema": "{\n    'input': {\n      'type': 'object',\n      'properties': {\n        'phrase': {\n          'type': 'string',\n          'description': 'phrase which we would like to translate'\n        },\n        'required': ['phrase'],\n        'sample': {\n          'phrase': 'Danke'\n        },\n        'output': {\n          'type': 'string',\n          'description': 'translated phrase'\n        }\n      }\n    }\n  }",
  "is_public": true
```

The Custom Functions Explorer displays that information and shows the user exactly what the model is for and what needs to be updated to bring in their data.

Use the Custom Functions Explorer

You may need to perform some or all of these steps, depending on your current configuration:

1. Deploy a TabPy server. See the [TabPy documentation on GitHub](#) for details.
 - **Note:** Custom functions explorer requires TabPy version 2.12.2 or later. To update your TabPy version, refer to the [GitHub documentation](#).
2. Start a TabPy server with a deployed model.
3. In Tableau, turn on the Analytics Extension Connection.
 - In Tableau Desktop: **Help** menu > **Settings and Performance** > **Manage Analytics Extension Connection...**
 - On the web: **Analysis** menu > **Analytics Extensions** > **Custom Functions Explorer**
4. Enter the **Hostname** and **Port**.

Once you're in a workbook with a data connection and Analytics Extensions connected to a running TabPy instance, you can use the Custom Functions Explorer:

1. On a worksheet with the data source already connected, go to the **Analysis** menu > **Analytics Extension Custom Functions Explorer** (on the web, **Analysis** > **Analytics Extensions** > **Custom Functions Explorer...**).
2. Select the one you want and click the **Copy to Clipboard** button.
 - Only models with the parameter `is_public=True` appear in the list. This parameter is False by default. Models where `is_public=False` is still available to use as model extension calculations just don't appear in the Custom Functions Explorer.
 - If the Custom Functions Explorer appears empty or is missing a deployed model you want to use, verify `is_public` is set to True for the deployed model. See the [TabPy documentation on GitHub](#) for details.
 - If a deployed model doesn't have a schema, the Custom Functions Explorer is less useful but still has the **Copy to Clipboard** option.
3. Create a new calculation and, for the function, paste in the syntax copied to clipboard.
4. Replace any **InputField** placeholder with the field in your data source you'd like to use in the model.
 - Note that as for all table calcs, you'll need to aggregate the input. For strings, MIN, MAX and ATTR are possible aggregations.

Einstein Discovery

Einstein Discovery is a powerful analytics tool in Salesforce that makes use of machine learning to provide insights and predictions. Einstein Discovery requires the Einstein Analytics Plus licence, Tableau CRM Plus licence, or the Einstein Predictions licence, which are available for an extra cost. For related information, see [Requirements for access on page 2625](#).

For more information about Einstein Discovery, see [Getting Started with Discovery](#), and [Explain, Predict and Take Action with Einstein Discovery](#) in Salesforce help. You can also expand your knowledge with the [Gain Insight with Einstein Discovery](#) trail in [Trailhead](#).

Note: Einstein Discovery in Tableau is powered by [salesforce.com](#). Consult your agreement with [salesforce.com](#) for applicable terms.

Integrate Einstein Discovery models into Tableau

With Tableau connected to the Einstein Discovery analytics extension, you can embed predictions directly in calculated fields and Tableau Table Extensions. In Salesforce, use Model Manager to auto-generate a Tableau table calculation script, and then paste that script into a calculated field for use in a Tableau workbook. The table calculation script accesses predictive models deployed in Salesforce by calling the prediction ID and passing the data required for the model.

Note: You can optionally include additional parameters in the script that has been generated by Model Manager for use with table calculations or Tableau Table Extensions. For more information, see [Add optional parameters to the script generated by Model Manager on page 2653](#).

Embed a prediction in a calculation

1. Open your Einstein Discovery Salesforce account and navigate to the Model Manager. Select a model to integrate into Tableau. On the model tab, select **Edit Settings > Create Tableau Table Calculation**.

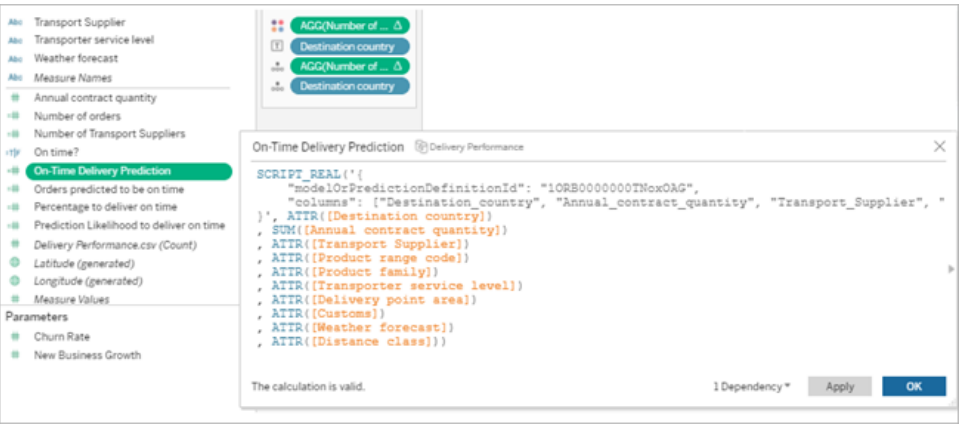

Model Manager generates a script containing the ID of the prediction definition you want to use, the fields (variables) used in the model, and the corresponding source fields in Tableau.

2. Click **Copy to Clipboard**.
3. In a Tableau workbook, select **Analysis > Create Calculated Field**, and then paste the generated script in the Calculation Editor.

Replace the fields names inside each ATTR or SUM function with the name of the matching field in your Tableau data, then save the calculated field.

The calculation can be used just like any other Tableau calculation. For more information, see [SCRIPT functions for expressions](#) on page 2645 below.

When the script runs, it sends a prediction request (with the input data) to the prediction definition in Salesforce. Einstein Discovery returns the results to Tableau, where it appears in your worksheet or dashboard.

Embed a prediction in a Tableau Table Extension

The script generated by Model Manager can also be used to create a Tableau Table Extension. To use a script generated by Model Manager for a table extension, remove the SCRIPT_REAL portion of the script and include only the request body that is contained in the curly brackets.

Add optional parameters to the script generated by Model Manager

You can optionally include additional parameters in the script that has been generated by Model Manager. These parameters are completely optional; the script will work with or without them. These optional parameters can be used with either a calculated field or with a table extension.

| Optional Parameters | Syntax | Description |
|---------------------|----------------------------|--|
| maxMiddleValues | "maxMiddleValues": integer | Specifies the number of top predictors to return in the response. Set to an |

| Optional Parameters | Syntax | Description |
|-----------------------------|---|--|
| | | integer number. Can only be used with Regression and Binary Classification Models. |
| maxPrescriptions | <code>"maxPrescriptions": integer</code> | Specifies the maximum number of improvements to return in the response. Set to an integer number. Can only be used with Regression and Binary Classification Models. |
| showMultiClassProbabilities | <code>"showMultiClassProbabilities": boolean</code> | Choose whether to show the probabilities for a Multi-class Classification Model. Set to true or false. Can be only be used with Multi- |

| Optional Parameters | Syntax | Description |
|---------------------|--------|----------------|
| | | class |
| | | Classification |
| | | Models. |

The following example script shows how you might use these optional parameters in a script for a calculated field.

```
SCRIPT_REAL(  
  '{ "modelOrPredictionDefinitionId": "1ORB0000000HC3KOAW",  
    "columns": ["Postal_Code", "City", "Ship_Mode", "Row_ID", "Profit",  
    "Category", "Sub_Category", "Order_Date",  
      "Quantity", "Ship_Date", "Region", "Sales", "State", "Segment"],  
    "maxMiddleValues": 3,  
    "maxPrescriptions": 5,  
    "showMultiClassProbabilities": false }',  
  SUM([Postal Code]), ATTR([City]), ATTR([Ship Mode]), SUM([Row ID]),  
  SUM([Profit]), ATTR([Category]), ATTR([Sub-Category]),  
    ATTR([Order Date]), SUM([Quantity]), ATTR([Ship Date]), ATTR  
  ([Region]), SUM([Sales]), ATTR([State]), ATTR([Segment])  
)
```

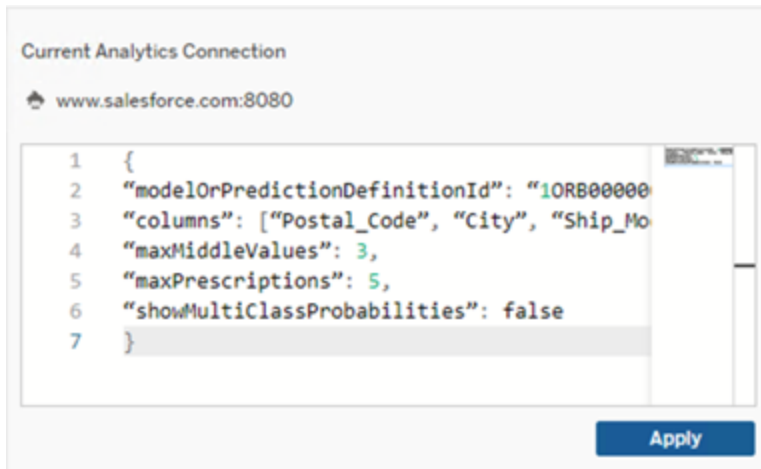

The next example shows use of this script with a table extension. For a table extension, include only the script in the curly brackets. Don't include the SCRIPT_REAL function and attributes outside of the curly brackets.

```
{  
  "modelOrPredictionDefinitionId": "1ORB0000000HC3KOAW",
```

```

"columns": ["Postal_Code", "City", "Ship_Mode", "Row_ID", "Profit",
"Category", "Sub_Category", "Order_Date",
    "Quantity", "Ship_Date", "Region", "Sales", "State", "Segment"],
"maxMiddleValues": 3,
"maxPrescriptions": 5,
"showMultiClassProbabilities": false
}

```

RServe

R is an open source software programming language and a software environment for statistical computing and graphics.

Implementing RServe connections

Tableau Desktop can connect to R via either plaintext or SSL-encrypted traffic. For direction on which type to use, consult your system administrator.

Note: For R integration, Tableau has been tested with R versions 3.4.4 through 3.5.1, and with RServe versions 0.6-8 through 1.7.3.

Intermediate certificate chain for RServe analytics extension

Note: Users don't have to use Tableau Server to connect Tableau Desktop to RServe.

You must install a full certificate chain on Tableau Desktop computers (Windows and Mac) that are connecting to a Rserve external connection through Tableau Server. This requirement is due to how Rserve manages the handshake on secure connections.

Importing a root certificate on the Tableau Desktop is not sufficient, the entire certificate chain must be imported onto the client computer.

MATLAB

MATLAB is a high-level language that connects through the **Analytics Extension API** that enables you to perform computationally intensive tasks faster than with traditional programming languages such as C, C++ and Fortran. You can use MATLAB in a wide range of applications, including signal and image processing, communications, control design, test and measurement, financial modeling and analysis, and computational biology. For information on how to configure your MATLAB server to work with Tableau please contact [MATLAB support](#).

To read more about the possibilities of MATLAB in Tableau, see [Put your MATLAB models and algorithms to work in Tableau](#).

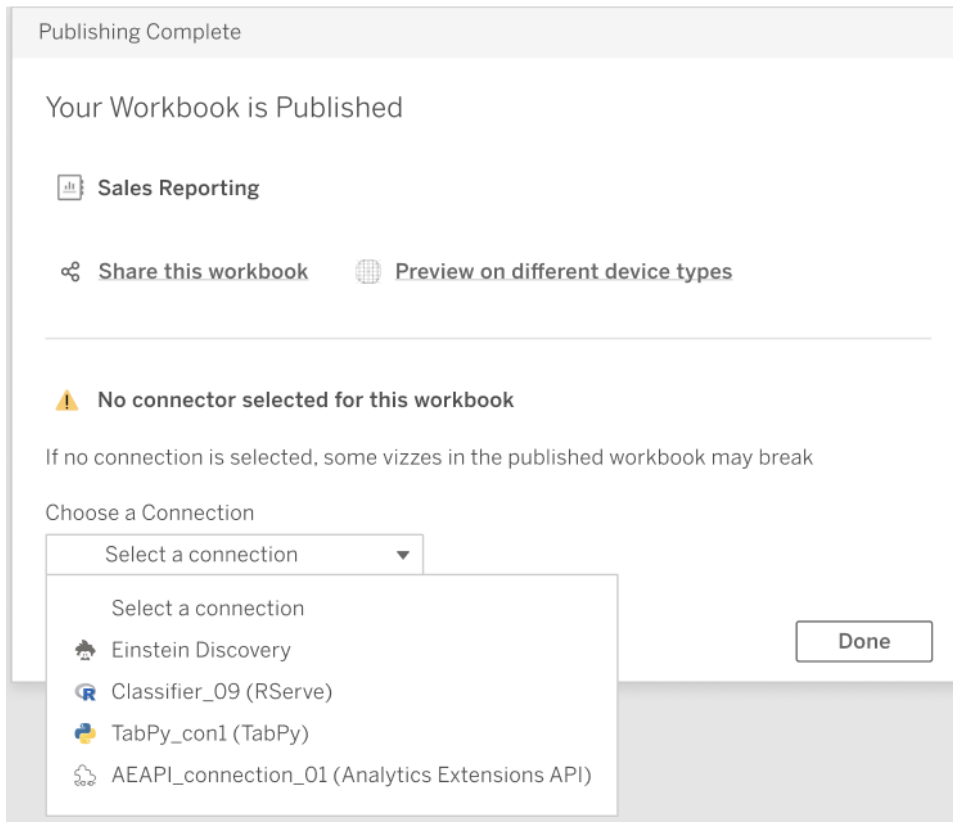

Share a workbook that requires an analytics extension connection

You might need to send a workbook that contains analytics extension functionality to other users, who may be using different copies of Tableau Desktop on other computers. Or, users may download a workbook from Tableau Server that contains analytics extension functionality. If you share your workbook with someone, they must configure analytics extension connections on their computers.

Publish a workbook that requires an analytics extension connection

- For Tableau Server, see "Configure Connection with Analytics Extension" ([Windows](#) | [Linux](#)).

Upon successfully publishing, you must select which of the configured analytics extensions to associate with the workbook.

Troubleshooting Analytics Extensions Connections

This topic describes errors you can receive when Tableau is connected to an external analytics extension service.

Note: Tableau technical support cannot assist with writing, troubleshooting, or debugging external scripts.

Errors that can occur when communicating with any analytics extension

| Error Message | Comments |
|--|--|
| Unsupported type passed as an argument to SCRIPT func- | <p>Tableau can only export the following Tableau data types to R:</p> <ul style="list-style-type: none"> Number (Decimal) |

| | |
|---|---|
| tion. | <ul style="list-style-type: none"> • Number (Whole) • Boolean • String • Date • Date/Time |
| Unexpected number of results returned by SCRIPT function. Function expected %2 values; %1 values were returned. | The script result must be either a scalar or vector of length one that is replicated for all rows, or a vector of length equal to the number of rows in the Tableau result table. |
| Certificate file is not valid for the specified connection (%1 %2:%3). Check that the same certificate is used for both server and client, the certificate file is not corrupted and has valid dates. | Verify that the certificate you are using to connect to the external service is encoded and formatted correctly. You must connect with a valid PEM-encoded x509 certificate with the extension .crt. |
| The result returned by the SCRIPT function is of an unexpected type. | <p>Occurs when an invalid data type is received. Tableau can only import the following data types from an Rserve server:</p> <ul style="list-style-type: none"> • RDouble • RInteger • RLogical • RCharacter <p>For TabPy, Tableau can import the following data types:</p> |

| | |
|---|---|
| | <ul style="list-style-type: none"> • List of floating point numbers • List of integers • List of Boolean operators • List of strings <p>This error is also reported if the result is null or if there was a script execution error for which Tableau could not collect an explanation from the external server.</p> |
| An error occurred while communicating with the external service. | Tableau runs all external scripts inside of the "try" external function. This error is displayed along with an external-service-generated error message when the "try" function traps an evaluation error. |
| This external service connection does not support authentication. Try connecting without specifying a password. | |
| Authentication failed. Please provide a valid external service username and password. | |
| An unsupported authentication type is enabled in the external service. | Either disable external service authentication or change to plaintext password authentication. |
| No external service connection con- | See Pass Expressions with Analytics Extensions on page 2643. |

| | |
|---|---|
| figured. Specify a server name and try again. | |
| The calculation '%1' contains a SCRIPT_ function that requires an internal service connection. Configure your external service connection to enable custom scripts. | See Pass Expressions with Analytics Extensions on page 2643 . |
| The workbook you are attempting to publish contains SCRIPT_ functions that require an external service connection. Custom scripts are not allowed in public workbooks. | You cannot publish workbooks containing external service scripts to Tableau Public. |
| Tableau Public does not support running custom scripts that require external services. To take advantage of external services, upgrade to Tableau Desktop Professional Edition. | The "Tableau Public" in this error refers to Tableau Desktop Public. |

| | |
|---|--|
| Tableau Reader does not support running custom scripts that require external services. To take advantage of external services, upgrade to Tableau Desktop Professional Edition. | You cannot view workbooks containing external service scripts in Tableau Reader. |
|---|--|

Errors that can occur only with an Rserve Server

| Error Message | Comments |
|---|---|
| Unrecognised Rserve signature. | The Rserve header signature must be "Rsrv". |
| Unrecognised Rserve version. | The Rserve header version must be "0103". |
| Unrecognised Rserve protocol. | The Rserve header protocol must be "QAP1". |
| Authentication failure when connecting to R. | Tableau attempted and failed to authenticate with Rserve. Verify that you entered a valid password. |
| Incorrect number of bytes in parameter/body. | |
| The length of data which Tableau read does not equal the length promised by | |

| | |
|--|---|
| the header. | |
| Unrecognised response type. | The transport protocol type when reading a result was not SEXP as expected. |
| Excessively long <type>vector. | Unreasonably large number measuring the length of data sent to or from Rserve possibly indicating a corrupt protocol header. |
| Invalid Rserve command. | Tableau may have improperly implemented the Rserve protocol. |
| Response from server was Error " << (uint32_t)status << ". See Rsrv.h for details. | Various error conditions are documented in the comments in Rsrv.h. |
| Excessively long header offset. | This may be due to a garbled header with an unreasonable offset to response data. |
| Rserve socket failed. | A login, script evaluation, read pending check, result read, or Tableau field to R script argument assignment threw a non-standard exception. |
| The external service uses an unsupported authentication type. | To support running both SSL-enabled and plaintext connections to an Rserve instance, the Rserve Server administrator must add the following entry to the Rserve configuration file on the Rserve Server: <code>plaintext enable</code> |
| A crypto-system error has occurred on RServe. | An error has occurred with RServe's encryption system. Check the RServe logs for more details. |
| RServe has initiated closing due to a security violation. | RServe closed the connection due to a security violation. Check the RServe logs for more details. |

| | |
|--|---|
| The External Service Configuration is set for a secure connection but missing a certificate. | When establishing a secure connection to an External Service, you are required to upload the certificate with which you expect this External Service to be signed. Connections to servers that are not signed by this certificate will be refused. This ensures that you are only sending your data to trusted servers. |
| Certificate file is not valid for the specified connection (%1 %2:%3). Check that the same certificate is used for both server and client, the certificate file is not corrupted and has valid dates | The certificate provided is not valid for this connection configuration. Check to see that it matches the certificate signing the External Service server, that it is PEM encoded, and that it is valid for today's date. |
| External service connection certificate is invalid | The certificate provided is invalid. Check to see that the certificate is PEM encoded, and that it is valid for today's date. |
| External service connection failed to create SSL/TLS context | Tableau failed to initialise a secure environment for this given External Service configuration. Check to see that the host and port are correct, and that the certificate is valid. |
| External service failed to connect with SSL/TLS | Tableau failed to establish a secure connection to the External Service. Verify that the External Service is configured to support secure connection, and that the certificate provided matches the one signing the External Service. |
| External service server protocol is unrecognised | A protocol was prepended to the host that is not recognised or supported by Tableau. If connecting to RServe, no protocol is expected. If connecting to TabPy, the HTTP protocol is expected when establishing a plaintext connection, and the HTTPS protocol is expected when establishing a secure connection. |

Other issues

SCRIPT functions run even in logical statements that evaluate as false

A function that sends an expression to a running external service instance will be executed even when it is within a logical statement that would otherwise prevent it from being executed. This is true for logical functions such as IF, IIF, and CASE. For example:

```
IF 1==0 THEN
  [[R script code]]
ELSE
  "1 does not equal 0"
END
```

Integrate External Actions

Note: External Actions in Tableau rely on functionality provided by Salesforce Flow. The feature sends your selected data to Salesforce Flow, which runs on separate Salesforce infrastructure. Use of Salesforce Flow and other Salesforce products and services is subject to your agreement with Salesforce.

After seeing and understanding your data in Tableau, what's next? Typically, taking action from data insights involves pivoting from one application to another, often copying and pasting data and losing context along the way. With the Tableau External Actions feature, you can create and interact with data-driven workflows directly from Tableau dashboards and automate your next steps using Salesforce Flow.

About Salesforce Flow

If you're not familiar with [Salesforce Flow](#), it's a no-code tool that provides time-saving process automations. A flow is a component of Salesforce Flow that collects data and performs actions in your Salesforce org. There are several [flow types available in Salesforce Flow](#), but External Actions workflows in Tableau are only compatible with auto-launched flows.

Note: To learn more about flows, check out [Build Flows with Flow Builder](#) on Trailhead.

How External Actions work

When an External Actions workflow is configured for a viz on a Tableau dashboard, a customised button appears on the corresponding viz in an unavailable (greyed out) state. When you select a relevant mark on the viz (1), the button becomes available. Then, when you click the button (2), data from the selected mark is sent directly to a flow that was built and configured in [Salesforce Flow](#) (3).

As the author of an External Actions workflow, you determine:

- Which flow the data is sent to
- Which dashboard the data comes from
- The text and appearance of the dashboard button that triggers the workflow

Note: You can add multiple External Actions workflows to a dashboard, but each of the corresponding flows must be deployed in the same Salesforce org.

Ways to use External Actions workflows

There are endless ways to use External Actions workflows to automate existing processes in your organisation. For example, think of the effort saved by a workflow that lets accounting team members send customer invoices directly from the same dashboard they use to track unpaid orders. Or maybe you're looking for ways to streamline your support team's case management. A workflow that lets support team members escalate cases directly from the dashboard they use to track cases could be a significant time-saver. External Actions workflows help keep users in the flow of work, and enables your organisation to benefit from increased efficiencies.

When you create an External Actions workflow, you're essentially building a bridge that connects any type of data source in Tableau with a flow at Salesforce. Your data source doesn't need to be connected to a Salesforce database because the workflow itself creates that connection. This is particularly useful when there are multiple groups using separate data sources to complete different steps of the same process.

For example, think about the different teams and tools involved when a customer places an order on an e-commerce site. E-commerce sales reps might use Salesforce to track the sale while supply chain managers use a supply chain management tool to deduct the purchased item from overall product inventory. Support teams that help the customer troubleshoot any issues that arise when they receive their product might be logged in Salesforce or analysed in a Tableau dashboard. With an External Actions workflow, you can connect all of this data from each of these teams to streamline processes and even automate some of the existing steps.

Best practices for External Actions workflow authors

Important: Dashboard authors using the External Actions feature to connect dashboard data with flows built in Salesforce Flow should closely collaborate with the Salesforce admins and architects who created the flows.

Flows built in Salesforce Flow are sophisticated business automation programs. Although your organisation can greatly benefit from these automations, it's important to understand how flows work before deploying External Actions workflows that use them. Be sure to complete the [Salesforce Flow training on Trailhead](#) and review the [Flows documentation](#). Consider [Flow Best Practices](#) in your design, and keep [Flow Limits and Considerations](#) in mind.

Note: There are several [flow types](#) available in Salesforce Flow, but External Actions workflows are only compatible with auto-launched flows.

External Actions workflows must be carefully implemented to align with the architectural constraints of flows built in Salesforce Flow. Flows are powerful, but they can also be resource-intensive and complex. There are potential licensing, execution throttling and concurrency issues to consider, and database read/write limits that must be evaluated and tested.

There are also important security considerations related to flows. Users with the Manage Flows permission can view and change all data and resources in the corresponding Salesforce org. Users with the Run Flows permission can run nearly any active flow in the Salesforce org. To restrict access to only those users who require it (such as dashboard authors and workflow users), your Salesforce admin can enable the override default behaviour setting for a flow. For more information, see [How Does Flow Security Work?](#)

Dashboard authors who are creating External Actions workflows should communicate with their Salesforce admins before implementing workflows to prevent undesired results.

Create a workflow

Before creating an External Actions workflow, dashboard authors should collaborate with their Salesforce admins to find or create a flow that meets their needs. For example, perhaps your goal is to help your accounting team send invoices directly from an unpaid orders dashboard. To accomplish this goal, you need a flow that can retrieve the customer contact information and order details from the dashboard and populate the invoices.

After you decide which flow to use, the next step is identifying a dashboard to connect it to. It's likely that your users are already interacting with an existing dashboard that would work well. However, if necessary, you can [create a new dashboard](#).

With the right flow and the right dashboard in mind, it's time to think about the compatibility of the data types in the dashboard with the flow's required input fields (known as variables). For example, your unpaid orders dashboard must contain a viz with all of the relevant order details needed to send customer invoices. These details might include information such as order date, customer name and contact information, item descriptions and amounts, and payment amount due.

When your dashboard contains all of the required components, add the Workflow object:

1. In a Tableau workbook, open an existing dashboard or [create a new one](#).
2. From the **Objects** section of the **Dashboard** pane, drag **Workflow** to a viz in the dashboard.

3. When prompted, enter your log-in credentials for the Salesforce org associated with your flow.

Note: When users access the dashboard where you set up your workflow, they must enter their Salesforce credentials. If their Salesforce credentials expire while viewing the dashboard, they're prompted to reauthenticate.

4. Click **Configure Workflow**.
5. In the **Add Workflow** dialog, search for a flow by flow name or flow author.
6. Select a flow to view its details, including the required inputs (Salesforce variables) it needs from the viz. Click **Back** to select a different flow, or click **Next** to continue.
7. From the **Select Sheet** drop-down, select a sheet (worksheet, dashboard or story) that contains the marks your users will select and send to the flow.

Note: Be sure to select a sheet that has marks with the encoded fields you want to map to the flow's required inputs. For example, if you want to map the `forecast_revenue` variable in the flow to the `SUM(Sales)` field in Tableau, you must select a sheet with marks that are encoded with the `Sum(Sales)` field.

8. Click **Next**.
9. For each of the flow's required inputs (Salesforce variables), select an appropriate field from the Tableau sheet you chose in the Select Sheet step.

Note: For each input, the data type of the Salesforce variable and Tableau field must match.

10. Click **Next**.
11. Configure the appearance of the button that users click to trigger the External Actions workflow. Specify a button title, background colour and border colour. Check the preview to confirm the button's appearance.

Note: Remember that users must select a mark from the viz that you chose in the **Select Sheet** step. Until a mark is selected, the button isn't available. Consider adding guiding text to the dashboard so that users know exactly what viz to interact with and what will happen when they click the button.

12. Click **Done** to create the workflow and add the corresponding button to the viz in the dashboard.

Use a workflow

To get started as a workflow user, open the dashboard where your dashboard author has added a workflow. You can confirm that a workflow is available if a workflow button displays. The dashboard author customizes the name and format of the button, and it should clearly indicate the action triggered when you click it (such as "Send Data" or "Update Record"). Select a relevant mark from a viz in the dashboard, and then click the button to start the workflow.

Clicking the workflow button triggers the transmission of data, and the mark you select determines what data is sent. For that reason, the button is unavailable (greyed out) until you select a mark. If you've selected a mark but the button is still unavailable, verify that you've selected a mark on a valid viz for the workflow. If you aren't sure which vizzes are valid, check with the dashboard author.

Depending on their configuration, some workflows might be long-running operations that aren't completed immediately. If you're unable to determine whether the workflow you selected is working as expected, check with the dashboard author or your Salesforce admin.

Troubleshoot a workflow

For help resolving issues with an External Actions workflow, see the following troubleshooting guidance.

Access issues

- **For dashboard authors using Tableau Desktop:** If the Workflow object doesn't appear in the Objects section of the Dashboard pane, confirm that you're signed in to a Tableau Server or Tableau Cloud site. If you aren't signed in, you won't be able to access the Workflow extension.

- **For dashboard authors:** If the Workflow object doesn't appear in the Objects section of the Dashboard pane, check with your Tableau admin to ensure that the extension is turned on.
- **For all users:**
 - If your Salesforce admin hasn't created a connected app, the External Actions feature won't work. Ask your Salesforce admin to [create a connected app](#) in Salesforce for Tableau Server.
 - If you're unable to click a workflow button that displays on a dashboard, confirm that you've selected a mark on a valid viz for the workflow. If you aren't sure which vizzes are valid, check with the dashboard author.

Authentication issues

- **For Tableau Cloud or Tableau Server users:** Refresh the dashboard in your browser.
- **For all users:** Confirm that you've signed in to the Salesforce org where the External Actions workflow was added. If necessary, check with your dashboard author to confirm the correct Salesforce org.

Error messages

| Error Message | Explanation and Resolution |
|--|---|
| Workflow is turned off on this site. For more information, contact your Tableau administrator. | Your Tableau admin has turned off the Workflow dashboard extension for your site, so it isn't available for your use. Contact your Tableau admin to discuss turning on access to the extension. |
| Workflow isn't supported by Tableau Reader | The Workflow dashboard extension and External Actions feature can only be used to send data to a flow using Tableau Cloud , Tableau Desktop , or Tableau Server versions 2022.3 and later. |
| Flow contains one or more unsupported data types. Go back to select a different flow, or contact your Salesforce Flow administrator to remove unsupported data types from this flow. | The selected flow requires a data type input that isn't available in Tableau dashboards or is otherwise incompatible with External Actions workflows. Select a different flow if a suitable alternative exists, or check with your Salesforce admin for next steps. |

| Error Message | Explanation and Resolution |
|---|--|
| One or more data type mismatches exist in the mapping of input fields. | <p>The data type for one or more of the dashboard values mapped to the input variable fields aren't identical.</p> <p>For example, the flow might require a numeric variable for Revenue, but the mapped value from the dashboard was a text string. Depending on your scenario, you have two options to fix this. You can change the data type of the Revenue field in Tableau from a text string to a numerical value. Or, you edit the workflow configuration to map a different field from the dashboard that has a numerical data type.</p> |
| Unable to submit data to Salesforce Flow. | An unknown error occurred while the External Actions workflow attempted to send data from the dashboard to the flow. Contact your dashboard author to troubleshoot. |
| Error occurred: <exception code>. Contact your Salesforce Flow administrator. | The flow interview (running instance of the flow) failed. Share the exception code with your Salesforce admin so they can find the corresponding error email and troubleshoot accordingly. |
| Workflow failed. Contact your Salesforce Flow administrator. | The data from the selected mark in the dashboard was sent to the flow, but there was an issue in translating that data to the flow. Contact your Salesforce admin to troubleshoot. |
| Unable to submit data to flow. Contact your workflow author. | The data from the selected mark in the dashboard wasn't sent to the flow. Contact your dashboard author to troubleshoot. |

Flow issues

- Some flows run asynchronously, so you may not immediately know whether a flow that's part of an External Actions workflow ran successfully. At times, a flow might fail and roll-back changes without immediately providing detailed feedback. However, when a flow fails, a detailed error email is sent to the workflow user, dashboard author and Salesforce admin. Workflow users should contact their dashboard authors when they receive a flow [error email](#). Dashboard authors and Salesforce admins can then work together to troubleshoot and resolve the error. For more information on troubleshooting flow issues, see [Troubleshoot Flows](#).

Licensing issues

- **For dashboard authors:** On the Tableau side, no special permissions are required to add a workflow to a dashboard (as long as External Actions are enabled for the site). On the Salesforce side, you'll need the [Manage Flows permission](#) added to your Salesforce profile.
- **For workflow users:** On the Tableau side, any user who can access a dashboard with a workflow can run it. From the Salesforce side, you'll need the [Run Flows permission](#) added to your Salesforce profile.

Turn External Actions On or Off

In Tableau 2022.3 and later, the External Actions feature is turned on by default. For more information on how Tableau admins can configure org-wide access to Tableau External Actions, see [Configure External Actions Workflow Integration](#).

Table Extensions

Table extensions allow you to create data tables with an analytics extensions script. You can write a custom TabPy or Rserve script and optionally add one or more input tables.

Note: A table extension refreshes every time you open up a workbook or refresh a data source.

Benefits

Table extensions have the following benefits for both new and experienced users.

- Easily integrate scripts or advanced functions into Tableau
- Easily drag data from Tableau data connections as input into scripts
- A low code editor makes adding code to data sources easy
- Integrates with [Data Guide](#) and [Explain Data](#)
- Integrates with TabPy, Rserve and other analytics extensions
- Results can be used to construct dashboards or visualisations

Prerequisites

Before you can use table extensions, you must complete the following list.

- Open a data source in Desktop or Web Authoring.
- Configure an analytics extension
 - For steps to configure analytics extension connections, see [Pass Expressions with Analytics Extensions](#).

Create a Table Extension

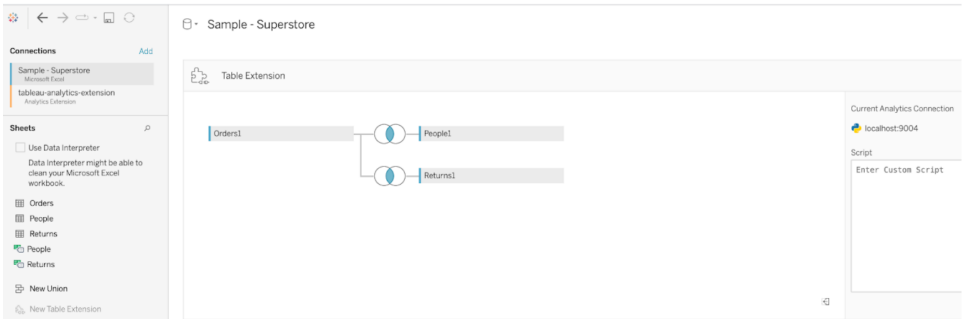

To create a table extension, complete the following steps.

1. Open a workbook.
2. Open a data source or create a one.
3. Under **Connections**, choose **New Table Extension**.
4. Drag the sheet into the data model.
5. *(Optional)* Drag tables from the data connection into the table extension pane to use as input into your analytics extensions script or function.

By default, data from Tableau is passed to the analytics extension and defined as the variable `_arg1`, a dictionary-like structure such as: `{ 'column_name': [1,2,3], 'column_name_2': [3,4,5] }`

- **Python input data:** The input data could be converted to a pandas dataframe using the following: `import pandas as pddf = (pd.DataFrame(_arg1))`
- **RServe input data:** The input data is defined as the `variable._arg1` and the data type are a named list of lists.
- **Custom SQL input data:** For supported relational data sources, you can use Custom SQL as an input into a table extension. When parameters are used in the Custom SQL query, changing the parameter causes the query to rerun and the script to recompute. This creates a path to dynamically update parameters in a dashboard and filter or otherwise pass values to the table extension script.

Note: If a parameter is used in a table extension, that parameter can't be deleted until it's removed from the extension. Deleting a parameter called in table extension can trigger a fatal error.

6. Under **Script**, enter your script or function call. The script must return a dictionary or list of lists, such as a JSON object. A script for RServe must return a data.frame or list of named lists. A script for Python must return a dictionary.

- **Python example:** Use the following explicit return command: `return df.to_dict(orient='list')`

Note: Table extensions don't support directly calling TabPy endpoints if TABPY_EVALUATE_ENABLE is disabled in TabPy.

7. Select **Apply** to run the script.

The screenshot shows the Tableau Desktop interface with the 'Table Extension' window open. The 'Script' tab is active, showing a script that calculates COGS (Cost of Goods Sold) as a percentage of Sales. The 'Output Table' shows the results of the script, including columns for COGS, Category, City, Country/Region, Customer ID, and Customer Name.

| Name | Table Extension |
|----------------|-----------------------------------|
| COGS | Tableau_33_7789106_1000-4154-8... |
| Category | Tableau_33_7789106_1000-4154-8... |
| City | Tableau_33_7789106_1000-4154-8... |
| Country/Region | Tableau_33_7789106_1000-4154-8... |
| Customer ID | Tableau_33_7789106_1000-4154-8... |
| Customer Name | Tableau_33_7789106_1000-4154-8... |

8. (Optional) If you're relating the table extension to another table in the data model, define the relationship between at least one field in each table.
9. In the data grid under **Output Table**, choose **Update Now**. The results appear in the Out-

put Table tab.

Table Extension 22 fields 10194 rows

Name
Table Extension

Fields

| Type | Field Name | Physical Table | Rem... |

Input Table Output Table

| COGS | Category |
|----------|-----------------|
| 10.90 | Office Supplies |
| 9.03 | Office Supplies |
| 7.51 | Office Supplies |
| 337.51 | Office Supplies |
| 14.65 | Office Supplies |
| 1,827.41 | Furniture |
| 4.00 | Office Supplies |

Note: If you don't define a relationship to a table in the data model, the Input Table tab is empty and displays the message 'Data preview unavailable'.

10. (Optional) In the **Name** field, enter a unique name for your new table extension.
11. Go to the **Sheet** tab to start exploring and visualising the data.
12. Publish the workbook to share it. The publishing destination must have an analytics extension of the appropriate type enabled and configured.

Troubleshooting tip: If your table extension is hitting an error, first ensure all code and formatting is correct. Then try using the circular Refresh Data Source button in the toolbar or click Apply again.

Compare extension types

While some of the following products aren't related, table extensions and analytics extensions share several features. The table extensions feature relies on a connection with analytics extensions to work. Let's break down each feature.

Dashboard Extensions

Dashboard extensions allow custom web applications to be added to dashboards using the Dashboard Extension SDK.

Table Extensions

Table extensions let you create a table in a data source that can send data and a script to your analytics extension and return a full table as a result. The returned results are displayed as a table in the data model and as measures and dimensions in a workbook.

Analytics Extensions

The **Analytics extensions** feature allows you to extend Tableau calculations with programming languages like Python, external tools and external platforms.

After you create a connection to an analytics extension, you can communicate with your external server through calculated fields called `SCRIPT_X` or `MODEL_EXTERNAL_X`, where X is the data type of the expected return values. For more information, see [Pass Expressions with Analytics Extensions](#).

Calculate Percentages in Tableau

Any analysis in Tableau can be expressed in terms of percentages. For example, rather than viewing sales for every product, you might want to view the sales of each as a percentage of the total sales for all products.

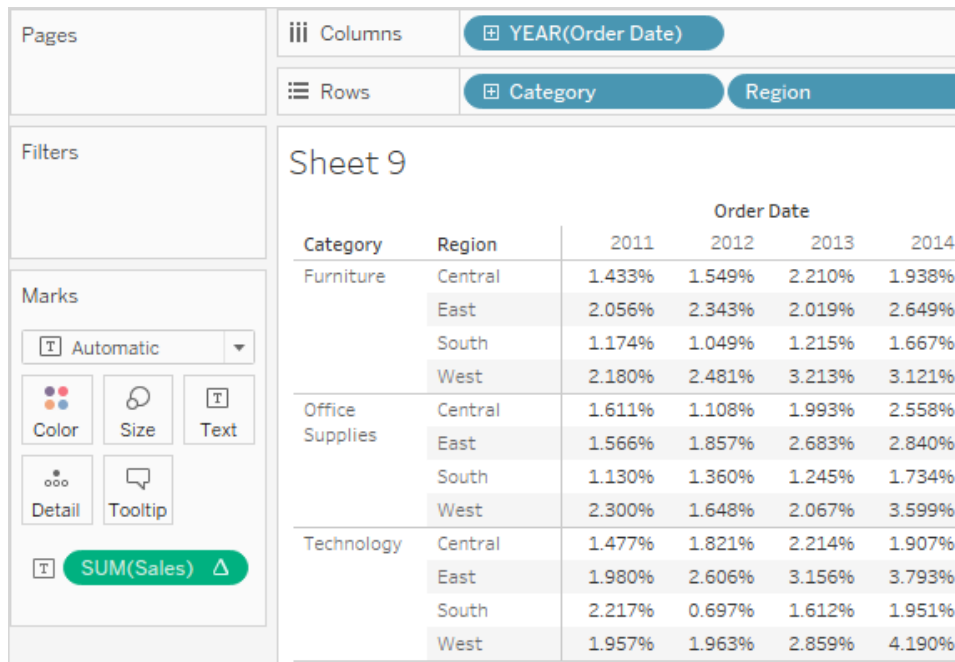

About percentages

There are two factors that contribute to the percentage calculation:

1. The data to which you compare all percentage calculations

Percentages are a ratio of numbers. The numerator is the value of a given mark. The denominator depends on the type of percentage you want, and is the number to which you compare all your calculations. The comparison can be based on the entire table, a row, a pane, and so on. By default, Tableau uses the entire table. Other percentage calculations are available via the **Percentage of** menu item. See [Percentage options on page 2680](#).

The figure below is an example of a text table with percentages. The percentages are calculated with the **Sales** measure aggregated as a summation, and are based on the entire table.

2. The aggregation

Percentages are computed on the basis of the aggregation for each measure. Standard aggregations include summation, average, and several others. See [Data Aggregation in Tableau on page 171](#) for more information.

For example, if the aggregation applied to the **Sales** measure is a summation, then the default percentage calculation (percent of table) means that each number displayed is the SUM(Sales) for that mark divided by the SUM(Sales) for the entire table.

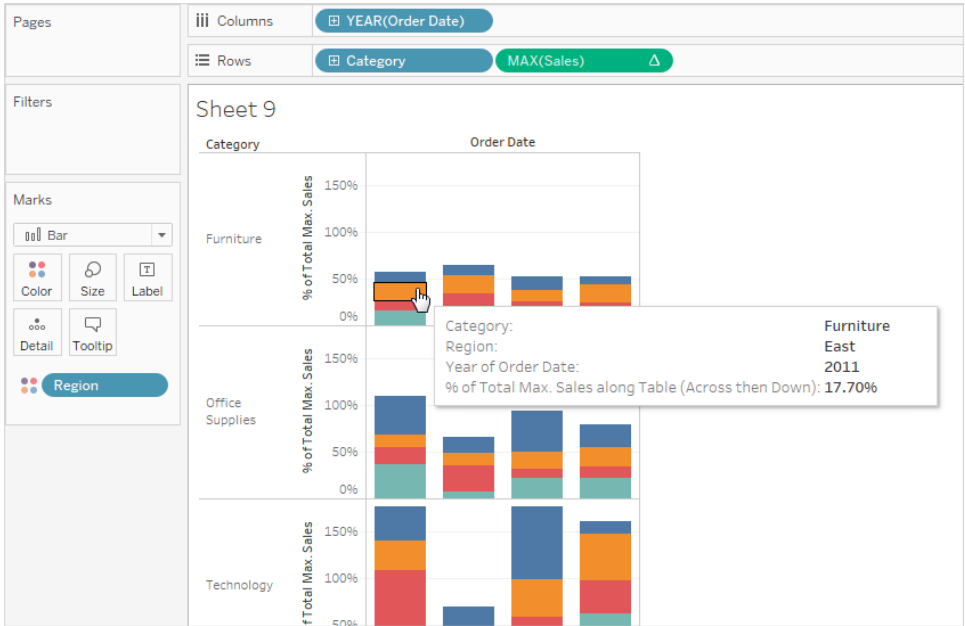

In addition to using predefined aggregations, you can use custom aggregations when calculating percentages. You define your own aggregations by creating a calculated field. Once the new field is created, you can use percentages on the field as you would any other field. See [Aggregate Functions in Tableau on page 2107](#) for more information.

Percent calculations can also be applied to disaggregated data. In this case, all values are expressed as the percentage of a summation. You cannot choose any other aggregation.

Example

The view below shows a nested bar chart created using two dimensions and a measure that is aggregated as a maximum. Additionally, the data are colour-encoded by a dimension and the default percentage calculation has been applied. Notice that the axis labels are modified to reflect the percent calculation.

The tooltip reveals that the maximum sales for furniture in the east in 2011 is 17.70% of the maximum for the entire table. What is the maximum for the table? If you recreate the view you'll see that the maximum occurs in the South, in the Technology category, in the year 2011. The tooltip for this bar segment would reveal a maximum sales of 100%.

The next view displays two disaggregated measures as a scatter plot. Again, the default percentage calculation has been applied as reflected by the modified axis labels.

The tooltip shows that the selected data point constitutes -0.475 percent of total profit and a 0.3552 percent of total sales. Percentage calculations are based on the entire data source.

How to calculate percentages

To calculate percentages in your visualisation:

- Select **Analysis > Percentages Of**, and then select a percentage option.

Percentage options

Computing a percentage involves specifying a total on which the percentage is based. The default percentage calculation is based on the entire table. You can also choose a different option.

The option you choose is applied uniformly to all measures that appear on a worksheet. You cannot choose **Percent of Column** for one measure and **Percent of Row** for another.

The percentage options on the Analysis menu correspond to the percentage table calculations. When you select a percentage option, you are actually adding a Percent of Total table calculation. See [Transform Values with Table Calculations](#) on page 2355 for more information.

If you are unsure what the current percentage calculation means, display the grand totals. This provides more information about each row and column. For example, if you select **Percent of**

Row while displaying grand totals, you will see that the total for each row is exactly 100%. See [Show Totals in a Visualisation on page 1361](#) for more information on grand totals.

The percent calculation options are described in the following sections. In each case, the grand totals are displayed as well.

Percent of Table

When you select **Percentage Of > Table** from the **Analysis** menu, each measure on the worksheet is expressed as a percentage of the total for the entire worksheet (table). For example, Technology in the East region accounts for 3.79% of total sales in 2014. The grand totals for rows show that 2014 accounts for 31.95% of the total sales. Summing the grand totals for rows or for columns yields 100% of the total.

Sheet 11

| | | Order Date | | | |
|-----------------|---------|------------|--------|--------|--------|
| Category | Region | 2011 | 2012 | 2013 | 2014 |
| Furniture | Central | 1.433% | 1.549% | 2.210% | 1.938% |
| | East | 2.056% | 2.343% | 2.019% | 2.649% |
| | South | 1.174% | 1.049% | 1.215% | 1.667% |
| | West | 2.180% | 2.481% | 3.213% | 3.121% |
| Office Supplies | Central | 1.611% | 1.108% | 1.993% | 2.558% |
| | East | 1.566% | 1.857% | 2.683% | 2.840% |
| | South | 1.130% | 1.360% | 1.245% | 1.734% |
| | West | 2.300% | 1.648% | 2.067% | 3.599% |
| Technology | Central | 1.477% | 1.821% | 2.214% | 1.907% |
| | East | 1.980% | 2.606% | 3.156% | 3.793% |
| | South | 2.217% | 0.697% | 1.612% | 1.951% |
| | West | 1.957% | 1.963% | 2.859% | 4.190% |

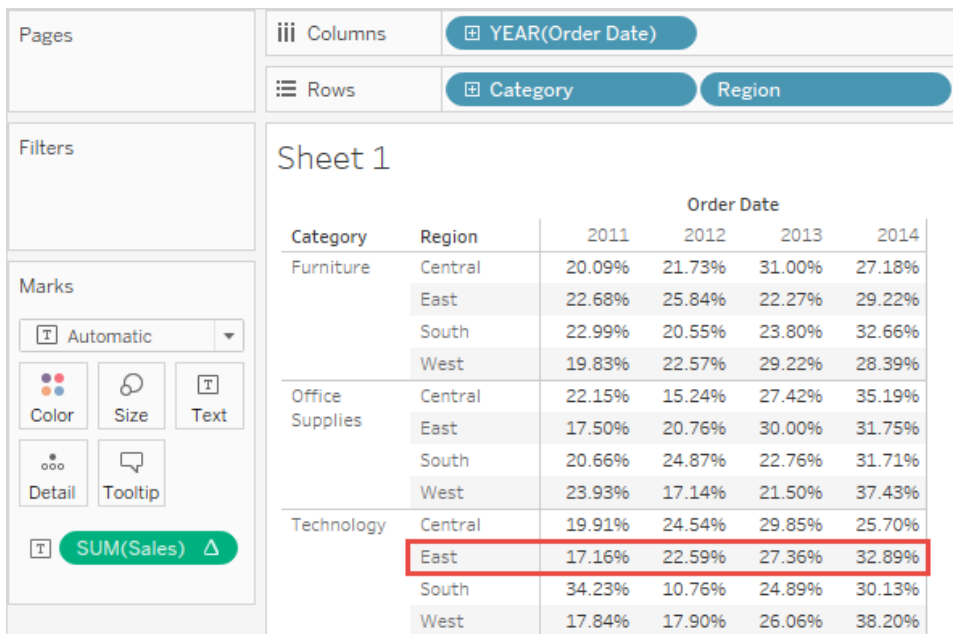

Percent of Column

When you select **Percentage of > Column** from the **Analysis** menu, each measure on the worksheet is expressed as a percentage of the total for the column. The values within the red box add up to 100%.

Percent of Row

When you select **Percentage of Row**, each measure on the worksheet is expressed as a percentage of the total for the row. The values within the red box add up to 100%.

Percent of Pane

When you select **Percentage of > Pane** from the **Analysis** menu, each measure on the worksheet is expressed as a percentage of the total for the panes in the view. This option is equivalent to **Percent of Table** when the table consists of only a single pane.

In the following view, the red box constitutes a single pane; the values within the red box add up to 100%.

The screenshot shows the Tableau interface with the following components:

- Columns shelf:** YEAR(Order Date)
- Rows shelf:** Category, Region
- Marks shelf:** SUM(Sales) (set to Automatic)

The resulting table view is titled "Sheet 1" and displays the following data:

| Category | Region | Order Date | | | |
|-----------------|---------|------------|--------|--------|---------|
| | | 2011 | 2012 | 2013 | 2014 |
| Furniture | Central | 4.435% | 4.797% | 6.843% | 6.000% |
| | East | 6.366% | 7.253% | 6.252% | 8.201% |
| | South | 3.635% | 3.248% | 3.763% | 5.162% |
| | West | 6.750% | 7.683% | 9.949% | 9.664% |
| Office Supplies | Central | 5.146% | 3.541% | 6.369% | 8.173% |
| | East | 5.002% | 5.932% | 8.573% | 9.074% |
| | South | 3.610% | 4.346% | 3.977% | 5.541% |
| | West | 7.350% | 5.266% | 6.603% | 11.497% |
| Technology | Central | 4.057% | 5.002% | 6.083% | 5.239% |
| | East | 5.439% | 7.159% | 8.670% | 10.421% |
| | South | 6.090% | 1.914% | 4.428% | 5.361% |
| | West | 5.376% | 5.393% | 7.855% | 11.512% |

A red rectangular box highlights the data for the 'Technology' category across all regions and years, indicating that these values represent 100% of the data within that specific pane.

Percent of Row in Pane

When you select **Percentage of > Row in Pane** from the **Analysis** menu, each measure on the worksheet is expressed as a percentage of the total for a row within a pane. This option is equivalent to as **Percent of Row** when the table is only a single pane wide.

In the following view, the red box constitutes a row within a pane; the values within the red box add up to 100%.

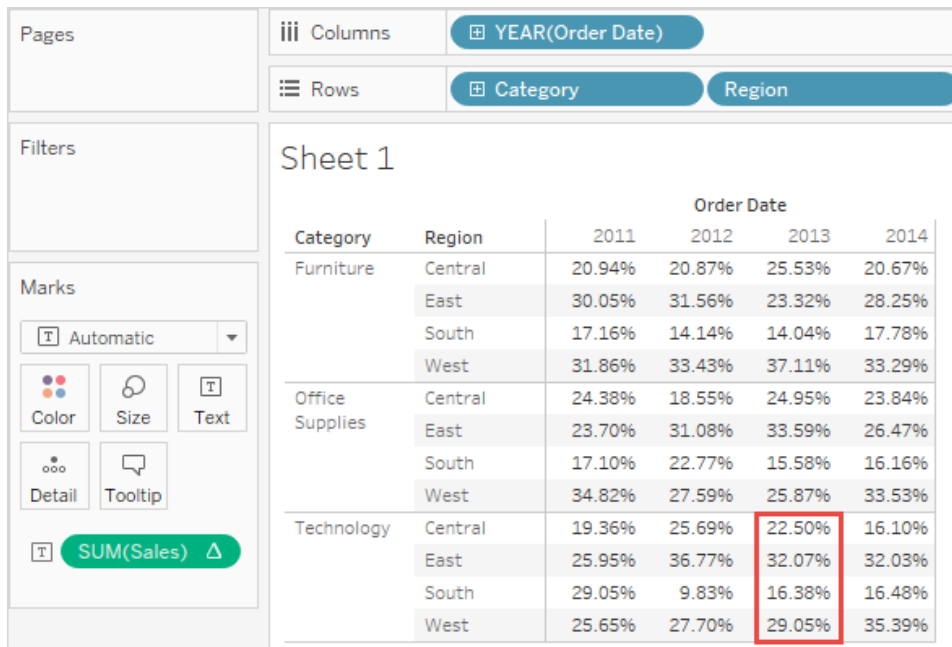

Note: If you place **Measure Names** as the inner dimension on the **Columns** shelf (that is, the dimension farthest to the right), Tableau will return 100% for each mark because you cannot total up the values for multiple measure names. For example, you can't total up the values for SUM(Sales) and SUM(Profit).

Percent of Column in Pane

When you select **Percentage of > Column in Pane** from the **Analysis** menu, each measure in the worksheet is expressed as a percentage of the total for a column within a pane. This option is equivalent to as **Percent of Column** when the table is only a single pane high.

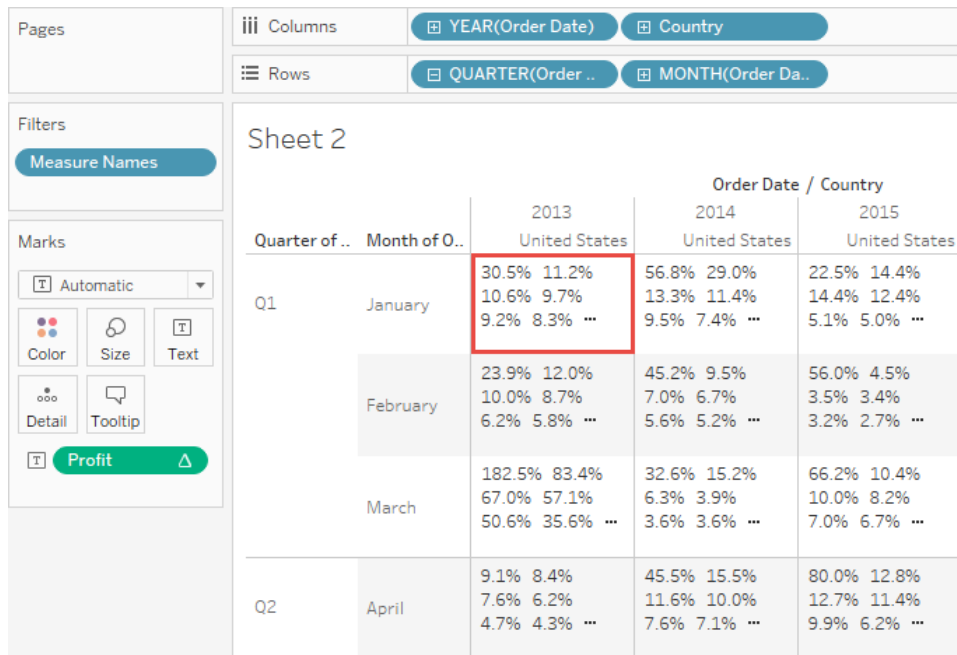

In the following view, the red box constitutes a column within a pane; the values within the red box add up to 100%.

If you place **Measure Names** as the inner dimension on the **Rows** shelf (that is, the dimension farthest to the right on the shelf), Tableau will return 100% for each mark because you cannot total up the values for multiple measure names. For example, you can't total up the values for SUM(Sales) and SUM(Profit).

Percent of Cell

When you select **Percentage Of > Cell** from the Analysis menu, each measure on the worksheet is expressed as a percentage of the total for each individual cell in the view. Most views show only one value per cell, in which case all cells show a percentage of 100%. But in some cases, as, for example, when you disaggregate data, a single cell can contain multiple values:

[Transform Values with Table Calculations](#) on page 2355

Dashboards

A dashboard is a collection of several views, letting you compare a variety of data simultaneously. For example, if you have a set of views that you review every day, you can create a dashboard that displays all the views at once, rather than navigate to separate worksheets.

Like worksheets, you access dashboards from tabs at the bottom of a workbook. Data in sheets and dashboards is connected; when you modify a sheet, any dashboards containing it change, and vice versa. Both sheets and dashboards update with the latest available data from the data source.

Best Practices for Effective Dashboards

A well-designed dashboard can align your organisation's efforts, help uncover key insights, and speed up decision-making. Use this topic for tips on best practices for creating effective dashboards in Tableau.

What's your goal?

Know your purpose and audience

The best visualisations have a clear purpose and work for their intended audience. What is it that you want to say with this dashboard? Are you presenting a conclusion or a key question?

Besides knowing what you're trying to say, it's important to know who you're saying it to. Does your audience know this subject matter extremely well or will it be new to them? What kind of cues will they need? Thinking about these questions before you head into the design phase can help you create a successful dashboard.

Leverage the most-viewed spot

Most viewers scan web content starting at the top left of a web page. Once you know your dashboard's main purpose, be sure to place your most important view so that it occupies or spans the upper-left corner of your dashboard. In the dashboard below, the author decided that the map view holds the key message.

Design for the real world

Author at your final display size

By default, Tableau dashboards are set to use a fixed size and if you keep this setting, be sure to construct your visualisation at the size it will be viewed at. You can also set **Size** to **Automatic**, which makes Tableau automatically adapt the overall dimensions of a visualisation based on screen size. This means that if you design a dashboard at 1300 x 700 pixels, Tableau will resize it for smaller displays – and sometimes this results in scrunched views or scrollbars. The **Range** sizing feature is helpful for avoiding this.

Dashboard | **Layout**

Device Preview

Size

min 800x600 - max 900x... ▼

Range ▼

☒ Minimum size

Width: 800 px Height: 600 px

☒ Maximum size

Width: 900 px Height: 700 px

If you're using Tableau Desktop to create dashboards, you can also design for specific device layouts, so that on tablets, for example, your dashboard contains one set of views and objects, and on phones it displays another. See [Create Dashboard Layouts for Different Device Types](#) on page 2778 for steps.

Limit the number of views

In general, it's a good idea to limit the number of views you include in your dashboard to two or three. If you add too many views, visual clarity and the big picture can get lost in the details. If you find that the scope of your story needs to grow beyond two or three views, you can always create more dashboards.

Too many views can also interfere with the performance of your dashboard after it's published. See [Make Visualisations Faster](#) on page 3069 for more details on performance.

[Click the image to replay it.](#)

Add interactivity to encourage exploration

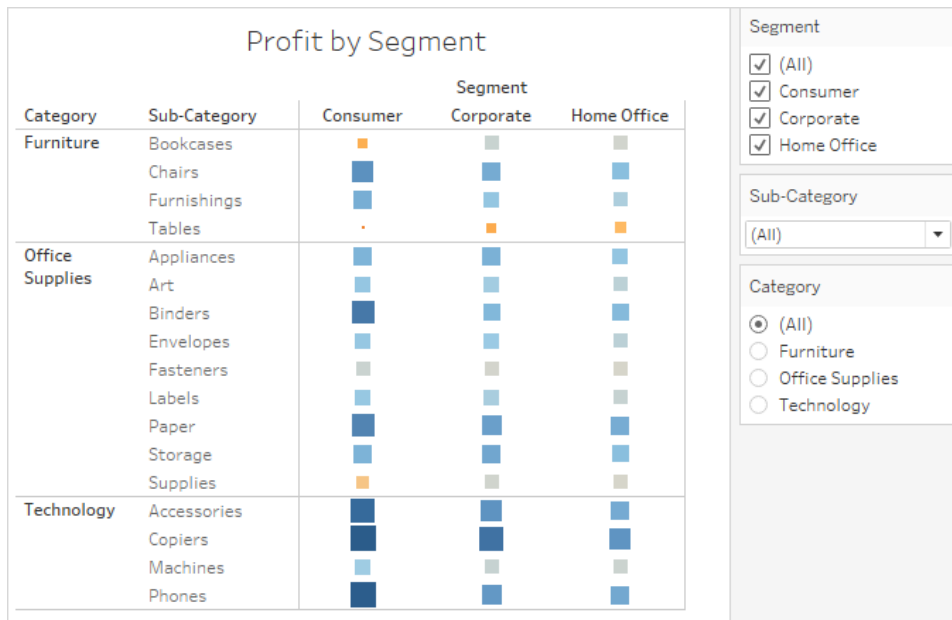

Show filters

Filters help users specify which data is shown in the view.

To turn on filters for a field:

- In Tableau Desktop – Right-click the field in the Data window and select **Show Filter**.
- In Tableau Server or Tableau Cloud – In the toolbar click **Show/Hide Cards > Filters**.

You can customise each filter for different types of data. For example, you can show filters as multi-select check boxes, single select radio buttons, or drop-down lists, etc. You can include a search button, the option to show all fields, null controls, and more. You can also edit the title of a filter to give your viewers clear instructions for interacting with the data.

Enable highlighting

You can use the **Highlight** button on the toolbar to set up highlighting between views. When highlighting is turned on, a selection in one view will highlight related data in the other views. You can turn on highlighting for all fields or select specific fields. For more information about the different methods you can use to highlight data, see [Highlight Actions](#).

You can also display a highlighter that allows your customers to highlight parts of a view based on what they enter or select.

To display a highlighter:

1. Go to the worksheet where the view is (or select **Go to Sheet** from the dashboard).
2. Right-click on the field you want to highlight – it must be a discrete field – and choose **Show Highlighter**:

In the highlighter, your users will be able to select or enter terms to highlight data in the view:

Create a Dashboard

After you've created one or more sheets, you can combine them in a dashboard, add interactivity and much more.

Tip: To quickly get up and running, see [Use Accelerators to Quickly Visualise Data on page 2711](#).

Create a dashboard, and add or replace sheets

You create a dashboard in much the same way you create a new worksheet.

1. At the bottom of the workbook, click the **New Dashboard** icon:

- From the **Sheets** list at left, drag views to your dashboard at right.

- To replace a sheet, select it in the dashboard at right. In the Sheets list at left, hover over the replacement sheet, and click the **Swap Sheets** button.

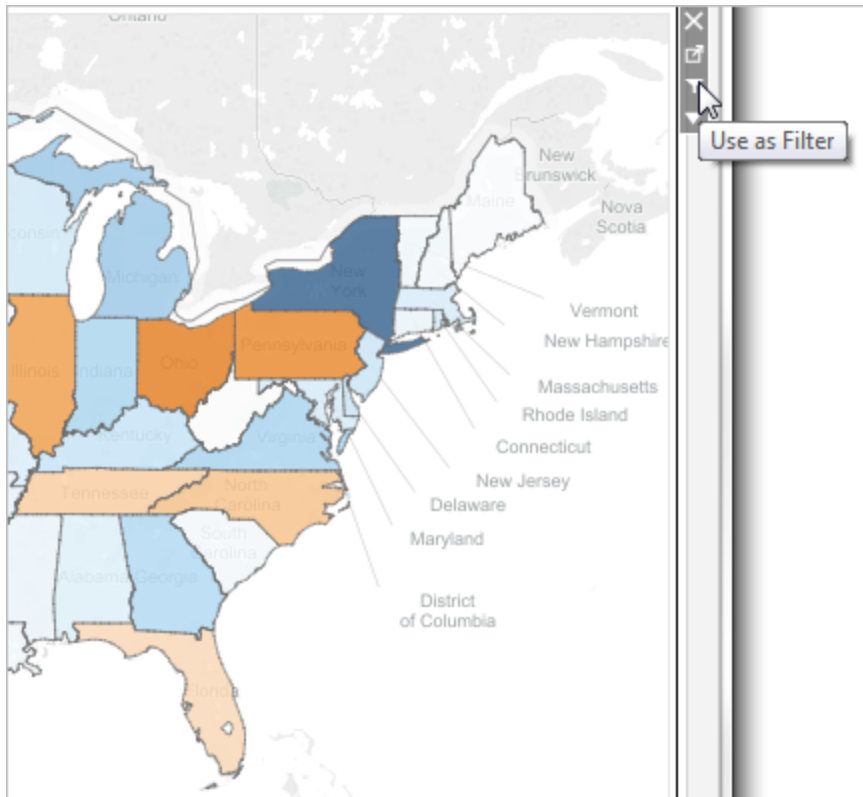

Note: When you replace a sheet, Tableau retains any padding, border or background colour. However, you may need to adjust sheet size if content differs significantly. You may also need to delete dashboard items specific to the previous sheet, such as filters, which become blank.

Add interactivity

You can add interactivity to dashboards to enhance users' data insights. Try these techniques:

- In the upper corner of sheet, enable the **Use as Filter** option to use selected marks in the sheet as filters for other sheets in the dashboard.

- When authoring in Tableau Desktop, add actions to use multiple sheets as filters, navigate from one sheet to another, display web pages and more. For details, see [Actions and Dashboards](#) on page 1470.

Add dashboard objects and set their options

In addition to sheets, you can add dashboard objects that add visual appeal and interactivity. Here is some guidance about each type:

- **Horizontal** and **Vertical** objects provide [layout containers](#) that let you group related objects together and fine-tune how your dashboard resizes when users interact with them.
- **Text** objects can provide headers, explanations and other information.
- **Image** objects add to the visual flavor of a dashboard, and you can link them to specific target URLs. (While Web Page objects can also be used for images, they are better for complete web pages. The Image object provides image-specific fitting, linking and alt-text options.)
- **Web Page** objects display target pages in the context of your dashboard. Be sure to review [these web security options](#), and be aware that some web pages don't allow themselves to be embedded – Google is one example.

Note: For security reasons, your Tableau administrator may prevent Web Page and Image objects from displaying target URLs.

- **Blank** objects help you adjust spacing between dashboard items.
- **Navigation** objects let your audience navigate from one dashboard to another, or to other sheets or stories. You can display text or an image to indicate the button's destination to your users, specify custom border and background colours and provide informational tool-tips.
- **Download** objects let your audience quickly create a PDF file, PowerPoint slide or PNG image of an entire dashboard, or a crosstab of selected sheets. Formatting options are similar to Navigation objects.

Note: Crosstab download is possible only after publishing to Tableau Cloud or Tableau Server.

- **Extension** objects let you add unique features to dashboards or integrate them with applications outside Tableau.
- **Pulse Metric** objects let you embed existing metric cards in your dashboard. The metrics that you can add are connected to the same published data sources that are used by the workbook.

Add an object

From the **Objects** section at left, and drag an item to the dashboard on the right:

Copy objects

You can copy and paste objects either within the current dashboard or from dashboards in other sheets and files. You can even copy objects between Tableau Desktop and Tableau in your web browser.

You can't, however, copy the following:

- Sheets in a dashboard
- Items that rely on a specific sheet, such as filters, parameters and legends
- Layout containers with something you can't copy inside them, like a sheet or filter
- Objects on a device layout
- Dashboard titles

Tip: In addition to the menu commands described below, you can also use the standard keyboard shortcuts for copying and pasting on your operating system.

1. Select a dashboard object, and from the object menu, select **Copy Dashboard Item**. Or from the main menu, select **Dashboard > Copy Selected Dashboard Item**.

2. Go to the dashboard where you want to paste the object. Then either select nothing to paste in the upper-left corner of the dashboard, or select an existing item to paste next to.
3. In Tableau Desktop, choose **File > Paste**. In a browser, either choose **Edit > Paste** or use the keyboard shortcut for pasting.
4. The object is pasted 10 pixels below and to the right of the upper-left corner of the dash-

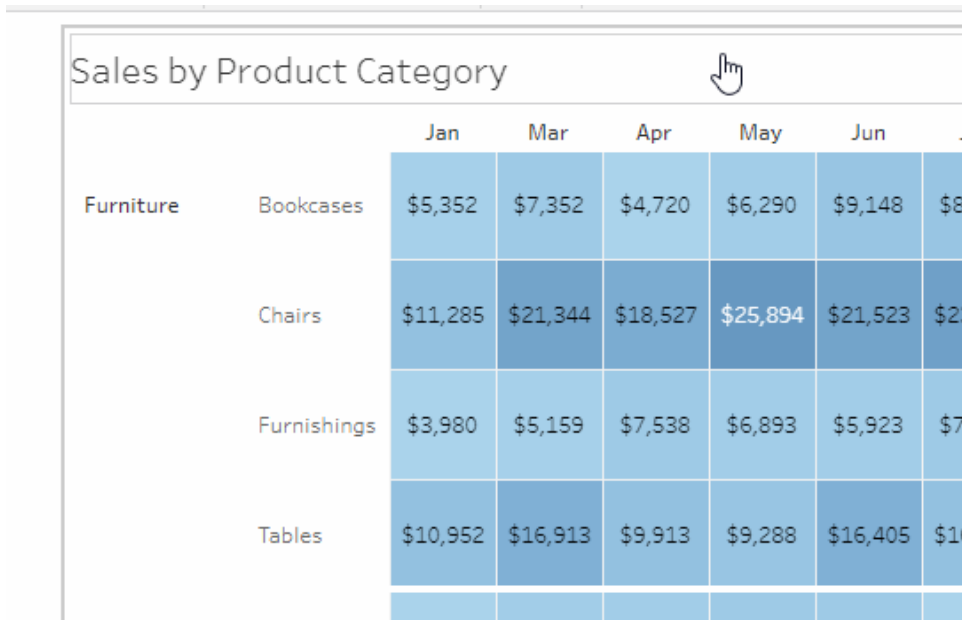

board or the selected object. To move the pasted object, drag the handle at the top.

Note: Copied Show/Hide buttons may target the original object or be disabled. For instructions on how to fix this, see [Show and hide objects by clicking a button on page 2701](#).

Set options for objects

Click the object to select it. Then click the arrow in the upper corner to open the shortcut menu. (The menu options vary depending on the object.)

| | | Jan | Mar | Apr | May | Jun | Jul |
|-----------|-------------|----------|----------|----------|----------|----------|----------|
| Furniture | Bookcases | \$5,352 | \$7,352 | \$4,720 | \$6,290 | \$9,148 | \$8,148 |
| | Chairs | \$11,285 | \$21,344 | \$18,527 | \$25,894 | \$21,523 | \$23,148 |
| | Furnishings | \$3,980 | \$5,159 | \$7,538 | \$6,893 | \$5,923 | \$7,148 |
| | Tables | \$10,952 | \$16,913 | \$9,913 | \$9,288 | \$16,405 | \$10,148 |
| | | | | | | | |

Detailed options for Image objects

With the Image object, you can either insert image files into dashboards or link to images posted on the web. In either case, you can specify a URL the image opens when clicked, adding interactivity to your dashboard.

Note: URLs for web-based images require the HTTPS prefix for improved security. For image URLs with other prefixes, use the Web Page object.

1. From the Objects section at left, drag an Image object to your dashboard at right. Or, on an existing Image object in a dashboard, click the pop-up menu in the upper corner, and choose **Edit Image**.
2. Click either **Insert Image File** to embed an image file into the workbook or **Link to Image** to link to a web-based image.

Consider linking to a web-based image when:

- The image is very large and your dashboard audience will view it in a browser. (Unlike web-based images, inserted images must be downloaded every time a sheet opens, slowing performance.)
- The image is an animated GIF file. (Inserted images don't support animated GIFs.)

Edit Image Object

3. If you're inserting an image, click **Choose** to select the file. If you're linking to an image, enter its web URL.
4. Set remaining image fitting, URL linking and alt text options. (Alt text describes the image in screen-reading applications for improved accessibility.)

Detailed options for Navigation and Download objects

Navigation and Download objects have several unique options that help you visually indicate a navigation destination or file format.

A navigation button using text for the button style

1. In the upper corner of the object, click the object menu and choose **Edit Button**.

2. Do one of the following:
 - From the **Navigate to** menu, choose a sheet outside the current dashboard.
 - From the **Export to** menu, choose a file format.
3. Choose image or text for **Button Style**, specify the image or text you want to appear, and then set related formatting options.
4. For **Tooltip text**, add explanatory text that appears when viewers hover over the button. This text is optional and typically best used with image buttons. (For example, you might enter "Open Sales viz" to clarify the destination for a navigation button that appears as a miniature sales chart.)

Note: When viewing a published dashboard, simply clicking a button navigates or exports. When authoring a dashboard, however, you need to Alt-click (Windows) or Option-click (macOS).

Show and hide objects by clicking a button

Show/Hide buttons let dashboard viewers toggle the visibility of dashboard objects, revealing them only when necessary.

How hidden objects affect layouts

When a floating object is hidden, it simply reveals any objects beneath it. Show/Hide buttons can be particularly helpful when you want to temporarily hide a floating group of filters to reveal more of a visualisation.

When a tiled object is hidden, the results depend on the object's level in the layout hierarchy.

- In most cases, you'll want to place objects you plan to hide in a Horizontal or Vertical layout container, because hidden objects will have their space filled in by other objects in the container.
- By contrast, in the Tiled layout container at the very top of the layout hierarchy, a hidden object leaves blank space behind.

Add and configure a Show/Hide button

1. Select a dashboard object.
2. From the pop-up menu in the upper corner of the object, select **Add Show/Hide Button**.

3. From the button menu, choose **Edit Button**.

4. Set these options:
 - **Dashboard Item to Show/Hide** specifies the target object. (An object can be the target of only one Show/Hide button at a time. Choose **None** if you want to target the object with another Show/Hide button.)
 - **Button Style** specifies whether image or text displays for the button.
 - **Button Appearance** specifies how the button looks when the item is both shown and hidden. Click **Item Shown** and **Item Hidden** to choose different images or text for each state.
 - **Tooltip text** provides explanatory text that appears when viewers hover over the button. (For example, you might enter "Show or hide filters" for a container with filter menus.)
5. If necessary, drag the button to a different location or resize it to better fit your layout.

Note: When viewing a published dashboard, simply clicking a Show/Hide button toggles object visibility. When authoring a dashboard, however, you need to Alt-click (Windows) or Option-click (macOS).

Security for Web Page objects

If you include Web Page objects in your dashboard, you can optimize security by doing the following.

Use HTTPS protocol when possible

As a best practice, use HTTPS (<https://>) in your URLs. This ensures that the connection from your dashboard to the web page is encrypted. Also, if Tableau Server is running HTTPS and you use HTTP in the URL, your users' browsers won't be able to display the web page that the URL points to. If you don't specify a protocol, HTTP will be assumed.

Security options for Web Page objects (Tableau Desktop only)

Choose **Help > Settings and Performance > Set Dashboard Web View Security**, and set the options below. (In some organisations, these options are controlled across all machines by a Tableau administrator.)

Note: Any changes you make to these security options apply to both existing and newly created web page objects.

- **Enable JavaScript** Allows JavaScript support in the web view. Clearing this option may cause some web pages that require JavaScript to function improperly in the dashboard.
- **Enable Plug-ins** Enables any plug-ins the web page uses, such as an Adobe Flash or QuickTime player.
- **Block Pop-ups** When selected, blocks pop-ups.
- **Enable URL Hover Actions** Allows URL hover actions. For more information, see [URL Actions on page 1412](#).
- **Enable Web Page Objects and Web Images** Allows the display of target URLs in Web Page and Image objects. If you deselect this option, Web Page objects and Image objects that link to the web remain in the dashboard but show no content.

Explore Dashboards with Data Guide

Have you ever discovered a new Tableau dashboard and wondered what the data means or how to use it? Or, have you ever published a new dashboard and wished that you could include instructions about how to use your dashboard?

Data Guide provides helpful information about a dashboard and insights about the data behind it. Data Guide allows dashboard creators to provide more explanatory context for end users – like descriptions and links to resources – directly in the dashboard. And Data Guide automatically surfaces insights powered by **Explain Data** to help users find outliers and learn about explanations for a mark. Explain the Viz (powered by Explain Data) identifies outlier measures and potential key drivers behind them.

These contextually relevant details can help dashboard users navigate and use new dashboards more easily, allowing users to find insights faster, trust that they're looking at the right data, provide context for data and establish confidence in their understanding of the viz.

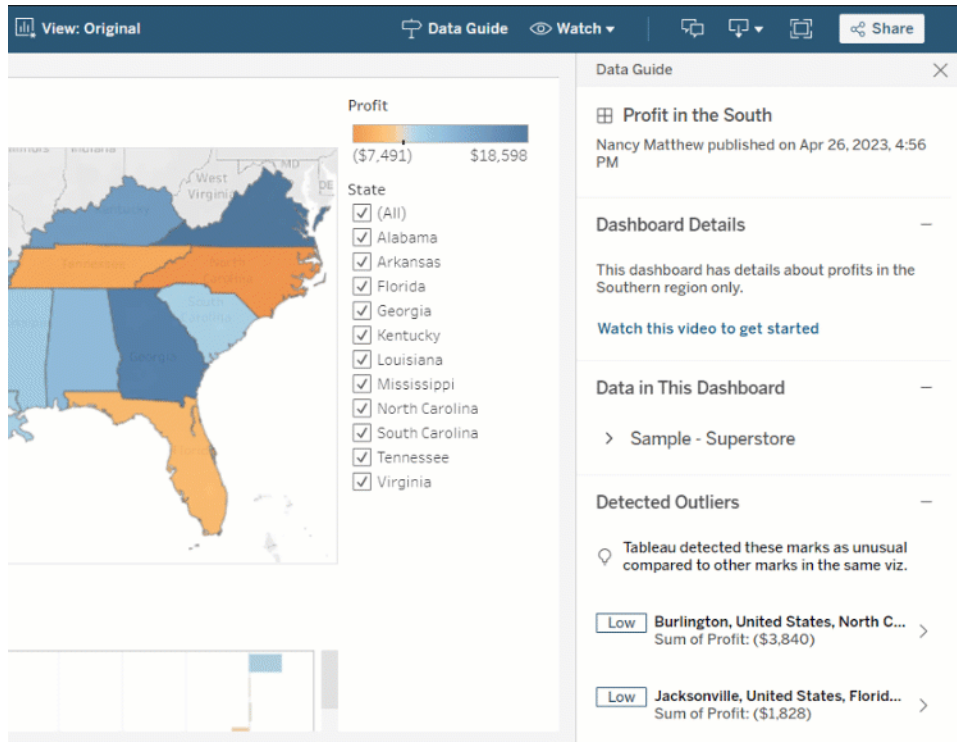

Customise Data Guide as an author

1. From your dashboard, choose the **Edit** button.
2. Choose **Data Guide** in the toolbar.
3. In the Data Guide pane, type a description to help your end users understand the purpose of your dashboard.
4. Select **Add link**, and enter a descriptive label for your link text and the URL.
5. Choose **OK**.
6. Select a viz (a sheet in the dashboard). Data Guide updates automatically so you can add a description and resources that are relevant to each viz in your dashboard.
7. Type a description, and add links relevant to the viz.
8. Choose **OK**.

Tip: To use Data Guide to write custom alt text to improve the accessibility of your vizzes, see [Show more text and make it helpful](#).

Explore Data Guide as a dashboard user

1. From the dashboard, choose **Data Guide** in the toolbar.
2. Read the description of the dashboard and explore resources provided by the dashboard author.
3. Expand **Data in This Dashboard** and **Detected Outliers** to learn more about the underlying data used in the dashboard.
4. Select a viz (an object in the dashboard).
5. Read the description of the viz and explore resources provided by the dashboard author.
6. Expand **Data Summary** and **Detected Outliers** to learn more about data in that viz.
7. Select a mark or multiple marks, such as a bar on a chart or a region on a map, to see information about **Data in This Mark** and **Applied Filters**. Select a single mark to see possible **Explanations** for its value.

Explore Data Guide at different levels

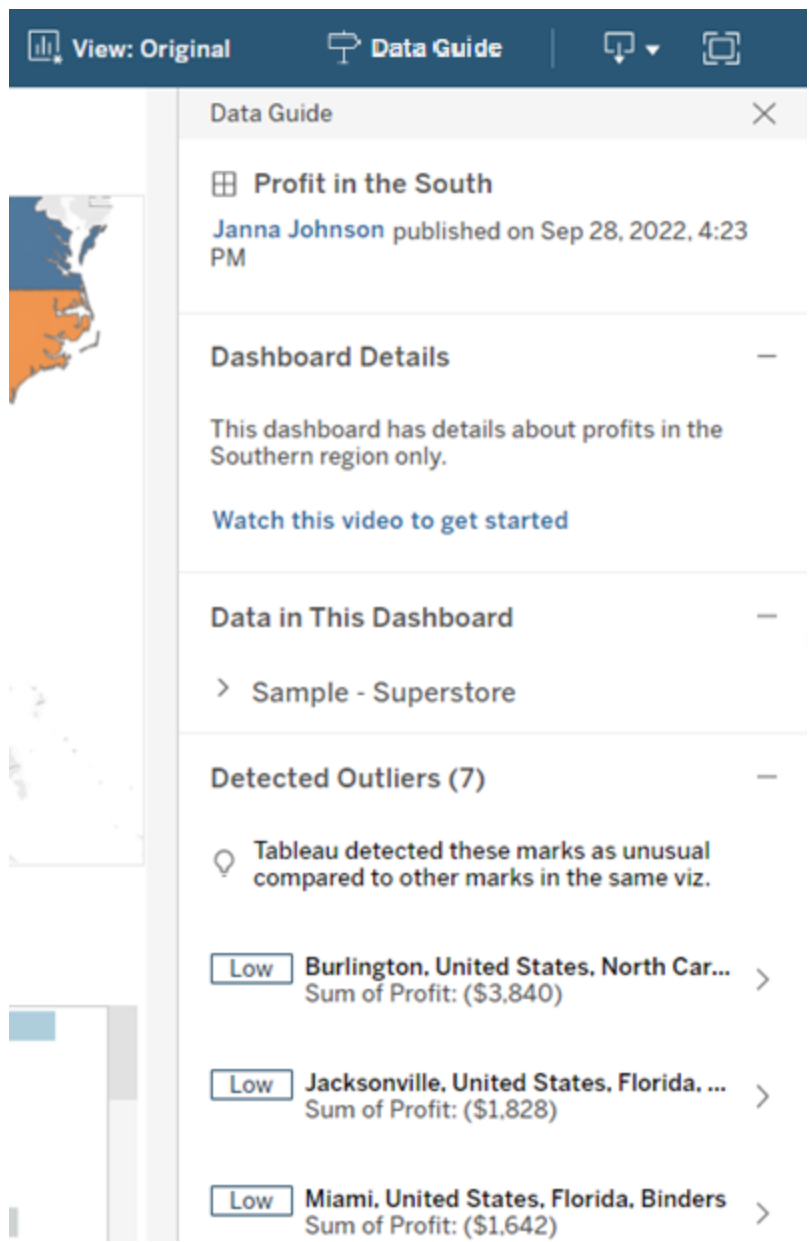

By default, Data Guide is closed when you open a workbook. And you can open Data Guide in the toolbar. At the top of the Data Guide pane, you see the name of the dashboard or viz that you selected. As a dashboard author, you can write descriptions for both the dashboard and for individual vizzes that make up your dashboard.

Understand dashboard-level details

At the dashboard level, Data Guide:

- Displays the dashboard's name, author and last published date.
- Can include a description written by the dashboard author and links to related resources, such as videos or wiki pages.
- Lists the data sources used by the dashboard and details about the data, such as which dimensions and measures are used.

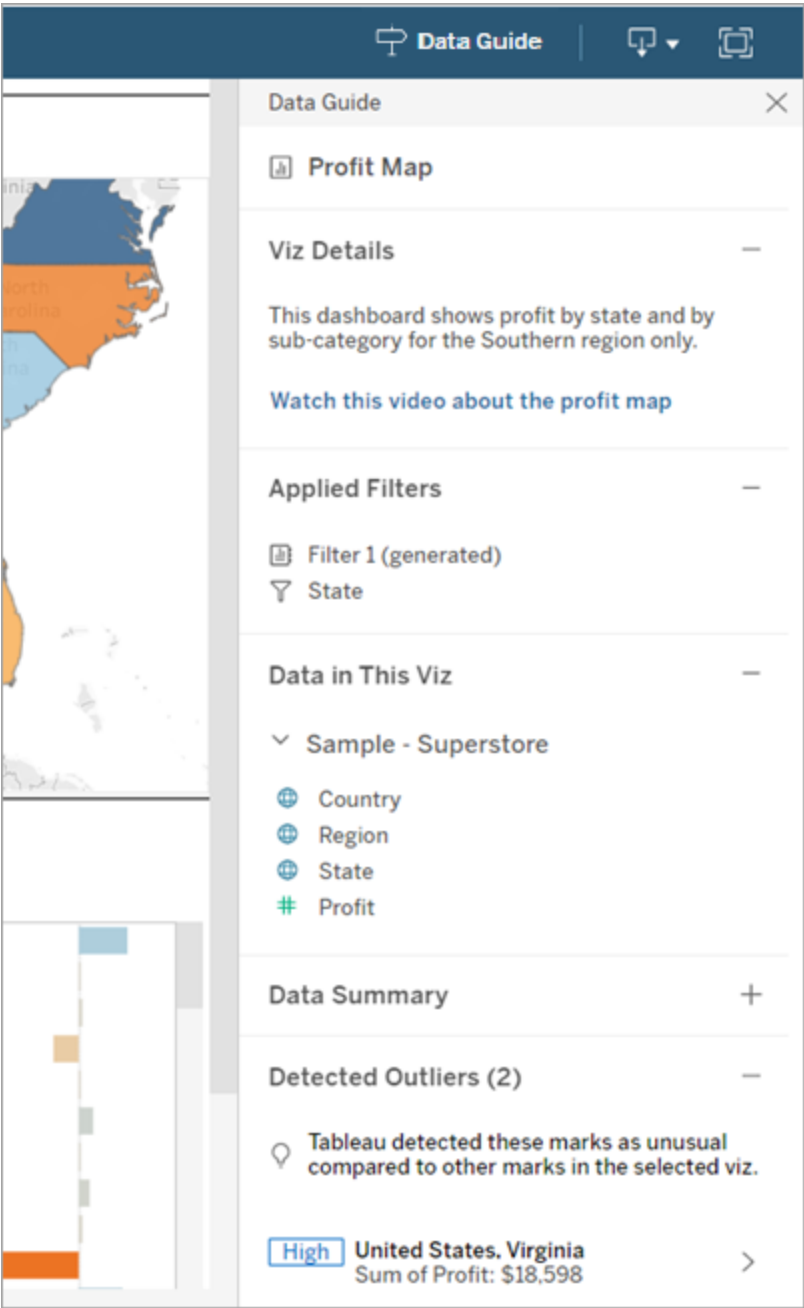

- Reveals detected outliers in the dashboard that are identified by Explain Data. For more information, see [Get Started with Explain Data](#) on page 1920.

Understand viz-level details

When a user selects a specific viz (dashboard object), Data Guide:

- Displays the viz's name.
- Can include a description written by the dashboard author and links to related resources, such as videos or wiki pages.
- Lists the data sources used by the dashboard, including the dimensions and measures used.
- Lists applied filters and data used in the viz, so you can identify how the data is being influenced by filters that users interact with. Only filters that a user can change are shown.
- Has a summary of the data used in the viz, including the number of data points and sorting details.
- Reveals detected outliers in the viz that are identified by Explain Data. For more information, see [Get Started with Explain Data on page 1920](#).

Understand mark-level details

When a user selects a mark (or marks) such as region on a map, Data Guide:

- Displays the name of the mark.
- Lists applied filters and data used in the viz, so you know what's included and what's excluded.
- Reveals detected outliers in the viz that are identified by Explain Data. For more information, see [Get Started with Explain Data](#) on page 1920.

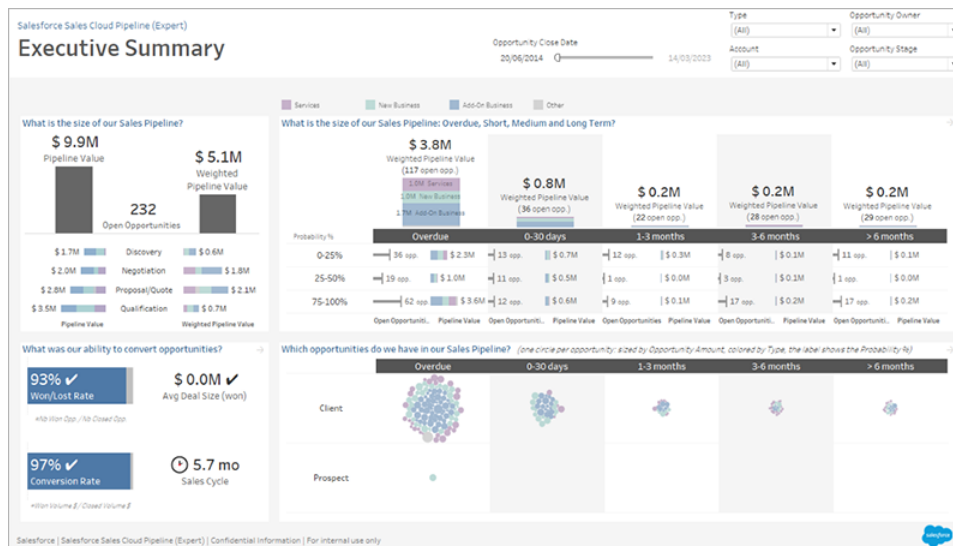

Control Data Guide visibility

By default, Data Guide is closed when you open a workbook. When you open or close Data Guide, it remains in this state for all workbooks on the site. In 2023.1 or later, a can hide Data Guide for all users. This removes the Data Guide button from the Tableau toolbar on all workbooks on the site. To hide Data Guide:

1. From the left pane, choose **Settings**.
2. From the **General** tab, scroll to **Availability of Data Guide**.
3. Choose **Hide**.
4. Choose **Save**.

Use Accelerators to Quickly Visualise Data

Tableau Accelerators are pre-built dashboards designed to help you get a jumpstart on data analysis. Tailored to specific industries and enterprise applications, Accelerators are built with sample data that you can swap out for your own data, allowing you to discover insights with minimal setup.

Salesforce Sales Cloud Pipeline Accelerator

Where to find Accelerators

You can access the complete set of Accelerators on the [Tableau Exchange](#) and in Tableau Desktop. Additionally, select Accelerators are available to use when you create a workbook in

Tableau Cloud.

On the Tableau Exchange website

1. Visit the [Accelerators page](#) on the Tableau Exchange website. You can filter to find Accelerators based on the industry they are applicable to and the type of data they connect to.
2. Sign in to the Tableau Exchange website. If you don't have an account, create one.
3. When you find an Accelerator you want to use, select **Download** to get the TWBX file.

Because Accelerators are simply packaged workbooks, you can open the downloaded file in Tableau Desktop or upload it to your site on Tableau Cloud or Tableau Server. For information about uploading workbooks, see [Upload Workbooks to a Tableau Site](#).

In Tableau Desktop

1. On the Start Page in Tableau Desktop, select **More Accelerators**.

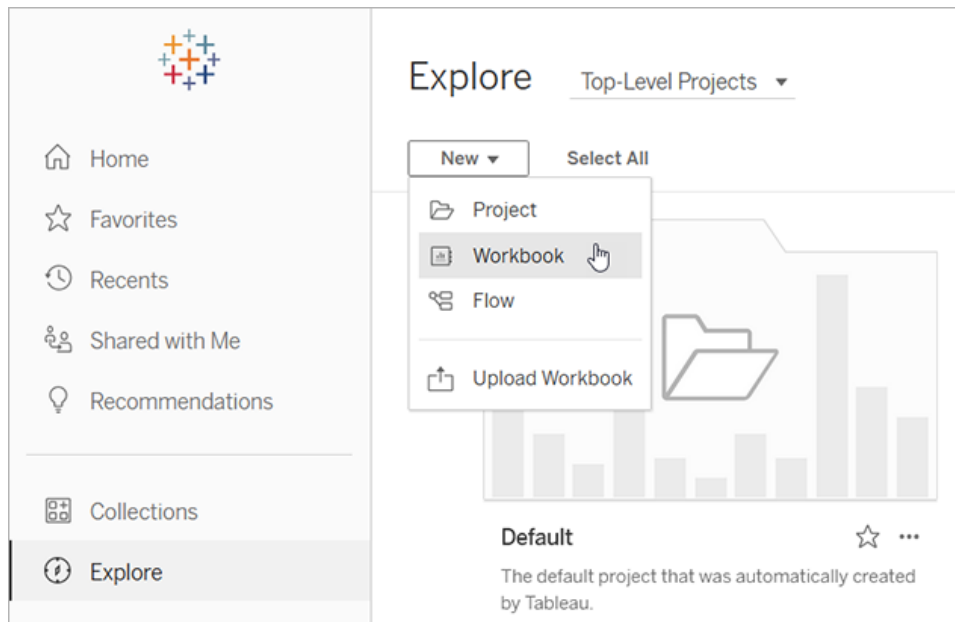

2. The Accelerators in this list are the same as those shown on the Tableau Exchange website, with the added convenience that you can open the Accelerators without leaving Tableau Desktop.
3. When you find an Accelerator you want to use, select **Open** to start working with it.

In Tableau Cloud

A limited number of Accelerators are available when you create a workbook in Tableau Cloud. These Accelerators connect to cloud-based data like Salesforce, ServiceNow ITSM, LinkedIn Sales Navigator, Marketo, and Oracle Eloqua.

1. If you're a Creator in Tableau Cloud, navigate to the Home or Explore page, then select the **New** button and select **Workbook**.

Note: Site administrators can also access Accelerators from the Home page, under the section labelled Accelerators.

2. At the top of the Connect to Data window, select **Accelerator** to browse the Accelerators available to connect to on Tableau Cloud.

You can also upload additional Accelerators from the Tableau Exchange to Tableau Cloud and use them as you would in Tableau Desktop. However, you will need to follow the Tableau Desktop instructions to get your data into the Accelerator instead of the Tableau Cloud instructions.

Use an accelerator from the Tableau Exchange

Follow the instructions in this section to use an Accelerator downloaded from the Tableau Exchange website or opened from within Tableau Desktop. For instructions on using Accelerators when you create a workbook in Tableau Cloud, see [Use an Accelerator directly in Tableau Cloud on page 2722](#).

Add your data to the Accelerator in Tableau Desktop

Use the data mapper

Data mapping was introduced for a limited number of Accelerators in Tableau Desktop in 2023.1.

Starting in 2023.2, the data mapper now:

- Saves your selections, if you close it, so that you can pick up where you left off
- Allows you to switch between different connected data sources
- Supports a larger number of Accelerators

The data mapper helps you connect to data and map the fields in your data to those required for the Accelerator. If the Accelerator you have downloaded supports the data mapper, a prompt will appear to help you get started. To find Accelerators that support the data mapper, select the filter **Data Mapping enabled** on the [Tableau Exchange website](#).

For Accelerators that don't support the data mapper, follow the instructions in the next section to [Manually add your data on page 2716](#).

When you open an Accelerator that supports it, the data mapper opens.

1. Select **Get Started**.

If you close the data mapper, you can reopen it at any time by selecting **Open Data Mapper** from the Data menu.

2. If you've already connected to data, select the data source to use for mapping. Otherwise, select **Connect to Data**, then select the file or cloud-based data to use with the Accelerator.
3. For unpublished data sources with more than one table, you must add data to the canvas so that Tableau can access the fields. If you see a prompt to set up your data, drag one or more tables or sheets to the data source canvas. The data you add will be available to map to the Accelerator.

For more information about building a data source, see [Use Relationships for Multi-table Data Analysis](#).

4. After you add your data, your fields appear in the **To** column on the data mapper. For each Accelerator field (From), select a field of the same data type as your data (To). Mouse over fields to see details about them.
 - If you notice that a field in your data is marked as the wrong type, change the **data type** so that it can be mapped.
 - If you want to switch the data source you're bringing into the Accelerator, select the data source name after **To**, then select a different connected data source, or select **New Data Source**. Switching the data source clears any selections you have made for individual fields.

5. The indicator in the lower left of the data mapper shows how many fields you have assigned. After you complete your assignments, select **Replace Data**.

Any fields you leave unmapped will cause the dashboards that use those fields to break. This is because all sample data is removed from the Accelerator when you replace the data.
6. Your data replaces the sample data in the Accelerator. Before you close the data mapper, check the dashboards to make sure that the data was mapped as you expected. If you notice issues with the data, select **Make Changes** to return to the assignment screen. Make your adjustments, then replace the data again.

Starting in Tableau Desktop 2023.2, if you want to make adjustments after you've closed the data mapper, select **Data > Open Data Mapper** to refine your selections. In Tableau Desktop 2023.1, the selections you made don't persist, and if you reopen the data mapper, you'll need to repeat the process of adding a data source and making assignments for each field.

Manually add your data

There are two methods to add your data to the Accelerator: replace the data source with a new data source (method 1) or add a new connection to the existing data source (method 2).

Method 1: Replace data source

Works with data sources that have more than one table.

Allows you to change field names to match the Accelerator.

Doesn't preserve the folder structure in the Accelerator.

Method 2: Add new connection

Data sources must have only one physical table.

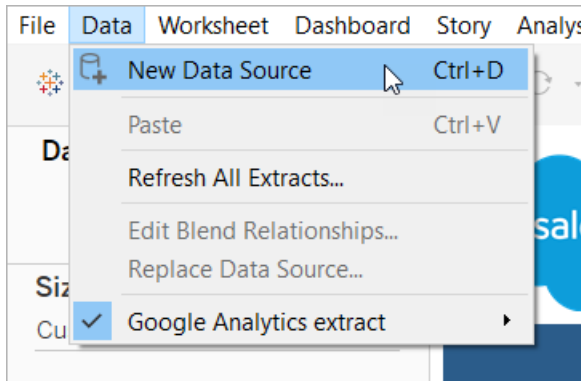

Field names in your data source must match the fields in the Accelerator.

Preserves the folder structure, which keeps the fields used by the Accelerator organised.

Method 1: Replace the data source

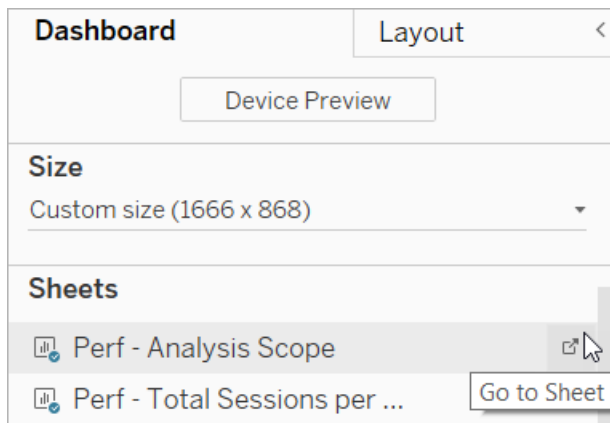

Use this method if you're adding a data source with multiple tables.

1. With the Accelerator open in Tableau Desktop, select **Data > New Data Source**.

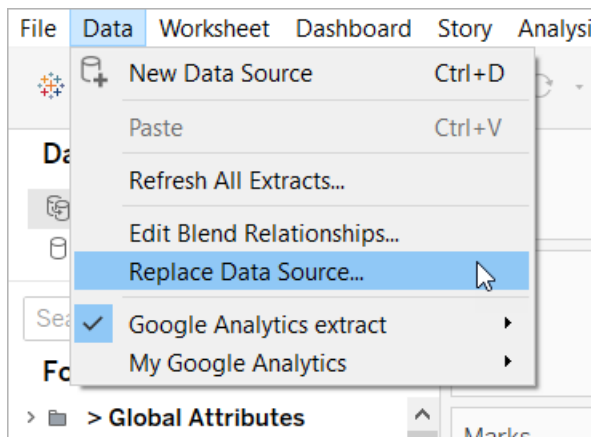

2. Connect to the data you want to use. For more information, see [Connect to Your Data](#). If you're using a Salesforce Accelerator, make sure your account has API access to your Salesforce instance.
3. On the Data Source tab, drag tables onto the canvas to build your new data source. For more information, see [Use Relationships for Multi-table Data Analysis](#).

4. Navigate to a dashboard. Then select the Go to Sheet icon for any of the sheets listed.

This step is necessary because you can only replace data from a worksheet, not from a dashboard or story tab. For more information about the types of sheets in a workbook, see [Workbooks and Sheets](#).

5. Select **Data > Replace Data Source**. For more information, see [Replace Data Sources](#).

6. Under **Replacement**, select the data source you added, then select **OK**.
7. In the Data pane, right-click the original data source, then select **Close**. For more information, see [Close Data Sources](#).

Fix broken references

If the new data source doesn't have the same field names as the original, parts of the Accelerator will be blank. Replace the broken references so that they use the correct fields from your new data source.

1. Navigate to a dashboard, then select the Go to Sheet icon for one of the sheets listed.

2. In the Data pane, identify the required fields for the Accelerator. The Accelerator page on the [Tableau Exchange](#) should list these fields in the description section.
3. Replace the field references for any fields that are marked with a red exclamation mark.
 - To do so, right-click on the field name and select **Replace References....** Then select the correct field name from the list.

- For more information, see [Replace Field References](#).

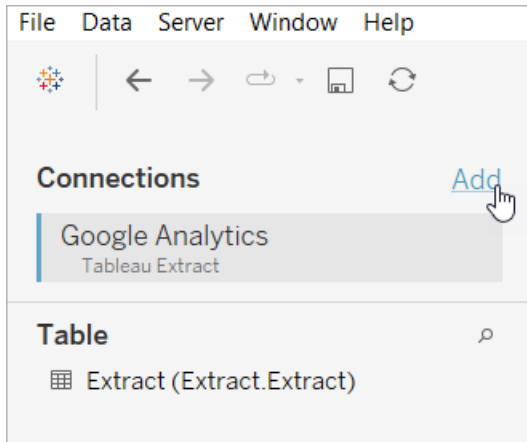

Method 2: Edit the data source

Use this method if you have a data source with only one physical table that can directly replace the physical table in the Accelerator.

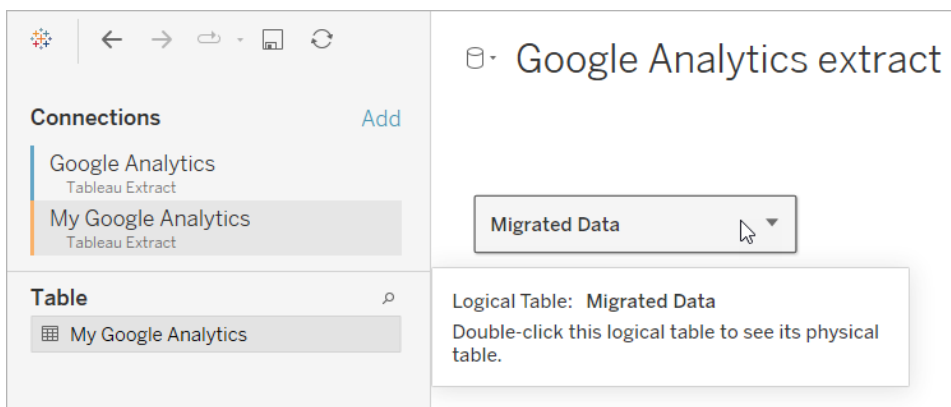

1. With the Accelerator open in Tableau Desktop, select the **Data Source** tab.

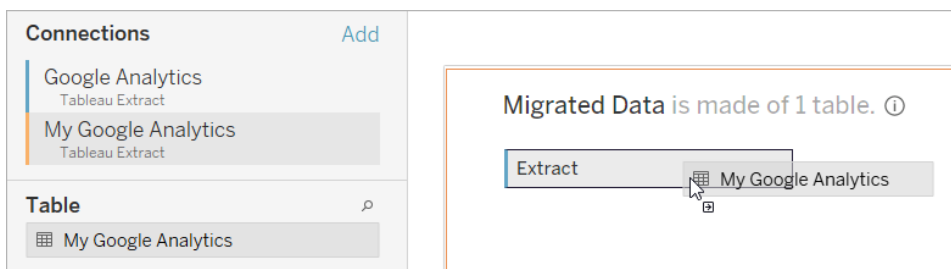

2. Next to Connections, select **Add**. Connect to the data you want to use. For more information, see [Connect to Your Data](#).

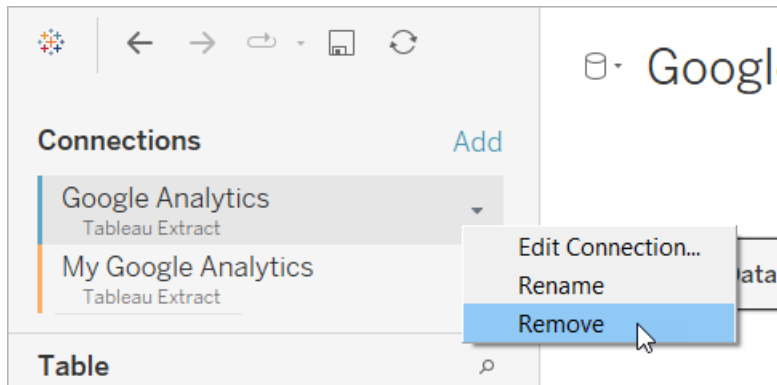

3. On the data source canvas, double-click the logical table to open the physical table. For information about logical and physical tables, see [Layers of the data model](#).

4. Drag the table from the data source you added and drop it onto the existing physical table to replace the sample data. Your data source must be only one physical table.

- Under connections, right-click the connection for the sample data, then select **Remove**.

Use an Accelerator directly in Tableau Cloud

A limited number of Accelerators are available for you to use when you create a workbook in Tableau Cloud. These Accelerators prompt you to connect directly to a cloud-based data source, rather than requiring you to add data manually.

- On Tableau Cloud, create a new workbook.
- At the top of the Connect to Data window, select **Accelerator**.
- From the list of pre-built designs, find an option that reflects the data source and business metrics you need, and select **Use Dashboard**.
- To quickly see how a workbook looks with sample data, select **Continue without signing in**. Or select **Continue** to create a workbook with your data.
- Specify a name and containing project for the workbook.
- If you chose to create a workbook with your data, connect to your data source. While Tableau prepares an extract of your data, sample data appears so you can explore the layout.

Note: If you download an Accelerator from the Tableau Exchange with the intention of uploading it to Tableau Cloud, you will need to replace the data by following the instructions under [Use an accelerator from the Tableau Exchange on page 2713](#).

Change permissions to share Accelerators with colleagues

To avoid exposure of confidential data, workbooks for Accelerators are visible only to authors and administrators by default. To share an Accelerator with your colleagues, follow these steps:

1. In Tableau Cloud, [navigate to the workbook](#) for the Accelerator.
2. On the workbook, select **Actions > Permissions**.
3. Give **View** permissions to any user or group you want to see the dashboard. For more information, see [Edit Permissions](#) in Tableau Cloud Help.

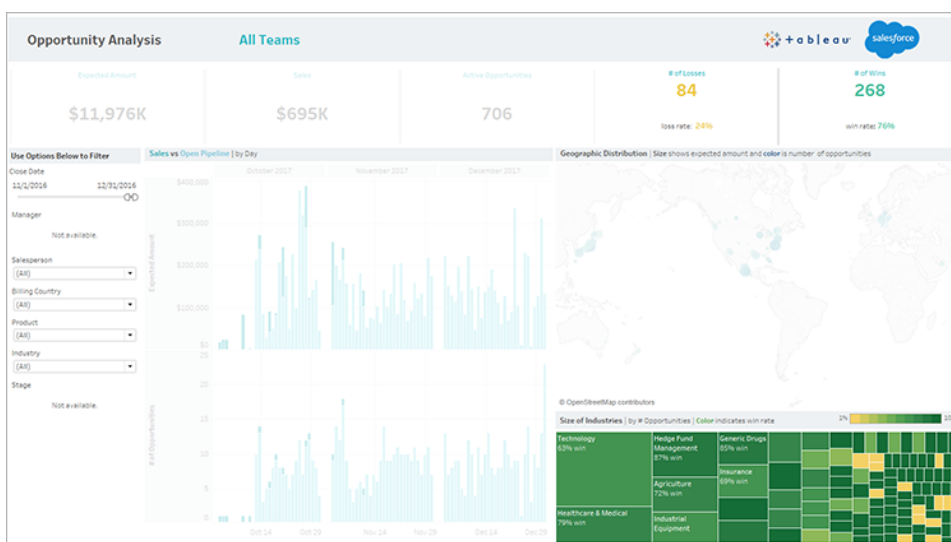

Replace sample data with your data

If you chose to use sample data in a dashboard, you can replace it with your data at any time.

1. In Tableau Cloud, [navigate to the workbook](#) for the Accelerator.
2. On the **Data Sources** tab, select the data source. From the Actions menu, choose **Edit Connection**.
3. For authentication, select **Embedded credentials in the connection**, and either choose an existing user account or add a new one. Then select **Save**.
4. On the **Refresh Schedules** tab, select the schedule. From the Actions menu, select **Run Now**.

Fix greyed-out views by replacing field names

If your organisation has customised the data structure for a cloud-based system, you may need to match those changes in Accelerators after your data loads in them. For example, if your organisation has renamed the Salesforce “Account” field to “Customer”, you’ll need to make a corresponding change in Accelerators to avoid greyed-out views like this:

Replace the field references to fix the broken fields.

1. On the dashboard, select **Edit**.
2. **Navigate directly to the greyed-out sheet.**
3. In the Data pane on the left, look for red exclamation points (!) next to field names, which indicate that your organisation uses different names.
4. Right-click each of those fields and select **Replace References...** Then select the correct field name from the list.

Fix empty dashboards by changing default date ranges

If a dashboard looks completely empty, the likely cause is a default date range that doesn't correspond to the dates in your source data.

1. [Download the workbook](#), then open it in Tableau Desktop.
2. Select the **Data Source** tab.
3. In the upper-left corner, select the arrow next to the data source name, and select **Edit Connection**. Then sign in.

4. Specify a date range that reflects the dates in your data, then select **Connect**.
5. Choose **Server > Publish Data Source** to update extracts of the data on Tableau Cloud.

Build an Accelerator for the Tableau Exchange

Tableau Accelerators are pre-built dashboards that help users jump-start their analysis in Tableau. With an Accelerator, users can connect their own data to a robust dashboard that is designed specifically for their industry or application and use it to investigate their data. A good Accelerator tells a story that provides insight into business problems and helps users answer questions about their data.

Accelerators are available for download on the [Tableau Exchange](#) and, in a limited subset, on the [Salesforce AppExchange](#). Accelerators are free to use, and users don't need to share their information in order to download an Accelerator. For information about using an Accelerator, see [Use Accelerators to Quickly Visualise Data](#) on page 2711.

Who can build an Accelerator

Only managed [Salesforce partners](#) can contribute Accelerators to the Tableau Exchange. For information about becoming a Salesforce partner, explore the [Salesforce Partner Programme](#). If

you aren't a partner, you can still create a workbook that functions like an Accelerator and publish it on [Tableau Public](#), but you aren't eligible to have it included on the Tableau Exchange.

Building an Accelerator doesn't guarantee that it will be listed on the Tableau Exchange. Accelerators built by partners must be approved, and the content of the Accelerator must be relevant to Tableau users. You'll work with a partner account manager to understand the specific requirements for Accelerators and to get yours ready for the Tableau Exchange.

Use Dynamic Axis Ranges

It's key that your users understand the range represented in a viz so that they can correctly analyse the data. Especially when analysing multiple vizzes in a dashboard or multiple worksheets at the same time, it can be easy for users to misinterpret data when the range of the axes is different between vizzes. For example, when two bar charts appear next to each other, the bars in both charts might appear to be equivalent sizes. However, the axes might have very different ranges, making the charts misleading.

To help users understand the range of the axis, in 2023.3 and later, authors can use Dynamic Axis Ranges to set the minimum and maximum values of an axis range by using numeric parameters or date parameters. Then, as users navigate across vizzes, the axes update synchronously. This makes it easier for your users to analyse data across vizzes easily and accurately. And by limiting the range of the data, you can view a subset of data without filtering the underlying data or impacting the moving average of your data.

Dynamic Axis Ranges can also be used to extend or shorten the range of an axis without filtering out the underlying data. This is ideal for showing progress against a goal or showing a moving average.

Supported field types

Dynamic Axis Ranges support any parameter that is compatible with the selected continuous axis, for example:

- Numeric parameters
- Temporal parameters (date or dateTime)

Configure a dynamic axis range

1. From a Tableau sheet, **create a parameter** for your axis.
2. Right-click the axis, and choose **Edit Axis**.
3. For the Range, choose **Custom**. Then, select the parameter that you created for either the start or end axis extent.
4. Close the dialog box.
5. If you're using multiple sheets on a dashboard, repeat these steps for the axes across the different sheets.

Understand limitations and edge cases

Dynamic Axis Ranges aren't updated within **Stories**. If the parameter used for the axis is deleted, then the most recent parameter value remains as the axis extent. The next time you edit the axis, an error message will prompt you to choose a new parameter to be used.

Use Dynamic Axis Titles

Tableau's flexibility empowers authors to quickly analyse different data sets and visualise data differently for deeper analysis. But with that flexibility, comes the responsibility to communicate accurately the data that is used in a viz. For example, it's critical to communicate the units of measure that change based on a parameter value. Imagine that you're looking at a viz of the weather that shows a forecast of 25 degrees. In Fahrenheit, that forecast might be a great ski trip. But in Celsius, that forecast might call for a trip to the beach.

As an author, you can use Dynamic Axis Titles to update the axis title based on the value of a parameter or a single-value field (for example, an LOD calculation). If you use [swap parameters](#), the axis titles update to match the data being used.

Supported field types

To be used as a Dynamic Axis Title, fields must be:

- A single-valued and a [fixed LOD calculation](#)
- A parameter
- A constant calculated field
- A top 1 set

Configure a dynamic axis title

1. From a Tableau sheet, drag a continuous field onto a shelf.
2. Double-click the axis to open the **Edit Axis** dialog.
3. Under the **Axis Titles** section, choose the field you want to use for your axis title from the list.
4. Close the **Edit Axis** dialog.

For a more complex use case, first follow the steps in [Example: Swap Measures Using Parameters](#). Then, follow these steps:

1. Double-click the X axis to open the **Edit Axis** dialog.
2. Under the **Axis Titles** section, select **Parameter**, and then choose the Placeholder 2 selector.
3. Close the **Edit Axis** dialog.
4. Repeat these steps for the Y axis using Placeholder 1.

Now, when the parameters are changed, the axes titles update to reflect the data being displayed.

Understand limitations and edge cases

Dynamic axis titles are cleared when the viz type is changed using Show Me. Also if you use subtitles, then the subtitle appears after the Dynamic Axis Title, just as it does for custom titles. Automatic subtitles are populated only when you have a continuous date value axis that is filtered to a single year with at least two time periods. The dynamic axis title functionality doesn't

work when using the worksheet in **Stories** (a sequence of visualisations that work together to convey information).

Use Dynamic Zone Visibility

Dashboard space is valuable, especially when you want to progressively reveal insights about data. With Dynamic Zone Visibility, you can hide or reveal zones (tiled or floating dashboard elements) based on the value of a field or parameter. As you interact, zones on your dashboard appear or disappear. The result is a dynamic dashboard that doesn't compromise your desired layout.

While you can **show or hide objects by clicking a button on a dashboard**, Dynamic Zone Visibility allows you to show and hide objects automatically. This is ideal for dashboards that are used by different user groups. For example, you might want to show different user groups different zones when they visit your dashboard.

And you can use Dynamic Zone Visibility with **Parameter Actions**. For example, when a user clicks a mark on a viz, a previously hidden zone appears. This is ideal for complex dashboards because it allows you to choose when deeper levels of data are revealed.

Supported field types

To be used for Dynamic Zone Visibility, a field or parameter must be:

- Boolean.
- Single value.
- Independent of the viz, meaning the field returns a constant value independent of the structure of the viz, such as a fixed level of detail (LOD) calculation.

Configure a dynamic dashboard zone

The following example has two sheets that use **Superstore data**: the first sheet has a bar chart with Sales by Category, and the second sheet has a bar chart with Sales by Sub-Category. By using Dynamic Zone Visibility, the second sheet is visible only after a mark is clicked in the Sales by Category zone. This example relies on a boolean calculated field, which is used as the source field for a parameter action. For the calculation to be used as the source field for the parameter action, the calculation must be added to the marks card.

1. From the Sales by Category sheet, **create a parameter**. In this example, the parameter **Data type** must be set to **Boolean**.
2. From the Sales by Category sheet, **create a calculated field**. This example uses the following calculation: `True`
3. On the Sales by Category sheet, drag the calculation that you created to **Details** on the marks card.
4. Create a dashboard.
5. Drag the sheet that you always want to be visible onto your dashboard. In our example, we want Sales by Category to be visible.
6. From your dashboard, click the Sales by Category zone (dashboard object). Then, from the Worksheet menu on your dashboard, **create a parameter action**. This example uses the following **Change Parameter** action:

The source sheet is set to use the dashboard you created and the Category Sales sheet.

The **Target Parameter** is the parameter you created.

The **Source Field** is the calculation you created.

Add Parameter Action

Name
Dynamic zone action Insert ▼

Source Sheets
☒ Dynamic product sales dashboard
☒ Category Sales
☐ Subcategory Sales

Run action on
☐ Hover
☒ Select
☐ Menu

Target Parameter
 T/F Hide zone with parameter ▼

Clearing the selection will
☐ Keep current value
☒ Set value to
 False ▼

Source Field
 T/F Calc for dy... ▼

Aggregation
 None ▼

Cancel OK

7. Drag the Sales by Sub-Category worksheet onto your dashboard.
8. Click the Sales by Category zone. From the upper right corner, click the drop-down arrow and select **Use as Filter**.
9. Click the Sales by Sub-Category zone, and then click the **Layout** tab.
10. Check the box for **Control visibility using value**.
11. From the drop-down, choose the parameter you created to control zone visibility.

Note: If the option to Control visibility using value doesn't contain the field you want to use, be sure that the field is a supported field type.

Now, when you click a category mark in the Sales by Category zone, the Sales by Sub-Category zone appears in your dashboard.

Understand limitations and edge cases

Dynamic Zone Visibility doesn't work when using the worksheet in **Stories** (a sequence of visualisations that work together to convey information).

Size and Lay Out Your Dashboard

After you create a dashboard, you can resize and reorganise it to work better for your users.

Control overall dashboard size

A best practice is to start with setting the size so any layout work starts at the correct size.

Dashboard size options

Fixed size (default): The dashboard remains the same size, regardless of the size of the window used to display it. If the dashboard is larger than the window, it becomes scrollable. You can pick from a preset size or specify a custom size.

Fixed size dashboards let you specify the exact location and position of the content on the dashboard, which can be useful if there are floating objects.

Published dashboards that use a fixed size can load faster because they're more likely to use a cached

version on the server. For other performance tips, see [Optimise Workbook Performance on page 3044](#).

Range: The dashboard scales between the minimum and maximum sizes that you specify. If the window used to display the dashboard is smaller than the minimum size, scroll bars are displayed. If it's larger than the maximum size, white space is displayed.

Use this setting when you're designing for two different display sizes that need the same content and have similar shapes – such as small- and medium-sized browser windows. Range also works well for mobile dashboards with vertical layouts. (The width is allowed to change for different mobile device widths, but the height is fixed for vertical scrolling.)

Automatic: The dashboard automatically resizes to fill the window used to display it.

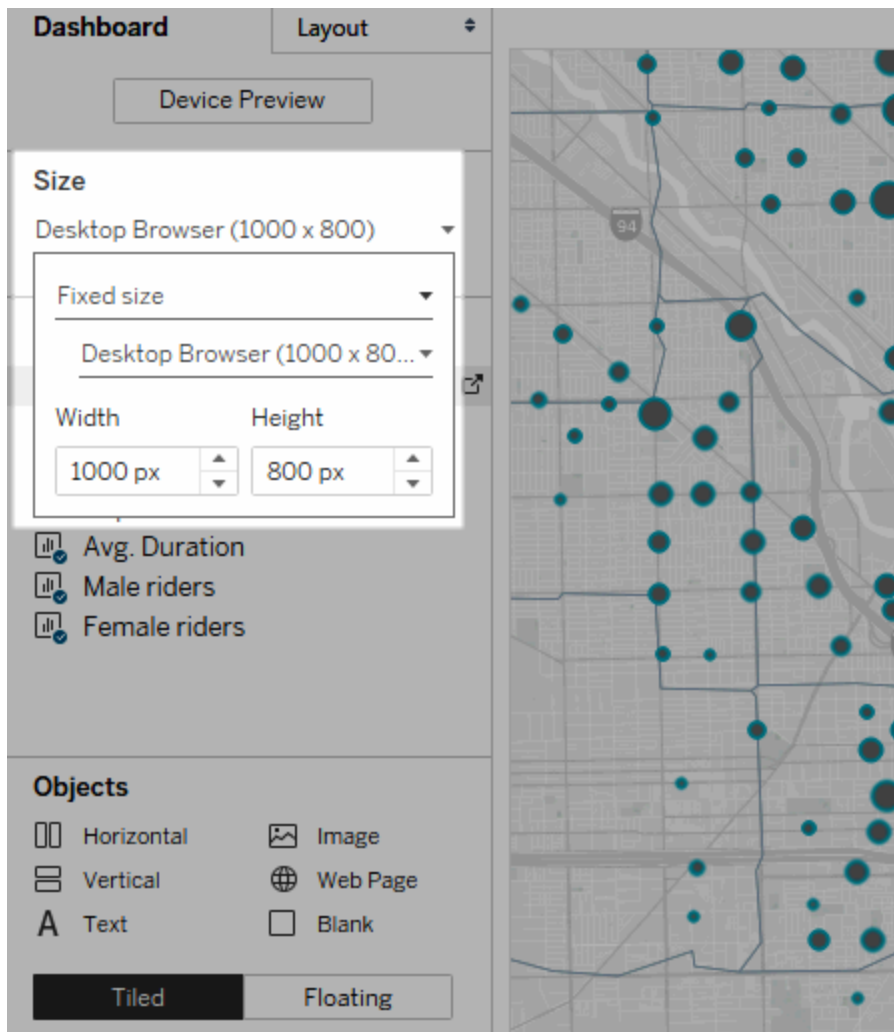

Use this setting if you want Tableau to take care of any resizing. For best results, use a tiled (rather than floating) dashboard layout. Automatic sizing can lead to unpredictable results on different screens, so use this setting with caution if you don't know where the dashboard will be consumed.

Dashboards with variable sizes must be freshly rendered for every browser request, which can have a performance impact.

Tip: If you use Tableau Desktop, see [Create Dashboard Layouts for Different Device Types on page 2778](#) to create unique layouts optimised for desktop computers, tablets and phones. In addition to adapting to different screen sizes, each device layout can contain different items.

Set overall dashboard size

- Under **Size** on the Dashboard pane, select the dashboard's dimensions (such as **Desktop Browser**) or sizing behaviour (such as **Fixed size**).

Group items using layout containers

Layout containers let you group related dashboard items together so you can quickly position them. As you change the size and placement of items inside a container, other container items automatically adjust. Layout containers can also be used for formatting.

Layout container types

A horizontal layout container resizes the width of the views and objects it contains; a vertical layout container adjusts height.

Horizontal layout container

The two views are arranged in a horizontal layout container.

Vertical layout container

The three views are stacked in a vertical layout container.

Add a layout container

1. Under **Objects** on the Dashboard pane, select **Horizontal** or **Vertical**.
2. Drag the container to the dashboard.

3. Add views and objects to the layout container.

Evenly distribute a layout container's items

1. Select the layout container. If you have trouble making the selection, select an individual item within the container and choose **Select Container** from its shortcut menu.
2. With the layout container selected, choose **Distribute Evenly** from its shortcut menu:

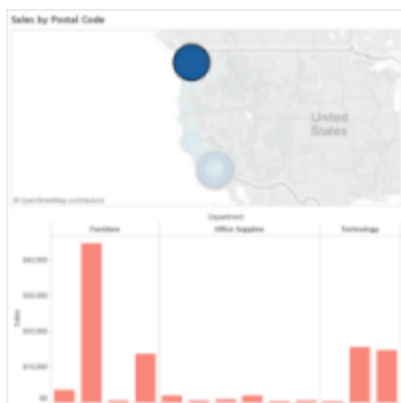

Items that are already within the layout container arrange themselves evenly; any items you add do the same.

Automatically resize sheets in layout containers

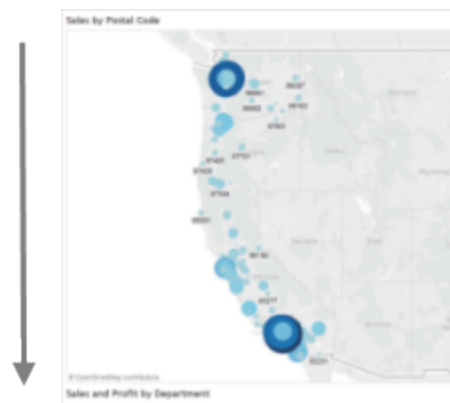

If you add multiple sheets with related data to a layout container, whenever marks are selected in one sheet, you can automatically resize related sheets.

In this example, when a mark is selected in the map, the bar chart updates to display profit and sales for that mark. When no marks are selected in the map, it automatically expands to fill the layout container.

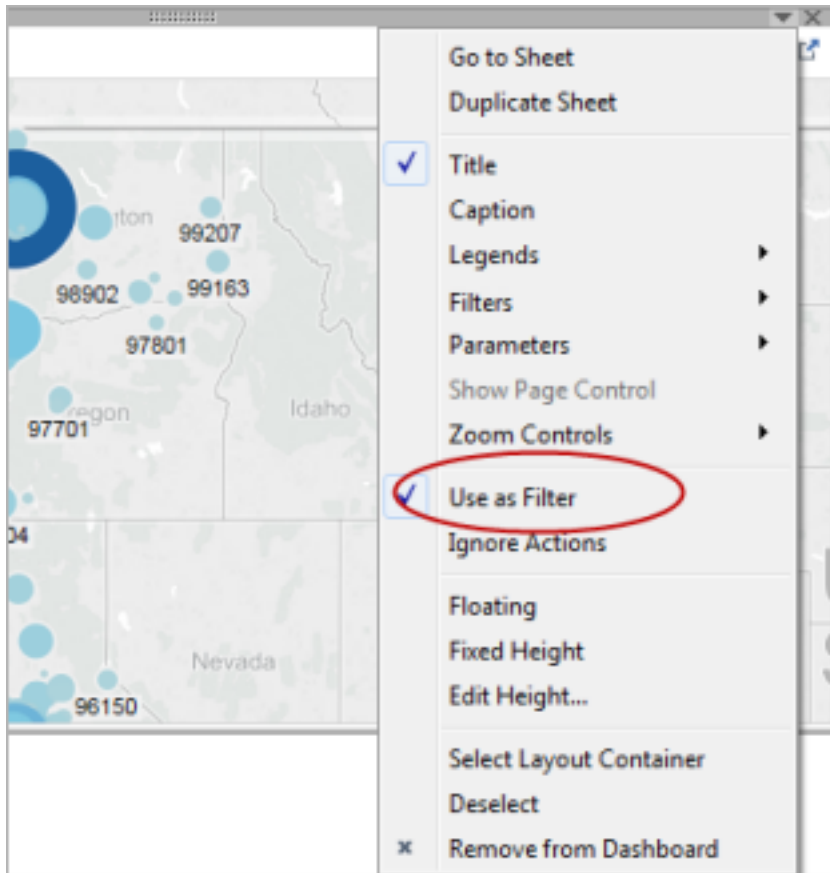

With mark selected

Without a selection

1. Add multiple sheets with related data to a layout container.
2. From the drop-down menu of the sheet you want to expand, choose **Use as Filter**.

3. Choose **Dashboard > Actions**, and double-click the generated filter you created.
4. In the **Target Sheets** section of the Edit Filter Action dialog box, select the other sheets in the layout container.
5. To control how target sheets resize when no marks are selected in the source sheet, select one of the following:
 - **Show all values** returns target sheets to their original size, showing all data.
 - **Exclude all values** collapses target sheets under their titles, hiding all data.

Remove a layout container to independently edit items it contains

1. Select the container either on the dashboard or in the **Item hierarchy** area of the Layout pane.
2. From the drop-down menu at the top of the container, select **Remove Container**.

Tile or float dashboard items

Tiled vs. floating layouts

Each object, layout container, and view that you place on a dashboard is either tiled (the default) or floating.

Tiled layout

Tiled items don't overlap; they become part of a single-layer grid that resizes based on the overall dashboard size.

Floating layout

Floating items can be layered over other objects. In the example below, a map floats over tiled views.

For best results, give floating objects and views a fixed size and position on a fixed size dashboard.

Float or tile a new item

1. Under **Objects** in the Dashboard pane, click the layout option you want to use: **Floating** or **Tiled**.

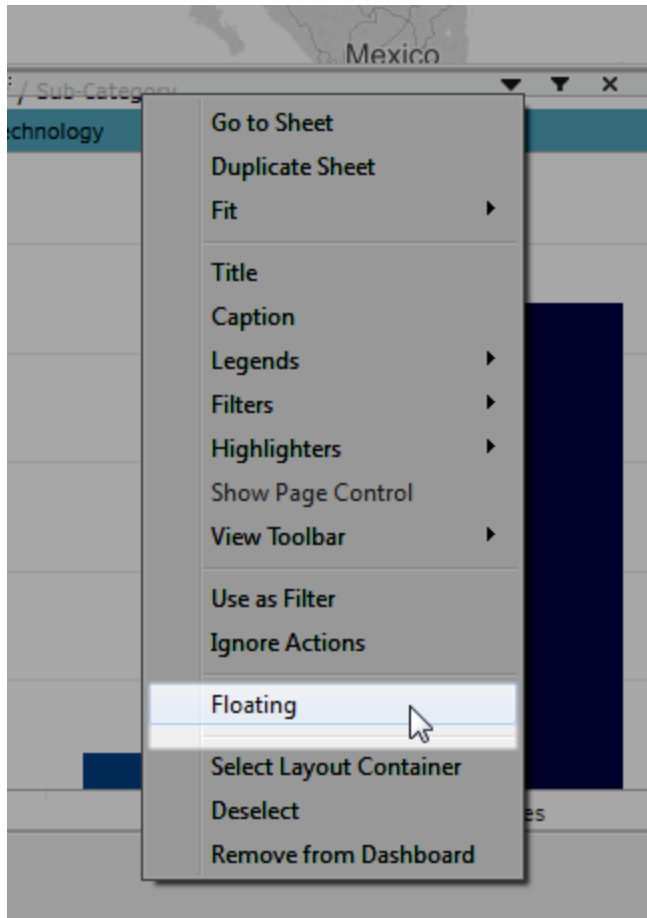

2. Drag the view or object onto the dashboard on the right.

Tip: You can also assign a floating layout to an item by holding down **Shift** on your keyboard as you drag it onto the dashboard.

Switch an existing item from tiled to floating

1. Select the item in the dashboard.
2. In the item's shortcut menu, select **Floating**:

Size, position, reorder and rename individual dashboard items

Set an item's size and position

If you want a high degree of control over the placement, choose **Fixed size** then set each item's size and position using the Layout pane.

1. Select the dashboard item you want to position and size. In the Layout pane, the item's name appears under **Selected item**.

Tip: To quickly switch between the Dashboard and Layout panes, press the T key.

2. Define the item's position **x** and **y** position in pixels as an offset from the top-left corner of the dashboard. For example, to place an object in the top-left corner of the dashboard, specify $x = 0$ and $y = 0$.

The values you enter can be positive or negative but must be whole numbers.

3. To resize an item, click and drag it in the dashboard. You can also use the settings under **Size**.
4. To hide the title of the item you've selected, clear the **Show title** check box. (The similar **Show dashboard title** check box on the Dashboard pane controls the overall dashboard title.)

Tip: To quickly position floating items, press arrow keys to move 1 pixel, or Shift+arrow keys to move 10 pixels. To quickly resize items, add Alt (Windows) or Option (macOS) to these shortcuts.

Align items with a grid

To present a visually consistent design, arrange and size dashboard items over a grid.

1. Choose **Dashboard > Show Grid**.
2. To change the grid size, choose **Dashboard > Grid Options**.

Tip: To quickly switch the grid on and off, press the G key.

Reorder objects

The **Item hierarchy** area on the Layout pane lets you quickly change how objects are layered and grouped on your dashboard. Items at the top of the list appear in the front, while items at the bottom appear in back.

Reorder any object in Tableau Cloud or Tableau Server

In Tableau Cloud and Tableau Server, you can reorder both tiled and floating objects in the hierarchy. You can also drag items both within their current containers, and into other containers at any level. This lets you nest items with more flexibility than editing on the canvas, which limits you to placing objects in the innermost container.

Reorder floating objects in Tableau Desktop

In Tableau Desktop, you can drag floating items at the top level of the hierarchy to change how they layer over each other.

Rename items

To better distinguish between dashboard items, you can rename them.

In the **Item hierarchy** area of the Layout pane, right-click an item, and choose **Rename Dashboard Item**. On the dashboard itself, this command is also available from the drop-down menu for each object.

Add padding, borders and background colours around items

Padding lets you precisely space items on the dashboard, while borders and background colours let you visually highlight them. Inner padding sets the spacing between item contents and the perimeter of the border and background colour; outer padding provides more spacing beyond the border and background colour.

Note: If you can't change the border or background colour for a particular dashboard item, change its formatting [at the worksheet level](#).

A. Outer padding B. Blue border C. Inner padding with light blue background

1. Select an individual item, or your entire dashboard.
2. On the **Layout** tab at left, specify border style and colour, background colour and opacity,

or padding size in pixels.

Here are some handy dashboard spacing tips:

- To precisely align one dashboard item with another, deselect **All sides equal**, and adjust padding for only one side.

- To create seamless designs, specify zero outer padding for adjoining items.

Visually integrate elements with transparency

Transparent elements create a seamless visual look for your dashboards, revealing underlying objects and images.

Tip: To create a background image that shows through floating transparent elements, add an image object as the only tiled item. **Fixed-size dashboards** ensure that the floating elements maintain a consistent visual relationship with the image, regardless of screen size.

Make worksheet backgrounds transparent

1. In your dashboard, select the sheet.
2. Choose **Format > Shading**, click the **Worksheet** menu, and choose **None** for the background colour.

If the sheet appears opaque, change the background colour to None for the underlying dashboard, object or layout container. You can quickly adjust these items on the Layout tab for the dashboard.

3. To smoothly integrate the transparent sheet with other dashboard items, choose **Format > Borders** and **Format > Lines**, and either remove borders and lines or change their colours.

More steps for transparent maps

1. Choose **Format > Shading**, click the **Pane** menu, and choose **None** for the colour.
2. Choose **Map > Map Layers**, and deselect the opaque **Base** layer. Then, to make transparent maps more distinct when zoomed out, select the **Coastline** layer.

Depending on the map style, you may also need to experiment with turning other layers on or off.

Make a sheet partially transparent

1. In the **Layout** pane for the dashboard, select the sheet.
2. Click the **Background** colour, and set the colour and opacity.

Float transparent legends, filters, highlighters and parameters

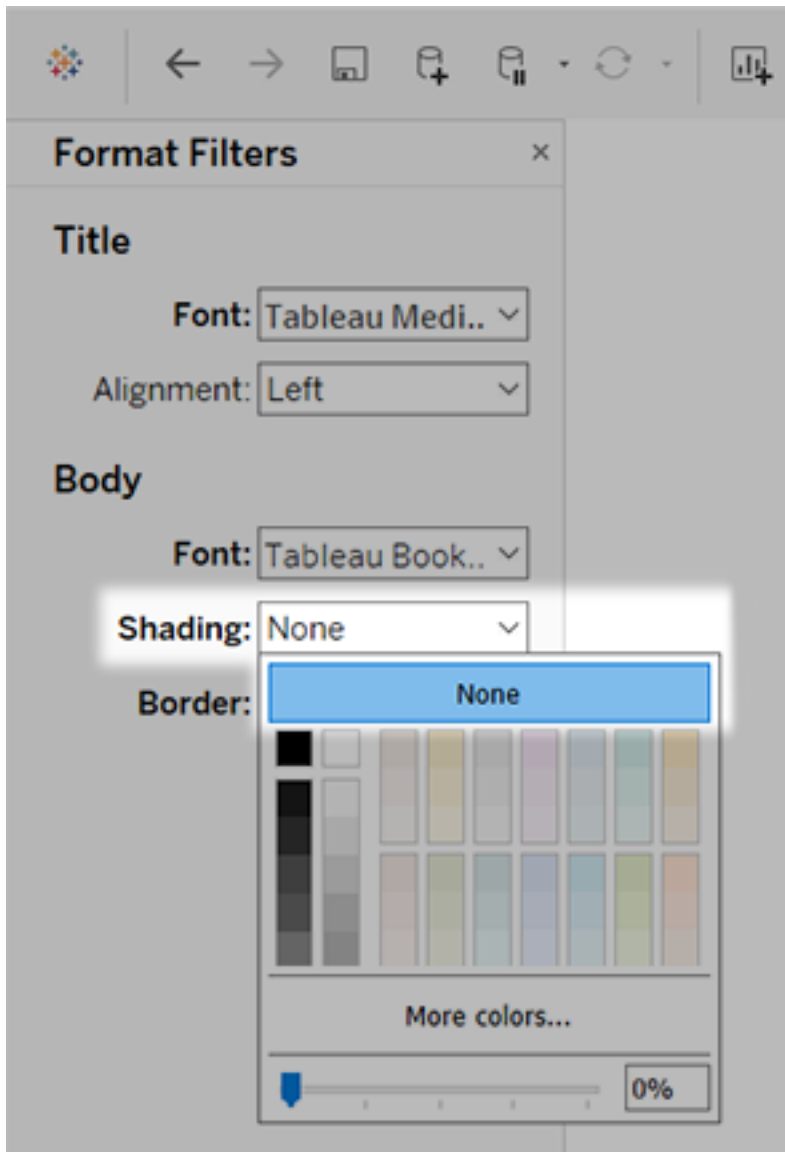

To visually connect filters, parameters and highlighters to related data, float these items, which are transparent by default. Text always remains fully opaque, maintaining legibility.

If a floating object continues to display a colour, check these object- and worksheet-level settings:

- Select the object, and on the **Layout** tab, click the **Background** colour, and choose **None**.
- Click the **Format** menu, and then choose **Legends**, **Filters**, **Highlighters**, or

Parameters. Then, in the Format pane at left, choose **Shading > None**.

For more information, see [Format at the Worksheet Level](#) on page 2932.

Refine Your Dashboard

After you've created and laid out your dashboard, take a moment to step back and evaluate it. This topic lists some areas to check and refine.

Is everything in the right place?

Confirm placement

Make sure that the view with your key finding or main question spans or occupies the upper-left corner of your dashboard. In your views, the most important data should be on the X or Y axis and your less important data should be on colour, size, or shape.

Check label orientation and readability

Important labels should be horizontal so that your viewers can easily read them.

Review sizing and layout

Test your work and adjust sizing

Once you finish your dashboard, it's a best practice to test it and experience it as your users will. For example, will they be using Tableau Reader on a laptop to view your dashboard, will the dashboard be published on Tableau Server, or will it be embedded in a web application and viewed from a tablet?

After you test your dashboard, you'll probably find some things to change – sizing and how and where items are positioned are usually among them.

Tableau dashboards are set to a fixed default size that's intended to work well on a typical desktop. However, when you publish (to the web, in a blog, for a presentation, etc.) you may find yourself more limited.

You can specify the overall size of the dashboard using the settings under **Size** in the **Dashboard** area on the left. Select a new size using the drop-down menu.

- **Automatic** - The dashboard automatically resizes to fill the window it's displayed in.
- **Fixed size** - The dashboard always remains a specific size. If the dashboard is larger than the window the dashboard becomes scrollable.
- **Range** - The dashboard scales between minimum and maximum sizes that you specify, after which scroll bars or white space display.

Customise image display (Tableau Desktop only)

When you add an **Image** object to a dashboard, you can customise how the image displays by selecting an option on the image's menu. For example, you can select whether to **Fit Image**, which scales the image to the size of image object on the dashboard.

By default, any high-resolution images that you use in a dashboard are displayed in standard resolution and will maintain the same size whether they're viewed on standard or Retina displays.

To take advantage of high-resolution images in a dashboard that are intended to be viewed on a Retina display, you can use the @2x naming convention:

1. Navigate to the high-resolution image on your computer with Retina display.
2. Rename your high-resolution image to include the @2x modifier by using `<image-name>@2x<file-extension>` format. For example, `logo@2x.png`.
3. In your workbook, click and drag an **Image** object onto your dashboard.
4. When you're prompted, select the image you just renamed using the @2x naming convention and then click **Open**.

Note: EMF image file formats are not compatible with Tableau Desktop on the Mac.

Use a layout container

A layout container can create a smoother experience for your users by helping dashboard objects reposition and resize when one view is filtering another.

The image below shows how a dashboard behaves when two views are placed in a vertical layout container versus how they behave when they are not placed in a layout container. Notice how, in the dashboard that uses a layout container, the views adjust vertically as different filters are applied.

[Click the image to replay it.](#)

To add a layout container

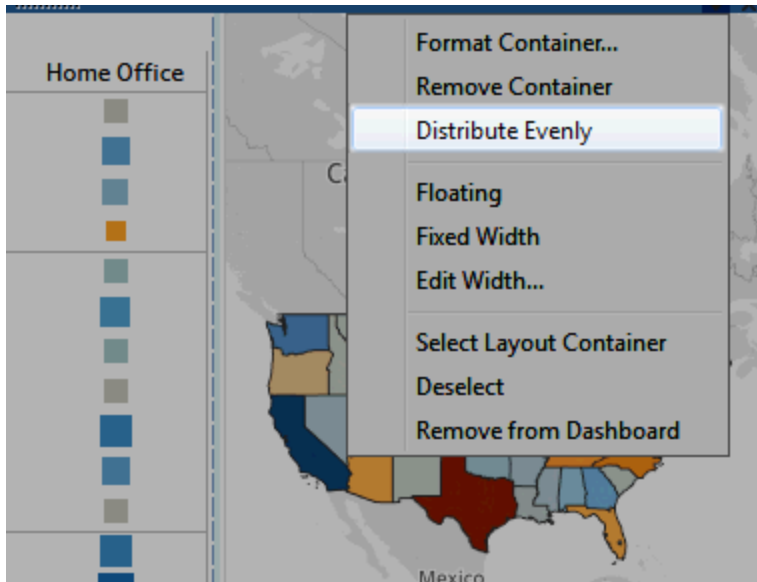

1. Drag a horizontal or vertical layout container to the dashboard.

2. Add sheets and objects to the layout container. As you hover over the layout container, a blue box indicates that the object is being added to the flow of the layout container.

3. To position items evenly, choose **Distribute Evenly** from the layout container's shortcut menu:

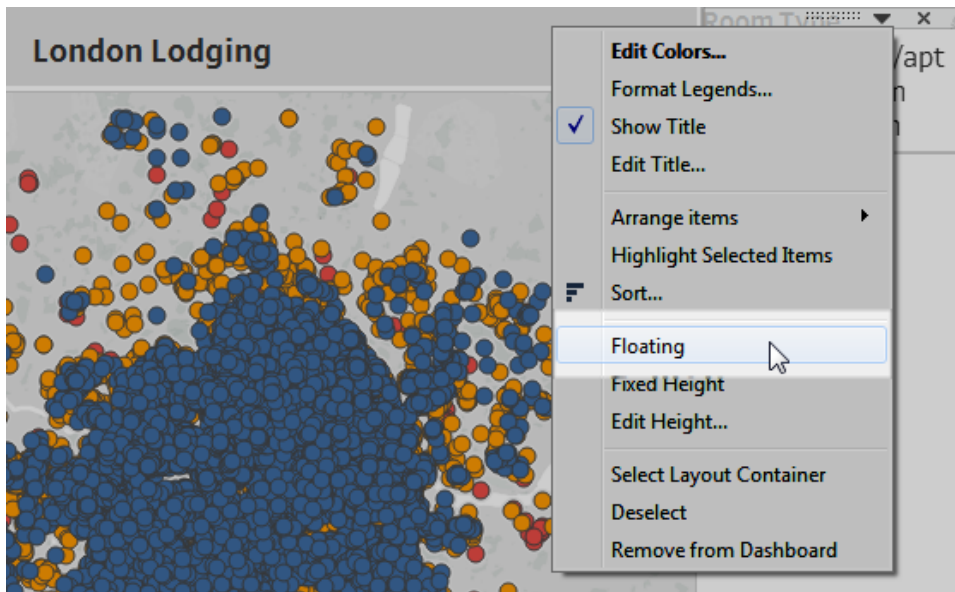

The **Distribute Evenly** command is only available for layout containers that you explicitly add to a dashboard. It's not available for layout containers that are automatically added when you add items.

Buy space with a floating layout

Tableau uses a tiled layout by default in dashboards, which means that each view, legend, and object is arranged in a single-layer grid, similar to a tiled floor.

If you want an item to overlap another, you can use a **Floating** layout for one or more items instead:

Legends can sometimes be floated over other items instead of remaining tiled.

See [Size and Lay Out Your Dashboard](#) on page 2732 for more details.

Tableau Desktop only: If you create device layouts for a dashboard, use a **Tiled** layout. It will give you the most control over where objects appear. See [Create Dashboard Layouts for Different Device Types](#) on page 2778 for steps.

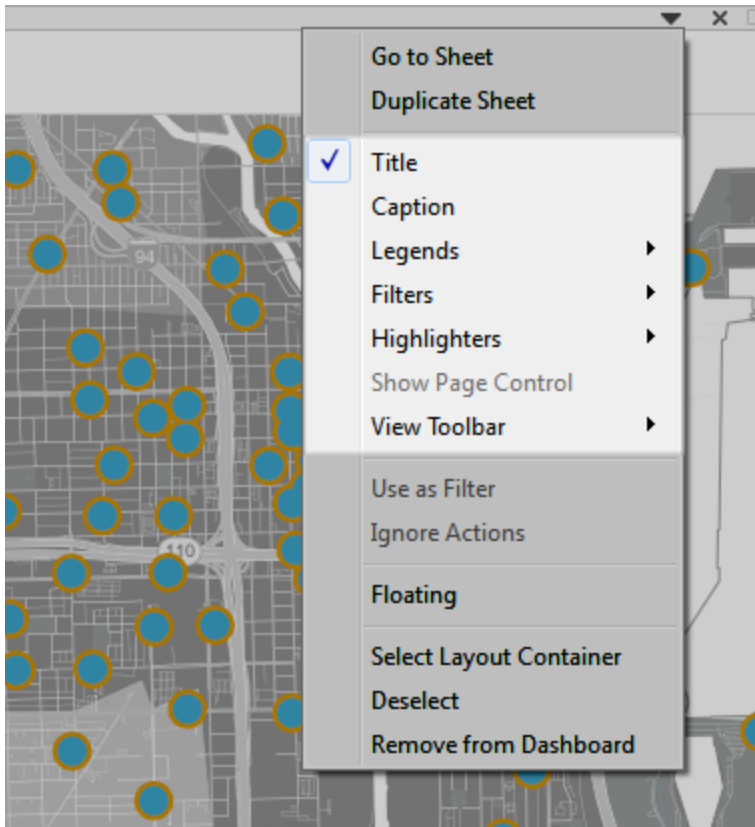

Highlight the essentials

Show just what your users need

Legends, titles, captions, and filters can be helpful for your viewers. Make sure you give your users what they need and no more.

To change what's displayed for your users:

1. Select a view in the dashboard.
2. Click the drop-down menu in the upper-right corner of the selected view and select the items you want to show. For example, you can show the title, caption, legends, and a variety of filters.

Alternatively, you can right-click an item in the **Layout** section of the **Dashboard** pane to access all of these same commands.

Note: Filters are only available for the fields used in the original view.

Eliminate clutter

In general, you should try to use no more than two colour palettes in a single dashboard, and ideally, just one palette if your data is quantitative. Remove unnecessary text, lines, or shading that don't provide actionable information for your viewers. Make sure every legend you provide is really needed, remembering to take into account the final, published size of your dashboard.

Cluttered

Scatter Plot

The trend of Median for Date. Color shows Median. Details are shown for Year of Date and Month of Date. The data is filtered on Month of Date, which ranges from January 1850 to March 2016 and keeps Null values. The view is filtered on Year of Date, which excludes 2016. The trend of Median for Date.

[Click the image to replay it.](#)

Create a Sheet Selection Menu for a Dashboard

Using a combination of a parameter and a calculated field, you can create a drop-down menu that lets users select an individual view that automatically expands to fill a dashboard.

Tip: To show sheets using separate buttons rather than a single menu, instead use **Show/Hide buttons**. This is a much simpler approach, though each button will reveal a separate object. To leave a dashboard and open a completely different sheet, use **Navigation objects**.

1. On an individual worksheet, right-click an empty area of the **Data** pane at left, and select **Create Parameter**.

2. In the Create Parameter dialog box, do the following:
 - Enter a name that will appear above the menu, like **Select a View**.
 - For **Data type**, select **String**.
 - For **Allowable values**, select **List**.
 - Under **List of values**, type **All** for the first value, and then add values with the

name of each view in the dashboard.

Edit Parameter [Select a View]

Name: Comment >>

Properties

Data type:

Current value:

Display format:

Allowable values: ☐ All ☒ List ☐ Range

List of values

| Value | Display As |
|------------|------------|
| All | All |
| Map | Map |
| Bar Chart | Bar Chart |
| Line Chart | Line Chart |
| Add | |
| | |
| | |
| | |

Add from Parameter Add from Field Paste from Clipboard

Clear All

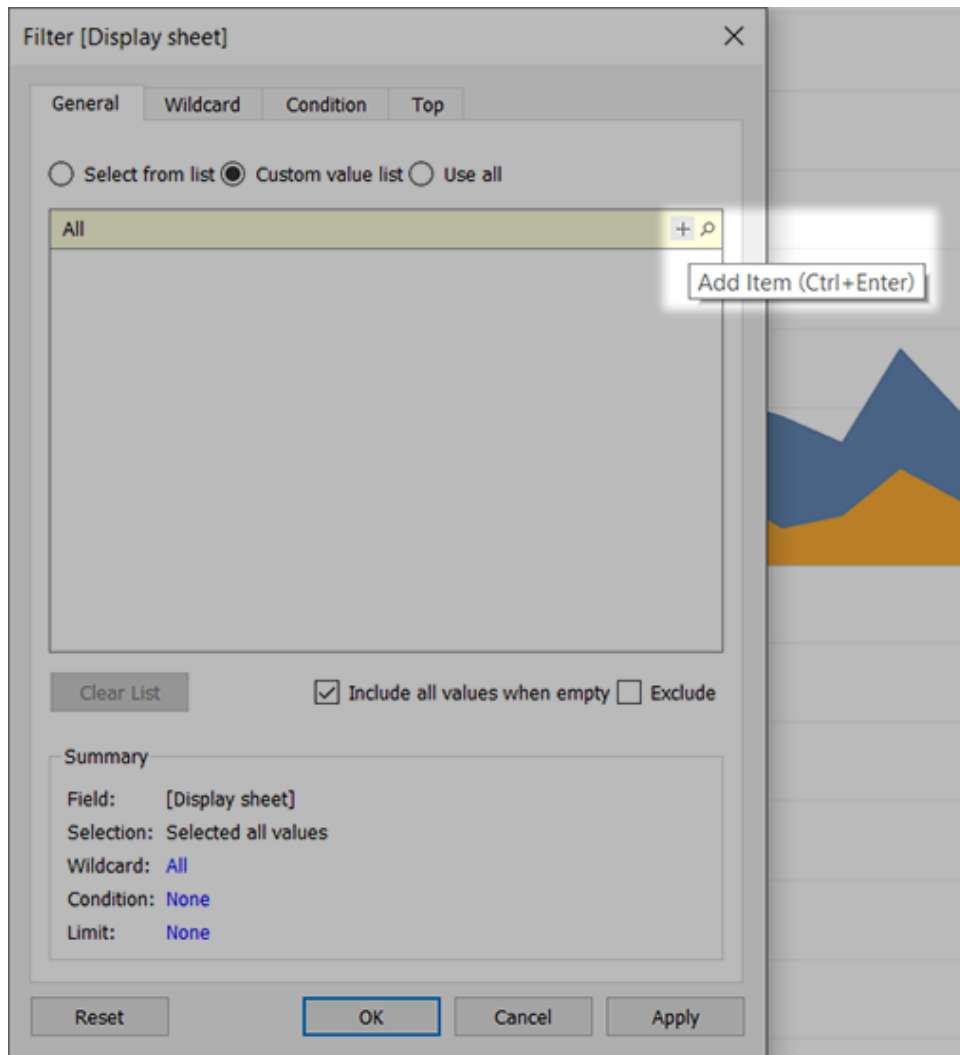

OK Cancel

3. Click **OK**.
4. On any sheet, right-click an empty area of the Data pane at left, and select **Create Calculated Field**.
5. Give the calculation a descriptive name like **Display sheet**. In the formula text box, enter the name of the parameter you created above. Then click **OK**.

6. Open a sheet you plan to add to your dashboard, and drag the new calculation to the Filters shelf. Then do the following in the Filter dialog box:
 - Select **Custom Value List**.
 - Type **All** in the text box, and click the **Add Item** button.
 - Type the current view's name (like "Map") in the text box, and click the **Add Item** button.

When you're done, click **OK**.

7. Repeat step 6 for every sheet you plan to add to your dashboard.
8. Select **Dashboard > New Dashboard**.
9. From the **Objects** section at lower left, drag a **Vertical** or **Horizontal** layout container to the dashboard.

10. Now drag each sheet to the layout container, identified by the dark blue outline.

11. To display the sheet selector, from the drop-down menu at the top of a view, choose **Parameters** > [new parameter name].

12. To ensure that selected views fill the dashboard, do the following:

- From the drop-down menu at the top of each view, ensure that **Fix Width** is *not* selected.
- Right-click the title area of each view in the dashboard, and select **Hide Title**.

Your sheet selector is ready to go! For similar examples, see [Use Parameters to Make Views More Interactive](#) on page 1140.

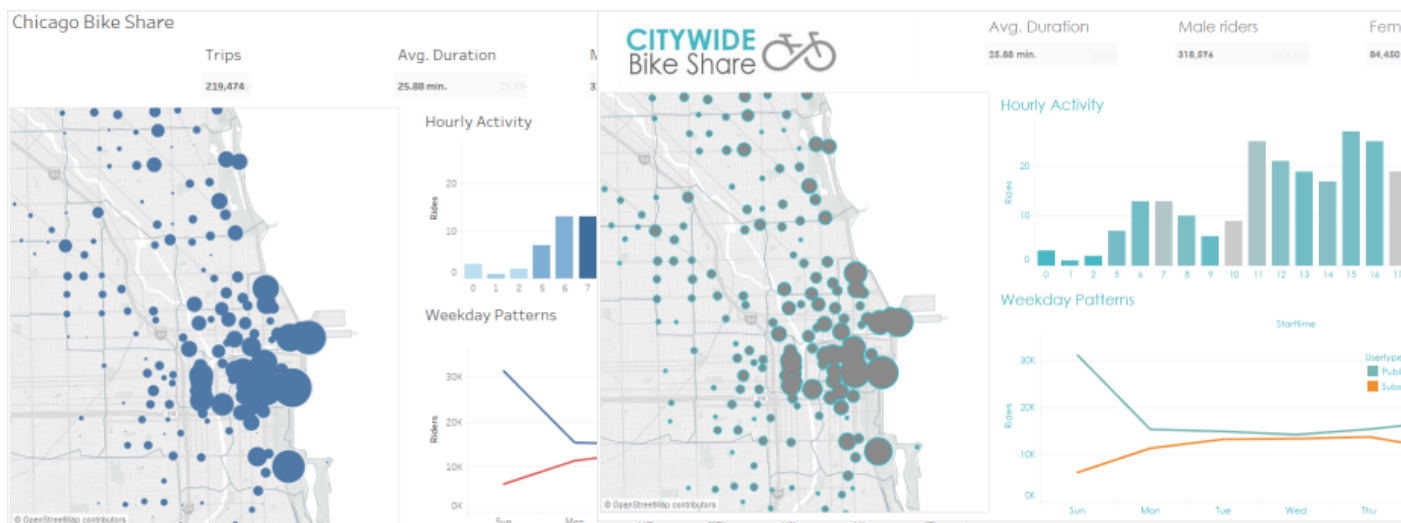

Rebrand a Dashboard

Tableau Desktop builds visual best practices into its default formatting settings so that your visualisations look great from the start. But you might want to change formatting settings for a dashboard – for example, to align them with your organisation's brand.

This article steps you through a dashboard rebranding process for a fictitious organisation called Citywide Bike Share. Its brand includes turquoise, orange and grey for its colours and Century Gothic for its font. The overall look is light and uncluttered and, of course, it's all about bikes!

Before

After

Change the fonts and font colour of your titles

Fonts and colours are usually an important part of an organisation's brand. The quickest way to make a fast, large-scale change to all the titles in your dashboard is to change them at the workbook level. A workbook is the largest possible container for formatting settings.

1. Click **Format > Workbook**.
2. Make your changes under **Fonts**, in the **Format Workbook** pane.

Here we've changed the font to Century Gothic and the font colour to turquoise. We've chosen to change every title in the workbook, but you could also change the look of individual titles.

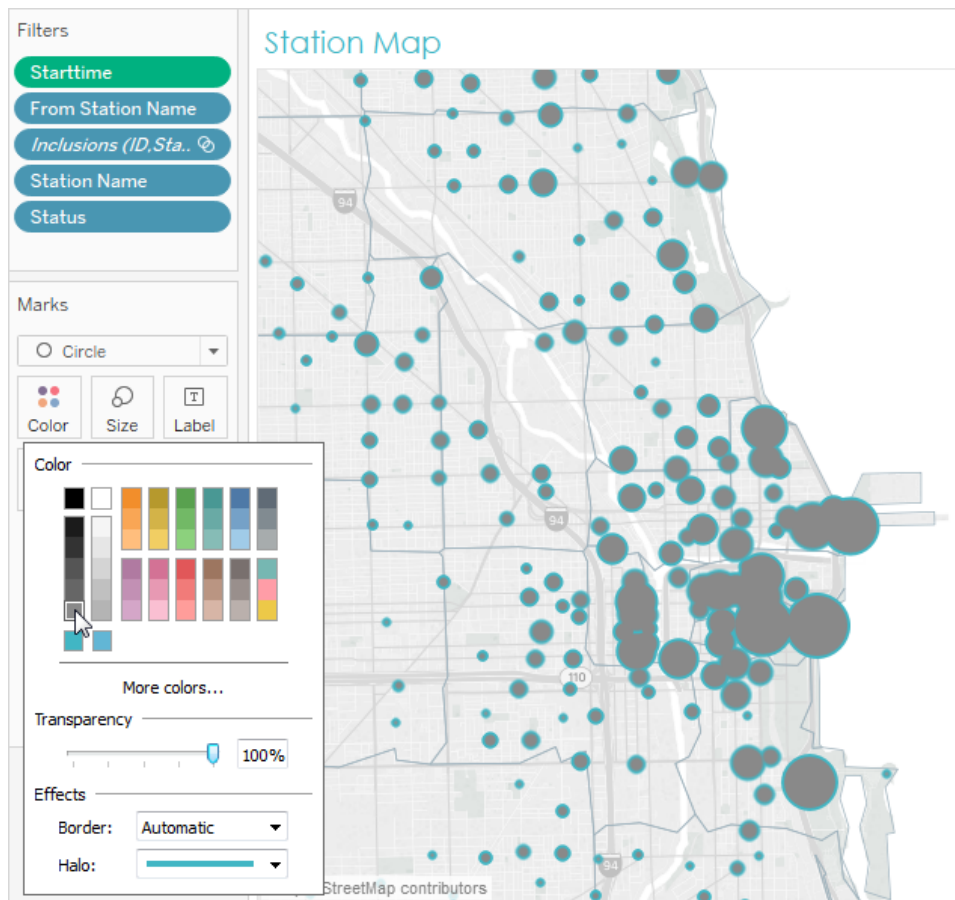

If the font you want to use doesn't exist in Tableau by default, you can add it. See [Use Custom Fonts](#) on page 2980 for details.

Change the marks colours

Marks represent data in a view. In this rebranding scenario, the marks show bike share locations. Changing marks colours is another way to communicate your organisation's brand to your audience. For certain types of marks, you can also add and format halos, which is a coloured ring around a mark.

1. Go a view on your dashboard and click **Go to Sheet** from the view's shortcut menu.
2. In the view, click **Colour** on the **Marks** card.
3. Make your new colour selection.

Here we've changed the marks in the Chicago Ride Share map to use grey with a turquoise halo:

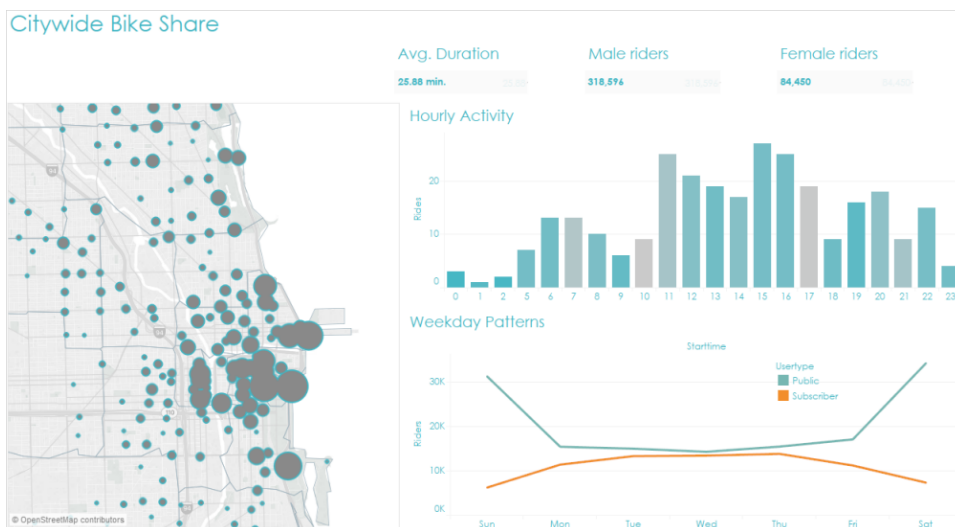

4. Repeat the above steps for every view in your dashboard.

If a colour you want to use isn't available, you can create your own custom palette. See [Create Custom Colour Palettes on page 3009](#) for details. For example, here we've changed the colours in the bar chart by created a custom diverging palette.

Now, with just a few changes to fonts and marks colours, the dashboard branding is already taking shape.

Customise your tooltips

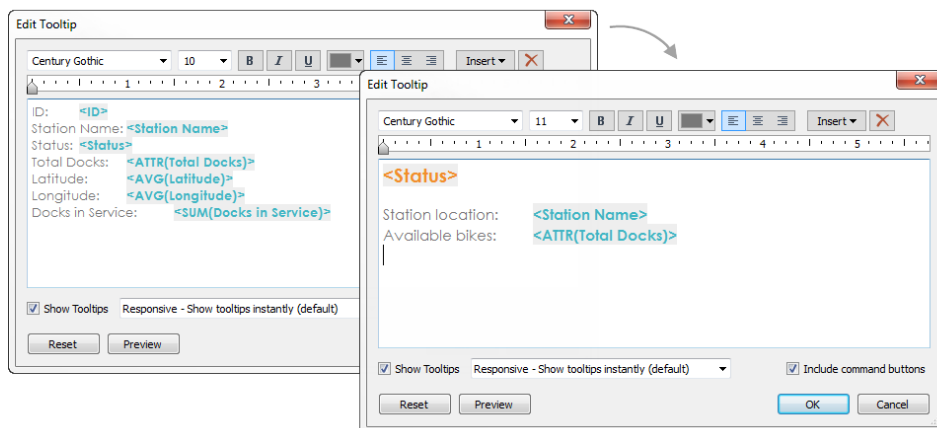

Tooltips appear when you hover the mouse pointer over a mark. Tooltips appear by default for most views. They're a great way to reinforce your brand and tell a better story.

Here's what the map tooltips looked like by default:

1. Go to the view's worksheet and click **Worksheet > Tooltip**.
2. Confirm that the tooltip has the details you want to display. You can change fonts, order, wording, alignment and colour.

For this rebranding scenario, we reduced the number of items displayed in the tooltip so that it's easier for users to quickly see what they're most interested in. We also reworded a few items and added the colour orange as a contrasting, brand-appropriate colour:

Here's what the map tooltips look like now:

Add an image or logo

Adding your own images can also be a way to bring your organisation's brand into a workbook. For example, you can import a logo and use it at the top of your dashboard instead of displaying the default dashboard title.

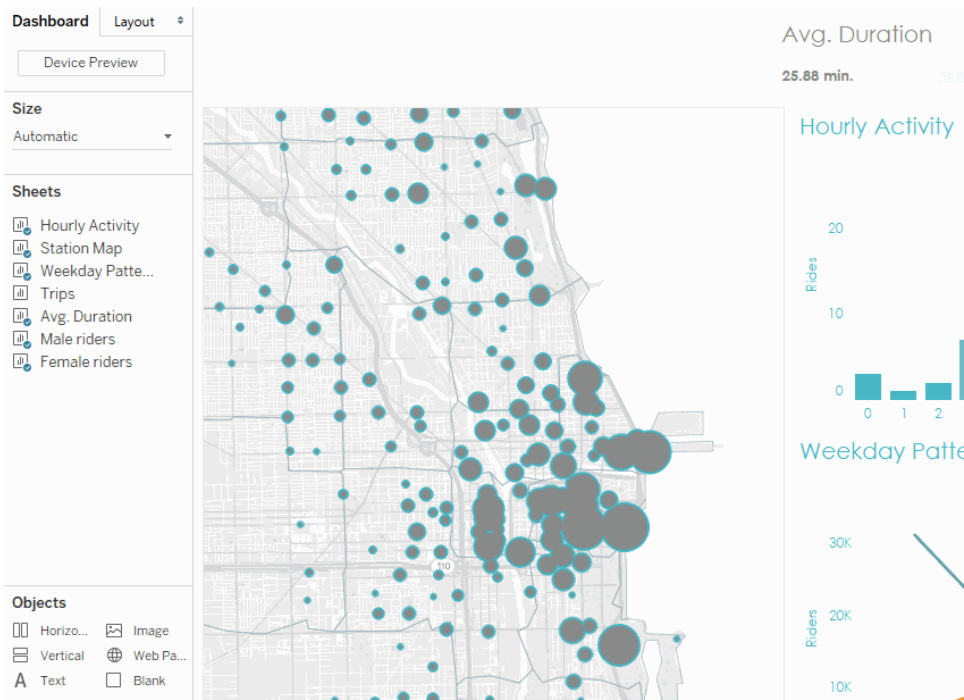

To remove the title and add an image:

1. In the Dashboard pane, stop displaying the dashboard title by clearing the **Show dashboard title** tick box in the lower left corner.

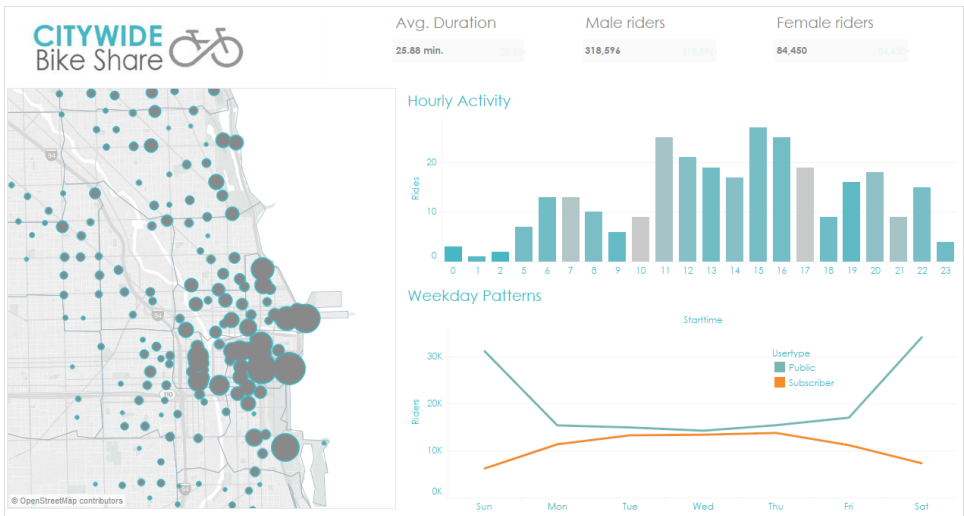

2. Drag the **Image** object to the area where you want to display your logo. You may also need to adjust or remove other dashboard objects.

Tableau Desktop and Web Authoring Help

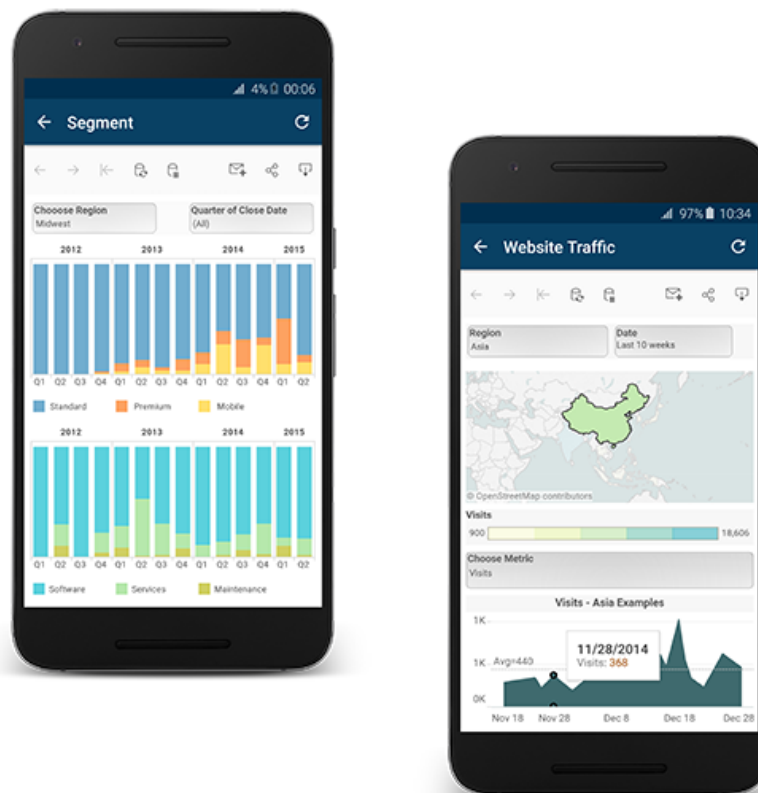

Click the image to replay it.

Here's our final, rebranded workbook:

Create Dashboard Layouts for Different Device Types

Dashboards can include layouts for different types of devices that span a wide range of screen sizes. When you publish these layouts to Tableau Server or Tableau Cloud, people viewing your dashboard experience a design optimised for their phone, tablet or desktop. As the author, you only have to create a single dashboard and deliver a single URL.

Tip: In addition to optimising layouts for mobile, [Optimise Workbook Performance on page 3044](#) to better meets the needs of mobile users, who often have limited bandwidth and are in a hurry.

How the Default dashboard relates to device layouts

Device layouts appear on the Dashboard tab, under Default. Initially, each device layout contains every item in the Default dashboard and derives its size and layout from Default as well.

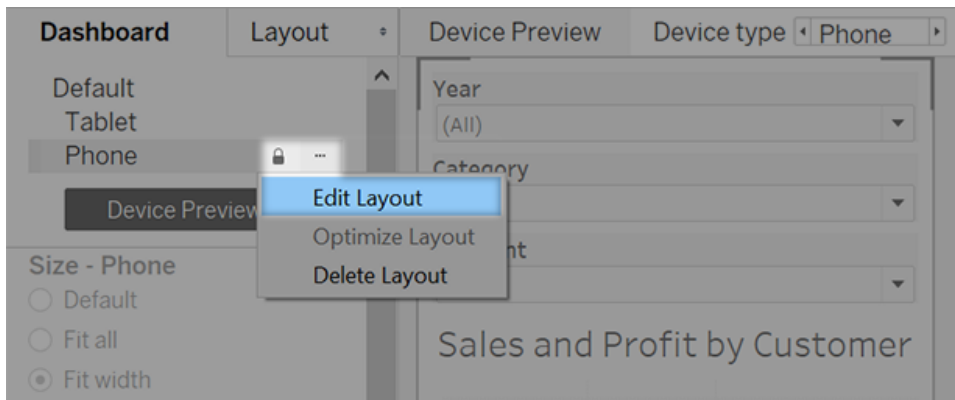

Think of the Default dashboard as the parent, and the device layouts (desktop, tablet, and phone) as its children. Any view, filter, action, legend or parameter that you want to add to a device layout must first exist in the Default dashboard.

Phone layouts and the Default dashboard

To save time with a unique Phone layout option that automatically reflects changes to the Default dashboard, either click the open lock icon , or choose **Auto-Generate Layout** from the pop-up menu.

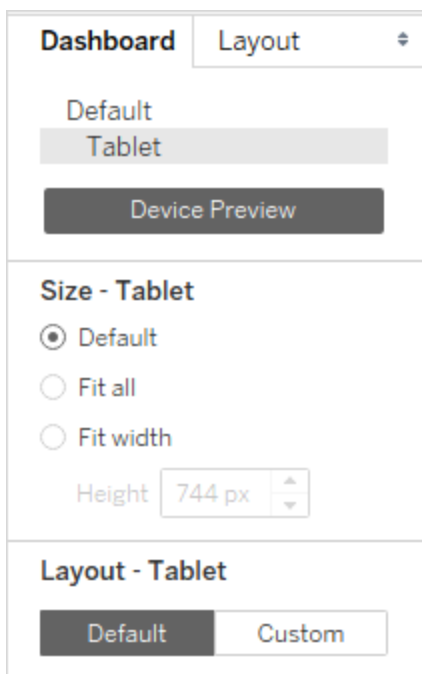

If you instead click the closed lock icon , or choose **Edit Layout** from the menu, the Phone layout becomes fully independent, so you'll need to manually add and arrange items to reflect changes to the Default dashboard.

Desktop and Tablet layouts and the Default dashboard

Unlike Phone layouts, you need to manually add Desktop and Tablet layouts to a dashboard. Desktop and Tablet layouts are always fully independent from the Default dashboard, so each device layout can contain a unique arrangement of objects.

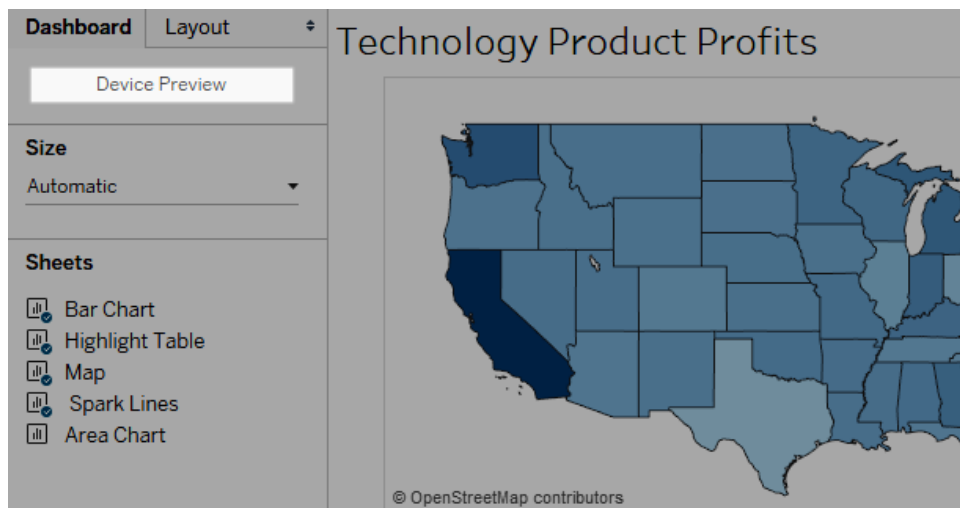

Automatically add phone layouts

Two options let you automatically add phone layouts:

- To create phone layouts whenever you open old dashboards that lack them, choose **Dashboard > Add Phone Layouts to Existing Dashboards**
- To create phone layouts whenever you create a new dashboard, choose **Dashboard > Add Phone Layouts to New Dashboards**. (This option is on by default.)

Preview and manually add device layouts

1. Open a dashboard.
2. On the **Dashboard** tab on the left, click **Device Preview**.

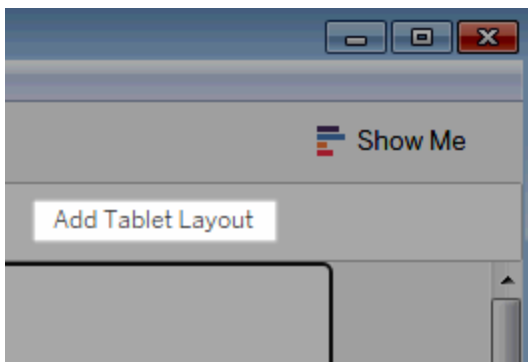

In device preview mode, these options appear above the dashboard:

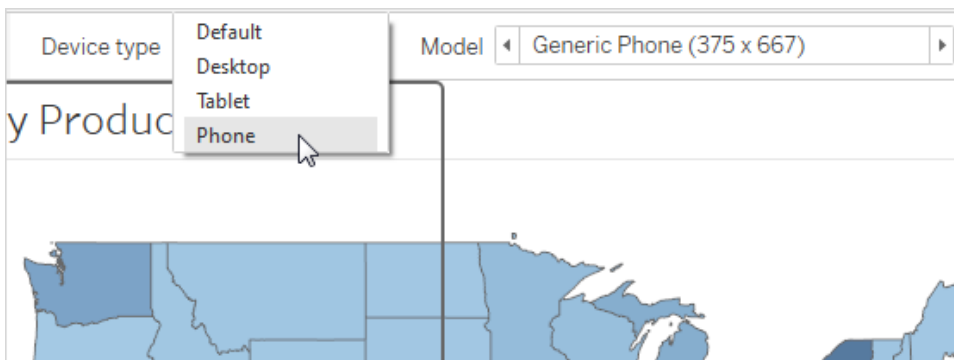

3. Take a moment to click through the **Device types** and **Models** and explore the different screen sizes. Then set these options:
 - To see how the dashboard will look in landscape vs. portrait mode, click . Usually, landscape is optimal for tablets and portrait is best for phones.
 - Select **Tableau Mobile app** to see how the dashboard will look with the app instead of the browser. This option is available for iOS or Android devices and shrinks the dashboard slightly, leaving space for the app controls.
4. Choose a **Device type**, such as **Tablet**.

5. In the upper-right corner, click the **Add Layout** button for the device type you selected (for example, **Add Tablet Layout**).

6. Add an additional layout by selecting a new **Device type** and clicking **Add Layout**.

Creating a layout for each device type gives you the most control over your users' experience as they view your dashboard from different devices. After you publish a

dashboard with all three layouts, users won't see the default dashboard layout; instead, they'll always see the appropriate device-specific layout.

Note: If you make changes to a view, double-check related devices layouts to ensure that they look as you expect.

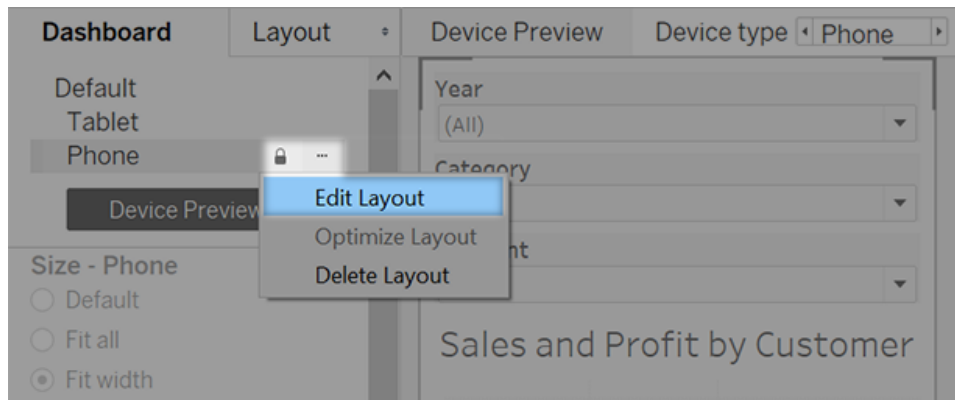

Customise a device layout

After you've added a device layout to your dashboard, you can start rearranging objects to create the look you want.

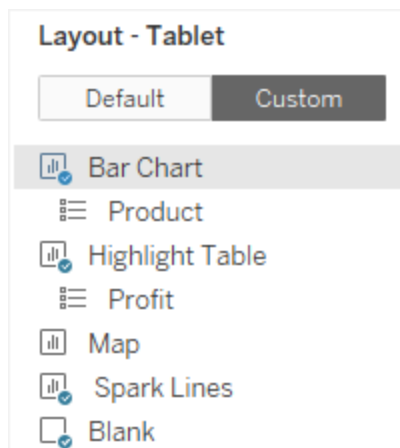

1. For Desktop and Tablet layouts, click **Custom**:

For Phone layouts, either click the lock icon , or choose **Edit Layout** from the pop-up menu:

2. Anything you can add to your layout is listed on the left, under **Layout**. If an item has a blue check mark, it means that it's part of the device layout that you're currently working on.

3. If you remove an item, it's only removed from the current device layout. It still exists on the default dashboard and can be added to the device layout again.

- Click through the **Device model** options to see how the layout will appear on different models.

Ultimately, it's the size of the web browser that loads the dashboard that determines which layout appears on the device. For details, see [Confirm which layout a device will display on page 2790](#).

- At left, explore the options under **Size**.

Default: The height and width of the device layout mimics whatever the default dashboard is using. For example, if you're creating a tablet layout and the default dashboard is set to a fixed size of Desktop Browser (1000 x 800), setting Size to Default for the tablet layout will make it use 1000 x 800 as well.

Fit all: All items are automatically resized to fit the device frame size. The device frame size is determined by the Device type, Model, and orientation (portrait or landscape) settings.

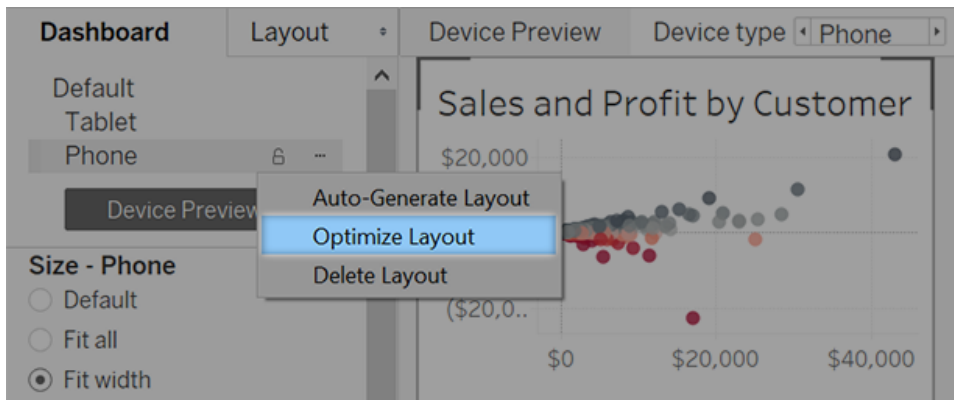

Fit width (recommended for phones): Items are automatically resized to fit the width of the device frame, but the height is fixed. This is a great option for phone layouts and vertical scrolling.

Optimise for phones

The small screens of mobile phones benefit from further optimisation. Try these techniques.

Optimise manual phone layouts

If you've chosen to edit a phone layout yourself, you can quickly optimise the placement of filters, remove white space and more. On the **Dashboard** tab, click the pop-up menu to the right of **Phone**, and select **Optimise Layout**.

Be aware that this command only rearranges items currently in the phone layout. If you want to continuously update the phone layout to reflect all changes to the default dashboard, select **Auto-Generate Layout**.

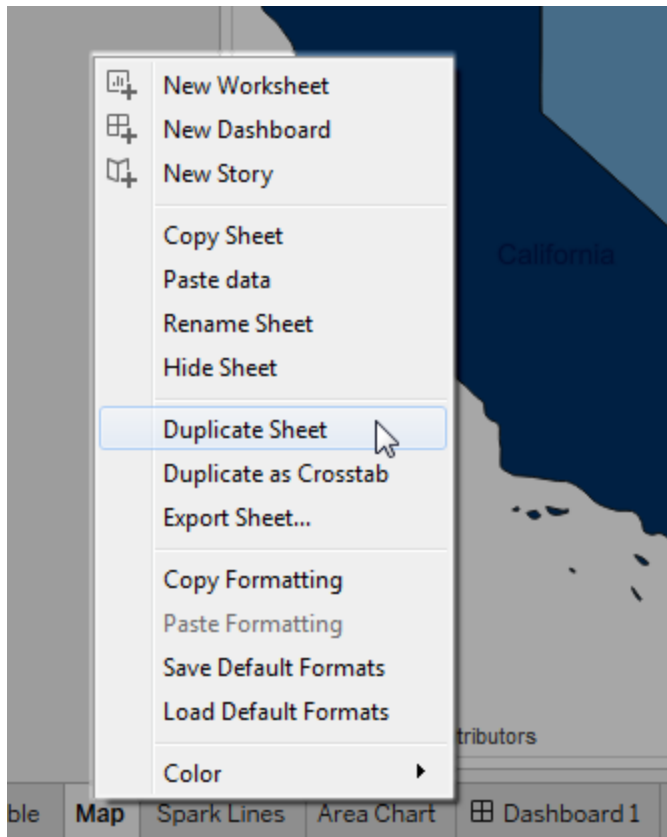

Add links that trigger instant messages and phone calls

To let phone users quickly contact key people about dashboard content, add **URL actions** to objects that automatically trigger SMS messages and telephone calls. Use the link format `sms:phone-number` or `tel:phone-number`. Be sure to include country and area codes if necessary.

Create phone-specific versions of views

Create duplicates of certain views in the default dashboard – one optimised for desktop viewing and a second optimised for phones.

1. Go to the worksheet for a view, click its tab, and select **Duplicate Sheet**.

2. Customise the view for mobile viewing.

For maps for example, you may want to zoom in to a specific region by default, or you may want to disable panning, zooming, and other functionality. See [Customise How People Interact with your Map](#) on page 1869.

3. Now add the new view to the default dashboard so that it can be available to the device layouts you're creating.

Shorten titles

Short titles work best for mobile viewing. To edit a title, double-click it.

Optimise white space

White space is another visual element to consider. While screen real estate on a phone is scarce and you want to make the most of it, you may also want to provide additional safe places for your users to tap or initiate scrolling, so they don't select filters and other items unintentionally.

To add white space, use padding or Blank objects. For more information, see [Size and Lay Out Your Dashboard](#) on page 2732.

Publish the dashboard

1. Click **Server > Publish Workbook**. If you're not already signed in, you're prompted for your credentials.
2. In the Publish Workbook to Tableau Server dialog box, make sure the **Show sheets as tabs** check box is cleared.

When this check box is selected for device-specific dashboards, the tabs' sizing requirements interfere with the server's ability to correctly detect the size of the web browser and load the correct layout.

3. Click **Publish**.

Test the dashboard

After you publish the dashboard to Tableau Server or Tableau Cloud, test the dashboard by viewing it from different browser sizes.

1. Open the dashboard on Tableau Server or Tableau Cloud.
2. In the upper-right corner of the page, click **Share** and copy the contents of the **Link** text box.

3. Paste the string into a web browser URL. The string should include the following:
embed=y
4. With the embed code string as your browser URL, test the different layouts by changing the size of your web browser window and refreshing it.

Confirm which layout a device will display

The dashboard layout a device displays is based on the smallest dimension (height or width) of the iframe in which the Tableau view appears. Sometimes Desktop, Tablet or Phone layouts may appear on other types of devices. For example, a Tablet layout may appear on a desktop computer if the display or browser window is small.

If the smallest iframe dimension is...

500 pixels or less

This device layout appears...

Phone

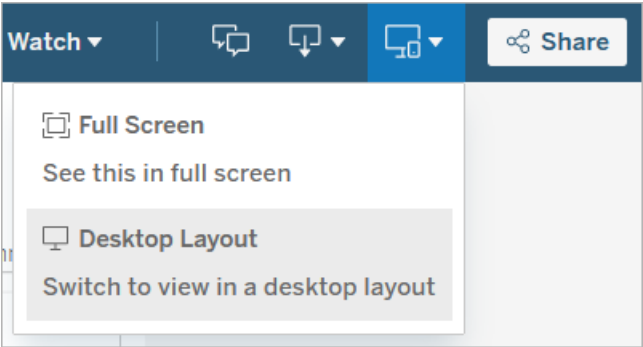

Between 501 and 800 pixels

Tablet

Greater than 800 pixels

Desktop

If Tableau Cloud and Tableau Server users find a Phone or Tablet layout too limiting, they can use the display settings button in the toolbar to view the Desktop layout. This button is a toggle that allows you to switch between Desktop and Mobile layouts. The button placement varies depending on the device you are viewing the dashboard on.

Display settings on a desktop device

Display settings on a tablet

Display settings on a phone

Build Accessible Dashboards

If you want to make your dashboards accessible to as many people as possible, or if you work in an environment that is subject to [US Section 508](#) requirements, or other accessibility-related laws and regulations, you can use Tableau to create dashboards that conform to the Web Content Accessibility guidelines (WCAG 2.2 AA).

To make an accessible dashboard:

1. Create a dashboard in either Tableau Desktop or in web authoring on Tableau Server or Tableau Cloud
2. Publish and embed that dashboard into a web page that conforms to Web Content Accessibility guidelines (WCAG 2.2 AA)

This topic explains how screen readers help users to navigate dashboards, the order that screen readers read objects or views in a dashboard, what items in a dashboard are accessible and how to take an existing dashboard and make it more accessible for all users.

Dashboard keyboard navigation and focus order

Tableau contains keyboard shortcuts that helps users navigate using only a keyboard. For more information, see [Keyboard Accessibility for Tableau on the Web on page 3255](#).

When creating a dashboard, note that screen readers read views or objects in a dashboard in the order in which they were added. For example, if your dashboard contains a text object containing information that helps explain the dashboard, add this object to your dashboard first.

You can also edit the dashboard hierarchy directly by editing the XML directly. For more information, see the Tableau community post [How can I set the focus order of the views and objects in a dashboard?](#)

Create accessible dashboards

Many items and objects in the Tableau workspace support keyboard navigation and are compatible with assistive technologies like screen reading software. You can use the following items on a dashboard you want to be accessible:

- [Add dashboard objects and set their options on page 2695](#)
 - Text objects
 - Web page objects
 - Button objects
 - Image objects
- Toolbar
- Dashboard titles
- Views, specifically:
 - Title
 - Workbook tabs
 - View Data window
 - Captions (when visible)
 - Categorical legends

Single and multi-value filters

For more information about views, see [Build Data Views for Accessibility](#) on page 1587

Note: Interactivity within a view (mark selection, tooltips, etc) is not accessible.

Walkthrough: make existing dashboards more accessible

Let's start with a finished workbook and work backward to make it more accessible.

For this workbook to be more accessible, we will:

1. **Format for accessibility at the dashboard and workbook level** on the next page
2. **Aggregate and reduce marks** on page 2798
3. **Eliminate redundant information** on page 2800
4. **Use colour and shape to differentiate marks** on page 2800
5. **Use filters to reduce the number of marks in a view** on page 2805
6. **Add captions and legends** on page 2809

This dashboard is designed to show total sales for each sales region and product type. The line chart at the bottom shows monthly sales by product type. The author of this dashboard wanted to use colour to brand the dashboard in the Superstore company's colours of green and grey.

Unfortunately, this dashboard has several features that pose accessibility problems for users, including the company colour scheme. The steps that follow show a few ways to make this dashboard more accessible.

Format for accessibility at the dashboard and workbook level

The green text on a grey background does not have a high enough contrast ratio to work for users with visual contrast sensitivity loss. To make this workbook accessible to all users and make the contrast ratio as high as possible, we're going to make the background white and change the text colours on our chart to black.

To update the dashboard shading colour, change **Dashboard Shading** in the **Format>Dashboard** menu to **None**.

For text formatting changes, we could manually change the formatting on each worksheet. But that will take a lot of time. This dashboard only has two views, but dashboards often contain more.

To update the text on our dashboard to black, select **Format>Workbook** and change **Fonts>All** to **Black**.

This changes the font colour in every sheet of our workbook to black, which is then applied to the views included in the dashboard. For external information on colour contrast, see [Colour Contrast and Why You Should Rethink It](#).

Less accessible – low contrast

More accessible – higher contrast

For more information about adding background colours around items, see [Add padding, borders and background colours around items](#).

Aggregate and reduce marks

You might have a lot of information that you want to communicate with your dashboard or view. However, a dense view with a lot of marks, like the bar chart at the top of our view, can be difficult to understand using a screen reader or keyboard.

The top view in our dashboard displays over 5,000 marks because each bar in the chart contains the name of each product in that category. If a view uses more than 1,000 marks, it causes the view to be rendered on the server instead of the browser, and server-rendered views are not supported for WCAG conformance. Limit the number of marks to only those that emphasise the most important data points.

To make this view more accessible, make the stacked bar chart into a bar chart by removing the field **Product Name** from **Details** in the **Marks** card. This reduced the number of marks in the view from over 5,000 to 68.

Less accessible – too many marks

More accessible – aggregated view

Users can also access the **View Data** window (enabled by default) to review the underlying data for the marks or can download the data from that page to an accessible application to view it that way.

To reduce cognitive overload and reduce the numbers of marks in our field even further, we can create groups of related members in a field. To create a group of similar products:

1. Right click on the field and select **Create > Group**.

2. In the Create Group dialog box, select several members that you want to group, and then click **Group**.

For more information on grouping, see [Group Your Data on page 1087](#). Here's what the view looked like before grouping and aggregating, compared to after:

Less accessible – too many marks

More accessible – aggregated and grouped view

For information and examples about how to build this type of view, see [Keep it simple on page 1597](#) in [Author Views for Accessibility on page 1596](#).

Eliminate redundant information

The aggregated and grouped bar chart reduces cognitive overload for users, but still uses colour to convey meaning when colour isn't necessary. Since the size of each bar already represents sales numbers, colour can be removed from the chart by removing the sales field from Colour in the **Marks** card. Removing colour also removes the colour legend that the screen reader reads.

Less accessible – unnecessary marks

More accessible – unnecessary marks removed

Use colour and shape to differentiate marks

The line chart in this dashboard contains marks that are only distinguished by colour, which makes it impossible or nearly impossible for people with colour-blindness to distinguish marks

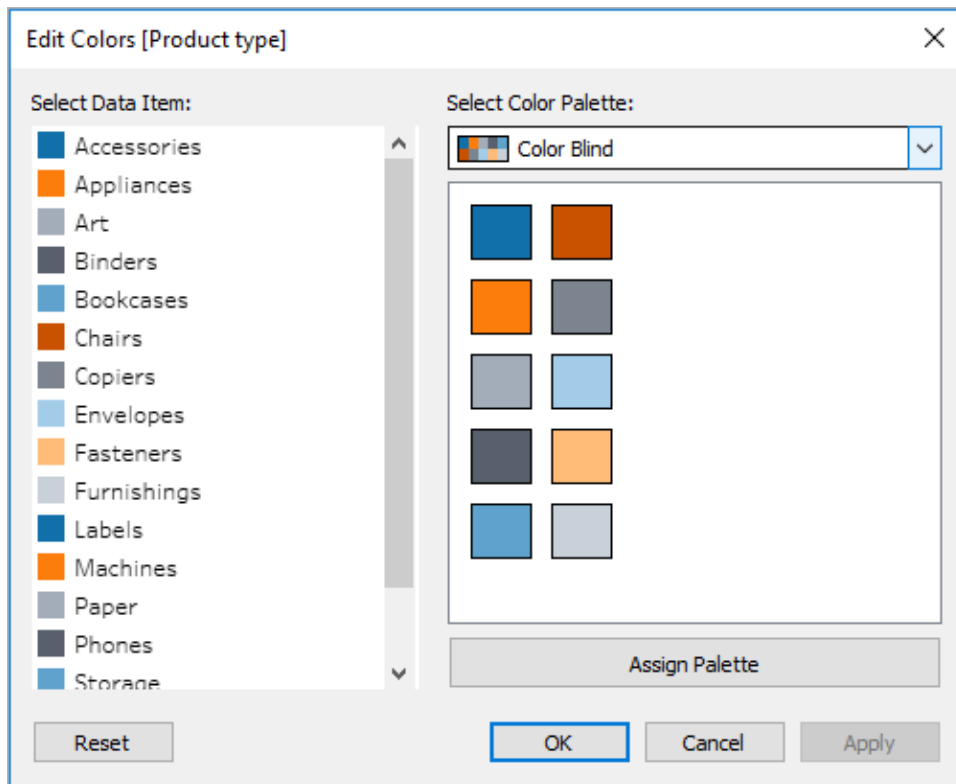

from one another. The line path provides helpful position information, but the colours do not provide clear distinction between the line marks.

Make this line chart more accessible by applying the **Colour Blind** palette and adding shapes to reinforce what is being shown in colour.

To apply the Colour Blind palette:

1. Select **Colour** on the **Marks** card.
2. Select **Colour Blind** from the **Colour Palette** menu.

3. Select **Assign Palette** and **Apply** to apply it to the view.

To add shapes in addition to colour to your line chart, create a combination chart, or dual axis chart:

1. Control-drag (command-drag on a Mac) the field in the **Rows** shelf to copy it and place it to the right of the first field. This creates two tabs in your Marks card, one for each field in the Rows shelf.

2. On the marks card, select the bottom tab, titled **[Field Name (2)]**. Select **Shape** from the drop down menu in the Marks card.

3. Select the Colour mark to the right of the field name and select Shape.

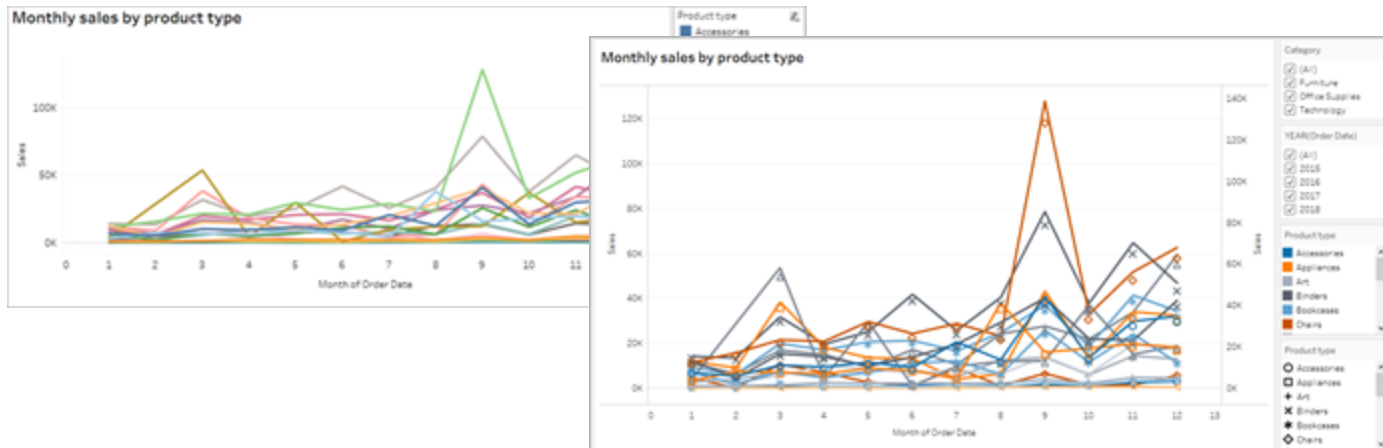

4.

This creates separate shapes for each of the marks in the field. At this point, there are two different charts; one a line chart of colours, another a scatter plot with shapes.

To merge these two charts together into a dual axis chart, in the Rows shelf, select the field on the right and select **Dual Axis**. For more information on combination charts, see [Build a Combination Chart](#) on page 1546.

Not easily accessible

More accessible – Colour Blind palette and shapes

The chart is improved, but the line colours and shapes have started repeating after the 10th mark applied. This makes the view look busy and hard to make sense of, leading to cognitive overload. Let's fix it by adding filters and legends.

Use filters to reduce the number of marks in a view

Using filters helps to focus the number of marks in the view to only what you want users to see.

You can show the following filter modes to allow users to control what data is in the view. The filter modes that Tableau currently supports for WCAG conformance are:

- **Single Value (list):** a filter with radio buttons. Only one item can be selected at a time. Giving your users single-value filters is a great way to reduce the number of marks in the view.
- **Multiple Values (list):** a filter with a list of items (with tick boxes) that can be selected at the same time. Multiple-value filters will allow more marks to be shown at the same time.

- **Single Value (drop-down)**: a filter with a dropdown list of items. Only one item can be selected at a time. Giving your users single-value filters is a great way to reduce the number of marks in the view.
- **Multiple Values (drop-down)**: a filter with a dropdown list of items that can be selected at the same time. Multiple-value filters will allow more marks to be shown at the same time.

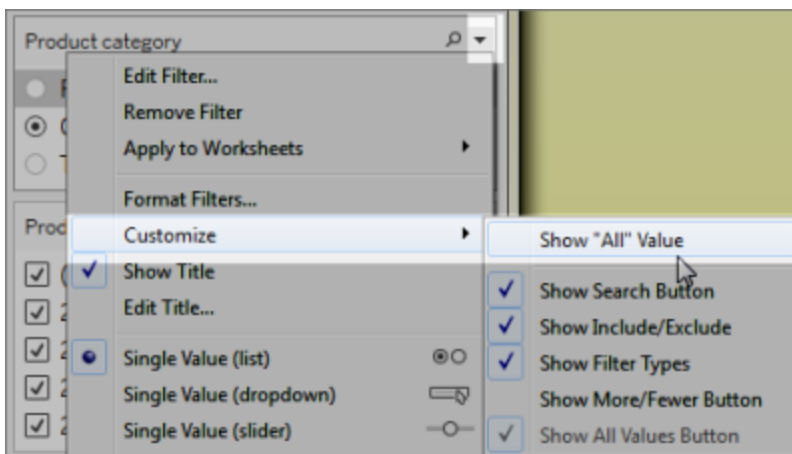

To show a filter, right-click the field you want to use as a filter, and then select **Show Filter**.

To select the filter mode, in the drop-down menu for a filter, select a **Single Value (list)**, **Single Value (dropdown)**, **Multiple Values (list)**, or **Multiple Values (dropdown)** filter.

Because the line chart is a Single Value list, we can remove the **All** option from the filter. In the drop-down menu for the filter, select **Customise** and then clear the **Show "All" Value** option.

This reduces the level of marks in the view to prevent cognitive overload for dashboard consumers.

Less accessible – too many marks

More accessible – less marks in the view

To learn more, see [Use filters to reduce the number of marks in a view](#).

Another way to make the viz easier to consume is to

Add captions and legends

To add clarity for our users, we can add a **Text object** with a description of the dashboard and instructions about how to filter and use each view in the dashboard, including how to use the filters and categorical legends that we've added. To add a text object:

1. Grab Text from the Objects menu and drag it onto the dashboard.

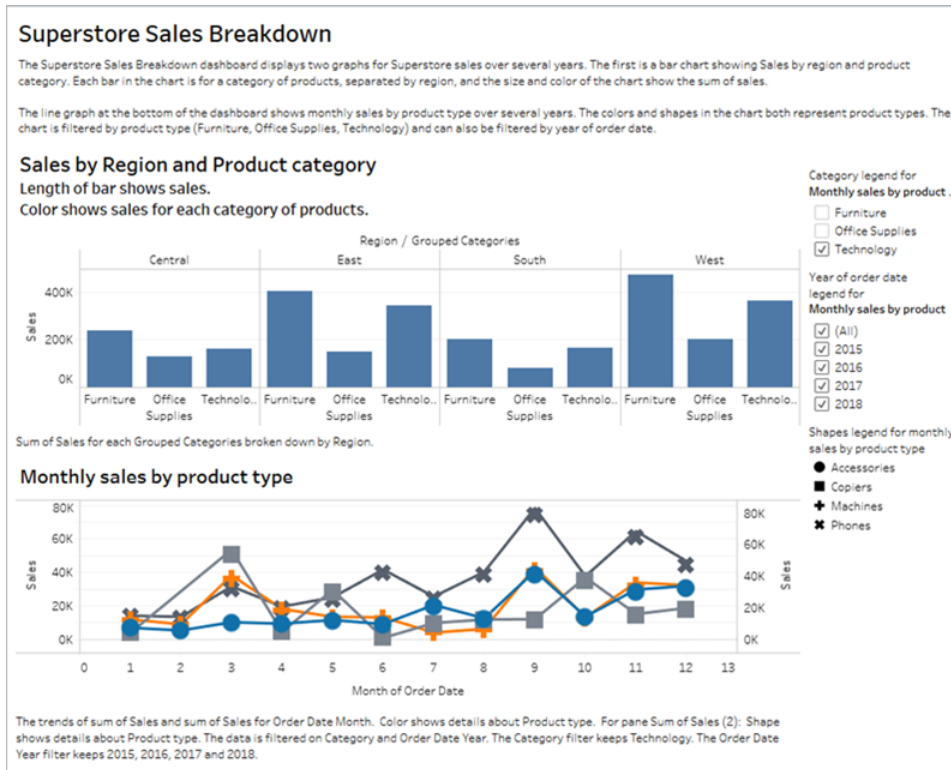

2. Use **Edit Text** window to add text that explains the dashboard's purpose and how to use it.

You can also add chart captions to the dashboard. The default caption text gives a summary of what is shown in the view, but you can add or edit this text to provide better context. To do this, click on a chart in the dashboard and select **Caption** from the **More Options** drop-down menu.

Last, we can update the titles of our legends to reference their associated charts and reduce the amount of redundant text that screen readers consume. To do this, double-click on the legend title, or right-click and select **Edit Title** to add or edit text in the **Edit Filter Title** window.

The result is a dashboard that includes an explanation of the dashboard and chart captions and eliminates redundant text for users.

Publish and embed the dashboard

After you create your views, to make them WCAG-conformant, you must:

- Publish views to Tableau Server or Tableau Cloud, and then embed the view in a WCAG-compliant web page. For information about how to publish a view, see [Comprehensive Steps to Publish a Workbook](#) on page 3120.
- Web editing is not supported in WCAG-conformant views, so Web Edit permissions must be turned off in the published workbook.
- In the embedded views, hide the Custom Views, Subscriptions, and Alerts buttons in the toolbar.
- Make sure users have permissions to access to the embedded views and are able to view the underlying data in the View Data window.

For information about each of these steps, see [Publish and embed the view](#) in Author Views for Accessibility.

Manage Sheets in Dashboards and Stories

Hiding, showing and navigating to sheets helps you more easily manage workbooks and design dashboards.

Hide and show sheets

To streamline the editing process for large workbooks, hide and show sheets as you work.

For Viz in Tooltip, see [Hide or show a Viz in Tooltip worksheet on page 1386](#).

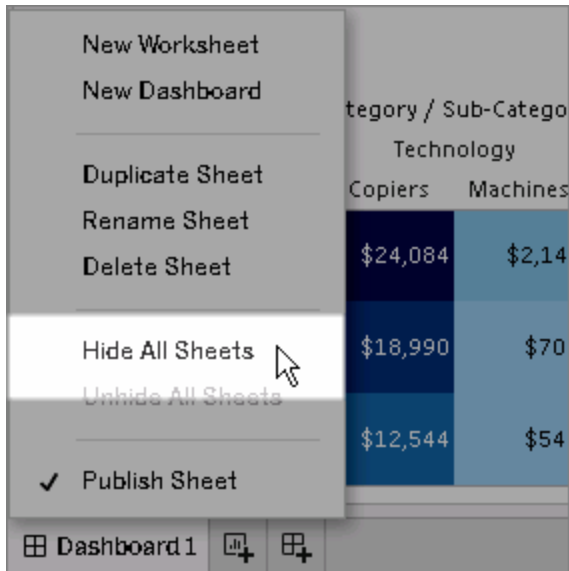

What sheets can I hide?

While editing a workbook, you can hide any sheet contained in a dashboard or story. (That includes dashboard sheets in stories.)

Sheets that aren't in a dashboard or story are always visible while editing workbooks. However, you can hide any sheet in workbooks you publish to Tableau Cloud or Tableau Desktop. See [Comprehensive Steps to Publish a Workbook on page 3120](#).

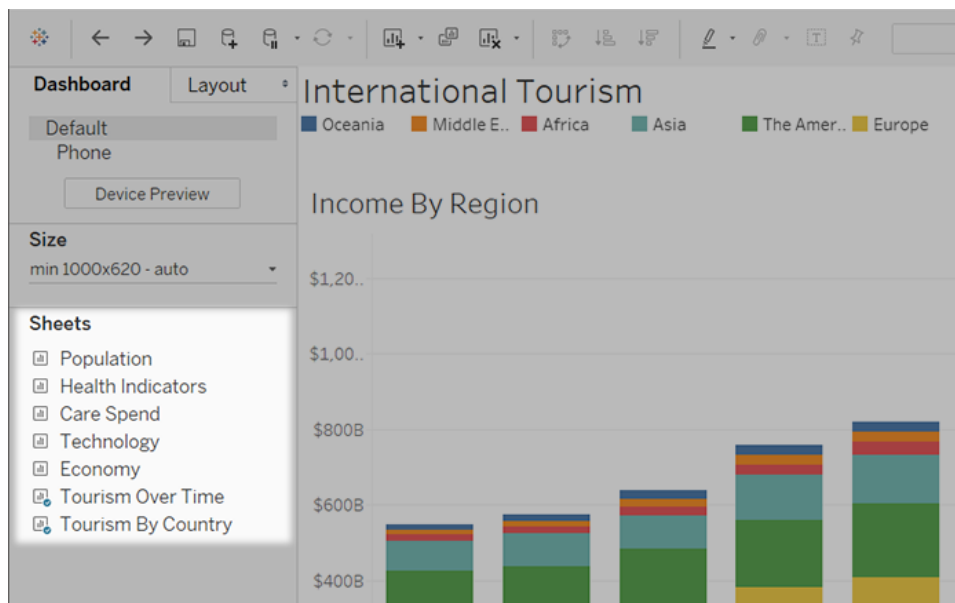

Hide or unhide all sheets

To hide all of a dashboard or story's sheets, right-click (Windows) or Control-click (macOS) the dashboard's tab at the bottom of the screen, and select **Hide All Sheets**. You can later select **Unhide All Sheets** if needed.

Hide an individual sheet

1. Look for the sheet in the tabs at the bottom of the screen. Or, if you're viewing a dashboard or story, look in the **Sheets** list at left:

2. Right-click (Windows) or Control-click (macOS) the sheet name, and select **Hide Sheet**.

Note: From the sheets list to the left of a dashboard or story, you can hide only sheets used in that particular dashboard or story. You can identify these sheets by the blue tick on the sheet icon.

Unhide an individual sheet

1. At the bottom of the screen, click the tab for the dashboard or story that contains the sheet. You can identify dashboards and stories by grid and book icons, respectively.

Note: If a story has a hidden dashboard that in turn has a hidden sheet, first go to the hidden dashboard from the story, and then to the hidden sheet from the dashboard.

2. In the list at left, right-click (Windows) or Control-click (macOS) the sheet, and clear the

Hide Sheet tick box.

Navigate between sheets, dashboards and stories

Tableau lets you quickly navigate back and forth between sheets and related dashboards and stories, helping you better optimise the design of each.

Go from a dashboard or story to a sheet it contains

Tip: If a sheet is hidden, this technique temporarily shows it so you can get a closer look at it. The sheet is hidden again when you switch to another sheet.

Do either of the following:

- On the dashboard itself, select the item that references the hidden sheet. Then click the drop-down arrow in the top left or right corner, and select **Go to Sheet**.

- In the **Sheets** list to the left of the dashboard, click the icon to the right of the sheet name.

Go from a sheet to related dashboards and stories

To quickly go to dashboards and stories a sheet appears in, right-click the sheet tab and open the **Used in** menu.

Use Dashboard Extensions

Extensions let you add unique features to dashboards or directly integrate them with applications outside Tableau. Adding extensions is easy; you incorporate them into dashboard layouts just like other dashboard objects.

Extensions expand dashboard functionality with the help of web applications created by third-party developers. If you're a developer and want to create your own extensions, see the [Tableau Extensions API documentation](#) on GitHub.

Note: Tableau administrators can turn off dashboard extensions for [Tableau Desktop](#), [Tableau Server](#) and [Tableau Cloud](#).

Add an extension to a dashboard

1. In a Tableau workbook, open a dashboard sheet.
2. From the **Objects** section, drag **Extension** to the dashboard.

3. In the “Add an Extension” dialog box, do either of the following:
 - Search for and select an extension.
 - Click **Access Local Extensions**, and navigate to a .trex file you previously downloaded.
4. If prompted, allow or deny the dashboard extension access to data in the workbook. For more information, see [Data security, Network-enabled and Sandboxed extensions on page 2819](#).

If you allow access, follow any on screen instructions for configuring the extension.

Note: If you're using Tableau Server or Tableau Cloud, Extension objects will appear blank in prints, PDFs and images of dashboards (including images in subscription emails).

Configure a dashboard extension

Some dashboard extensions provide configuration options that let you customise features.

1. Select the extension in the dashboard, and from the drop-down menu in the upper-right corner, choose **Configure**.
2. Follow the on-screen instructions to configure the extension.

Reload a dashboard extension

If a dashboard extension becomes unresponsive, you might need to reload it, which is similar to refreshing a web page in a browser.

1. Select the extension in the dashboard, and from the drop-down menu in the upper-right corner, choose **Reload**.

The dashboard extension is refreshed and set to its original state.

2. If reloading the extension fails to return it to a usable state, try removing it from the dashboard and adding it again.

Data security, Network-enabled and Sandboxed extensions

Dashboard extensions are web applications that come in two forms:

- *Network-enabled extensions* run on web servers located outside of your local network.
- *Sandboxed extensions* run in a protected environment without access to any other resource or service on the web.

Before adding a Network-enabled extension or viewing a dashboard with one, be certain that you trust the website that hosts it. By default, dashboard extensions use the HTTPS protocol, which guarantees an encrypted channel for sending and receiving data, and ensures some privacy and security.

For more information about data security when using dashboard extensions, see [Extension Security - Best Practices for Deployment](#).

Allow or deny data access to a Network-enabled extension

Depending on how an extension is designed, it can access either visible data in a view, or full underlying data, table and field names from data sources, and information about data source connections. When you add an extension, or view a dashboard with one, you're given an opportunity to allow or deny the extension to run and access this data.

If you're viewing a dashboard with an extension that requires full data access, and that access has been denied, a message appears in place of the extension. If you trust the extension and want to use it, you can reset permissions and allow the extension to run.

1. Select the extension in the dashboard, and from the drop-down menu in the upper-right corner, choose **Reset Permissions**.

2. Click either **Allow** to let the extension run and access data, or **Deny** to prevent the extension from running.

Ensure that JavaScript is enabled in Tableau Desktop

Dashboard extensions interact with data using the Tableau Extensions API library, a JavaScript library. If you want to use extensions, be sure that JavaScript is enabled in the dashboard security settings:

Choose **Help > Settings and Performance > Set Dashboard Web View Security > Enable JavaScript**.

Ensure that extensions run on Tableau Cloud or Tableau Server

You can add extensions to workbooks that you publish from Tableau Desktop or directly in the web-authoring mode of Tableau Cloud and Tableau Server. A Tableau administrator must allow extensions to run on a site and add Network-enabled extensions to a safe list. Administrators should only allow extensions that you have tested and trust.

If you want to use a dashboard extension on Tableau Cloud or Tableau Server, direct your administrator to [Manage Dashboard Extensions in Tableau Cloud](#) or [Manage Dashboard Extensions in Tableau Server](#).

Supported web browsers for Sandboxed extensions

Sandboxed extensions run in all browsers supported by [Tableau Server](#) and [Tableau Cloud](#) except Internet Explorer 11.

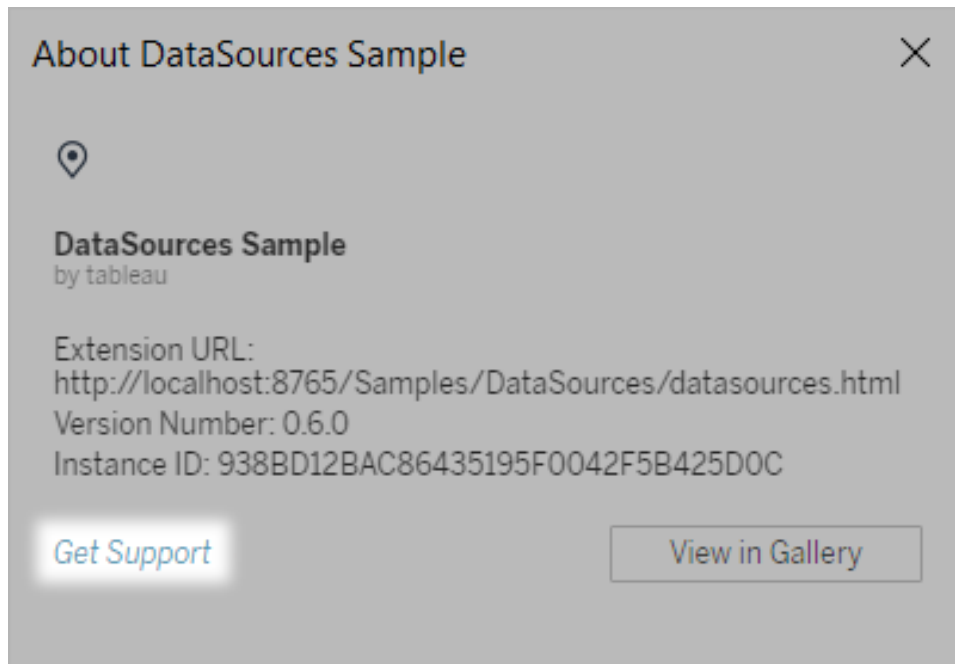

Supported versions of Tableau Server for Sandboxed extensions

You can use Sandboxed extensions in Tableau Server 2019.4 and later.

Get support for dashboard extensions

To get help for an extension, you'll need to contact the developer or company who created it.

1. Select the extension in the dashboard, and from the drop-down menu in the upper-right corner, choose **About**.
2. Click **Get Support** to go to the support page of the extension developer.

Note: Tableau doesn't provide support for extensions or for other programs that interface with the Extensions API. However, you can submit questions and ask for help in the [Tableau developer community](#).

Stories

In Tableau, a **story** is a sequence of visualisations that work together to convey information. You can create stories to tell a data narrative, provide context, demonstrate how decisions relate to outcomes or to simply make a compelling case.

A story is a sheet, so the methods you use to create, name and manage worksheets and dashboards also apply to stories (for more details, see [Workbooks and Sheets on page 95](#)). At the same time, a story is also a collection of sheets, arranged in a sequence. Each individual sheet in a story is called a **story point**.

When you share a story – for example, by publishing a workbook to Tableau Public, Tableau Server or Tableau Cloud – users can interact with the story to reveal new findings or ask new questions of the data.

Note: Stories don't support dynamic features, such as zone visibility, axis titles or axis ranges.

The Story Workspace

As you work on a story, you can use the following controls, elements and features.

A. Options for adding a new story point: Choose **Blank** to add a new point or **Duplicate** to use the current story point as the starting place for your next point.

B. The Story pane: Use this pane to drag dashboards, sheets and text descriptions to your story sheet. This is also where you set the size of your story and display or hide the title.

C. The Layout pane: This is where you choose your navigator style and display or hide the forward and back arrows.

D. The Story menu: Use this menu in Tableau Desktop to format the story or copy or export the current story point as an image. You can also clear the entire story here or show or hide the navigator and story title.

E. The Story toolbar: This toolbar appears when you mouse-over the navigator area. Use it to revert changes, apply updates to a story point, delete a story point or create a new story point out of the current, customised one.

F. The navigator: The navigator allows you to edit and organise your story points. It's also how your audience will step through your story. To change the style of the navigator, use the Layout pane.

For more information on these options, see [Create a Story](#) on page 2830.

Best Practices for Telling Great Stories

A good data story brings data and facts to life. Use this article for tips on best practices to use with Tableau's story points feature.

What's the purpose of your story?

Before you start to build your story, take some time to think about the purpose of your story and what you want your viewers' journey to be. Is it a call to action, is it a simple narrative, or are you presenting a case?

If you're presenting a case, decide whether you want to present data points that lead up to a conclusion at the end, or start with a conclusion then show the supporting data points. The latter approach works well for a busy audience.

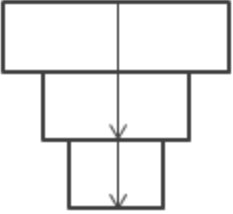

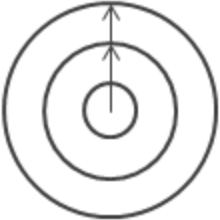

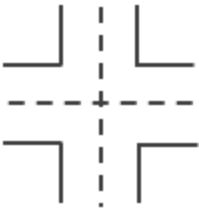

Finally, sketching out your story first on paper or a whiteboard can help you quickly identify problems with your sequence.

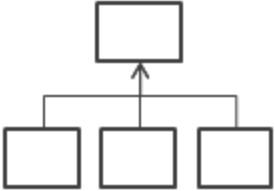

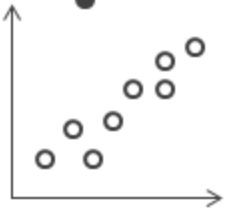

The seven types of data stories

When you use the story feature, you are building a sequence of points. Each point can contain a view, dashboard, or even just text. Some stories show the same view throughout the story, with text annotations and different filters applied to different points to support the narrative arc.

The following table describes seven different data story approaches you can take and provides an example for each. Each data story type is also illustrated in the [Data Story Examples Workbook](#) on Tableau Public. A single story can also use more than one approach—see [Example - A Story That Examines a Trend](#) on page 2838.

| Data Story Type | Description |
|---|---|
|  | <p>What it does: Uses a chronology to illustrate a trend.</p> <p>Discussions it starts: Why did this happen, or why does it keep happening? What can we do prevent or make this happen?</p> |

| Change Over Time | |
|--|--|
|  <p data-bbox="329 575 456 604">Drill Down</p> | <p>What it does: Sets context so that your audience better understands what's going on in a particular category.</p> <p>Discussions it starts: Why is this person, place or thing different? How does the performance of this person, place, or thing compare?</p> |
|  <p data-bbox="329 942 453 972">Zoom Out</p> | <p>What it does: Describes how something your audience cares about relates to the bigger picture.</p> <p>Discussion it starts: How does something you care about compare to the bigger picture? What effect does one area have on the bigger picture?</p> |
|  <p data-bbox="337 1287 446 1316">Contrast</p> | <p>What it does: Shows how two or more subjects differ.</p> <p>Discussions it starts: Why are these items different? How can we make A perform like B? Which area should we focus on and which area is doing fine?</p> |
|  <p data-bbox="313 1642 470 1671">Intersections</p> | <p>What it does: Highlights important shifts when one category overtakes another.</p> <p>Discussions it starts: What causes these shifts? Are these shifts good or bad? How do these shifts affect other aspects of our plan?</p> |

| | |
|---|---|
|  <p>Factors</p> | <p>What it does: Explains a subject by dividing it into types or categories.</p> <p>Discussions it starts: Is there a particular category we should focus on more? How much do these items affect the metric we care about?</p> |
|  <p>Outliers</p> | <p>What it does: Shows anomalies or where things are exceptionally different.</p> <p>Discussions it starts: Why is this item different?</p> |

Keep it simple

A common error is trying to cram too many views and dashboards into a single story. The result is too many points for your viewers to take in.

The clarity of each story point is also important. Take a step back and consider your story from the perspective of someone who's never seen it. Every element should serve a purpose. If captions, titles, legends, or grid lines aren't necessary, get rid of them!

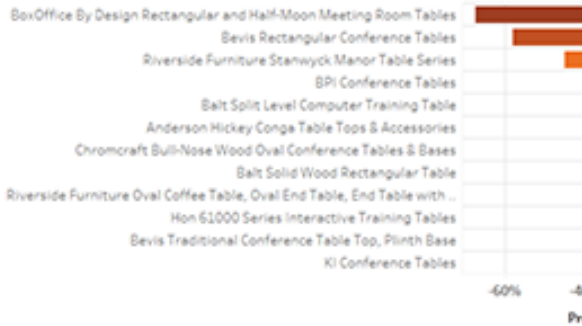

Before

After

A Case Study on Tables

Least Profitable Tables

Most Profitable Tables

A Case Study on Tables

Least Profitable Tables

Most Profitable Tables

Use 'Fit to' in your dashboards

Dashboards are a common ingredient in Tableau stories. For dashboards that you plan to include in your story, you can use the **Fit to** option under **Size** on the Dashboard pane. It will resize your dashboard so that it's the right size for the story you're creating.

Plan for fast load times

The most wonderful story in the world won't have much impact if it takes too long to load once it's published. People find long waits frustrating.

Filtering is a common culprit for slow load times. Although filters are effective in restricting the amount of data being analysed, they also impact query performance. For example, **Exclude** filters tend to be slower than **Keep Only** filters. This is because **Exclude** filters load all of the data for a dimension instead of just what you want to keep. Knowing [Tableau's Order of Operations on page 161](#) can also shave time off your load times.

Some of the most critical performance decisions you make as an author begin before you even create your first view or story, in the data preparation stage. Take a moment to familiarise yourself with the data you're working with. See [Know Your Data at the Database Level on](#)

[page 3061](#) and [Test Your Data and Use Extracts on page 3062](#) in the Tableau Desktop online help for tips on what to look for and smart ways to work with your data.

Create a Story

Use stories to make your case more compelling by showing how facts are connected, and how decisions relate to outcomes. You can then publish your story on the web, or present it to an audience.

Each story point can be based on a different view or dashboard, or the entire story can be based on the same visualisation seen at different stages, with different filters and annotations.

Create a story point

1. Click the **New Story** tab.

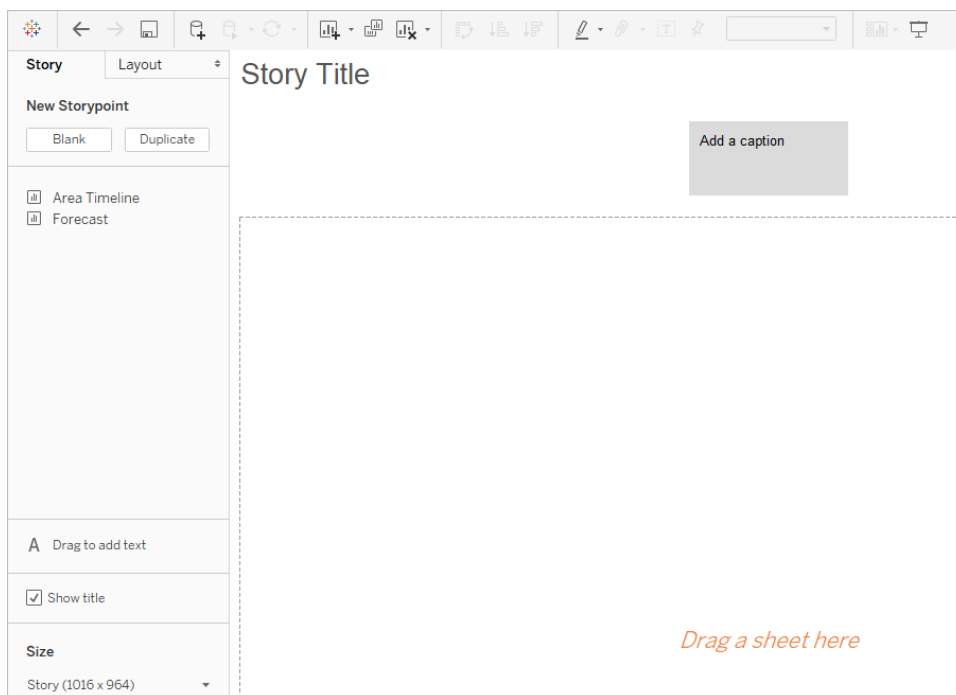

Tableau opens a new story as your starting point:

2. In the lower-left corner of the screen, choose a size for your story. Choose from one of the predefined sizes, or set a custom size, in pixels:

Note: Choose the size your story will be viewed at, not the size you're authoring in.

3. By default, your story takes its title from the sheet name. To edit it, right-click the sheet tab, and choose **Rename Sheet**.

If you're using Tableau Desktop, you can also rename a story by double-clicking the title.

4. To start building your story, double-click a sheet on the left to add it to a story point.

In Tableau Desktop, you can also drag sheets into your story point.

When you add a sheet to a story point, that sheet remains connected to the original sheet. If you modify the original sheet, your changes will automatically be reflected on the story points that use it.

If you are using Tableau Cloud to author on the web and the original sheet has **Pause Auto Updates** enabled, the story sheet will be blank until auto-updates are resumed.

5. Click **Add a caption** to summarise the story point.

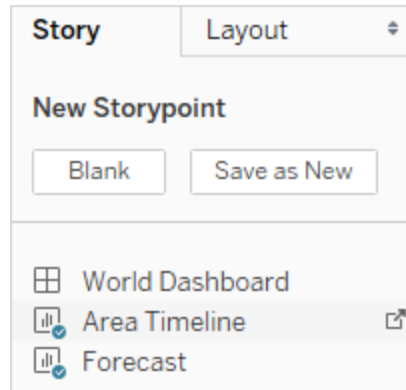

In Tableau Desktop, you can highlight a key takeaway for your viewers by dragging a text object to the story worksheet and typing a comment.

6. To further highlight the main idea of this story point, you can change a filter or sort on a field in the view. Then save your changes by clicking **Update** on the story toolbar above the navigator box:

7. Add another story point by doing one of the following:

- Click **Blank** to use a fresh sheet for the next story point.

- Start customising a story point and click **Save as New** on the toolbar above the navigator box.

- Click **Duplicate** to use the current story point as the basis for a new one.

Explore layout options

You can refine the look of your story using the options on the **Layout** tab.

- Click the **Layout** tab.
- Choose a navigator style that best suits your story, and show or hide the next and previous arrows.

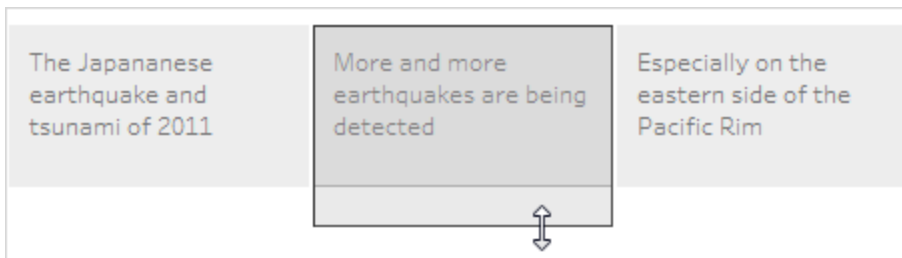

Format a story

Resize captions (Tableau Desktop only)

Sometimes the text in one or more of your captions is too long to fit inside the height of the navigator. In this case, you can re-size the captions vertically and horizontally.

1. In the navigator, select a caption.
2. Drag the border left or right to resize the caption horizontally, down to resize vertically, or select a corner and drag diagonally to resize the caption both horizontally and vertically.

All captions in the navigator update to the new size.

When you resize a caption, you can only select the left, right, or bottom border of the caption.

Fit a dashboard to a story

You can fit a dashboard to the exact size of a story. For example, if your story is exactly 800 by 600 pixels, you can shrink or expand a dashboard to fit inside that space.

Click the **Size** drop-down menu and select the story you want the dashboard to fit inside.

•

Format a story's shading, title, and text objects (Tableau Desktop only)

To open the **Format Story** pane, select **Format > Story**.

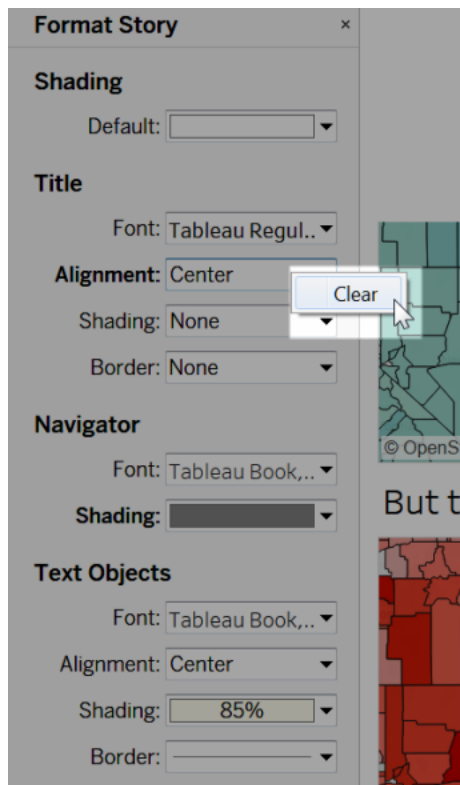

Clear all formatting (Tableau Desktop only)

- To reset a story to its default format settings, click the **Clear** button at the bottom of the **Format Story** pane.
- To clear a single format setting, right-click (Windows) or control-click (macOS) the format setting you want to undo in the **Format Story** pane. Then select **Clear**.

For example, if you want to clear the alignment of the story title, right-click (control-click on

Mac) **Alignment** in the **Title** section, and then select **Clear**.

Delete a story point

Click the X in the toolbar above the point's caption:

Present your story

1. In Tableau Desktop, click the **Presentation Mode** button  on the toolbar. Or, **publish the story** to Tableau Cloud or Tableau Server, and click the **Full Screen** button in the upper-right corner of the browser.

2. To step through your story, click the arrow to the right of the story points. Or, in Tableau Desktop, use the arrow keys on your keyboard.
3. To exit Presentation or Full Screen mode, press **Esc**.

Example - A Story That Examines a Trend

The example in this article walks you through building a story about earthquake trends over time.

The story feature in Tableau is a great way to showcase this type of analysis because it has a step-by-step format which lets you move your audience through time.

Rather than showing you how to create all the views and dashboards from scratch, this example starts from an existing workbook. What you'll do is pull the story together. To follow along and access the pre-built views and dashboards, download the following workbook from Tableau Public: [An Earthquake Trend Story](#).

Frame the story

A successful story is well-framed, meaning its purpose is clear. In this example, the story's purpose is to answer the following question: Are big earthquakes becoming more common?

There are several approaches you could take – see [Best Practices for Telling Great Stories on page 2825](#) for a list – but the one used here as an overall approach is Change over Time, because it works especially well for answering questions about trends. As you build the story you'll notice that other data story types, such as Drill Down and Outliers, are blended in to support the overall approach.

Build the story

Create a story worksheet

1. Use Tableau Desktop to open the Earthquake Trend Story workbook that you downloaded.

If you also have Tableau Server or Tableau Cloud and you want to do your authoring on the web instead of in Tableau Desktop, publish the workbook to your Tableau server, click **Workbooks**, select the workbook, then under **Actions** choose **Edit Workbook**.

Once you open the workbook, you'll see that it has three dashboards. You'll be using those dashboards to build your story. The workbook also has a finished version of the story.

Tip: To see the individual views that are in a dashboard, right-click the dashboard's tab and select **Unhide all Sheets**.

2. Click the **New Story** tab.

Tableau opens a new worksheet as your starting point.

3. Right-click the **Story 2** tab, choose **Rename Sheet**, and type **Earthquake story** as the worksheet name.

State the question

Story titles are in view at all times and they're a handy way to keep your story's purpose in the spotlight. By default, Tableau uses the worksheet name as the story title. In Tableau Desktop you can override that by doing the following:

1. Double-click the title.
2. In the Edit Title dialog box, replace **<Sheet Name>** with the following:

Are big earthquakes on the rise?

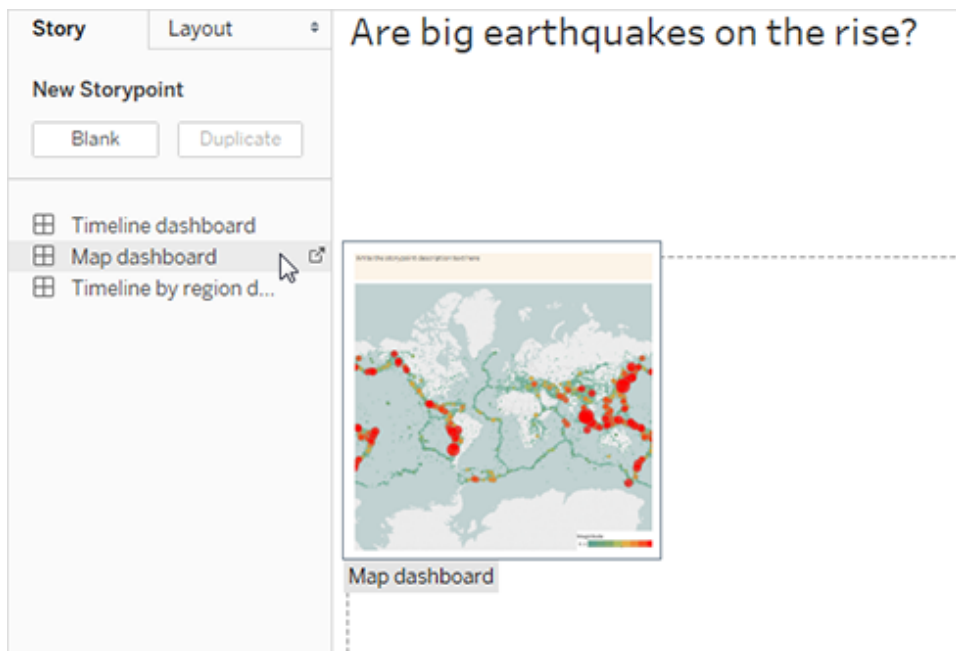

3. Click **OK**.

If you're authoring in Tableau Server or Tableau Cloud, the story tab is the only place where you can change the title.

Start big

To help orient your audience, the first story point you create will show the broadest possible viewpoint – all earthquakes, across the entire planet.

1. On the Story pane, double-click **Map dashboard** to place it on the story sheet. If you're using Tableau Desktop, you can also use drag-and-drop to add views and dashboards to a story sheet.

Notice how there's a horizontal scroll bar and the legend isn't fully displayed.

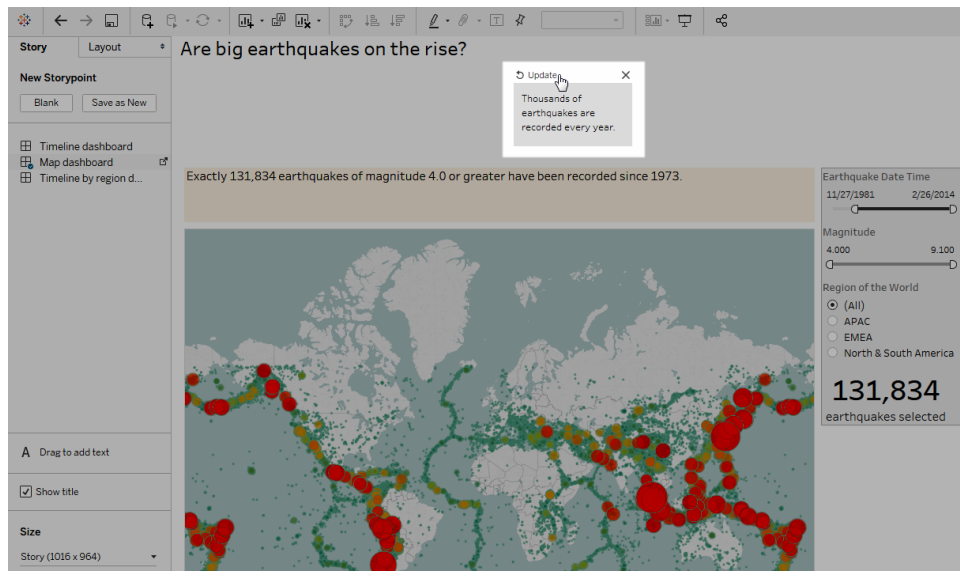

There's a special setting you can use on your dashboards to prevent this from happening.

2. Select **Map dashboard** and under **Size** on the Dashboard pane, select **Fit to Earthquake story**. This setting is designed to make dashboards the perfect size for a story.

Look at the Earthquake story again. You see that its size has been adjusted and the scroll bars are gone.

3. If you're using Tableau Desktop, add a description for this story point, such as *Exactly 131,834 earthquakes of magnitude 4.0 or greater have been recorded since 1973.*
4. Add caption text by clicking the area that reads **Write the story point description text here.**
5. Click **Update** on the caption to save your changes to the story point.

Drill down

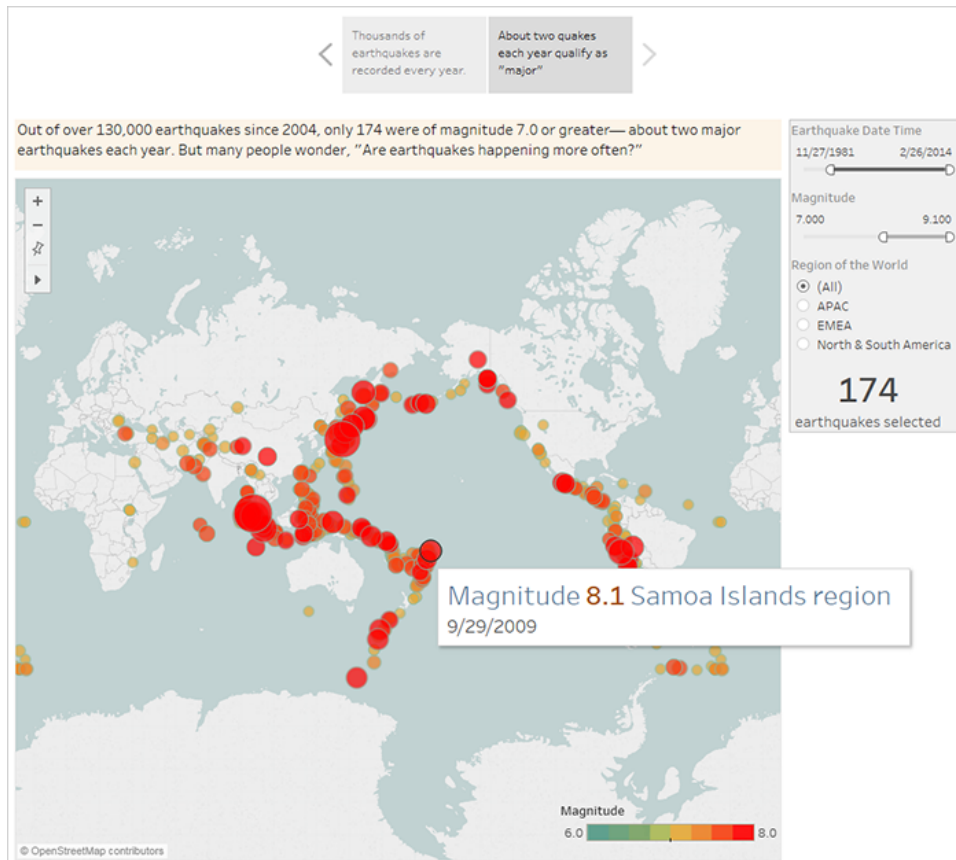

Just like the plot of a good novel needs to move the action along, so does a data story. Starting with your next story point, you'll use the drill-down technique in order to narrow down the scope of the story and keep the narrative moving.

1. To use your first story point as a baseline for your next, click **Duplicate** under **New Storypoint** on the left.

2. Change the **Magnitude** filter to **7.000 – 9.100** so that the map filters out smaller earthquakes. The map pans to show the Pacific 'Ring of Fire', where the majority of the large earthquakes occurred.
3. Add a caption, such as *About two quakes each year qualify as 'major'*

- If you're using Tableau Desktop, edit the description to describe what you've done in this story point. For example: *Out of over 130,000 earthquakes since 2004, only 174 were of magnitude 7.0 or greater – about two major earthquakes each year. But many people wonder, "Are earthquakes happening more often?"*
- Click **Update** in the story toolbar above the caption to save your changes.

In the next story point, you're going to drill down further, narrowing the story's focus so that a specific type of earthquake – the 'megaquake' – comes into view.

- Click **Duplicate** in your second story point to use it as the baseline for your third story point.
- Change the **Magnitude** filter to **8.000 – 9.100** so that the map filters out everything except the megaquakes.
- Add the caption and description text.

- Caption: *These megaquakes have drawn a lot of attention*
- Description (Tableau Desktop only): *Recent megaquakes of magnitude 8.0 and higher have often caused significant damage and loss of life. The undersea megaquakes near Indonesia and Japan also caused tsunamis that have killed many thousands of people.*

4. Click **Update** to save your changes.

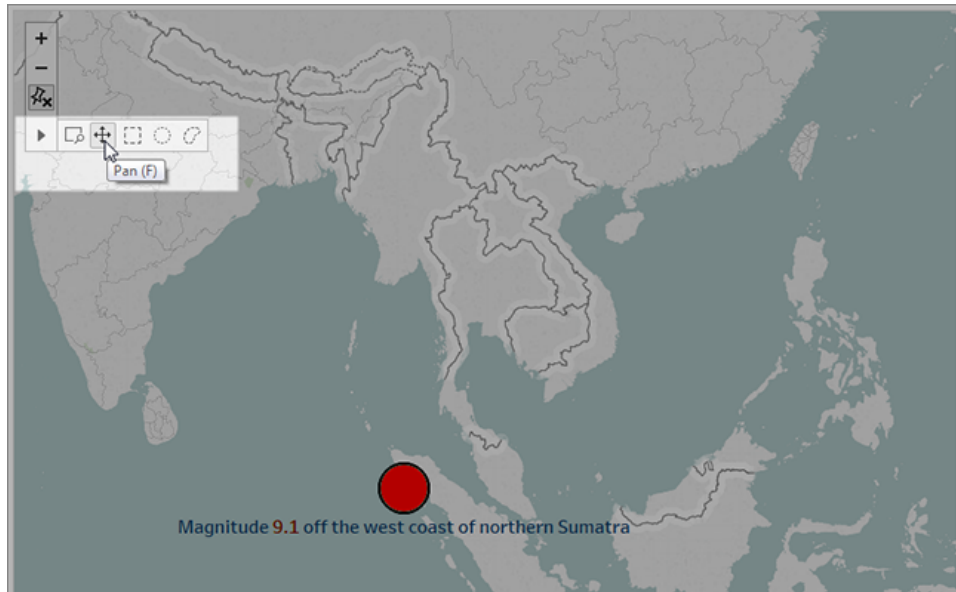

Highlight outliers

In the next two story points, you're going to further engage your audience by examining data points at the far end of the scale: the two most deadly earthquakes in recent history.

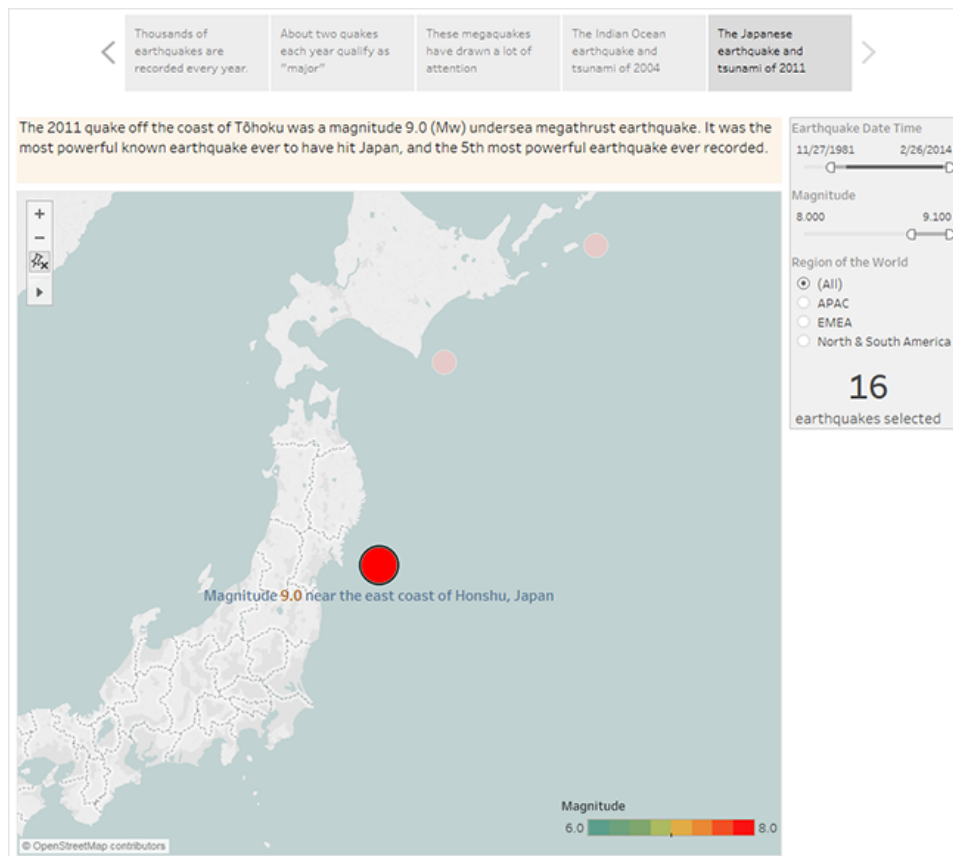

1. As you've done before, use **Duplicate** to create a new story point as your starting point.
2. Adjust **Magnitude** to **9.000–9.100** and you'll see just two data points.

3. Select one of the marks, such as the Indian Ocean earthquake and tsunami of 2004 that had a magnitude of 9.1.
4. Use the pan tool on the maps menu to centre it in your story point.

5. Add caption and description text. For example:
 - Caption: *The Indian Ocean earthquake and tsunami of 2004*
 - Description (Tableau Desktop only): *The 2004 Indian Ocean earthquake was an undersea megathrust earthquake that occurred on 26 December 2004. It is the third largest earthquake ever recorded and had the longest duration of faulting ever observed, between 8.3 and 10 minutes.*
6. Click **Update** to save your changes.
7. Repeat the preceding steps for the Japanese earthquake and tsunami of 2011, using the following as caption and description text.
 - Caption: *The Japanese earthquake and tsunami of 2011*
 - Description (Tableau Desktop only): *The 2011 quake off the coast of Tōhoku was a magnitude 9.0 undersea megathrust earthquake. It was the most powerful known earthquake ever to have hit Japan, and the 5th most powerful earthquake ever recorded.*

Notice that you've already created a compelling visual story using just a single dashboard – all by filtering the data and zooming and panning the map.

We still haven't answered the key question, however: Are big earthquakes on the rise? The next story points will dig in to that angle.

Show a trend

In the next story point, you'll switch to a line chart (the Timeline dashboard) to show your audience a trend you spotted when you were initially creating views and dashboards.

1. Switch from the story you're building to **Timeline dashboard**.

2. On the Timeline dashboard, set size to **Fit to Earthquake story**.
3. Go back to your story and click **Blank** to create a fresh story point.
4. Double-click the **Timeline dashboard** to add it to your story sheet.

More earthquakes are being reported over time since 1973. In fact, it's increased significantly!

5. Add a caption, such as: *More and more earthquakes are being detected*
6. Use **Drag to add text** to add a description of the trend (Tableau Desktop only): *Since 1973, there's been a steady increase in the number of earthquakes recorded. Since 2003, the trend has accelerated.*

Offer your analysis

From your earlier work in this story with the **Map dashboard** you know that there are regional differences in earthquake frequency. In your next story point, you'll pull in the **Timeline by region dashboard**, which breaks out earthquakes by region, and adds trend lines, which help reduce the variability in the data.

1. Click **Blank** to create a new story sheet.
2. Double-click the **Timeline by region dashboard** to the story sheet. The APAC region clearly stands out.
3. Add a caption then use **Drag to add text** to add a comment that points out the large number of earthquakes in the APAC region.
 - Caption: *Especially on the eastern side of the Pacific Rim*
 - Description (Tableau Desktop only): *A rough categorisation of earthquakes into*

geographic regions (by longitude) shows that the most significant increase in recorded earthquakes has occurred around the Pacific Rim.

Answer the question

Thus far, your data story has concluded that earthquake frequency in the Pacific Rim has increased since 1973, but your original question was about whether big earthquakes are becoming more frequent.

To answer this question, in your final story point, you'll filter out weaker earthquakes and see what the resulting trend line is.

1. Click **Duplicate** to create a new story sheet.
2. Set the **Magnitude** filter to **5.000–9.100**. Notice how the trend lines have flattened out but there's still a slight increase.
3. Add a caption then use **Drag to add text** to add your answer to the story point.

Caption: *But the trend in big quakes is not as clear*

Description (Tableau Desktop only): *It appears that big earthquakes are increasing slightly. There should be more investigation, however, on whether this trend is real or the result of a small number of exceptionally strong recent earthquakes.*

As is often the case with a data story, the story ends with additional questions.

Yes, there's a trend, but it's slight. More big earthquakes (magnitude 5.000 - 9.100) have been reported in recent years, especially in the Asia-Pacific region, but could that be natural variation? That might be a good topic for another story.

Create a Tableau Data Story (English Only)

Important changes for Tableau Data Stories

Tableau Data Stories were retired in Tableau Desktop, Tableau Cloud and Tableau Server in January of 2025 (2025.1). With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of changes. For more information, see [How Tableau Pulse powered by Tableau AI is Reimagining the Data Experience](#).

If you've ever written an executive summary of your Tableau dashboard, then you know it can be time-consuming. It takes time to choose which insights to share, and you have to rewrite your summaries each time the data is updated. Tableau Data Stories automatically generates narrative insights within your dashboard, saving time and surfacing relevant insights. As you explore the vizzes in your dashboard, the stories written by Data Stories adjust, allowing you to dive deeper into data and identify key insights faster.

From where you're already working in Tableau, you can quickly add the **Data Story** object to your dashboard. And you can customise the terms and metrics used in your story so Data Stories speaks the language used by your business.

Today, you can write and view a Tableau Data Story anywhere you use Tableau. After you create your story, you can also view your Data Story in Tableau Mobile. However, Data Stories aren't included if you export your dashboard, for example to a PDF.

Understand how Data Stories handles data

To write Data Stories, Tableau uses a service hosted in your Tableau Cloud or Tableau Server environment. When you [Add a Tableau Data Story to a Dashboard on the facing page](#) or view a Data Story from a dashboard, Tableau sends associated worksheet data to the environment that you're logged in to (i.e. your Tableau Cloud site or your Tableau Server instance), using the security standards outlined in [Security in the Cloud](#) and [Security in Tableau Server](#). Data Stories can be written and viewed from anywhere you use Tableau.

Learn about how Data Stories are written

Tableau Data Stories is powered by rules-based templated natural language generation (NLG). Data Stories performs automated analytics to determine relevant and accurate facts about the underlying data – from basic calculations to more advanced statistics. To write a story, Data Stories uses a library of predefined language templates to synthesise these facts into natural language insights. Data Stories processes these templates at run-time, using the most up-to-date summary data from the Tableau worksheet it is connected to. You can leverage the [custom language feature](#) to generate your own language templates, add functions and define business rules, helping you build a more relevant and contextual Data Story.

Note: Data Stories doesn't use generative AI, large language models (LLMs), or machine learning to write insights and stories.

Manage Data Stories for your site

Tableau administrators can choose whether Tableau Data Stories are available for their site. Data Stories are turned on by default.

1. Sign in to your Tableau site.
2. From the left pane, choose **Settings**.
3. From the **General** tab, scroll to the **Availability of Data Stories** section.
4. Choose whether you want to **Turn on** or **Turn off** Data Stories.

Note: If Data Stories are turned off, turning the feature back on restores Data Stories that were already in dashboards.

Add a Tableau Data Story to a Dashboard

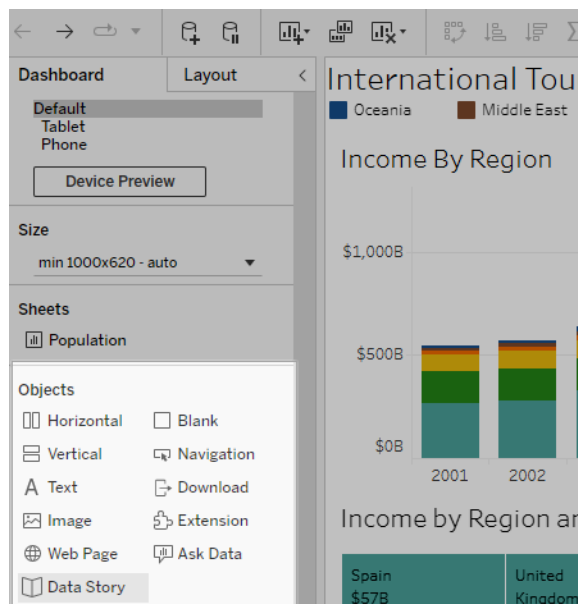

Important changes for Tableau Data Stories

Tableau Data Stories were retired in Tableau Desktop, Tableau Cloud and Tableau Server in January of 2025 (2025.1). With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of changes. For more information, see [How Tableau Pulse powered by Tableau AI is Reimagining the Data Experience](#).

After you [Create a Dashboard](#), you can add the **Data Story** object to your dashboard to display insights about your viz that are written in natural language. Today, Tableau Data Stories are written in English only and are available in Tableau Cloud, Tableau Server (version 2023.1 and later), and Tableau Desktop. There is no data size limit when creating **Data Stories**. However, story generation times out after 45 seconds if it's trying to analyse a lot of data. We recommend using **Data Stories** with visualisations that have 1,000 or fewer data points.

Note: Tableau Data Stories opens in a pop-up window, so make sure you allow pop-ups. If you're using full screen mode, Data Stories can open in a new tab.

1. Drag the **Data Story** object into your Tableau dashboard. If you haven't already, add a sheet to your dashboard to use Tableau Data Stories.

2. In the Data Story dialog box, configure your story by first choosing the worksheet to write about. When you click **Next**, Tableau sends all associated workbook data to the Tableau

Cloud or Tableau Server instance that you are logged in to.

Configure

4. Choose the type of story that best describes your data:

Configure

Views Fields **Story**

Choose the option that best describes your data. You can see a preview in the container.

- ☒ **Discrete (best fit)** For qualitative values such as names or dates.
- ☐ **Continuous** For quantitative values over time.
- ☐ **Percent of Whole** For proportions of a whole.
- ☐ **Scatter Plot** For relationships between numerical variables.

Back **Done**

Discrete is best for qualitative values such as names or dates, such as in bar or column charts.

Continuous is best for quantitative values over time, such as a plotted-in-a-line chart.

Percent of Whole is best for proportions of a whole, such as a pie chart.

Scatter Plot is best for relationships between numerical values, such as a scatter plot chart.

5. Click **Done**.

To filter your Data Story by clicking different sections on your visualisation, open the menu on your visualisation and click **Use as filter**.

After your story is generated, click **Settings** at the top of your **Data Story** object for a guided experience that helps you personalise and contextualise your story. For more information, see [Configure Settings for a Tableau Data Story on page 2861](#).

Note: If you experience a discrepancy in your Tableau Data Story (for example, if the numbers in your story are different from your visualisation), it may be caused by way your visualisation is set up. Try creating a new visualisation on a different sheet, and then add a new Data Story with the [Use a hidden sheet on page 2902](#) technique to uncover the underlying issue.

Choose the Right Story Type for Your Tableau Data Story

Important changes for Tableau Data Stories

Tableau Data Stories were retired in Tableau Desktop, Tableau Cloud and Tableau Server in January of 2025 (2025.1). With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of changes. For more information, see [How Tableau Pulse powered by Tableau AI is Reimagining the Data Experience](#).

When you [Add a Tableau Data Story to a Dashboard on page 2853](#), it's important to choose the right type of story for your data. Do you want your story about trends over time? Or do you want your story about two values that you're comparing? To help you tell the right story, this topic describes the different types of stories, including an example of each story type.

Continuous

Continuous stories are best for analysing trends or progress over time.

When you create a continuous story, it includes content for performance, segments, volatility and trend lines. The story also includes contribution analysis and correlation for stories that use more than one dimension. To use a continuous story, your worksheet must have:

- 1 dimension that has between 1–10 measures
- 2 dimensions and up to 3 measures

The following example is a continuous story for a line chart that has a single dimension and multiple measures:

Discrete

Discrete stories are best for comparing values and understanding the distribution of data in each value. When you create a discrete story, the story includes content about the distribution and groupings or clusters across the data. And the story includes contribution analysis for worksheets that use multiple dimensions.

Consider using a discrete story when you want to:

- Understand drivers of your key performance indicators (KPIs) in sales reports.
- Identify and understand outliers quickly during data discovery.
- Identify trends that aren't easily observable in the visual when performing an audit.
- Uncover complex utilisation insights instantly for geographic analysis.
- Identify and call out key relationships, for example, between sales and profit.

To use a discrete story, your worksheet must have:

- 1 dimension that has between 1–10 measures
- 2 dimensions and up to 3 measures

The following example is a discrete story for a bar chart that has a single dimension and two measures:

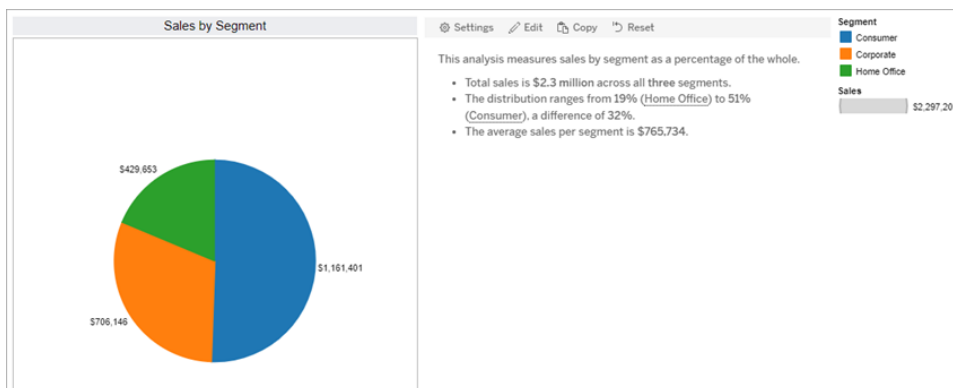

Percentage of whole

Percent-of-whole stories are best for pie charts. To use a percent-of-whole story, your worksheet must have:

- 1 dimension
- 1 measure

The following example is a percent-of-whole story that uses a pie chart with a single dimension and a single measure:

Scatter plot

Scatter plot stories are best for understanding the relationship between two measures. When you create a scatter plot story, the story includes content about the relationship (regression)

between two measures. And the story includes content about groups (clusters) within the data, when they exist.

Consider using a scatter plot story when you want to:

- Call out relationships between two measures to identify impact (regression analysis).
- Identify and understand outliers that are above or below defined thresholds.
- Analyse how your data is distributed.

To use a scatter plot story, your worksheet must have:

- 1 dimension
- 2 or 3 measures

Note: When you create your scatter plot story, the first measure you select is treated as the independent variable and the second measure is the dependent variable.

The following example is a scatter plot story that uses a scatter plot that has a single dimension and two measures:

Configure Settings for a Tableau Data Story

Important changes for Tableau Data Stories

Tableau Data Stories were retired in Tableau Desktop, Tableau Cloud and Tableau Server in January of 2025 (2025.1). With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of

changes. For more information, see [How Tableau Pulse powered by Tableau AI is Reimagining the Data Experience](#).

After you [Add a Tableau Data Story to a Dashboard on page 2853](#), you can configure and edit your Tableau Data Story, so it's tailored to your needs – use language specific to your data, specify which analytics are written about and customise how your Tableau Data Story is displayed.

Configure Tableau Data Story Settings: Analytics

Important changes for Tableau Data Stories

Tableau Data Stories were retired in Tableau Desktop, Tableau Cloud and Tableau Server in January of 2025 (2025.1). With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of changes. For more information, see [How Tableau Pulse powered by Tableau AI is Reimagining the Data Experience](#).

Within your Tableau Data Story, you can choose which analytics to write about and when those analytics are written about. Different types of analytics are available depending on your story type and how many dimensions and measures your story has. However, analytics aren't currently supported for scatter plot story types. For more information, see [Choose the Right Story Type for Your Tableau Data Story on page 2858](#).

Configure analytics for your story

1. [Add a Tableau Data Story to a Dashboard on page 2853](#).
2. From your dashboard, click on the **Settings** icon in the top-left corner of your **Data Story** object.
3. In the Data Story dialog box, click the **Analytics** tab.
4. Click the switches to turn on different types of analytics.
5. For **Segments** and **Trend line**, expand **Settings** to set thresholds for performing those analytics.
6. Click **Save**.

Understand different types of analytics

Correlation

Use **Correlation** to identify true statistical correlations between two series. If you have more than two series, then all combinations are analysed for correlations. For example, you might turn

on **Correlation** to identify when two products are often purchased together.

Clustering

Use **Clustering** to identify distinct groups of data points (clusters) using a single statistical analysis. For example, you might turn on **Clustering** to identify when a product is very popular in a specific geographic region.

Distribution

Use **Distribution** to rank data points relative to each other using non-statistical observations, such as mean, median, skew, etc. For example, you might turn on **Distribution** to identify which product has the highest profit ratio.

Segments

Use **Segments** to highlight noteworthy changes to data points within a series. First, set the minimum percentage of change that you want to be written about in a segment. Changes that fall below your defined threshold aren't written about. For example, if you set your segment threshold for changes that are greater than 60%, then your story doesn't write about a trough in a time series that features a 30% decrease.

After you've set your threshold, choose whether to **Apply formatting**, and set the minimum percentage of change that you want formatted.

Trend line

Use **Trend line** to calculate a linear best fit line and identify data that falls within a defined percentage of confidence. Data that has high variability has a lower confidence level than data that's more consistent, and that confidence level affects whether trend lines are written about. You can use trend lines for stories that have one dimension and one measure, or you can use trend lines in a drilldown. For more information about drilldowns, see [Configure Tableau Data Story Settings: Narrative](#) on page 2875.

Set the minimum percentage of confidence for your trend line. If you set your threshold at 95%, but a trend line could be drawn at 90% confidence, then your story doesn't write about trend lines. After you've set your threshold, choose whether to **Apply formatting**. Then set the minimum percentage of change that you want formatted.

Tableau Data Stories about trend lines communicate the absolute change over a period. The story written about your trend line varies depending on the level of verbosity you set for your story. If your story uses high verbosity, then your story writes about the R-squared value, which is a statistical concept that quantifies how well your data fits the trend line. For more information

about verbosity settings, see [Configure Tableau Data Story Settings: Narrative on page 2875](#).

Within the **Trend line** settings, you can also choose how many periods into the future for which you want your story to write predictions. When you use predictions, your story uses the slope and intercept of the trend line to calculate predicted values for future periods. The confidence of the prediction adds upper and lower bounds to the confidence threshold you set for trend lines. You can use predictions when your story has at least 30 data points that are linear.

Volatility

Use **Volatility** to analyse standard deviations over time. For example, use **Volatility** when you want your story to write about values that fall outside the average range for your data.

Break down how analytics are used to generate stories

At this point, you might be wondering how the analytics for different story types work. Let's take a look at an example for each story type and break down each sentence in the story.

Understand analytics for discrete stories

Because continuous stories measure trends over time, Data Stories writes about performance, progression, averages, totals, streaks, volatility, segments and predictions.

The following example of a continuous story is about sales per month:

This analysis measures Sales by month.

- Average Sales was **\$47,858** across all **48** months.
- The minimum value was **\$4,520** (February 2014) and the maximum was **\$118,448** (November 2017).
- Sales increased by **489%** over the course of the series but ended with a downward trend, decreasing in the final month.
- The largest single increase on a percentage basis occurred in March 2014 (**+1,132%**). However, the largest single increase on an absolute basis occurred in September 2014 (**+\$53,868**).
- Sales experienced cyclical, repeating each cycle about every **12** months. There was also a pattern of smaller cycles that repeated about every **three** months.
- Sales had a **significant positive peak between October 2014 (\$31,453) and February 2015 (\$11,951), rising to \$78,629 in November 2014.**
- The **overall linear trend of the series rose at \$902 per month** for an absolute change of **\$42,394** over the course of the series.

| Example story | Story breakdown |
|--|--|
| <ul style="list-style-type: none"> • Average Sales was \$47,858 across all 48 months. • The minimum value was \$4,520 (Febru- | <p>The first two sentences use average and range functions to write about the average, maximum and minimum values across the</p> |

| | |
|---|--|
| ary 2014) and the maximum was \$118,448 (November 2017). | period you're analysing. |
| <ul style="list-style-type: none"> Sales increased by 489% over the course of the series but ended with a downward trend, decreasing in the final month. | The third sentence is about overall performance of the measure over the period. For example, a sentence can be about whether sales increased, decreased or trended differently during a specific period. |
| <ul style="list-style-type: none"> The largest single increase on a percentage basis occurred in March 2014 (+1,132%). However, the largest single increase on an absolute basis occurred in September 2014 (+\$53,868). | The fourth sentence uses progression analysis. This sentence writes about the largest increase and decrease based on the measure during the period using both a percentage basis and an absolute basis. |
| <ul style="list-style-type: none"> Of the three series, the strongest relationship was between Corporate and Home Office, which had a moderate positive correlation, suggesting that as one (Corporate) increases, the other (Home Office) generally does too, or vice versa. | This sentence is a Correlation insight. This type of analytic insight writes about notable correlations between different series in your data. |
| <ul style="list-style-type: none"> Sales experienced cyclical, repeating each cycle about every 12 months. There was also a pattern of smaller cycles that repeated about every three months. Sales had a significant positive peak between October 2014 (\$31,453) and February 2015 (\$11,951), rising to \$78,629 in November 2014. | This sentence is a Segment insight. This type of analytic insight writes about noteworthy increases and decreases over time. |
| <ul style="list-style-type: none"> The overall linear trend of the series rose at \$902 per month for an absolute change of \$42,394 over the course of the series. If this trend continued for the next one month, Sales is predicted to be about \$69,958. | This sentence is a Trend line insight. This type of insight writes about how well trends fit your data with a certain percentage of confidence, and trend lines allow you to make predictions based on historic trends. |

Understand analytics for discrete stories

Because discrete stories allow you to compare values and understand the distribution of the data, the story writes about distribution, averages, totals and groupings or clusters across the data.

The following example of a discrete story is about sales by product:

This analysis measures Sales by product.

- Total Sales is **\$2.3 million** across all **17** products.
- The Sales of **\$2.3 million** was driven by Phones with **\$330,007**, Chairs with **\$328,449** and Storage with **\$223,844**.
- The distribution ranges from **\$3,024** (Fasteners) to **\$330,007** (Phones), a difference of **\$326,983**, averaging **\$135,129**.
- The distribution is positively skewed as the average of **\$135,129** is greater than the median of **\$114,880**.
- Sales is somewhat concentrated with **eight** of the **17** products (**47%**) representing **78%** of the total.
- The top **two** products represent over a quarter (**29%**) of overall Sales.
- Phones (**\$330,007**) is more than **two** times bigger than the average across the **17** products.

| Example story | Story breakdown |
|---|---|
| <ul style="list-style-type: none"> • Total Sales is \$2.3 million across all 17 products. | The first sentence calculates the total value of your measure. |
| <ul style="list-style-type: none"> • The Sales of \$2.3 million was driven by <u>Phones</u> with \$330,007, <u>Chairs</u> with \$328,449 and <u>Storage</u> with \$223,844. | The second sentence writes about the dimension drivers. In this example, the dimension drivers are the products that contributed the most to total sales. |
| <ul style="list-style-type: none"> • The distribution is positively skewed as the average of \$135,129 is greater than the median of \$114,880. • Sales is relatively concentrated with 78% of the total represented by eight of the 17 products (47%). | The third and fourth sentences analyse the distribution of the data. This analyses the averages, medians, concentration of data (if any exist), and how the data is skewed. This helps identify how balanced these grouped variables are compared to one another. |
| <ul style="list-style-type: none"> • The top two products combine for over a quarter (29%) of overall Sales. | This sentence uses Clustering to write about measures that can be grouped. This helps identify whether there are distinct groups that stand out in the data. |
| <ul style="list-style-type: none"> • <u>Phones</u> (\$330,007) is more than two | The final sentence writes about notable out- |

| | |
|--|--------|
| times bigger than the average across the 17 products. | liers. |
|--|--------|

Understand analytics for scatter plot stories

Scatter plot story types are best used to understand the relationship between two measures, and for that reason, scatter plot stories require 2–3 measures. The scatter plot analysis writes about the relationship (regression) between two measures, and it writes about groups (clusters) within the data, if they exist.

The following example of a scatter plot story is about profit and sales across a dimension:

| | |
|--|--|
| This analysis measures profit, quantity and sales across 793 customer. | |
| <ul style="list-style-type: none">As quantity increased and profit increased, sales increased based on the data provided. Specifically, when quantity increased by 1, sales increased \$49.55, and when profit increased by \$1.00, sales increased \$1.20.Few customers deviated from this general relationship, indicating a good fit.When organized into groups of similar profit, quantity and sales values, one distinct group stands out. There were 651 customers that had values of profit between -\$6,626 and \$1,488, quantity between 2 and 122 and sales between \$4.83 and \$5,690.Tamara Chand, Raymond Buch and Sanjit Chand, among others were outliers with high profit and sales values. Sean Miller stood out with a low profit and high sales value.The minimum value for profit is -\$6,626 (Cindy Stewart) and the maximum value is \$8,981 (Tamara Chand), a difference of \$15,608. The average profit per customer is \$361 and the median is \$228.The minimum value for quantity is 2 (Anthony O'Donnell) and the maximum value is 150 (Jonathan Doherty), a difference of 148. The average quantity per customer is 47.76 and the median is 44.The distribution of sales ranges from \$4.83 (Thais Sissman) to \$25,043 (Sean Miller), a difference of \$25,038. The average sales per customer is \$2,897 and the median is \$2,256. | |

| Example story | Story breakdown |
|---|---|
| <ul style="list-style-type: none">As quantity increased and profit increased, sales increased based on the data provided. Specifically, when quantity increased by 1, sales increased by \$49.55, and when profit increased by \$1.00, sales increased by \$1.20.Few customers deviated from this general relationship, indicating a good fit. | The first two sentences are powered by regression analytics. Regression shows how one measure affects another. Notice that in the first sentence, the story has identified a relationship between profit and sales. |

| | |
|--|---|
| <ul style="list-style-type: none"> When organised into groups of similar profit, quantity and sales values, one distinct group stands out. There were 651 customers that had values of profit between -\$6,626 and \$1,488, quantity between 2 and 122 and sales between \$4.83 and \$5,690. | <p>The third sentence is derived from clustering. Clustering analytics tries to identify key groups or clusters across all the variables in the data.</p> |
| <ul style="list-style-type: none"> <u>Tamara Chand</u>, <u>Raymond Buch</u> and <u>Sanjit Chand</u>, among others, were outliers with high profit and sales values. Sean Miller stood out with a low profit and high sales value. | <p>The fourth sentence is written about outliers – values that fall significantly above or below the average.</p> |
| <ul style="list-style-type: none"> The minimum value for profit is -\$6,626 (<u>Cindy Stewart</u>) and the maximum value is \$8,981 (<u>Tamara Chand</u>), a difference of \$15,608. The average profit per customer is \$361 and the median is \$228. The minimum value for quantity is 2 (<u>Anthony O'Donnell</u>) and the maximum value is 150 (<u>Jonathan Doherty</u>), a difference of 148. The average quantity per customer is 47.76 and the median is 44. The distribution of sales ranges from \$4.83 (<u>Thais Sissman</u>) to \$25,043 (<u>Sean Miller</u>), a difference of \$25,038. The average sales per customer is \$2,897 and the median is \$2,256. | <p>The remaining sentences for scatter plot stories use range and average analysis to write insights.</p> |

Understand analytics for percentage of whole stories

Percentage of whole story types is best for understanding what part of a whole a dimension or measure represents.

The following example of a percentage of whole story is about sales by segment:

This analysis measures sales by segment as a percentage of the whole.

- Total sales is \$2.3 million across all three segments.
- The minimum value is 19% (Home Office) and the maximum is 51% (Consumer), a difference of 32%.
- The average sales per segment is \$765,734.

| Example story | Story breakdown |
|---|---|
| <ul style="list-style-type: none">• Total SUM (Sales) is 2.3 million across all three entities. | The first sentence calculates the total value of your measure. |
| <ul style="list-style-type: none">• The SUM (Sales) of 2.3 million was driven by Consumer with 1.2 million, Corporate with 706,146 and Home Office with 429,653. | The second sentence writes about drivers. In this example, the drivers are segments that contributed the most to total sales. |
| <ul style="list-style-type: none">• The minimum value is 429,653 (Home Office) and the maximum is 1.2 million (Consumer), a difference of 731,748, averaging 765,734. | The final sentence analyses the distribution of the data. |

Configure Tableau Data Story Settings: Characteristics

Important changes for Tableau Data Stories

Tableau Data Stories were retired in Tableau Desktop, Tableau Cloud and Tableau Server in January of 2025 (2025.1). With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of changes. For more information, see [How Tableau Pulse powered by Tableau AI is Reimagining the Data Experience](#).

Within your Tableau Data Story, you can configure the characteristics settings to give context to your data, so you get more insightful stories. For example, in your story, you can specify that in the context of sales, a higher number is good. But in the context of customer complaints, a higher number is bad.

Use dimension and measure characteristics

Your story and number formatting adjust based on what the measure is. By default, your story writers all measure values as numbers, and your story won't perform any additional calculations

or apply any special rendering rules.

1. [Add a Tableau Data Story to a Dashboard on page 2853](#).
2. From your dashboard, click on the **Settings** icon in the top-left corner of your Data Story object.
3. In the Data Story dialog box, click the **Characteristics** tab.
4. Configure your formatting, such as number type, decimal places and negative values.
5. Click **Save**.

Learn more about measure characteristics

Formatting

If values are formatted as **Percentages**, then the story writes about percentage point differences, rather than percentage changes as a story would for number values. When you format a number as a **Percentage** in the **Characteristics** tab, the **Data Story** multiplies the value of the number by 100 to create the percentage that appears in your story.

If values are formatted as **Currency**, then you can specify your preferred currency. You can also specify how you want large values (numbers greater than one million) formatted, for example \$1.3 million instead of \$1,300,000.00.

For both **Numbers** and **Currency**, you can specify how you want large values and negative values to be written about. If you choose to have negative values written about in brackets, you might see nested brackets in your story when the negative value is written about in a parenthetical phrase.

When you choose **Number** formatting, you can also specify whether you want numbers less than or equal to 10 to be spelled out (rather than using a numeral) in your story.

For decimal places, **Dynamic** is the default option. This means that the story rounds to different decimal places depending on how large or small the number is. If the percentage value is less than 10, then the number has two decimal places. If the percentage value is greater than 10, then the number rounds to the nearest whole number. You can also specify how many decimal places you want used, which is used consistently throughout your story.

Content

You can assign meaning to larger values. For example, larger values for sales are good, but larger values for losses are bad.

In addition, you can choose how to aggregate values by sum or average. It's a best practice to choose the same aggregation method that you're using in the viz. For ratio measures, choose

Average and then define the ratio by selecting the component measures of that ratio measure. Measures that are components of a ratio must be summable.

For cumulative measures (available for continuous stories only), choose **Sum** and then specify that the measure is already cumulative. Continuous stories write about the total of the measure across the series.

Sorting

To sort dimension values, click the arrow up/down icon to sort based on the oldest or newest time values in your dimension.

Note: Sorting dimension values is available only for continuous stories.

Configure Tableau Data Story Settings: Display

Important changes for Tableau Data Stories

Tableau Data Stories were retired in Tableau Desktop, Tableau Cloud and Tableau Server in January of 2025 (2025.1). With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of changes. For more information, see [How Tableau Pulse powered by Tableau AI is Reimagining the Data Experience](#).

You can configure how the text in your Tableau Data Story is displayed, such as font colour and size. You can also choose whether your story uses bulleted lists or paragraphs.

Configure the display for your story

1. [Add a Tableau Data Story to a Dashboard on page 2853](#).
2. From your dashboard, click on the **Settings** icon in the top-left corner of your Data Story object.
3. In the Data Story dialog box, click on the **Display** tab.
4. Choose whether you want your story structure to be **Bullets** or **Paragraphs**.
5. Choose your **Font Size**.
6. Pick colours to represent good and bad changes (available for continuous stories).
7. Choose whether to use **Dynamic Ordering**.
8. Choose whether to use a **Condensed View**.
9. Click **Save**.

Understand when to use story display settings

To use colour, your story must be continuous. When using colour, you can choose colours from the palette to represent good changes and bad changes. For your story to know whether a change is good or bad, you must assign meaning to larger values in the **Characteristics** tab. For more information, see [Configure Tableau Data Story Settings: Characteristics on page 2869](#). After you configure your display, the styles and colours are applied in your story based on thresholds for trend line or segment analytics.

If you turn on **Dynamic Ordering**, the insights for measures in a story are dynamically ordered from the best to the worst average value. If you already have an order you want to maintain, turn off **Dynamic Ordering**.

If you turn on **Condensed View**, additional space is removed from your story. This is helpful if you don't have much extra space in your dashboard or when you have multiple Data Story objects in a dashboard.

Configure Tableau Data Story Settings: Drivers

Important changes for Tableau Data Stories

Tableau Data Stories were retired in Tableau Desktop, Tableau Cloud and Tableau Server in January of 2025 (2025.1). With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of changes. For more information, see [How Tableau Pulse powered by Tableau AI is Reimagining the Data Experience](#).

Hypothetically, let's say your month-over-month sales increased significantly. What drove that increase in sales? And what might have detracted from (offset) those increased sales? Setting up drivers in your Data Story can answer those questions.

In Data Stories, drivers contribute towards a total value. Offsetters detract from a total value. You'll find insights about drivers and offsetters in discrete and continuous stories. And these insights make it easy to understand exactly what's going on in the data and why.

Set dimension drivers

1. [Add a Tableau Data Story to a Dashboard on page 2853.](#)
2. From your dashboard, click on the **Settings** icon in the top-left corner of your Data Story object.
3. In the Data Story dialog box, click the **Drivers** tab.
4. From the **Dimension Drivers** section, select the type of driver that has the greatest impact on your analysis:
 - For **Count**, set the maximum number of contributors and offsetters.
 - For **Individual %**, set thresholds for writing about individual contributors and offsetters.
 - For **Cumulative %**, set thresholds for writing about contributors and offsetters based on their collective value.
5. Click **Save**.

Understand dimension driver types

- **Count** specifies the number of entities (contributors and offsetters) called out in your story. For example, use **Count** to see the top three contributors and offsetters in your data.
- **Individual %** sets a threshold, and values higher than that threshold are included in your story. For example, use **Individual %** to specify that you want to write about only entities that represent more than 5% of the total value.
- **Cumulative %** sets a percentage threshold of the total value that included entities collectively account for. For example, use **Cumulative %** to specify that you want to write about the entities that contributed to at least 90% of that total value. In this example, entities are written about in order of magnitude until the cumulative value of those entities account for 90% of the total value.

Use secondary contributors

To use secondary contributors, you must have a second dimension that isn't time. When you use secondary contributors, each driver that is written about also has details about and drivers for its secondary contributor. For example, if you are analysing store sales, a secondary contributor

would be a class within a department. Secondary contributors allow for deeper analysis. But secondary contributors can also contain a lot of information to fit into a single sentence in your story.

Set metric drivers

For measures that are composed of other subcategory measures, driver analysis can explain the impact that each measure had on the top-level value. For example, material costs and operating costs contribute to total cost.

To use metric drivers, you must have multiple measures for metric analysis. Then, you can specify the relationships between each measure.

1. [Add a Tableau Data Story to a Dashboard on page 2853.](#)
2. From your dashboard, click on the **Settings** icon in the top-left corner of your Data Story object.
3. In the Data Story dialog box, click the **Drivers** tab.
4. From the **Metric Drivers** section, first choose the measure that is a subcategory of another measure.
5. Then, choose the measure that is the primary category.
6. Click **Save**.

Tip: The verbosity setting also applies to drivers. By changing your story's verbosity setting, you can adjust the way insights are written. If you use high verbosity, then you'll see more information in brackets. If you use low verbosity, then you'll get a more concisely written insight about your drivers. For more information, see [Configure Tableau Data Story Settings: Narrative on the facing page](#).

Configure Tableau Data Story Settings: Narrative

Important changes for Tableau Data Stories

Tableau Data Stories were retired in Tableau Desktop, Tableau Cloud and Tableau Server in January of 2025 (2025.1). With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of changes. For more information, see [How Tableau Pulse powered by Tableau AI is Reimagining the Data Experience](#).

You can customise the narrative settings of your Tableau Data Story. Specifically, you can specify the verbosity and level of analytical detail in your story, and you can add terms that are unique to your data. These settings help you write a story that uses the right language and speaks to the right level of detail for your dashboard.

Set verbosity

Verbosity specifies the length and analytical detail written in your story. If you choose high, your story has longer insights, with more analytic analysis. If you choose low, your story is more concise, with fewer details.

If you allow viewers to change verbosity, viewers of published dashboards can change the level of verbosity in the Data Story object. This is helpful when your dashboard is used by a broader audience with viewers who want varying levels of detail from your story.

Set drilldowns

A drilldown includes two dimensions, and drilldowns describe figures associated with each dimension of your dashboard.

Let's say you have a dashboard that has monthly sales by product category. Your story is configured to write about both the **Time** and **Category** dimensions. In this case, this story includes an insight for each Category that describes its performance in and across the **Time** dimension.

By setting the maximum number of drilldowns, you can control how many insights are included in your story. Drilldown insights are also ranked based on the meaning assigned to the measure characteristics. As the number of drilldowns is reduced, the lowest performing measures (measures that are assigned a Bad meaning) are eliminated.

Add dimension terms

By adding terms, you can define the way each of your measures and dimensions are labelled and referenced in your story.

1. [Add a Tableau Data Story to a Dashboard on page 2853](#).
2. From your dashboard, click on the **Settings** icon in the top-left corner of your Data Story object.
3. In the Data Story dialog box, click on the **Narrative** tab.
4. Expand the dimension to see how it will be written about in both singular and plural form.
5. Click **Add Term** to add another variation for your story to use to describe your dimension.
6. Click **Save**.

Your story uses (at random) the terms you've added when writing about a dimension.

Manage measure labels

Similarly to dimensions, you can manage labels used for measures in your story.

1. From the **Narrative** tab, expand the measure to see its label.
2. Enter the new label that you want used for your measure.
3. Click **Save**.

Configure Tableau Data Story Settings: Relationships

Important changes for Tableau Data Stories

Tableau Data Stories were retired in Tableau Desktop, Tableau Cloud and Tableau Server in January of 2025 (2025.1). With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of changes. For more information, see [How Tableau Pulse powered by Tableau AI is Reimagining the Data Experience](#).

The **Relationships** setting allows you to assign relationships between measures in a Tableau Data Story that has multiple measures. To configure Relationships, your story must have one dimension and multiple measures. For more information, see [Create Custom Measure Relationships in Your Tableau Data Story](#) on page 2907.

There are two types of relationships:

- Actual vs. Benchmark
- Current/Most Recent vs. Previous Period

Use **Actual vs. Benchmark** when you want to know if you're performing above or below your performance benchmarks, for example, when performing quota reporting. This type of relationship is also helpful for identifying data points that require additional analysis because they're significantly above or below your benchmark. To use **Actual vs. Benchmark**, the measures you're comparing must have the same value type.

Use **Current/Most Recent vs. Previous Period** when you want to see if your key performance indicators (KPIs) are increasing, decreasing or remaining consistent over time. To use **Current/Most Recent vs. Previous Period**, you must use a discrete story type. For more information, see [Choose the Right Story Type for Your Tableau Data Story](#) on page 2858.

Additionally, you can use **Actual vs. Benchmark** and **Current/Most Recent vs. Previous Period** relationships simultaneously. Measures in your viz that aren't part of the configured relationships are written about in separate paragraphs.

Create Actual vs. Benchmark relationship for continuous or discrete stories

Use the **Actual vs. Benchmark** relationship when one measure is a benchmark for other measures. For example, you could compare actual sales to a sales target so your story writes insights about whether you outperformed or underperformed your goal. When you use this type of relationship, the story removes unnecessary content and focuses on what's most important – comparing a metric to its associated benchmark.

1. [Add a Tableau Data Story to a Dashboard on page 2853.](#)
2. From your dashboard, click on the **Settings** icon in the top-left corner of your Data Story object.
3. In the Data Story dialog box, click the **Relationships** tab.
4. Tick the box for **Actual vs. Benchmark**.
5. First, select the measure that is the benchmark.
6. Then, select the measure that you want to compare against the benchmark.
7. Click **Save**.

Create Current/Most Recent vs. Previous Period relationship

Use the **Current/Most Recent vs. Previous Period** relationship to compare the performance of two measures over a period. For example, you could compare two products to see which product generated the most revenue over the last year.

1. [Add a Tableau Data Story to a Dashboard on page 2853.](#)
2. From your dashboard, click on the **Settings** icon in the top-left corner of your Data Story object.
3. In the Data Story dialog box, click the **Relationships** tab.
4. Tick the box for **Current/Most Recent vs. Previous Period**.
5. First select the measure for the previous period.
6. Then, select the measure for the current period.
7. Enter the label for the period that you're measuring, for example, year.
8. Choose the number of periods to measure.
9. Click **Save**.

Customise Your Tableau Data Story

Important changes for Tableau Data Stories

Tableau Data Stories were retired in Tableau Desktop, Tableau Cloud and Tableau Server in January of 2025 (2025.1). With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of changes. For more information, see [How Tableau Pulse powered by Tableau AI is Reimagining the Data Experience](#).

You can use custom language, tailored to your audience, to supplement your Tableau Data Stories with insights specific to your business. Identify the analytics and data from the Data Story that matters most to your audience, and use your own language to create the most

impactful story. As with the overall Tableau Data Story, data and variables used in custom content are dynamic, adjusting along with the dashboard.

Add your own insights

1. In your **Data Story**, click **Edit** to open the Edit dialog box.
2. Find the section you want to write about and click **Add Custom Item**.

3. Enter your custom text in the field that appears.
4. Click **Save**.

Add headers and footers

You can insert custom text at the top and bottom of your **Data Story**. With headers and footers, you can add your own qualitative analysis to stories, include additional explanations of data trends or append legal and privacy disclaimers.

1. In your **Data Story**, click **Edit** to open the Edit dialog box.
2. Click the **Show note** switch.
3. Enter your custom note.

4. Click **Save**.

Your note now appears at the top or bottom of your **Data Story**.

Add functions

Using a function in your Data Story is a great way to customise your story and find the insights that are most important to you and your business.

For example, if you want to know the average sum of tourism revenue over a period, select Average as your function and then designate the measure as SUM (Tourism Inbound). This returns the average sum of inbound tourism.

1. In your **Data Story**, click **Edit** to open the Edit dialog box.
2. Click the menu on the right-hand side of the box and select **Add Function**.

3. Select a Data Story Function and fill in the required fields.

4. Click **Add to Section**.
5. Click **Save**.

The custom content now appears in your Data Story.

Add conditions

For each custom sentence you write, you can add a condition that determines whether the sentence renders in your **Data Story**. If the condition is met, the custom sentence appears in your story. If the condition isn't met, the custom sentence doesn't appear.

You can apply multiple conditions to each custom sentence, and the conditions can be combined using the **Any** or **All** buttons within the Add a condition dialog box.

Conditional statements are most often used with numerical comparisons, but the function also supports string matching using the equal (=) or not equal (!=) symbols.

1. In your Data Story, click **Edit** to open the Edit dialog box.
2. Enter your custom sentence.
3. Click the menu on the right-hand side of the box and select **Add Condition**.
4. Define the custom function to be used to inform the conditional logic. In this example, the sentence "We have met our quota" appears if the Sum of Tourism Inbound is greater than 5 trillion.

5. Click **Add to Section**.
6. Click **Save**.

The custom sentence now appears in your Data Story only if the conditions are met.

Duplicate custom content

You can easily duplicate custom content added to your Data Story, making it easier to build different variations of a sentence. We recommend copying a fully built custom sentence when applying thresholds, building in language variation and creating different logical variations.

1. In your Data Story, click **Edit** to open the Edit dialog box.
2. Create a custom sentence, complete with functions and conditions, if desired.
3. In the completed sentence box, Click the menu in the right-hand side of the box and select **Duplicate**.

4. Click into your duplicated sentence, update as desired and click **Add to Section**.
5. Click **Save**.

When you copy a sentence, all functions and conditional statements also copy over. The copied bullet appears directly below the original bullet in the same section.

Note: Copied bullets can only be added to the section that the original bullet is in.

Add custom content in drilldown sections

For stories that have two dimensions, each section after the first section is called a drilldown section. Drilldown sections focus on an individual primary dimension entity (i.e. The Americas in the following example).

Because the drilldown sections have the same content structure, custom content added in the first section (i.e. Europe) is applied to each additional section (i.e. The Americas). You can only create or edit content in the first drilldown section.

1. In your Data Story, click **Edit** to open the Edit dialog box.
2. In the first drilldown section, click **Add Custom Item** to each entity.
3. Enter your custom content.
4. Click **Save**.

Custom content in drilldown sections already has a context variable called Current Category value (dynamic). This creates a dimension value option called Current Category value (dynamic), which always represents the section that the drilldown section is about.

Tip: To create content that only appears in a single specific drilldown section, you can use conditional logic to ensure it only writes where appropriate.

Customise Your Tableau Data Story: Context Variables

Important changes for Tableau Data Stories

Tableau Data Stories were retired in Tableau Desktop, Tableau Cloud and Tableau Server in January of 2025 (2025.1). With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of changes. For more information, see [How Tableau Pulse powered by Tableau AI is Reimagining the Data Experience](#).

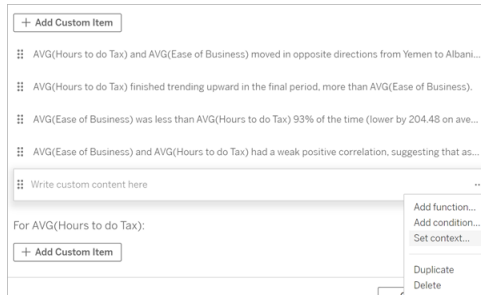

Context variables are functions that can be referenced by other functions. In other words, you can use context variables to nest functions within other functions.

After you define your context variable, it appears as a function that you can use when adding new functions to your Tableau Data Story.

Note: You can have multiple context variables set for each custom sentence, but you must define each context variable separately for each piece of custom content.

Set a context variable

1. In your **Data Story**, click **Edit** to open the Edit dialog box.
2. Click **Add Custom Item**.
3. Click the menu in the right-hand side of your custom content box and select **Set context**.

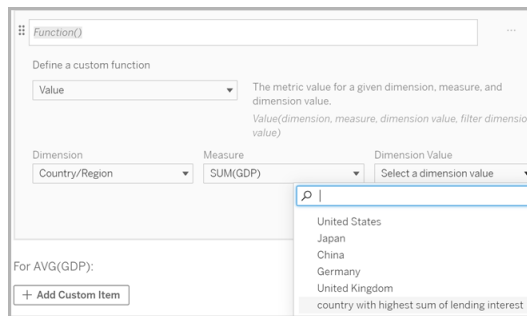

4. Click **Add context**.
5. Name the context variable and click **Set Function**.
6. Define your custom function and choose a dimension.

7. Click **Add to Section**.
8. Click back into the sentence where you set your context variable.

9. Follow the steps to [Add functions on page 2880](#).

Now your context variable is listed as an option in the **Dimension Value** drop-down list when adding your function.

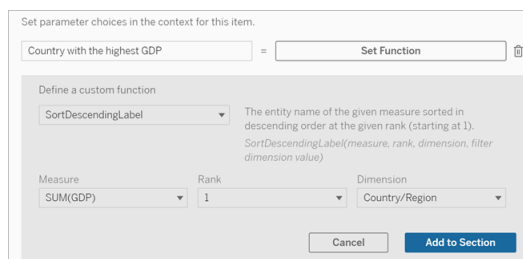

When to use a context variable: reference two or more measures

Let's say that you want to refer to two or more measures in one analytical sentence in your **Data Story**. Without a context variable, we can write a sentence for only one measure at a time. But if we use a context variable, we can reference more than one measure in one sentence.

To reference two or more measures with a context variable, your **Data Story** must have:

- 1 dimension
- 2 or more measures

1. In your **Data Story**, click **Edit** to open the Edit dialog box.
2. Click **Add Custom Item**.
3. Click the menu in the right-hand side of your custom content box and select **Set context**.
4. Click **Add context**.
5. Name the context variable and click **Set Function**.
6. Define your custom function and choose a dimension.
7. Click **Add to Section**.

8. Click back into the sentence where you set your context variable.
9. Add your first function and fill in the required fields. In this example, we selected **DimensionValueLabel**, then chose Country/Region from **Dimension** and then country with the highest GDP (our context variable) from **Dimension Value**.

Function()

Define a custom function

DimensionValueLabel The label for a dimension value. Most useful in combination with "Current (dynamic)."
DimensionValueLabel(dimension, dimension value)

Dimension: Country/Region Dimension Value: Country with the highest GDP

Cancel Add to Section

10. Click **Add to Section**.
11. Add your second function and fill in the required fields. In this example, we selected **Value**, then chose Country/Region from **Dimension**, SUM(Lending Interest) from **Measure** and country with the highest GDP (our context variable) from **Dimension Value**.

DimensionValueLabel(Country/Region, Country with highest GDP), which has the highest AVG
(GDP, has a SUM of function)

Define a custom function

Value The metric value for a given dimension, measure, and dimension value.
Value(dimension, measure, dimension value, filter dimension value)

Dimension: Country/Region Measure: SUM(Lending Interest) Dimension Value: Country with highest GDP

Cancel Add to Section

12. Click **Add to Section**.
13. Click **Save**.

Your **Data Story** writes a sentence that gives us insight into a secondary measure (Lending Interest) for the country that we're interested in (the country with the highest GDP).

For AVG(GDP):

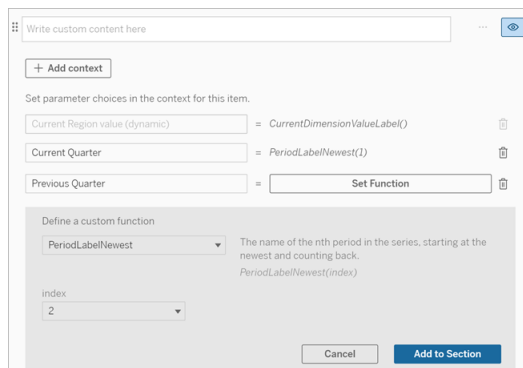

- Total AVG(GDP) is **348.03 trillion** across all **five** entities.
- The AVG(GDP) of **348.03 trillion** was driven by United States with **173 trillion**, Japan with **62.36 trillion** and China with **46.99 trillion**.
- The minimum value is **28.48 trillion** (United Kingdom) and the maximum is **173 trillion** (United States), a difference of **144.52 trillion**, averaging **69.61 trillion**.
- United States (**173 trillion**) is more than **two** times bigger than the average across the **five** entities.
- United States, which has the highest AVG (GDP), has a Lending Interest SUM of 0.7 billion.

When to use a context variable: period-over-period analysis

A context variable is helpful when you want to analyse performance over two different periods in your **Data Story**. You can create a custom sentence that writes about a measure displayed in your drilldown section and compares the measure against different periods, such as year on year or month on month.

To set up a period-over-period analysis, your Data Story must have:

- 2 dimensions: 1 time period dimension (primary) and 1 non-time period dimension (secondary)
 - 1–3 measures
1. Create your **Data Story**.
 2. In the Fields dialog box, make sure your time period dimension is ordered first and click **Next**.
 3. In the Story dialog box, select **Continuous** and click **Done**.
 4. Open the Edit dialog box and select **Add Custom Item** in the first drilldown area.
 5. Create two context variables that represent your time periods. For example, "Current Quarter" and "Previous Quarter."

6. Create an *increased* sentence by adding custom language and functions. The content of this sentence results in "[CurrentDimensionValueLabel] increased [X%] over the quarter."
7. Type in the function followed by the word "increased" in the custom text box.
8. Add the function that returns the percentage change of your measurement during your time period.

CurrentDimensionValueLabel() increased Function()

Define a custom function

PercentDifference

The percent difference in measure values between the two provided dimension values.

PercentDifference(dimension, measure, first dimension value, second dimension value, filter dimension value)

Dimension: QUARTER(Order Date)

Measure: total orders

First Dimension Value: Previous Quarter

Second Dimension Value: Current Quarter

Filter Dimension Value (Optional): Current Region value (dynamic)

Cancel Add to Section

9. Click **Add to Section**.
10. **Duplicate custom content on page 2881** and create a *decreased* version by replacing the word "increased" with "decreased." The functions stay the same.

West was higher than Central over the entire series, higher by 220 on average. West was higher than ...

CurrentDimensionValueLabel() increased PercentDifference(QUARTER(Order Date), total orders, Previous Quarter, Current Quarter, Current Region value (dynamic)) over the quarter

For East:

Total total orders was 2,848 across all four quarters.

The minimum value was 362 (Q1) and the maximum was 1,022 (Q4), averaging 712.

Add function...
Add condition...
Set context...
Duplicate
Delete

11. **Add conditions on page 2880** for each sentence so that only one is written, depending on the data.

CurrentDimensionValueLabel() increased PercentDifference(QUARTER(Order Date), total orders, Previous Quarter, Current Quarter, Current Region value (dynamic)) over the quarter

+ Add condition

Write this custom content when the following condition is met:

Value(QUARTER(Order Date), total orde...) > Value(QUARTER(Order Date), total orde...)

Cancel Add to Section

12. For the *increased* sentence, set conditions in line with the following example:

Left Argument = Value function

Dimension = Quarter (OrderDate). Select your time period dimension

Measure = SUM (Total Orders). Select the measure you used for the calculation

Dimension Value = Current Quarter. One of the context variables

Filter Dimension Value = Current Region value (dynamic). This is the preset context variable

Middle Argument = > (greater than)

Right Argument = Value function

Dimension = Quarter (OrderDate). Select your time period dimension

Measure = Total (Total Orders). Select the measure you used for the calculation

Dimension Value = Previous Quarter. One of the context variables

Filter Dimension Value = Current Region value (dynamic). This is the preset context variable

The screenshot shows the Tableau Data Story editor interface. At the top, a text box contains the sentence: "CurrentDimensionValueLabel() increased PercentDifference(QUARTER(Order Date), total orders, Previous Quarter, Current Quarter, Current Region value (dynamic)) over the quarter". Below this is a button labeled "+ Add condition". Underneath, a prompt says "Write this custom content when the following condition is met:". Below the prompt, there is a condition builder with two fields: "Value(QUARTER(Order Date), total orde..." and a dropdown menu showing ">". To the right of the dropdown is another field: "Value(QUARTER(Order Date), total orde...". At the bottom right are two buttons: "Cancel" and "Add to Section".

13. For the *decreased* sentence, set the same conditions, but replace the > (greater than) sign with the < (less than) sign. The right and left arguments remain the same.
14. Click **Save**, and your **Data Story** writes a sentence that includes the insights from analysing the two time periods.

Customise Your Tableau Data Story: Functions

Important changes for Tableau Data Stories

Tableau Data Stories were retired in Tableau Desktop, Tableau Cloud and Tableau Server in January of 2025 (2025.1). With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of changes. For more information, see [How Tableau Pulse powered by Tableau AI is Reimagining the Data Experience](#).

If you'd like to customise your Tableau Data Story with a function, it helps to know what functions you can use, what each function does and what dimensions and measures you'll need for each function.

Learn how to [Add functions on page 2880](#) to your Data Story.

Click a letter to see functions that begin with that letter. If no functions start with that letter, the functions that start with the next letter in the alphabet are shown. You can also press Ctrl+F (Command-F on a Mac) to open a search box that you can use to search the page for a specific function.

A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

Average

Description: The average value of the given measure.

Syntax: Average(dimension, measure, filterDimensionValue)

Count

Description: The number of dimension values within a given dimension.

Syntax: Count (dimension)

Difference

Description: The difference in measure values between the two provided dimension values.

Syntax: Difference (dimension, measure, firstDimensionValue, secondDimensionValue, filterDimensionValue)

DifferenceFromMean

Description: The difference between the mean and the measure value for the given dimension value.

Syntax: DifferenceFromMean (dimension, measure, firstDimensionValue, filterDimensionValue)

Direction

Description: Language describing the direction (e.g. increase or decrease) between measure values for the two provided dimension values.

Syntax: Direction (dimension, measure, firstDimensionValue, secondDimensionValue, filterDimensionValue, phrase)

Ending Label

Description: The name of the last period in the series.

Syntax: Label (measure)

EndingValue

Description: The value at the last period in the series for the given measure.

Syntax: EndingValue (measure, filterDimensionValue)

Label

Description: The label for the given measure.

Syntax: Label (measure)

LargestNegativeChangeDifference

Description: The value of the largest negative period-over-period difference, on an absolute basis, in the given series.

Syntax: LargestNegativeChangeDifference (measure, filterDimensionValue)

LargestNegativeChangeEndingLabel

Description: The name of the ending period for the largest negative period-over-period difference, on an absolute basis, in the given series.

Syntax: LargestNegativeChangeEndingLabel (measure, filterDimensionValue)

LargestNegativeChangeEndingValue

Description: The ending value of the largest negative period-over-period difference, on an absolute basis, in the given series.

Syntax: LargestNegativeChangeEndingValue (measure, filterDimensionValue)

LargestNegativeChangePercentDifference

Description: The percentage change of the largest negative period-over-period difference, on an absolute basis, in the given series.

Syntax: LargestNegativeChangePercentDifference (measure, filterDimensionValue)

LargestNegativeChangeStartingLabel

Description: The name of the starting period for the largest negative period-over-period difference, on an absolute basis, in the given series.

Syntax: LargestNegativeChangeStartingLabel (measure, filterDimensionValue)

LargestNegativeChangeStartingValue

Description: The starting value of the largest negative period-over-period difference, on an absolute basis, in the given series.

Syntax: LargestNegativeChangeStartingValue (measure, filterDimensionValue)

LargestNegativePercentChangeDifference

Description: The value of the largest negative period-over-period difference, on a percentage basis, in the given series.

Syntax: LargestNegativePercentChangeDifference (measure, filterDimensionValue)

LargestNegativePercentChangeEndingLabel

Description: The name of the ending period for the largest negative period-over-period difference, on a percentage basis, in the given series.

Syntax: LargestNegativePercentChangeEndingLabel (measure, filterDimensionValue)

LargestNegativePercentChangeEndingValue

Description: The ending value of the largest negative period-over-period difference, on a percentage basis, in the given series.

Syntax: LargestNegativePercentChangeEndingValue (measure, filterDimensionValue)

LargestNegativePercentChangePercentDifference

Description: The percent change of the largest negative period-over-period difference, on a percentage basis, in the given series.

Syntax: LargestNegativePercentChangePercentDifference (measure, filterDimensionValue)

LargestNegativePercentChangeStartingLabel

Description: The name of the starting period for the largest negative period-over-period difference, on a percentage basis, in the given series.

Syntax: LargestNegativePercentChangeStartingLabel(measure, filterDimensionValue)

LargestNegativePercentChangeStartingValue

Description: The starting value of the largest negative period-over-period difference, on a percentage basis, in the given series.

Syntax: LargestNegativePercentChangeStartingValue (measure, filterDimensionValue)

LargestPositiveChangeDifference

Description: The value of the largest positive period-over-period difference, on an absolute basis, in the given series.

Syntax: LargestPositiveChangeDifference (measure, filterDimensionValue)

LargestPositiveChangeEndingLabel

Description: The name of the ending period for the largest positive period-over-period difference, on an absolute basis, in the given series.

Syntax: LargestPositiveChangeEndingLabel (measure, filterDimensionValue)

LargestPositiveChangeEndingValue

Description: The ending value of the largest positive period-over-period difference, on an absolute basis, in the given series.

Syntax: LargestPositiveChangeEndingValue (measure, filterDimensionValue)

LargestPositiveChangePercentDifference

Description: The percentage change of the largest positive period-over-period difference, on an absolute basis, in the given series.

Syntax: LargestPositiveChangePercentDifference (measure, filterDimensionValue)

LargestPositiveChangeStartingLabel

Description: The name of the starting period for the largest positive period-over-period difference, on an absolute basis, in the given series.

Syntax: LargestPositiveChangeStartingLabel (measure, filterDimensionValue)

LargestPositiveChangeStartingValue

Description: The starting value of the largest positive period-over-period difference, on an absolute basis, in the given series.

Syntax: LargestPositiveChangeStartingValue (measure, filterDimensionValue)

LargestPositivePercentChangeDifference

Description: The value of the largest positive period-over-period difference, on a percentage basis, in the given series.

Syntax: LargestPositivePercentChangeDifference (measure, filterDimensionValue)

LargestPositivePercentChangeEndingLabel

Description: The name of the ending period for the largest positive period-over-period difference, on a percentage basis, in the given series.

Syntax: LargestPositivePercentChangeEndingLabel (measure, filterDimensionValue)

LargestPositivePercentChangeEndingValue

Description: The ending value of the largest positive period-over-period difference, on a percentage basis, in the given series.

Syntax: LargestPositivePercentChangeEndingValue (measure, filterDimensionValue)

LargestPositivePercentChangePercentDifference

Description: The percent change of the largest positive period-over-period difference, on a percentage basis, in the given series.

Syntax: LargestPositivePercentChangePercentDifference (measure, filterDimensionValue)

LargestPositivePercentChangeStartingLabel

Description: The name of the starting period for the largest positive period-over-period difference, on a percentage basis, in the given series.

Syntax: LargestPositivePercentChangeStartingLabel (measure, filterDimensionValue)

LargestPositivePercentChangeStartingValue

Description: The starting value of the largest positive period-over-period difference, on a percentage basis, in the given series.

Syntax: LargestPositivePercentChangeStartingValue (measure, filterDimensionValue)

LongestStreakDifference

Description: The difference over the longest streak of consecutive increases or decreases for the given series.

Syntax: LongestStreakDifference (measure, filterDimensionValue)

LongestStreakDirection

Description: The direction (positive or negative) of the longest streak of consecutive increases or decreases for the given series.

Syntax: LongestStreakDirection (measure, filterDimensionValue)

LongestStreakEndingLabel

Description: The name of the ending period for the longest streak of consecutive increases or decreases for the given series.

Syntax: LongestStreakEndingLabel (measure, filterDimensionValue)

LongestStreakEndingValue

Description: The ending value of the longest streak of consecutive increases or decreases for the given series.

Syntax: LongestStreakEndingValue (measure, filterDimensionValue)

LongestStreakLength

Description: The largest number of periods of consecutive increase or decrease for the given series.

Syntax: LongestStreakLength (measure, filterDimensionValue)

LongestStreakPercentDifference

Description: The percent difference over the longest streak of consecutive increases or decreases for the given series.

Syntax: LongestStreakPercentDifference (measure, filterDimensionValue)

LongestStreakStartingLabel

Description: The name of the starting period for the longest streak of consecutive increases or decreases for the given series.

Syntax: LongestStreakStartingLabel (measure, filterDimensionValue)

LongestStreakStartingValue

Description: The starting value of the longest streak of consecutive increases or decreases for the given series.

Syntax: LongestStreakStartingValue (measure, filterDimensionValue)

MaxLabel

Description: The name of the entity with the maximum value for the given measure.

Syntax: MaxLabel (dimension, measure, filterDimensionValue)

MaxValue

Description: The maximum value for the given measure.

Syntax: MaxValue (measure)

Median

Description: The median value for the given measure.

Syntax: Median (dimension, measure, filterDimensionValue)

MinLabel

Description: The name of the entity with the minimum value for the given measure. Syntax:

MinLabel (dimension, measure, filterDimensionValue)

MinValue

Description: The minimum value for the given measure.

Syntax: MinValue (dimension, measure, filterDimensionValue)

PercentDifference

Description: The percentage difference in measure values between the two provided dimension values.

Syntax: PercentDifference (dimension, measure, firstDimensionValue, secondDimensionValue, filterDimensionValue)

PercentOfWhole

Description: The percentage in measure values for a given dimension value over the total measure values for that dimension.

Syntax: PercentOfWhole (dimension, measure, DimensionValue, filterDimensionValue)

PeriodLabel

Description: The name of the nth period in the series, starting at 1.

Syntax: PeriodLabel (index)

PeriodLabelNewest

Description: The name of the nth period in the series, starting at the newest and counting back.

Syntax: PeriodLabelNewest (index)

PeriodValue

Description: The value of the given measure at the nth period in the series, starting at 1.

Syntax: PeriodValue (measure, index, filterDimensionValue)

PeriodValueNewest

Description: The value of the given measure at the nth period in the series, starting at the newest and counting back.

Syntax: PeriodValueNewest (measure, index)

Range

Description: The difference between the maximum and minimum values for the given measure.

Syntax: Range (dimension, measure, filterDimensionValue)

SortAscendingLabel

Description: The entity name of the given measure sorted in descending order at the given rank (starting at 1).

Syntax: SortAscendingLabel (measure, rank, dimension, filterDimensionValue)

SortAscendingValue

Description: The value of the given measure sorted in ascending order at the given rank (starting at 1).

Syntax: SortAscendingValue (measure, rank, dimension, filterDimensionValue)

SortDescendingLabel

Description: The entity name of the given measure sorted in descending order at the given rank (starting at 1).

Syntax: SortDescendingLabel (measure, rank, dimension, filterDimensionValue)

SortDescendingValue

Description: The value of the given measure sorted in descending order at the given rank (starting at 1).

Syntax: SortDescendingValue (measure, rank, dimension, filterDimensionValue)

StartingLabel

Description: The name of the first period in the series.

Syntax: StartingLabel()

StartingValue

Description: The value at the first period in the series for the given measure.

Syntax: StartingValue (measure, filterDimensionValue)

StartToFinishDifference

Description: The difference between the values for the first and last periods in the given series.

Syntax: StartToFinishDifference (measure, filterDimensionValue)

StartToFinishPercentDifference

Description: The percentage difference between the values for the first and last periods in the given series.

Syntax: StartToFinishPercentDifference (measure, filterDimensionValue)

StdDev

Description: The standard deviation value for the given measure.

Syntax: StdDev (dimension, measure, filterDimensionValue)

Sum

Description: The sum of measure values for the two provided dimension values.

Syntax: Sum (dimension, measure, firstDimensionValue, secondDimensionValue, filterDimensionValue)

Total

Description: The sum total value for the given measure.

Syntax: Total (dimension, measure, filterDimensionValue)

Value

Description: The metric value for a given dimension, measure and dimension value.

Syntax: Value (dimension, measure, dimension value, filterDimensionValue)

Z-Score

Description: The z-score for the given measure.

Syntax: Z-Score (dimension, measure, firstDimensionValue, filterDimensionValue)

Customise Your Tableau Data Story: Hide and Reorder Content

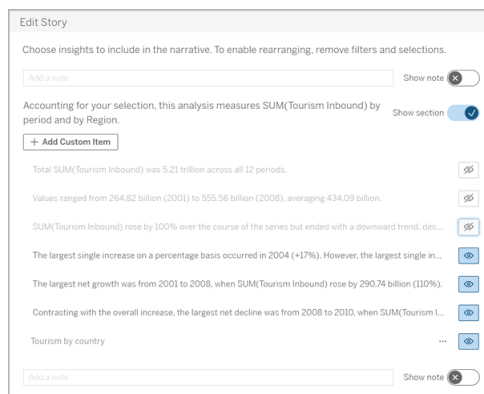

Important changes for Tableau Data Stories

Tableau Data Stories were retired in Tableau Desktop, Tableau Cloud and Tableau Server in January of 2025 (2025.1). With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of changes. For more information, see [How Tableau Pulse powered by Tableau AI is Reimagining the Data Experience](#).

Customise your Tableau Data Story with the content that is most important to you and your audience by hiding or reordering content within your story.

Hide content and sections

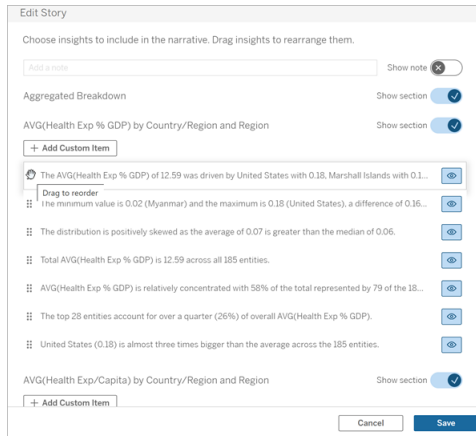

1. Create your **Data Story** and click **Edit** to open the Edit dialog box.
2. Set sections to show or hide by clicking the **Show section** switch to the on or off position.
3. Hover over the blue box to the right of each individual sentence, and click on the box to show or hide from view.
4. Click **Save**.

Now, only the sentences and sections that are set to **Show** appear in your Data Story.

Reorder content within a section

1. Create your **Data Story** and click **Edit** to open the Edit dialog box.
2. Hover over the left-side menu of the content you want to reorder. Your cursor turns into a hand icon.
3. Click the item with your cursor and drag it anywhere within the same section.
4. Click **Save**.

Now, the sentences appear in your **Data Story** in the order that you set them to.

Note: Currently, content can only be moved within the same section. Moving entire sections isn't yet supported.

Add More Data to Your Tableau Data Story

Important changes for Tableau Data Stories

Tableau Data Stories were retired in Tableau Desktop, Tableau Cloud and Tableau Server in January of 2025 (2025.1). With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of changes. For more information, see [How Tableau Pulse powered by Tableau AI is Reimagining the Data Experience](#).

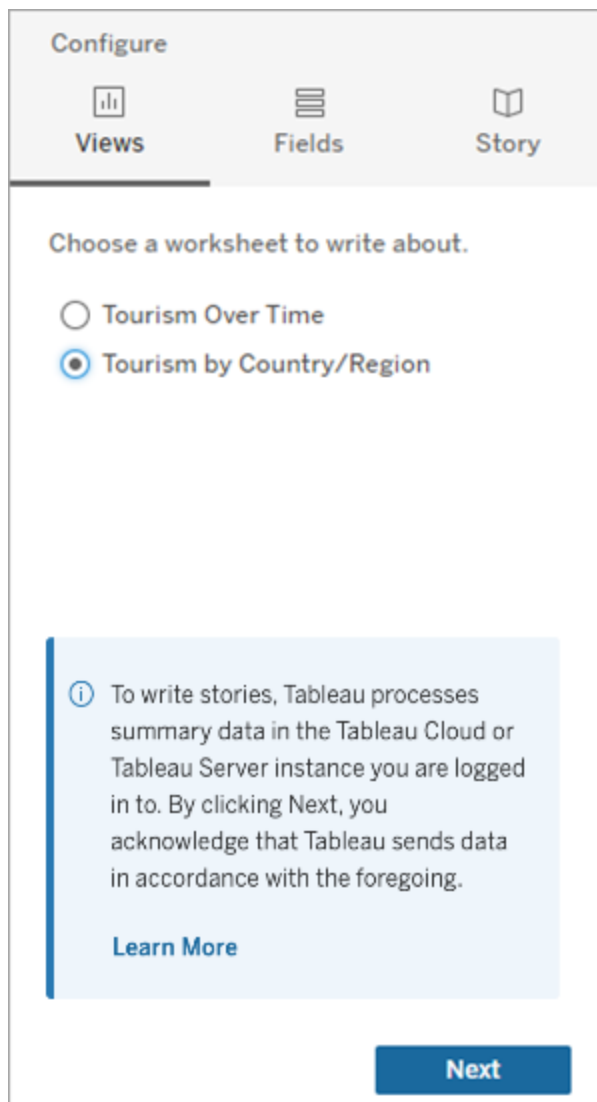

Data Stories currently supports stories with two dimensions and one measure, or one dimension and up to 10 measures. If you'd like to write about data that you don't need to show on your dashboard, then use a hidden sheet to simplify your dashboard. If you'd like to add more than two dimensions to your story, then concatenate dimensions or create multiple data stories and stack them.

Use a hidden sheet

If you have data that you want to include in a Tableau Data Story and don't need to show all the data that drove the insight, you can use a hidden sheet to bring additional measures and

dimensions into your story without cluttering the dashboard.

1. Drag the **Data Story** object to your dashboard to see which worksheets you can write about in the Data Story dialog box. In this example, there are two worksheets available to write about.

2. Bring in another data source, such as "Population", by navigating to the left-hand menu, selecting **Floating** and dragging that sheet onto your dashboard.

The Data Story dialog box updates with the new available data source.

3. Click into **Layout** and adjust the size to 1 x 1 to hide the sheet but keep the underlying data in your story.

You can now configure your stories using this hidden sheet.

Note: You may need to deselect additional legend elements to keep the sheet hidden.

Concatenate dimensions

If your data contains three dimensions and one measure and is a **Discrete Story**, you can concatenate (link together) two of those dimensions by creating a calculated field.

1. From the worksheet you want to use in your story, click **Analysis** and select **Create Calculated Field**.
2. Name the calculated field and use the following formula to create your calculation, using the + sign to join the dimensions.
[Dimension 1] + [Dimension 2]

Tip: Drag your dimensions into the **Calculated Field** box and place them in the formula.

3. Click **OK**.
4. Drag your new calculated field into the **Detail** pane to make it accessible in your data story.

Stack multiple data stories

Write about more measures and dimensions by creating multiple **Data Stories** and stacking them vertically or horizontally on your dashboard.

For example, if you wanted to create a story about actual revenue vs. benchmark revenue, you could create two different stories – one with the actual revenue and the first benchmark, and another with the actual revenue and the second benchmark – and compare them.

Add a Pop-up Tableau Data Story to Your Dashboard

Important changes for Tableau Data Stories

Tableau Data Stories were retired in Tableau Desktop, Tableau Cloud and Tableau Server in January of 2025 (2025.1). With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of changes. For more information, see [How Tableau Pulse powered by Tableau AI is Reimagining the Data Experience](#).

You can place a Tableau Data Story in a pop-up window that allows your users to open a story, read it and then close it when they're done. This is a great way to save space being used by already-established dashboards or to reduce the amount of clutter and information on a dashboard.

1. [Add a Tableau Data Story to a Dashboard on page 2853.](#)
2. Set the container to **Floating** by clicking on the menu and selecting **Floating**.

Tip: Another way to set the container to **Floating** is by holding the shift key while dragging the container onto your dashboard.

3. Navigate to the **Layout** tab in the left-hand column and set the background colour to **white**.

4. Click on the menu that is associated with your floating container to show its settings, and select **Add Show/Hide Button**. This creates an "X" icon that allows you to show or hide your story.

Note: If your story is selected, your button is partially obscured by the sidebar options that are part of the Data Story object. Click anywhere outside of the story to reveal the button.

5. Hover over the "X" icon to show instructions for opening or closing the story. In this example, you're being prompted to press the Alt key at the same time as you click on the "X" icon.

6. Collapse the story by clicking the "X" icon at the same time as pressing the key indicated in your prompt.

The story collapses, but the menu remains on the dashboard so that the user can expand the story when needed. You can move your collapsible, floating story around your dashboard as desired.

Create Custom Measure Relationships in Your Tableau Data Story

Important changes for Tableau Data Stories

Tableau Data Stories were retired in Tableau Desktop, Tableau Cloud and Tableau Server in January of 2025 (2025.1). With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of changes. For more information, see [How Tableau Pulse powered by Tableau AI is Reimagining the Data Experience](#).

You can create a relationship story in your Tableau Data Story to see how data compares to another set of data. To build a relationship story, you must have at least two measures and one dimension. Data that you'd like to compare is often grouped into one column of data named something such as "Year" or "Month", with values such as "2022" or "March".

You can [Create a Simple Calculated Field](#) to separate "2022" from "2021" (or March from February) so that you can compare the two time periods in a relationship story.

1. Start in the sheet that you want to use in your **Data Story**.
2. Click **Analysis** and select **Create a Calculated Field**.
3. Create a calculated field such as "Current Period".

Tip: Follow the structure of the calculated field shown here, but substitute your own dimension or measure names (orange text).

4. Create a calculated field such as "Previous Period".

5. Drag the new measures onto the **Detail** mark.
6. From your dashboard, click on the story and add the two new measures into your **Data Story**.

The screenshot shows the 'Configure' dialog box in Tableau, specifically the 'Fields' tab. At the top, there are three tabs: 'Views', 'Fields' (which is selected and underlined), and 'Story'. Below the tabs, there is a header that says 'Drag and drop fields to include in your story.' The main area is divided into three sections: 'Dimensions', 'Measures', and 'Ignored'. In the 'Dimensions' section, there is a single field 'YEAR(Year) 1' in a blue pill. In the 'Measures' section, there are two fields: 'SUM(Current Period) 1' and 'SUM(Previous Period) 2', both in green pills. The 'Ignored' section is currently empty. At the bottom of the dialog, there are two buttons: 'Back' and 'Next'.

7. From your dashboard, click the **Settings** icon in the top-left corner of your Data Story object.
8. In the Data Story dialog box, click the **Relationships** tab.
9. Set up a relationship story with the two custom measures.

The screenshot shows the 'Relationships' dialog box in Tableau. On the left is a sidebar with tabs: Narrative, Characteristics, Analytics, Drivers, Relationships (selected), and Display. The main area is titled 'Relationships' and contains the following elements:

- Select measures that have relationships with other measures in your chart.**
 - ☐ Actual vs. Benchmark
 - ☒ Current/Most Recent vs. Previous Period
- Identify related measures.**
 - Measure: SUM(Previous Period) (dropdown)
 - is 1 periods prior to (text)
 - Select a measure (dropdown) showing SUM(Current Period)
- Number of periods:** 1 (spinner)
- Label for periods:** periods (text box)

At the bottom are 'Cancel' and 'Save' buttons.

10. Click **Save**.

Your story now writes sentences that compare the custom measures.

Refresh Parameters in a Tableau Data Story

Important changes for Tableau Data Stories

Tableau Data Stories were retired in Tableau Desktop, Tableau Cloud and Tableau Server in January of 2025 (2025.1). With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of changes. For more information, see [How Tableau Pulse powered by Tableau AI is Reimagining the Data Experience](#).

If you've added a parameter to your dashboard and are using Data Stories, you'll notice that clicking the parameter refreshes your visualisation, but not the story. This happens because the parameter doesn't refresh the underlying data like a filter does.

To refresh your Tableau Data Story with the parameter data, add a "refresh" button to your dashboard that updates your story to align with your parameter.

1. Create a new sheet in your workbook.
2. Create a **Calculated Field** in the new sheet with the following info:

Name: Refresh

Contents: "refresh"

Tableau Desktop and Web Authoring Help

3. Click **OK**, and then drag the new calculated field (Refresh) onto your new sheet.
4. Right-click in the field and click **Show Header** to hide the header.

5. Choose a shape for your button.

6. Return to your dashboard and drag the sheet containing the refresh button onto your dashboard next to the parameter.
7. Hover over the button, select **More Options** and click **Title** to hide the title.
8. Hover over the button and click **Use as Filter**.

9. Adjust your parameter and then click on the new refresh button. The button updates your story to align with the parameter.

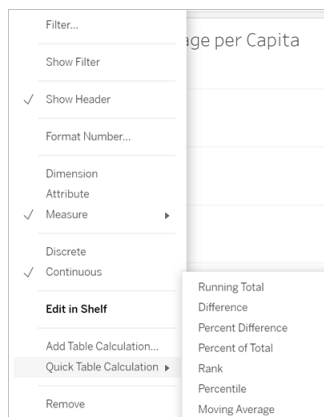

Use a Table Calculation in a Tableau Data Story

Important changes for Tableau Data Stories

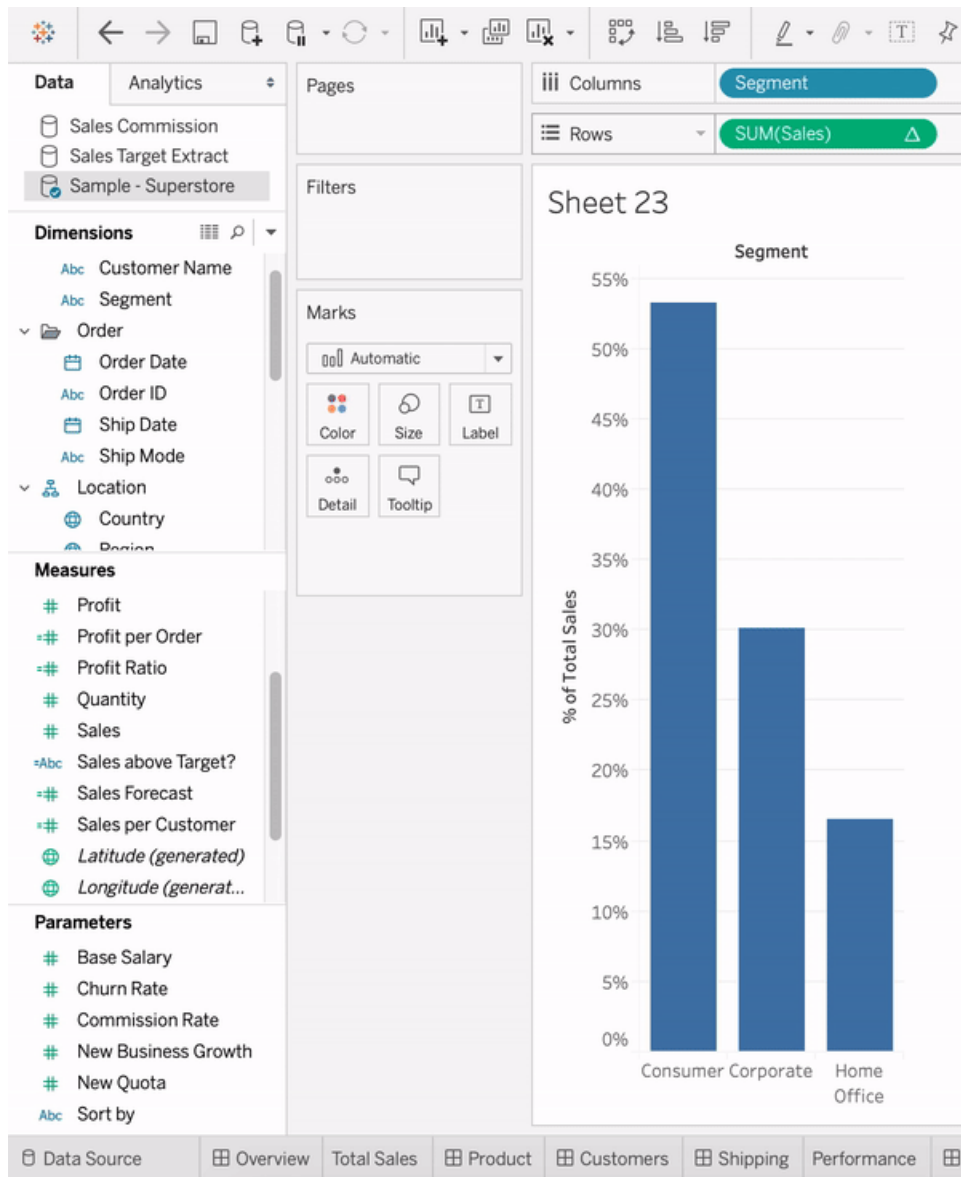

Tableau Data Stories were retired in Tableau Desktop, Tableau Cloud and Tableau Server in January of 2025 (2025.1). With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of changes. For more information, see [How Tableau Pulse powered by Tableau AI is Reimagining the Data Experience](#).

You can use a **Table Calculation** as a measure in a Tableau Data Story in addition to the measure that you used to create the table calculation.

1. From the **Marks** card, click on the right side of your field to open a menu, and click **Quick Table Calculation**.

2. After you create your table calculation, drag it to **Measures** in the **Data** pane and rename it.

3. Drag your original measure (e.g. Sales) back to the **Rows** shelf, and then drag your new calculation (e.g. Sum of Sales) into the **Tooltip**. Your visualisation may remain the same, but you now have access to the new measure.

4. Go to your dashboard and drag the **Data Story** object onto the dashboard. Both measures appear when creating your story.

Format Your Work

Choosing the right formatting is important to both your analysis and your presentation. You can change the formatting for almost everything you see on a worksheet, including fonts, shading, alignment, borders and graph lines. For example, in a text table, you can add banded shading to help you visually separate consecutive groups of rows or fields.

In a scatter view with reference lines, you can change the line thickness and colour. All of these settings can be changed using the Format pane. You can specify format settings for the entire worksheet, all rows or all fields. You can also format individual parts of the view. For example, you can format a single field, resize cells and tables and edit individual axes.

Visual Best Practices

The fonts, colours, shading, alignment, borders, and grid lines in your visualisation are important parts of both your analysis and the story you're telling. Tableau products are designed so that you can create great-looking visualisations that use visual best practices by default, freeing you from the need to think about things like fonts and colours – unless you want to.

If you do want to customise, you can control the look of almost everything you see on a worksheet. This article outlines visual best practices and tips to keep in mind while you customise, from ideal workflow to how to get the most out of tooltips.

Format from largest to smallest

As you change the look and feel of your work, use a biggest-to-smallest workflow. Start by formatting fonts and titles at the workbook level, then move on to the worksheet level. Save formatting the individual parts of a view for last. A workbook is the largest possible container for formatting changes, and making changes at the workbook level first will save you time.

See [Format at the Workbook Level](#) on page 2922, [Format at the Worksheet Level](#) on page 2932 and [Format Text and Numbers](#) on page 2971 for details.

Change colour with purpose

If you want to change the colours used by your visualisation, Tableau makes it easy: just click the **Colour** card, then **Edit Colours**. For example, you might want to emphasise a key finding. You can use neutral colours with a single, bright colour to highlight what you want your viewers to pay attention to. If you want to match your company's brand, you can create a custom palette. See [Create Custom Colour Palettes](#) on page 3009 for steps.

When you change colours, keep the following best practices in mind.

Discrete fields and categorical palettes

Discrete fields are those in which the values of the field are unique. One example of this is customer names. Tableau automatically associates discrete fields with *categorical* palettes, which have colours that are designed to be distinct from one another yet also work well together in the visualisation as a whole.

Change colours for individual fields

After you've selected a categorical palette, you can manually change the colours associated with specific fields.

1. From the **Edit Colours** dialog, double-click (Control-Click on Mac) any of the fields in the **Select Data Item** panel.
2. The colour palette for your operating system opens, allowing you to define a new colour for the item selected.

Continuous fields and quantitative palettes

With continuous fields, the field's values are part of a whole (such as sales over time). Tableau automatically associates these fields with *quantitative* palettes, in which colours appear on a continuum or range. If the field's values are positive, a single-colour range is best:

If there are both positive and negative values, choose a two-colour range:

Limit colours

Colour used correctly can enhance analysis. Too many colours can result in visual overload for your users and impede analysis. In the view below, the stacked bars represent cell phone subscriptions and the trend line is internet usage over time. In the first image, Years is on the **Colours** shelf. Notice how hard it is to pick out the trend line among all the other colours and how easy it is to spot the trend line in the second image, where there are only two colours.

[Click the image to replay it.](#)

Use fonts that optimise online readability

The fonts in the Tableau typeface were designed to be paired with data visualisations and are optimised for legibility at small sizes. Tableau visualisations use them by default.

If you need to use a different font, choose one that optimises readability online, such as the following:

- Arial
- Trebuchet MS
- Verdana
- Times New Roman
- Lucida sans

Reinforce your story with tooltips

People looking at your dashboard will intuitively use their mouse to explore marks, and this makes tooltips appear. Tooltips appear by default for most views, and they are a great way to reinforce your data story. You can customise your tooltips by clicking **Worksheet > Tooltip**.

For example, here's a tooltip for a view on pageviews for a web site:

Here's an example of how the above tooltip could be rewritten and formatted to highlight what's important to the people looking at this view:

You can also rewrite your tooltips to tell a mini-story. For example, here's a tooltip about the number of oil rigs in Italy.

In the following example, the tooltip is rewritten as a sentence, and key elements are made bold to draw the viewer's attention.

Consider your axes

By default, an axis range in Tableau automatically adjusts based on the data in your visualisation. Filtering and other actions can change the axis range. If you are trying to create a specific comparison between two views, changing axes ranges can make analysis difficult for your users. If this is the case, you can set your axes to a specific, fixed range. For steps on how to do this, see [Examples: Use Different Axis Ranges \(Uniform, Independent, Fixed\)](#) on [page 2961](#).

If you're working with data that has a very large range, a fixed axis may not be practical. If this is the case, add grid lines to your visualisation. Grid lines can help your users stay oriented when the axis automatically adjusts. See [Format lines](#) on [page 2937](#) for more information.

Format at the Workbook Level

You can quickly change how fonts, titles and lines look in every view in a workbook by specifying format settings at the workbook level, instead of the worksheet level.

For example, you might want to use a specific font, size and colour so that all views adhere to your company's brand. You might also want to remove grid lines from your views – or make them more noticeable by increasing their pixel size or colour.

You can also change the theme used by your workbook. Themes control items like the default font, colours and line thickness. When you create a new workbook, it automatically uses the Default theme, which uses visual best practices.

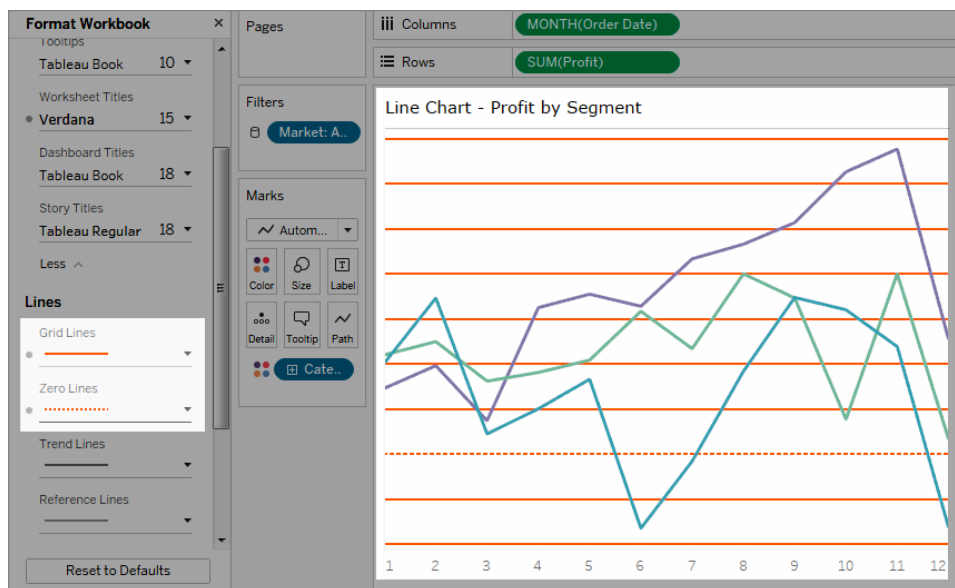

Change lines in your workbook

You can change every type of line for all views in your workbook, or you can change just certain types of lines, such as trend lines. You can also turn off certain types of lines, including grid lines.

When you make changes to the line settings in your workbook, a grey dot appears next to the setting in the **Format Workbook** pane. You can quickly switch back to default settings using the **Reset to Defaults** button.

In Tableau, line opacity is linked to line colour. If you set a line's opacity at the workbook level, all worksheets in the workbook will receive the workbook's colour setting for that line as well. If you need to change line opacity and maintain different colour settings for a line type, change opacity at the worksheet level instead of at the workbook level.

1. On the **Format** menu, select **Workbook**.
2. The **Format Workbook** pane replaces the **Data** pane on the left and provides a series of drop-down lists where you can change all line settings in a workbook.

To confirm that your change has been applied to every view in your workbook, you can use thumbnails. Right-click a thumbnail, and select **Refresh All Thumbnails**.

Change fonts in your workbook

You can change all fonts in your workbook or you can change fonts for only certain areas, such as just worksheet titles.

1. On the **Format** menu, select **Workbook**.
2. The **Format Workbook** pane replaces the **Data** pane on the left and provides a series of drop-down lists where you can change all font settings in a workbook, as well as the font settings for titles of worksheets, stories and dashboards.

Note: If you are editing your workbook online, the **Format Workbook** pane will appear on the right.

If you have made font changes at the worksheet level, such as on a filter card or a worksheet title, changing the font at the workbook level will overwrite those changes.

Upgrade or change your workbook theme (Tableau Desktop only)

If your workbook is set to a theme other than Default, it will retain that theme when you upgrade from one version of Tableau to another, but you can easily change the theme to Default.

Conversely, you can change your workbook's theme from Default to a different, earlier theme.

If you upgraded from version 9.3 to version 10.x and your theme was set to Default in version 9.3, it will be set to Previous in version 10.x. After you switch to the Default theme, check your workbook to confirm that items are sized appropriately. You might need to make some manual adjustments.

1. On the **Format** menu, select **Workbook Theme**.
2. Choose a theme.

Each theme is associated with a different version of Tableau Desktop.

| This workbook theme... | Is associated with these Tableau versions... |
|------------------------|--|
| Smooth | Version 10.x and newer |
| Clean | Versions 8.0.x – 9.3.x |
| Modern | Versions 3.5 – 7.0.x |
| Classic | Versions 1.0 – 3.2 |

Reset a workbook to its default settings

When you make changes to your workbook's font settings, a grey dot appears next to the setting in the **Format Workbook** pane. You can quickly switch back to default settings using the **Reset to Defaults** button.

1. On the **Format** menu, select **Workbook**.
2. In the **Format Workbook** pane, click **Reset to Defaults**.

Format Animations

Animate visualisations to better highlight changing patterns in your data, reveal spikes and outliers and see how data points cluster and separate.

Animations visually transition between filter, sort and zoom settings, different pages and changes to filter, parameter and set actions. As visualisations animate in response to these changes, viewers can more clearly see how data differs, helping them make better informed decisions.

Understanding simultaneous and sequential animations

When you author animations, you can choose between two different styles: simultaneous or sequential. Here are examples of each type.

Simultaneous animations

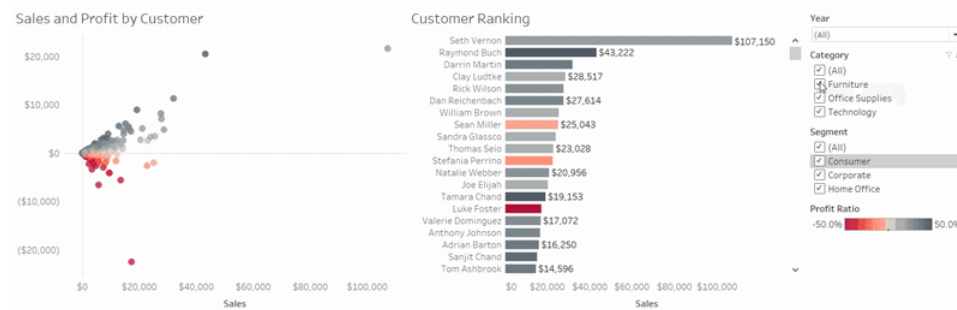

The default simultaneous animations are faster and work well when showing value changes in simpler charts and dashboards.

[Click the image above to replay the animation.](#)

Sequential animations

Sequential animations take more time but make complex changes clearer by presenting them step-by-step.

[Click the image above to replay the animation.](#)

Animate visualisations in a workbook

When you create a new workbook, Tableau enables animations for your viz by default. You can turn animations on or off at the user and workbook level.

1. Choose **Format > Animations**.
2. If you want to animate every sheet, under **Workbook Default**, click **On**. Then do the following:
 - For **Duration**, choose a preset, or specify a custom duration of up to 10 seconds.
 - For **Style**, choose **Simultaneous** to play all animations at once or **Sequential** to fade out marks, move and sort them and then fade them in.
3. To override workbook defaults for a particular sheet, change the settings under **Selected Sheet**.

Note: In the Selected Sheet section, “(Default)” indicates a setting that automatically reflects the related Workbook Default setting.

To replay an animation, click the **Replay** button in the toolbar. From the **Replay** button, you can also choose the speed at which the animation replays: actual speed, 2x speed or 1/2 speed.

Reset animation settings for a workbook

You can reset animations to return an entire workbook to the default animation settings. Be aware that this turns animations off by default.

1. Choose **Format > Animations**.
2. In the middle of the **Animations** pane, click **Reset All Sheets**.

Completely disable all animations

When you create a new workbook, animations are enabled by default. If you find animations distracting while viewing vizs, you can completely disable them so they never play. (This isn't a system-wide setting; each user needs to apply it separately.)

- In Tableau Desktop, choose **Help > Settings and Performance**, and deselect **Enable Animations**.
- In Tableau Cloud or Tableau Server, click your profile image or initials in the top-right corner of the browser, and choose **My Account Settings**. Then scroll down to the bottom of the page, deselect **Enable animations**, and click **Save Changes**.

Note: When animations are disabled, you can still choose **Format > Animations** in authoring mode and adjust settings – but they will have no effect.

Format decimals for axes animations

If the number of decimal places for a measure is set to the default, then the number of decimals shown during the axis animation might fluctuate during the axes animation. To avoid this, format the number of decimal places displayed for a measure. For more information, see [Format Numbers and Null Values](#).

Why animations won't play

Server rendering

Animations won't play if a viz is server-rendered. To ensure that vizzes render on a client computer or mobile device, use these techniques:

- If you're a viz author, **reduce viz complexity**.
- If you're a Tableau Server administrator, **increase the complexity threshold for client-side rendering**.

Note: On computers with lower processing power, animations may appear choppy, but users can continue to interact with vizzes without any delays in responsiveness.

Unsupported browsers and features

Animations are supported by all web browsers except Internet Explorer.

The following Tableau features don't animate:

- Maps, polygons and density marks in web browsers
- Pie and text marks
- Headers
- Forecasts, trends and reference lines
- Page history trails (If a viz includes these, turn off animations to avoid unexpected behaviour.)

Format at the Worksheet Level

You can format settings for fonts, alignment, shading, borders, lines and tooltips at the worksheet level. For example, you might want to remove all the borders in a text table, or add shading to every other column in a view.

When you make formatting changes at this level, they apply only to the view you are working on. See [Format at the Workbook Level on page 2922](#) for how to make changes that apply to every view in your workbook.

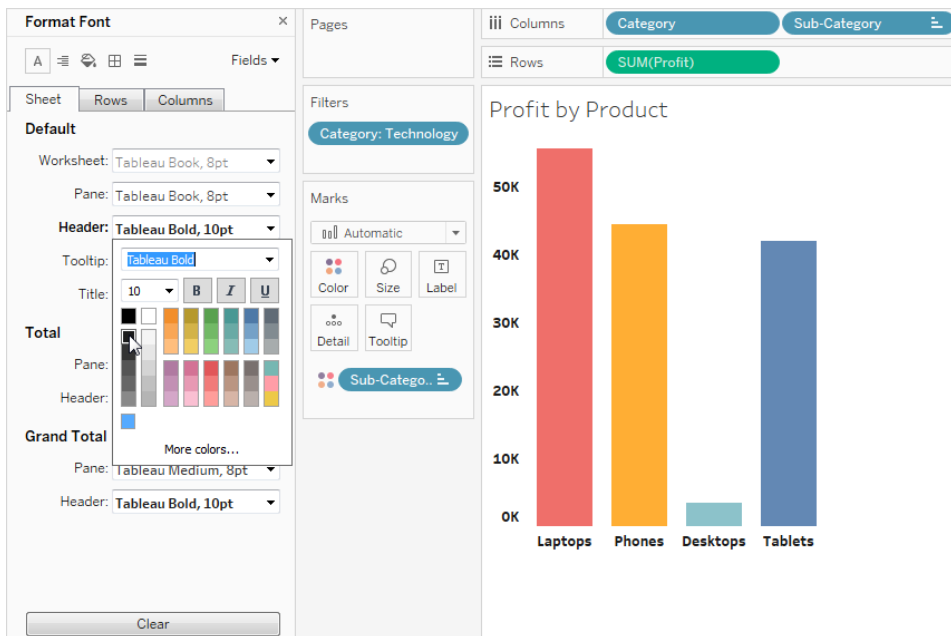

Access worksheet formatting settings from Tableau Desktop

Are you formatting your worksheets on the web? See [Access worksheet formatting settings from Tableau Cloud on page 2940](#)

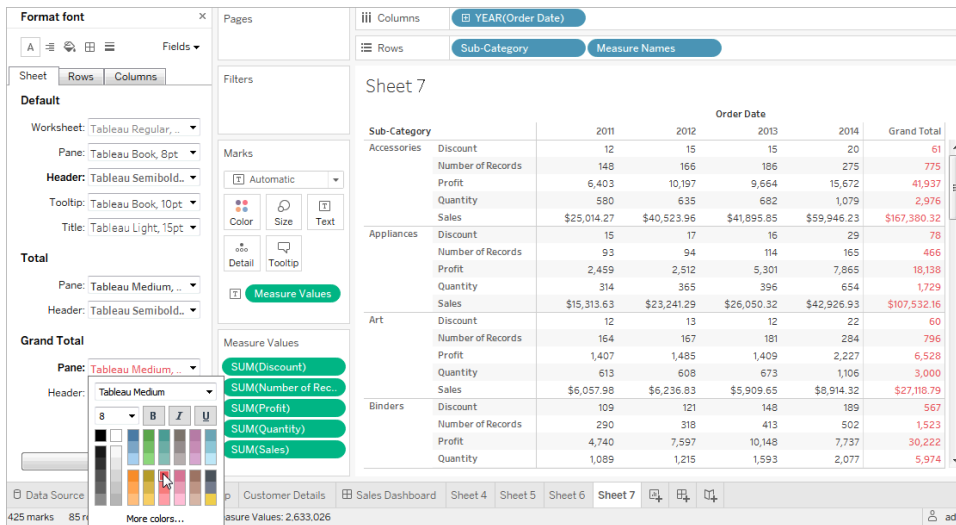

1. Display a worksheet or dashboard.
2. From the **Format** menu, choose the part of the view that you want to format, such as **Font**, **Borders**, or **Filters**.

Format fonts

For a view, you can specify the font, style, size, and colour for either the pane text or header text, or both. For example, in the view below, the header text is set to use the Tableau Bold font.

If you have totals or grand totals in the view, you can specify special font settings to make these values stand out from the rest of the data. This is particularly useful when you are working with a text table. The view below shows a text table in which the grand totals are formatted to appear in dark red.

Format text alignment

Tableau uses visual best practices to determine how text is aligned in a view, but you can also customise text. For example, you can change the direction of header text so that it is horizontal (normal) instead of vertical (up).

Note: Tableau adheres to regional standards when determining when to begin or end line breaks.

Header Text is Vertical

[Click the image to replay it.](#)

For each text area, you can specify the following alignment options:

Horizontal – Controls whether text aligns to the left, right or centre.

Vertical Alignment – Controls whether text aligns to the top, middle or bottom.

Direction - Rotates text so that it runs horizontally (normal), top-to-bottom (up), or bottom-to-top (down).

Wrap - Controls whether long headers wrap to the next line or are abbreviated, but does not control text marks.

Note: If cells are not large enough to show more than one row of text, turning on wrapping will have no visible effect. If this happens, you can hover the cursor over a cell until a double-sided arrow appears, and then click and drag down to expand the cell size.

Format shading

Shading settings control the background colour of the pane and headers for totals, grand totals, as well as for the worksheet areas outside those areas.

You can also use shading to add *banding*, alternating colour from row to row or column to column. Banding is useful for text tables because the alternating shading helps the eye distinguish between consecutive rows or columns.

Table with Banding

| | | |
|------------------------------|-------|-------|
| Clinton St & Washington Blvd | 1,033 | 2,873 |
| Canal St & Jackson Blvd | 942 | 2,355 |
| Clinton St & Madison St | 994 | 1,946 |
| Franklin St & Jackson Blvd | 1,649 | 1,829 |
| Daley Center Plaza | 1,147 | 1,772 |
| Michigan Ave & Lake St | 2,919 | 1,522 |
| Dearborn St & Adams St | 1,456 | 1,464 |
| Clark St & Randolph St | 956 | 1,447 |
| Clinton St & Lake St | 701 | 1,370 |
| Dearborn St & Monroe St | 838 | 1,353 |
| State St & Kinzie St | 1,957 | 1,304 |
| Kingsbury St & Erie St | 877 | 1,049 |

[Click the image to replay it.](#)

For row and column banding, you can use the following options:

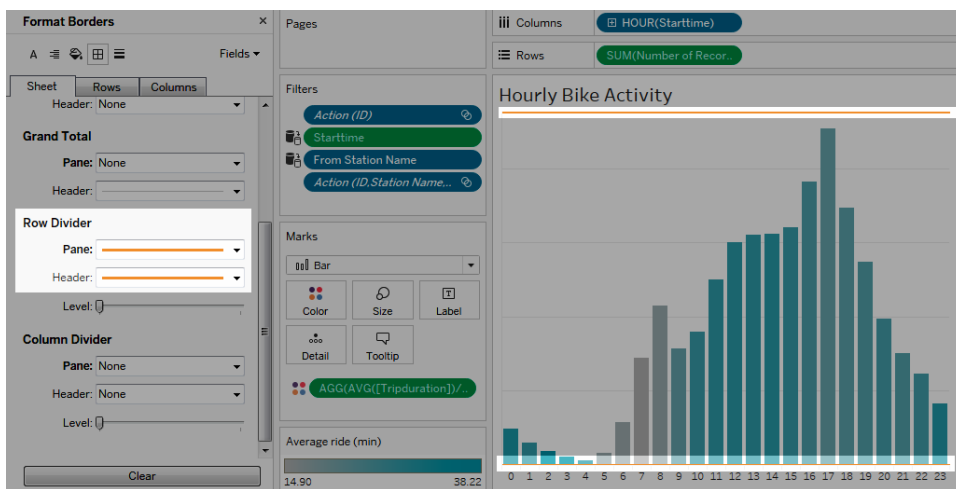

Pane and Header- The colour the bands use.

Band Size - The thickness of the bands.

Level – If you have nested tables with multiple fields on the rows and columns shelves, this option allows you to add banding at a particular level.

Format borders

Borders are the lines that surround the table, pane, cells, and headers in a view. You can specify the border style, width, and colour for the cell, pane, and header areas. Additionally, you can format the row and column dividers. For example, in this view the **Row Divider** borders are formatted to use an orange colour:

Row and column dividers serve to visually break up a view and are most commonly used in nested text tables. You can modify the style, width, colour, and level of the borders that divide each row or each column using the row and column divider drop-downs. The level refers to the header level you want to divide by.

Format lines

You can control the appearance of the lines that are part of the view, such as grid lines and zero lines, as well as lines that help you inspect data, such as trend lines, reference lines, and drop lines.

For example, you can set trend lines to use a red colour and an increased thickness:

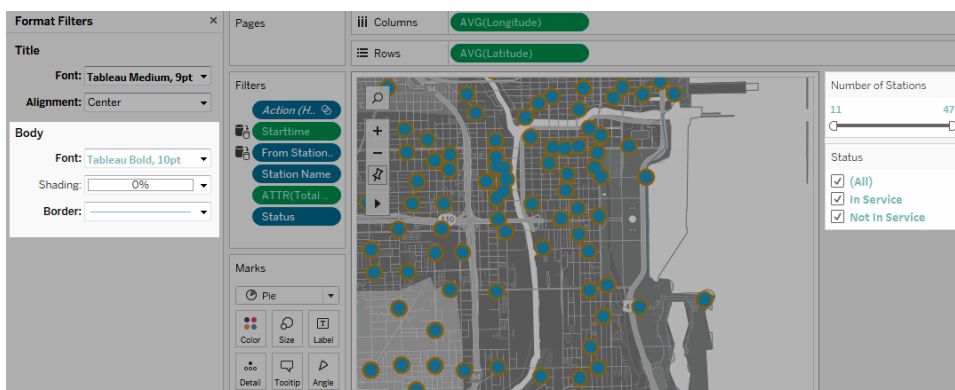

Format highlighters

The highlighter on your worksheet can be formatted to use a different font, style, colour, background colour, font size, and border. Formatting highlighters allows you to better integrate them into your dashboard or worksheet style. You can also edit the title that displays on each highlighter that shows in the view.

For more information about using highlighters, see [Highlight Data Points in Context on page 1405](#).

Format a filter card

Filter cards contain controls that let users interact with your view. You can change filter cards to use custom formatting. For example, the body text in the filters below is formatted to use the Tableau Bold font, in aqua.

Note: For filters and parameters, title formatting appears only on dashboards or in views published to the web.

Format a parameter control card

Parameter controls are similar to filter cards in that they contain controls that let users modify the view. If you create a parameter control, you can customise how it looks. For example, in the view below, the Sales Range parameter is formatted so that the sales amount appears in orange.

Copy and paste worksheet formatting (Tableau Desktop only)

Once you have formatted a worksheet, you can copy its formatting settings and paste them into other worksheets. The settings that you can copy are anything you can set in the **Format** pane, with the exception of reference lines and annotations. Adjustments like manual sizing and level of zoom are not copied.

1. Select the worksheet from which you want to copy formatting.
2. Right-click (control-click on Mac) the worksheet tab and select **Copy Formatting**.
3. Select the worksheet you want to paste the formatting into.
4. Right-click (control-click on Mac) the worksheet tab and select **Paste Formatting**.

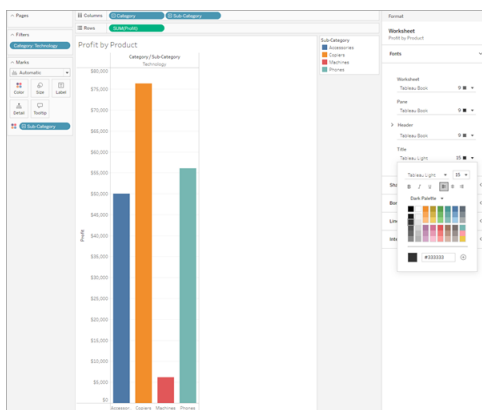

Access worksheet formatting settings from Tableau Cloud

Are you formatting your worksheets on Tableau Desktop? See [Access worksheet formatting settings from Tableau Desktop on page 2932](#).

1. Display a worksheet.
2. From the toolbar, click **Format > Worksheet**, and then choose the part of the view that you want to format, such as Font, Lines, or Borders and Dividers.

Format fonts

For a view, you can specify the font, style, size, and colour for your worksheet, pane, header (columns and rows together or separate) and title. In this example, the pane is set to use Tableau Bold, the row header is set to Tableau Medium, the column header is set to Tableau Regular and the title is set to the Tableau Light font.

Rotate labels

Tableau uses visual best practices to determine how label text is aligned in a view, but you can also customise your alignment. For example, you can change the direction of label text so that it's horizontal (left to right) or vertical (up and down).

To rotate your labels, right-click (control-click on Mac) on a label and select **Rotate Labels**.

Note: Tableau adheres to regional standards when determining when to begin or end line breaks.

Format shading

Shading settings control the background colour of the worksheet, pane and headers.

To access these settings, to go **Format > Worksheet > Shading**.

You can also add banding, alternating color from row to row or column to column. Banding is useful for text tables because the alternating shading helps the eye distinguish between consecutive rows or columns.

Table with Banding

Click the image to replay it.

For row and column banding, you can use the following options:

Pane and Header- The colour the bands use.

Band Size - The thickness of the bands.

Level – If you have nested tables with multiple fields on the rows and columns shelves, this option allows you to add banding at a particular level.

Format lines

You can control the appearance of the lines that are part of the view, such as grid lines and zero lines. You can turn the lines on or off and format the line type (for example, solid, dotted or

dashed) and the thickness of the lines. You can also format the colour and the opacity of the lines.

For example, you can turn on grid lines to help give quantitative cues to the viewer. In this example, grey dotted grid lines have been added to the viz.

You can also format trend lines, reference lines and reference bands on the web. You can access these formatting settings by clicking the tooltip on the line, or by clicking on the line while the format pane is open. In this example, the trend line has been formatted to be a solid green line.

Format interactive controls

You can format all of your interactive controls, including legends, filters, highlighters and parameters at the same time using the Interactive Controls section of the worksheet format pane.

To access these settings, go to **Format > Worksheet > Interactive Controls**.

If you'd like these controls to have consistent formatting, formatting at this level will save you time.

Alternatively, you can format each interactive control individually.

Format legends

If you have a legend on your worksheet, you can customise how it looks. For example, in this example, the *Sales above Budget* legend is formatted so that the title is in bold and the background is light grey.

You can access legends formatting by either going into **Format > Legends**, or by clicking into the menu on the legend and selecting **Format Legends**. You can also edit the colours for each of the items in the legend, edit the title or choose to hide the title or legend through this menu.

Format filters

Filter cards contain controls that let users interact with your view. You can change filter cards to use custom formatting. For example, the body text in the filter shown is set to Tableau Medium, the title text is set to Tableau Semibold, the background is set to green with 50% opacity and a black border has been added.

You can access Filters and Sets formatting by either going into **Format > Filters and Sets**, or by clicking into the menu on the Filter card and selecting **Format Filters and Sets**.

Format highlighters

The highlighter on your worksheet can be formatted to customise your font, background colour and border. Formatting highlighters allows you to better integrate them into your dashboard or worksheet style. You can also edit the title that displays on each highlighter that shows in the view.

You can access highlighter formatting by either going into **Format > Highlighters**, or by clicking into the menu on the Highlighter card and selecting **Format Highlighters**.

For more information about using highlighters, see [Highlight Data Points in Context on page 1405](#)

Format parameters

Parameter controls are similar to filter cards in that they contain controls that let users modify the view. If you create a parameter control, you can customise how it looks. For example, in the view below, the New Business Growth parameter is formatted so that the growth percentage text appears in green.

You can access Parameters formatting by either going into **Format > Parameters**, or by clicking into the menu on the parameter card and selecting **Format Parameters**.

Format borders and dividers

Borders are the lines that surround the table, pane, and headers in a view. You can specify the border style, width and colour for the pane and header areas. Additionally, you can format the row and column dividers. For example, in this view the Row Divider borders are formatted to use a blue colour.

Row and column dividers serve to visually break up a view and are most commonly used in nested text tables. You can modify the style, width, colour, and level of the borders that divide each row or each column using the row and column divider drop-downs.

By default, the Pane and Header dividers are formatted simultaneously to save you time. If you'd like the pane and the headers to have different formatting, click the link icon to unlink the formatting and format each member separately.

You can also switch the formatting settings for Row and Column Dividers on or off to hide styling options you don't want to use. In this example, Row Dividers formatting is turned off, and the Column Dividers pane and header formatting is unlinked.

Row and column divider level settings

The level refers to the header level you want to divide by. For example, if you have two fields on your measures column, such as category and sub-category, you can choose to have row dividers just by category (level 1) or by category and sub-category (level 2).

In this example, the row divider is set at level 1.

In this example, the row divider is set at level 2.

Edit Axes

When you add a continuous field (a field with a green background) to the Columns or Rows shelf, it adds an axis to the view. An axis shows data points that lie within a range of values. For each axis, you can specify the range, scale and tick mark properties.

Double-click an axis to open the **Edit Axis** dialog box and change the axis configuration and formatting. If you can't edit the axis, see [Why can't I edit my axis? on page 2950](#)

In this example, the Profit field (a continuous measure) on the Rows shelf creates a vertical axis, and the Order Date field (a continuous date dimension) on the Columns shelf creates a horizontal axis.

Note: For more information on formatting headers and field labels, see [Format at the Worksheet Level](#) on page 2932 and [Format Fields and Field Labels](#) on page 2989. For details on continuous and discrete fields, see [Dimensions and Measures, Blue and Green](#) on page 146.

Edit an axis range

To edit an axis range, double-click the axis that you want to edit.

Note: In Tableau Desktop, you can right-click (control-click on Mac) the axis, and then select **Edit Axis**. In web authoring, you can click the arrow button on an axis, and then select **Edit Axis**.

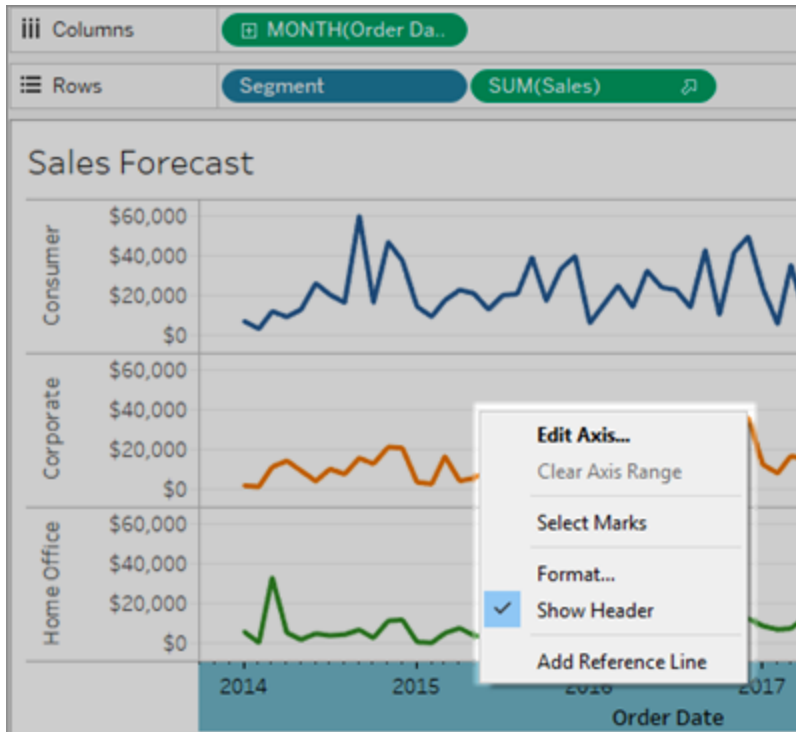

When you select an axis, the marks associated with the axis are not selected so that you can edit and format the axis without modifying the marks.

To select the marks associated with the axis, right-click the axis and select **Select Marks**. You can also select each mark individually. For more information, see [Select marks on page 1985](#).

Why can't I edit my axis?

If you can't edit an axis, it's most likely a header rather than axis.

- Continuous fields (green background) on the Rows and Columns shelves create axes in the view. When you right-click an axis, you will see this menu:

- Discrete fields (blue background) on the Rows and Columns shelves create headers, not axes. When you right-click a header, you will see this menu:

You can edit the formatting of headers by right-clicking a header, and then selecting **Format**.

For more details on formatting headers and field labels, see [Format at the Worksheet Level on page 2932](#) and [Format Fields and Field Labels on page 2989](#). For details on continuous and discrete fields, see [Dimensions and Measures, Blue and Green on page 146](#).

Hide and reshow axes and headers

If you have hidden an axis or a header in the view, you can show it again from its related field in the view.

To hide an axis

Right-click (control-click on Mac) the axis in the view, and then clear the check mark next to the **Show Header** option.

To show a previously hidden axis

Right-click (control-click on Mac) the continuous field in the view that is associated with axis you want to show, click its drop down menu, and then click **Show Header**.

For related details, see [Axes](#) on page 80 in [Parts of the View](#) on page 76.

To hide a header

Right-click (control-click on Mac) a header in the view, and then clear the check mark next to the **Show Header** option.

To show previously hidden header

Right-click (control-click on Mac) the discrete field in the view that is associated with headers that you want to show, click its drop down menu, and then click **Show Header**.

For related details, see [Headers](#) on page 77 in [Parts of the View](#) on page 76.

For details on continuous and discrete fields, see [Dimensions and Measures, Blue and Green](#) on page 146.

Change an axis range

You can limit the axis range to focus the view on certain data points.

For example, assume your view shows sales over four years. The automatic axis might show a range from 0 to £750,000. If sales never go below £470,000, you can adjust the axis range to start at £470,000 to keep the focus on where the data points actually lie.

To change an axis range:

1. Double-click on the axis that you want to edit. You can also right-click (control-click on Mac) on the axis, then select **Edit Axis**.
2. In the **Edit Axis** dialog box, select one of the following options:
 - **Automatic.** Automatically bases the axis range on the data used in the view.
 - **Uniform axis range for all rows or columns.** Sets the axis range uniformly to the maximum data range for all panes in the view.
 - **Independent axis ranges for each row or column.** Makes the axis range independent. The axis range varies for each pane in the view, depending on the range of data in each pane.
 - **Fixed.** Specifies to start and/or end the axis at a specific value. You can fix both ends of the axis or only one end. When you fix both ends of the axis, the axis range is determined by the values you specify. When you fix only one end of the axis, you must set the other end of the axis as automatic, uniform or independent.
3. You can also specify whether to include zero. When you clear the **Include zero** check box, the axis range adjusts to show only the range of values in the data.
4. Click **OK**.

Change the axis scale to reversed or logarithmic

Axis scale options include **Reversed** and **Logarithmic**.

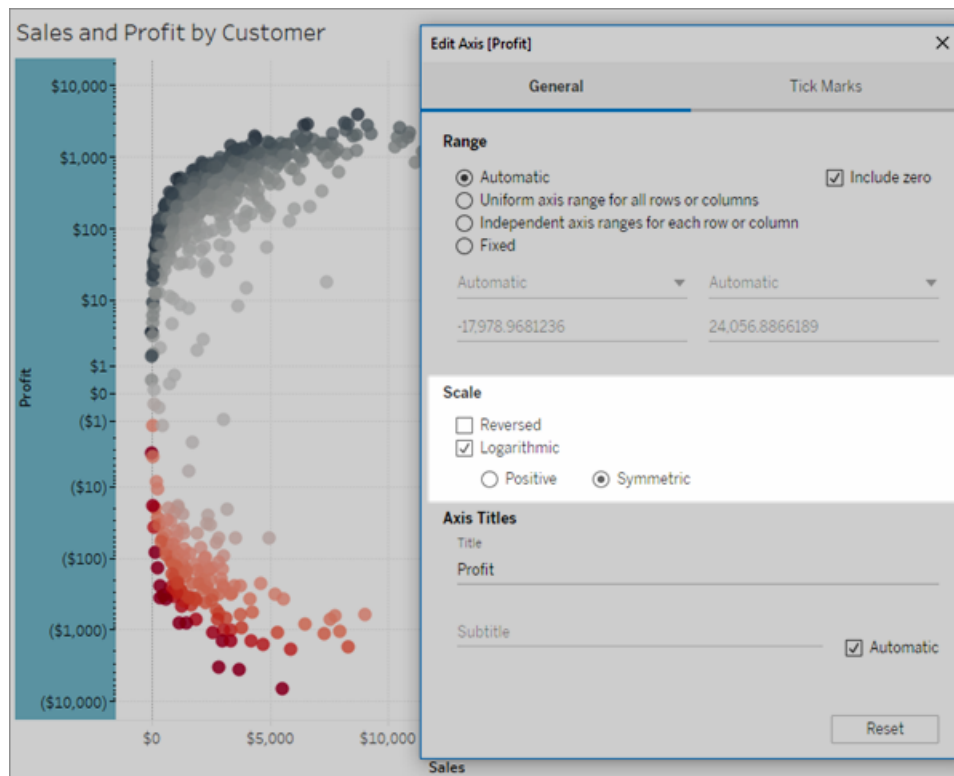

When you select **Logarithmic**, you can then specify **Positive** or **Symmetric**. Symmetric displays data that contains positive, 0, or negative values on a log scale axis, and is best used to visualise large negative values on a logarithmic scale, as well as large positive values, or both. For related details, see [About the symmetric log axis transform on page 2958](#).

To change the scale of an axis:

1. Double-click on the axis that you want to edit. You can also right-click (control-click on Mac) on the axis, then select **Edit Axis**.
2. In the **Edit Axis** dialog box, on the General tab, select **Reversed** or **Logarithmic** for the axis scale.

The option to choose **Symmetric** or **Positive** is only available when the axis range extends outside of the closed interval $[-10, 10]$.

Logarithmic: Select **Positive** or **Symmetric** for the log scale. The **Symmetric** option displays data that contains positive, 0, and negative values on a log scale axis. By default, the tick marks are drawn at powers of ten, but you can specify any base that is greater than 1.

3. Click the **Tick Marks** tab and select one of the following options:
 - **Automatic** - the major tick marks are drawn at powers of 10.
 - **Fixed** - the major tick marks are drawn at a specified exponent. Type a number into the Powers of text box.
 - **None** - major tick marks are not shown.
4. When finished, click **OK**.

You can also reverse the axis by selecting **Reverse** in the Scale area on the General tab of the Edit Axis dialog box.

About the symmetric log axis transform

The symmetric log axis applies an area hyperbolic sine transform to the axis:

$$\text{asinh}(x) = \ln(x + \sqrt{x^2 + 1})$$

For large values ($|x| \gg 1$),

$$\text{asinh}(x) \sim \ln(x), \quad x > 0$$

$$\text{asinh}(x) \sim -\ln(x), \quad x < 0$$

Because *asinh* is defined for all real values (negative numbers in particular) this transform allows you to visualise large negative values on a logarithmic scale, as well as large positive values, or both.

However, while a log axis can be used to visualise the scale of very small values, a symmetric log axis cannot be used to visualise the scale of very small values.

For small values ($|x| < 1$),

$$\text{asinh}(x) \approx x$$

Using a symmetric log axis scale for small values has a similar effect to using a linear scale (i.e., a normal quantitative axis).

Change the appearance of an axis

Every axis has a title that is automatically generated based on the fields in the view. You can specify a custom axis title and add a subtitle using the Edit Axis dialog box. You can also specify the scale of the axis, such as whether to use a logarithmic scale or whether to reverse the axis.

To change the appearance of an axis:

1. Right-click (control-click on Mac) on the axis that you want to edit and select **Edit Axis**.
2. In the Edit Axis dialog box, type a new title in the **Title** text box.

Format tick marks

You can specify how often the tick marks are displayed along the axis. Tableau allows you to modify both the Major and Minor tick marks. Major tick marks are accompanied by unit labels while Minor tick marks simply represent smaller increments between the major marks. You can choose to use automatic or fixed tick marks or have none at all.

To format tick marks:

1. Right-click (control-click on Mac) the axis you want to edit and select **Edit Axis**.
2. In the Edit Axis dialog box, select the **Tick Marks** tab.
3. For both **Major** and **Minor tick marks**, select from one of the following options:

- **Automatic** - select this option to automatically show tick marks based on the data in the view.
- **Fixed** - select this option to specify how often the tick mark should display and the starting value.
- **None** - select this option to hide the tick marks completely.

4. Click **OK**.

Examples: Use Different Axis Ranges (Uniform, Independent, Fixed)

In this example you will build three views using the same data. However, each view will use a different axis range format. These views use the **Sample-Superstore** data source to display the aggregated total sales for three product categories over the course of four years.

Build a view with a uniform axis range below

Build a view using independent axis ranges on page 2964

Build a view using a fixed axis range on page 2967

Build a view with a uniform axis range

A uniform axis range means that the same range is applied to each row or column in your view. The range is automatically generated based on the underlying data values.

1. Place the **Order Date** dimension on the **Columns** shelf and the **Category** dimension on the **Rows** shelf.
2. Place the **Sales** measure on the **Rows** shelf.

The measure is automatically aggregated as a summation and an axis is added to the view. By default the view uses a uniform axis range. Notice that the axis range is the

same, from zero to 250,000 for each product category.

Build a view using independent axis ranges

When you use an independent axis range, each row or column will have its own axis range based on the underlying data values.

1. Right-click (control-click on Mac) the SUM(Sales) axis in the view and select **Edit Axis**.

2. In the Edit Axis dialog box, select **Independent axis ranges for each row or column**.

3. Click the X to close the dialog box with the current settings.

The axis range for each product category are now independent from each other. The Technology and Office Supplies categories still range from zero to 250,000, but the Furniture category ranges from zero to a little over 200,000.

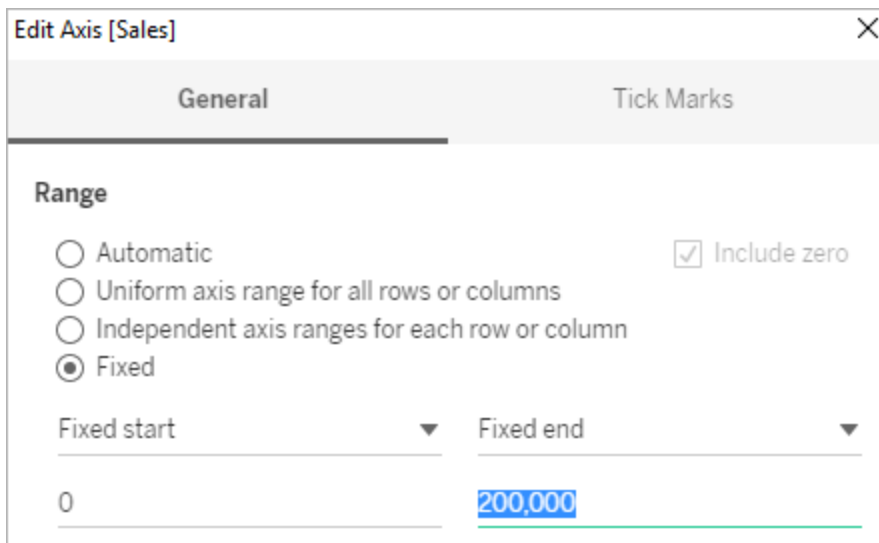

Build a view using a fixed axis range

You can fix one or both ends of an axis in order to customise how much of the data you can see in the view.

The first example shows how to fix both ends of the axis. The second shows how to fix only one end of the axis, and then define the axis range for all panes in the view.

To fix both ends of the axis:

1. Right-click (control-click on Mac) the **SUM(Sales)** axis in the view and select **Edit Axis**.
2. In the Edit Axis dialog box, select **Fixed**, and then define **Start** and **End** values either by typing into the text boxes or by dragging the sliders toward each other. For this example, type **0** for **Start** and **200,000** for **End**.

The screenshot shows the 'Edit Axis [Sales]' dialog box with the 'General' tab active. The 'Range' section has four radio buttons: 'Automatic', 'Uniform axis range for all rows or columns', 'Independent axis ranges for each row or column', and 'Fixed'. The 'Fixed' option is selected. Below these, there are two input fields: 'Fixed start' with the value '0' and 'Fixed end' with the value '200,000'. The 'Include zero' checkbox is checked. The 'Tick Marks' tab is also visible but not selected.

3. Click the X to close the dialog box with the current settings.

The categories now display only up to \$200,000 in sales. The axes are marked with a pin symbol  , which indicates that you have limited the axis range and that some data might

not be displayed.

To fix one end of the axis:

1. Right-click (control-click on Mac) the **SUM(Sales)** axis in the view and select **Edit Axis**.
2. In the Edit Axis dialog box , select **Fixed**, click the **Fixed End** drop-down menu, and then select **Independent**.

3. Click the X to close the dialog box with the current settings.

Notice that the categories now have slightly different axis ranges. For example, Office Supplies has an axis range from 0 to 250,000 dollars, while Furniture only has a range from 0 to 200,000 dollars.

For more information about the difference between automatic, uniform and independent axis ranges, see [Edit Axes](#) on page 2948.

Format Text and Numbers

To learn how to format specific items, click the links below.

Format Text

The proper font selection can take your visualisation from good to great. Whether you're changing the font size, position, colour or direction, Tableau provides a wide range of customisation options for your text.

When you make formatting changes at this level, they apply only to the view you are working on. See [Format at the Workbook Level on page 2922](#) to learn how to make changes that apply to every view in your workbook.

To access worksheet-level format settings, select the **Format** menu, then choose the part of the view, such as **Font** or **Border**, that you want to format.

Format fonts

If you're working in Tableau Server or Tableau Cloud, select **Format** and then choose the element you want to format from the menu. You can choose to format the **Individual Title**, **Caption**, **Legends**, **Filters and Sets**, **Highlighters**, and **Parameters**. You can also **Clear Worksheet Formatting** in the Format menu.

If you're working in Tableau Desktop, select **Format > Font**. A **Format Font** control pane will open. This control pane will let you customise the text in the view.

Worksheet

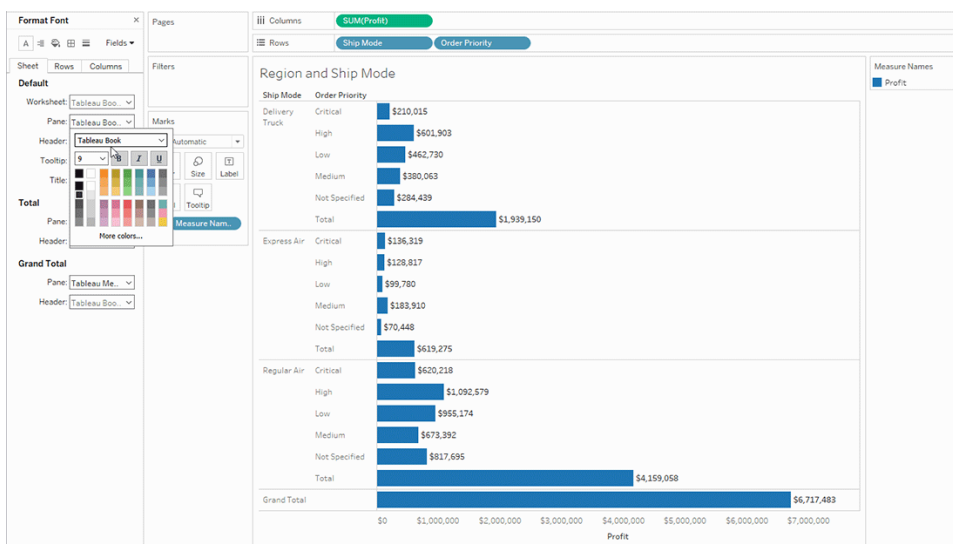

Editing the font at the worksheet level applies the changes you make to all text fields in view except the Header and Tooltip fields.

Note: Tableau treats Worksheet formatting as a new default, and any changes to any other fields (such as Title, Pane or Header) will overwrite the Worksheet format.

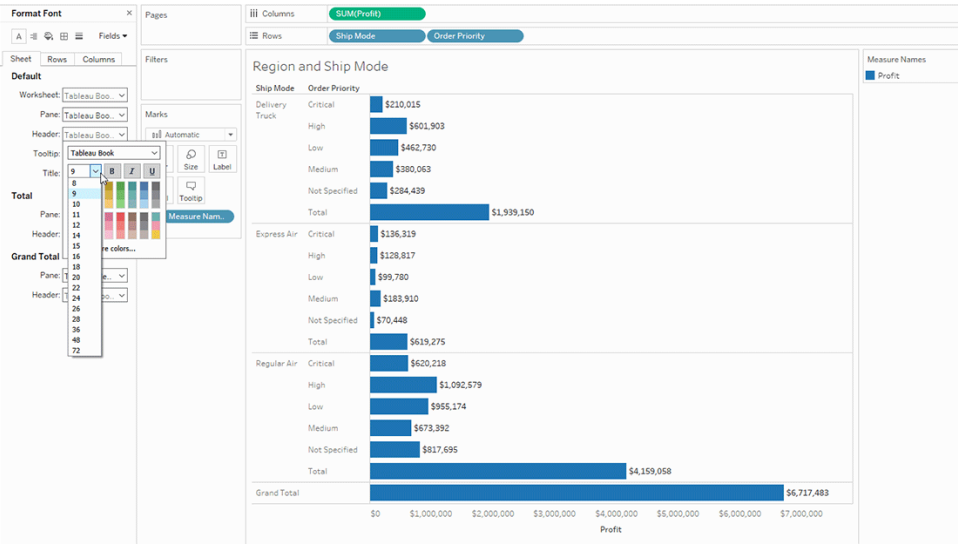

Pane

Adjusting the font here will affect the pane view, which is where Tableau displays the results of your visualisations.

Header

Select this option to adjust font for the headers in your view. Headers display the dimensions used in your viz.

Tooltip

Adjusting the font here will apply changes to all the text in the tooltip, the field that pops up when someone hovers over a mark in your view. If you want more control over the fields in the tooltip, see [Format Text on page 2971](#)

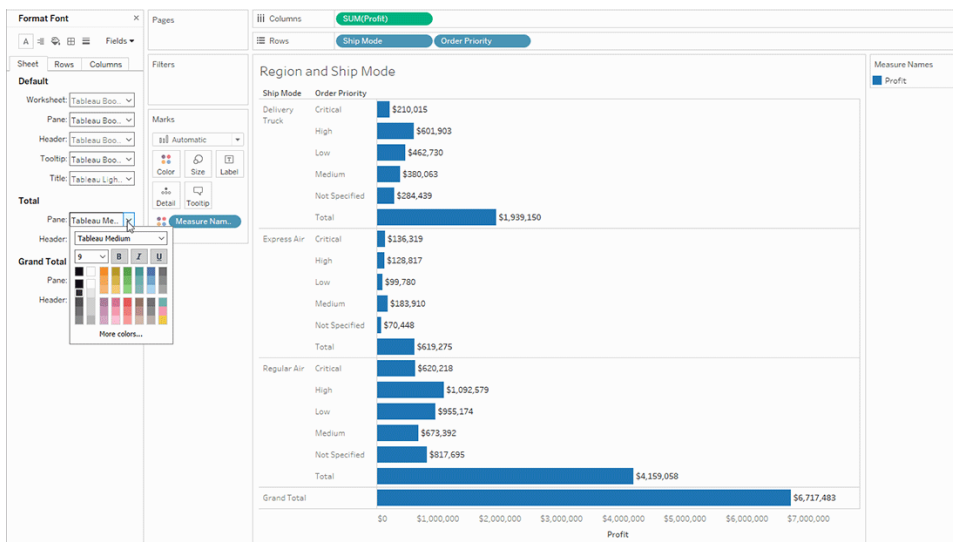

Title

Select this formatting option to quickly adjust the appearance of the Title. For more information, see [Format Text on page 2971](#)

Total Pane

Adjusting the font for totals at the pane level will change both the subtotals and grand totals. For information on setting up totals, see [Show Totals in a Visualisation on page 1361](#).

Total Header

Adjusting the font for totals at the header changes the appearance of the **Total** and **Grand Total** label in the view.

Grand Total Pane

Select this option to adjust the font for the grand total result in your view.

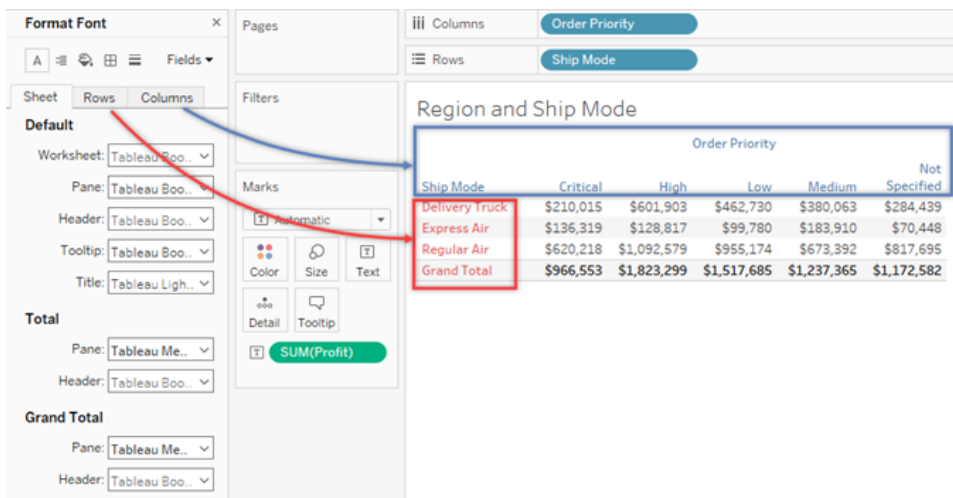

Grand Total Header

Select this option to adjust the font for the grand total label in your view.

Row and Column Text Formatting

If you have dimensions on both the row and column shelves, you can independently format the fonts through the **Rows** and **Columns** tabs on the Formatting pane.

The format font options are limited to the Header, Total and Grand Total selections.

Format text alignment

Tableau uses visual best practices to determine how text is aligned in a view, but you can also customize your text alignment. For example, you can change the direction of header text so that it is horizontal (default) instead of vertical (up).

To format the text alignment, select **Format > Alignment** to open the text alignment pane.

Header Text is Vertical

For each text area, you can specify the following alignment options:

Horizontal – Controls whether text aligns to the left, right or centre.

Vertical Alignment – Controls whether text aligns to the top, middle or bottom.

Direction – Rotates text so that it runs horizontally (default), top-to-bottom (up) or bottom-to-top (down).

Wrap – Controls whether long headers wrap to the next line or are abbreviated. It does not control text marks in the visualisation.

Note: If cells are not large enough to show more than one row of text, turning on wrapping will have no visible effect. If this happens, you can hover the cursor over a cell until a double-sided arrow appears, and then click and drag down to expand the cell size.

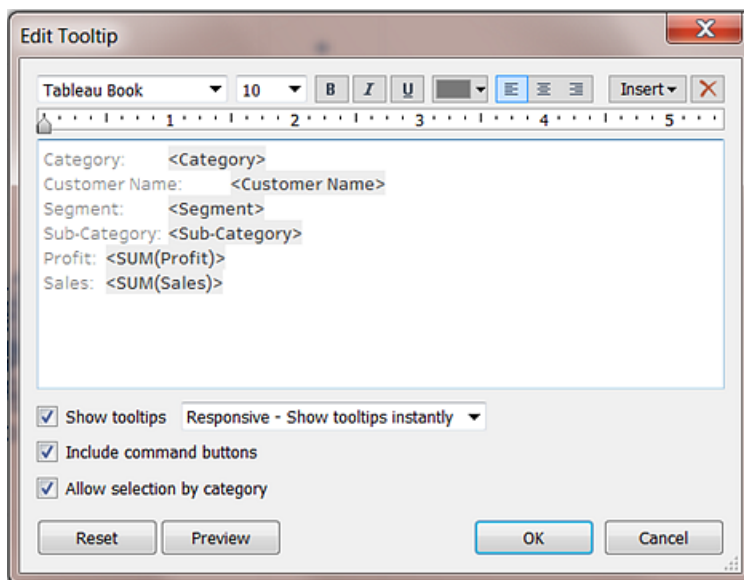

Tableau adheres to regional standards when determining when to begin or end line breaks.

Format tooltips

Tooltips are details that appear when you rest the pointer over one or more marks in the view. Tooltips also offer convenient tools to quickly filter or remove a selection, select marks that have the same value or view underlying data. You can edit the tooltip to include both static and dynamic text. You can also modify which fields are included in the automatic tooltip.

To edit a tooltip:

1. Select **Worksheet > Tooltip**. Tooltips are specified for each sheet and can be formatted using the formatting tools along the top of the Edit Tooltip dialog box. Use the **Insert** menu at the top of the dialog box to add dynamic text such as field values, sheet properties and more.

2. Use the formatting tools along the top of the Edit Tooltip dialog box.
3. (Optional) Use the **Insert** drop-down list at the top of the dialog box to add dynamic text such as field values, sheet properties and more.

The **All Fields** option on the **Insert** menu adds all field names and values that are used in the view. Inserting the All Fields parameter updates the tooltip as you change the view. You can also use the All Fields option to exclude fields.

4. (Optional) Select the **Include command buttons** option to show filtering and view data options in the tooltip. For example, including command buttons will add **Keep Only**, **Exclude** and **View Data** buttons to the bottom of the tooltip. These command buttons are available both in Tableau Desktop and when the view is published to the web or viewed on a mobile device.
5. (Optional) Tick the **Allow selection by category** box to select marks in a view that have the same value by clicking on a discrete field in a tooltip. For more information see [Tool-tips on page 84](#).

Edit worksheet titles, captions and legend titles

1. Do one of the following:
 - On Tableau Server or Tableau Cloud, double click the item you want to change.
 - On Tableau Desktop, Right-click (control-click on Mac) the item you want to change and select **Edit <item>**, for example, **Edit Title**.
 - On a worksheet, hover on the title, click the drop-down arrow on the right-hand side and select **Edit Title** or **Edit Caption** from the context menu.
2. In the Edit dialog box, modify the text and format the font, size, style, colour and alignment. Use the **Insert** menu to add dynamic text such as sheet properties and field values. Click **OK**.

To reset the title back to the default, click **Reset**.

Use Custom Fonts

Tableau provides a variety of fonts for you to use in your visualisations, including the fonts in its default typeface: Tableau. However you might want to use a font other than what's provided. For example, you may want to use a font that's unique to your company's brand.

To use a custom font in Tableau, the first step is to install it on the computers that are running Tableau. This includes Tableau Desktop and, if you're publishing to Tableau Server, any computers running Tableau Server.

Important: If a font specified in Tableau Desktop isn't also installed on all nodes of Tableau Server, Tableau Server substitutes a default font.

To ensure that Tableau Server can render the font correctly, make sure the font is on the list of fonts installed with most browsers. These commonly installed fonts are called "web-safe" fonts, as detailed [here](#).

Note: If you download a workbook from Tableau Server, custom fonts are not downloaded with the workbook.

For more information about installing fonts, see the following links:

- [How to install or remove a font in Windows](#) (Microsoft Knowledge Base)
- [Mac Basics: Font Book](#) (Apple Support)

After you install the font it appears in the formatting pane in Tableau Desktop, where you can use it to change fonts at the workbook or worksheet levels. See [Format at the Workbook Level](#) on page 2922, [Format at the Worksheet Level](#) on page 2932 and [Format Text and Numbers](#) on page 2971 for details.

Publish custom fonts

Publishing a workbook with a custom font correctly depends on knowing how the author and published workbook interact.

Publishing a custom font work flow

A. Workbook is created in Tableau Desktop.

or

B. Workbook is created using Web Authoring.

then

C. Workbook is published to Tableau Server.

or

D. Workbook is published to Tableau Cloud.

| If | Then |
|--|--|
| A- The workbook is created in Tableau Desktop. | You can use any font installed on your computer in the workbook. |
| B- The workbook is created using Web Authoring. | Only fonts installed on the Tableau Server or Tableau Cloud are functional when formatting your text. |
| C- The workbook is published to Tableau Server. | Any custom font must be installed on all server nodes. If the font is not installed on Tableau Server, the uninstall font will be replaced with a substitute font upon publishing. |
| D- The workbook is published to Tableau Cloud. | Only fonts supported by Tableau Cloud will appear. Any unsupported fonts in the workbook will be replaced with a substitute font upon publishing. For a list of supported fonts, see Knowledge Base: Fonts not displaying as expected . |

Troubleshoot custom fonts in published workbooks

Once published, any viewer of the published workbook will need to have the custom fonts installed on their computer. This is why it is a best practice to limit fonts to either Tableau fonts or web safe fonts.

| Issue | Possible Solution |
|--|--|
| Some fonts are accurate in the view, but others are not. | When a view has many marks, the server will render the marks on the server side and display the marks as a static image. This can result in some fonts in the view appearing inconsistent with the rest of the view. To resolve this issue, reduce the number of marks per view. |
| The spacing on the font appears different for | If the viewer has the custom font installed on their computer, the viewer will see the font displayed accurately. However, each browser uses a slightly different method for rendering fonts, so seeing slight differences in fonts between browsers is expected. |

| Issue | Possible Solution |
|---------------------------------------|---|
| different viewers. | |
| A different font appears for viewers. | If the viewer does not have the custom font installed on their computer, any uninstalled fonts in the workbook will be replaced with a substitute font selected by the browser. |

Format Individual Parts of the View

You can format individual parts of the view, including text elements such as titles, captions and tooltips. You can also format individual controls, including legends, filters, highlighters and parameter controls.

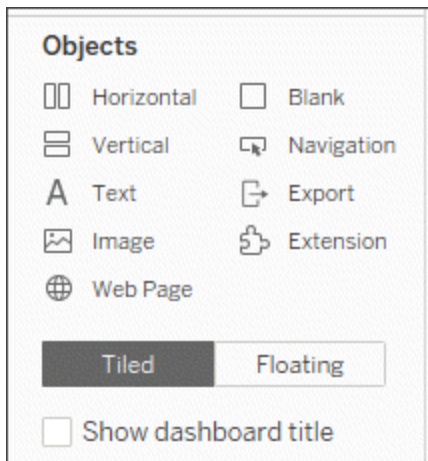

Text elements

There are several ways that text elements, such as titles, captions and tooltips, can appear on your view. You can choose to hide or show titles and captions on your worksheet. You can also add tooltips to Marks.

Show titles and captions

If a title or caption isn't showing, open the Worksheet menu and select **Show Title** or **Show Caption**.

For dashboards and stories, there are equivalent options in their respective menus (such as Dashboard > Show Title). There's also a tick box to turn the dashboard or story title on or off, available in the left-hand pane.

Edit titles and captions

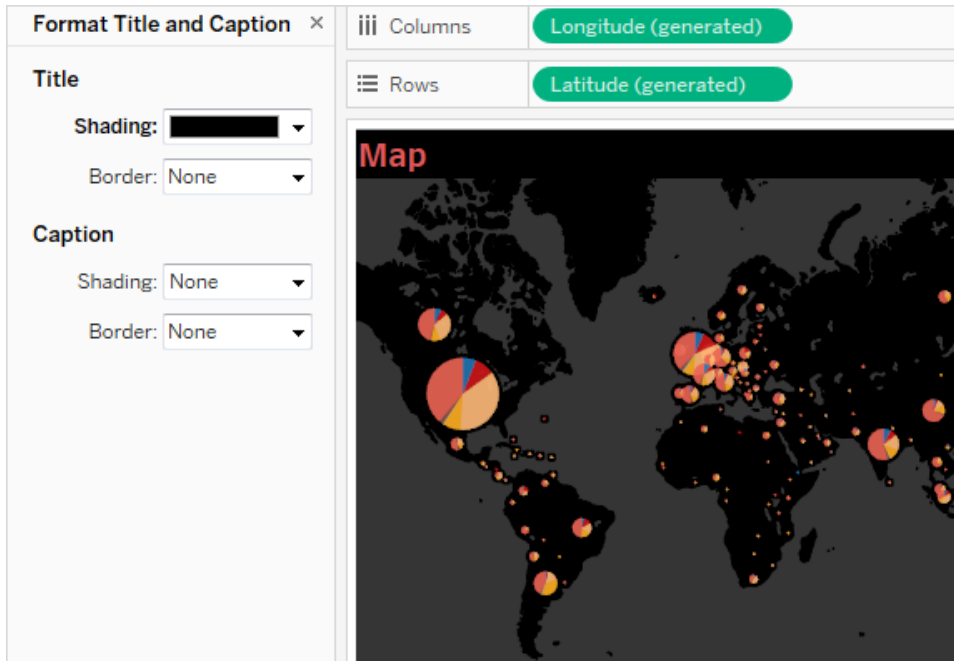

1. On a worksheet, hover on the title to access the context menu, select the drop-down arrow on the right-hand side and select **Edit Title** or **Edit Caption**. Alternatively:
 - a. Right-click (control-click on Mac) on the item you want to change and select **Edit**.
 - b. In Tableau Cloud, double-click the worksheet title.
2. In the Edit Title dialog box, modify the text and format the font, size, style, colour and alignment. If desired, use the **Insert** menu to add dynamic text such as sheet properties and field values. To reset a title or caption back to the default, click **Reset**.

Format titles and captions

For information on showing or hiding a title, see [Titles](#) on page 86.

1. On a worksheet, right-click (control-click on Mac) the title, caption or legend and select **Format <item>** – for example, **Format Title**.
2. In the **Format** pane, use the drop-down lists to change the default shading or border.

Edit dashboard titles

For information on showing or hiding a title, see [Titles on page 86](#).

1. On a dashboard, double-click on the title.
2. In the Edit Title dialog box that appears, format the title as you like. You can enter a new title for the dashboard or a description, and change the font type, size, emphasis, colour and alignment. You can also type in a website URL and Tableau will automatically create a hyperlink.

Note: If you edit the hyperlink, make sure to delete the entire hyperlink and then reenter the new one. If you don't do this, the text of the hyperlink is updated, but the URL path won't be.

3. When finished, click **OK**. The dashboard title updates with the changes.

Format tooltips

Tooltips are details that appear when you rest the pointer over one or more marks in the view.

Tooltips also offer convenient tools to quickly filter or remove a selection, select marks that have

the same value or view underlying data.

- For more information on tooltips, see [Tooltips on page 84](#).
- To show a visualisation in a tooltip, see [Create Views in Tooltips \(Viz in Tooltip\) on page 1378](#).

You can edit the tooltip to include both static and dynamic text. You can also modify which fields are included in the automatic tooltip.

1. On the Marks card select **Tooltip**. Tooltips are specified for each sheet and can be formatted using the formatting tools along the top of the Edit Tooltip dialog box.
2. Use the **Insert** menu at the top of the dialog box to add dynamic text such as field values, sheet properties and more.
3. Use the formatting tools along the top of the Edit Tooltip dialog box.

There are several optional customisations as well.

Dynamic text values

Use the **Insert** drop-down list at the top of the dialog box to add dynamic text such as field values, sheet properties and more.

The **All Fields** option on the **Insert** menu adds all field names and values that are used in the view. Inserting the All Fields parameter updates the tooltip as you change the view. You can also use the All Fields option to exclude fields.

Command buttons

Select the **Include command buttons** option to show filtering and view data options in the tooltip.

For example, including command buttons adds **Keep Only**, **Exclude** and **View Data** buttons to the tooltip. These command buttons are available both in Tableau Desktop and when the view is published to the web or viewed on a mobile device. Unticking **Include command buttons** will also hide the aggregation summary if multiple marks are selected.

Selection by category

Select the **Allow selection by category** tick box to select marks in a view that have the same value by selecting a discrete field in a tooltip. For more information see [Tooltips on page 84](#).

Controls

As of Tableau version 2024.2, you can format controls, including legends, quick filters, highlighters and parameter controls individually or all together. In Tableau versions 2024.1. and earlier, these controls take on whatever formatting is applied at the worksheet level.

Show Controls

Legends

A legend automatically appears on the worksheet when you encode marks by dropping them on the **Colour**, **Shape** or **Size** cards.

Filters

If you aren't seeing a filter control, hover over the field in the filters box, expand the context menu and select **Show Filter**.

Highlighters

A highlighter automatically appears on the worksheet when it has been turned on.

To learn more about highlighters, see [Highlight Data Points in Context](#).

Parameters

If you aren't seeing a parameter control, hover over the parameter in the data pane, expand the context menu and select **Show Parameter**.

To learn more about parameters, see [Create Parameters](#).

Format Controls on Tableau Desktop

1. From the control, expand the context menu by clicking the drop-down arrow on the top right of the box.

2. Select **Format...**
3. Select **This [Control]...** or **All [Controls]...**

If you select **This [Control]...**, any formatting updates you make will apply to the selected control only. If you select **All [Controls]...**, any formatting you update will apply to all of that type of control, such as all parameters.

4. Make your formatting changes in the formatting pane on the left side of the viz. You can format the Title and Body text, including font, font style, text and colour. You can also format the background shading and border.

Note: On Tableau Desktop, formatting an individual control overrides formatting applied at the worksheet level. If you'd like to make subsequent formatting changes apply to all elements, you must first clear the formatting applied at the individual control level. Some formatting elements, such as borders, may not render on a worksheet but will appear on the viz when added to a dashboard.

Format Controls on Tableau Cloud and Tableau Server

1. From the control, expand the context menu by clicking the down arrow on the top right of the box.
2. Select Format.

A formatting pane appears to the right of the viz.

3. By default, changes are set to apply to the **Selected** control only. If you'd like to format all of the types of control for this view, such as all filters, select **All**.
4. Make your formatting changes. You can format the text, including font, font style, text and colour, and you can format the background shading and border. You can also choose to show or hide the title of the control from this pane.

Note: On Tableau Cloud, you can access individual formatting controls on the worksheet; formatting individual controls isn't accessible on a dashboard.

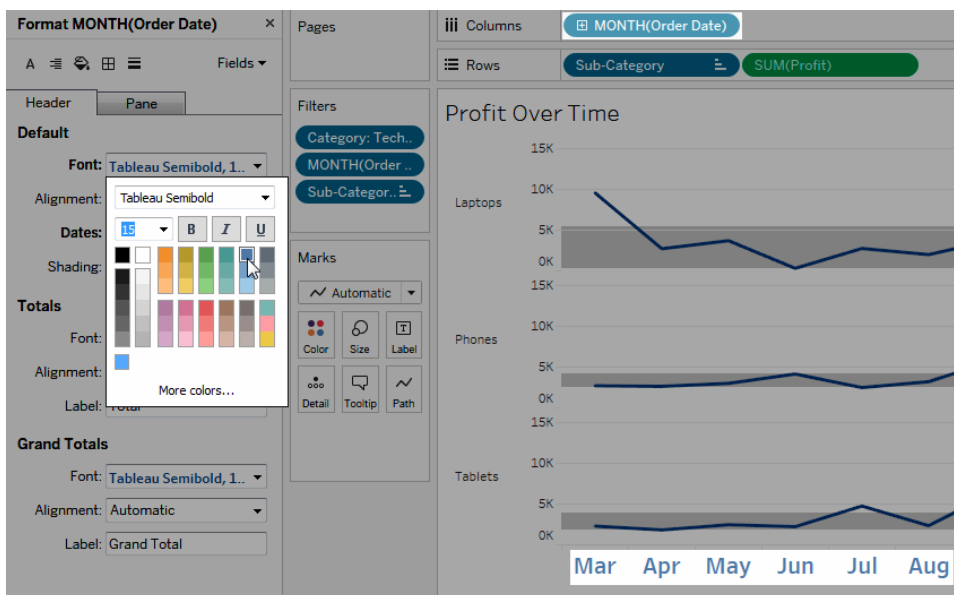

For more information about adding controls, including legends, filters and parameter controls to a worksheet, see [Additional Shelves, Legends, Cards and Controls](#).

Format Fields and Field Labels

You can format a specific field in a view, as well as individual field labels. When formatting is done this way, your formatting changes are scoped to only where the field appears in the view, or only an individual label.

Format a field

In the view below, the **Month(Order Date)** field has been formatted so that the headers use the Tableau Semibold font, in blue. Notice that the header values along the Profit axis are not affected.

To format a specific field:

1. Right-click (control-click on Mac) the field and select **Format**.

The **Format** pane opens to settings for the selected field.

2. Make your changes in the **Format** pane.

For discrete fields, such as Region or Customer Name, you can specify font and alignment properties for both header and pane areas. For continuous fields, such as Profit or Sales, you can format font properties for the pane and axis as well as number and tick mark colours. For more information about other axis options, see [Edit Axes on page 2948](#). The view is updated as you make changes so you can quickly see the colours and formats that work with your view.

Format a field label

Field labels are row and column headings that indicate the data fields used to create a view. By default, Tableau shows field labels, but you can choose to hide them. When field labels are showing they appear in three different parts of the view: rows, columns and the corner. The view below shows an example of each of these types of field labels.

Columns

Region

YEAR(Order Date)

Rows

Category

| Region / Order Date | |
|---------------------|-----------------------------|
| East | |
| Category | |
| Furniture | 47,233 53,817 46,387 60,854 |
| Office Supplies | 35,969 42,655 61,645 65,247 |
| Technology | 45,479 59,859 72,497 87,138 |

You can format the font, shading, alignment, and separators for each of these types of field labels.

To format a specific field label:

1. Right-click (control-click on Mac) the field label in the view and select **Format**.
2. In the **Format** pane, specify the settings of the font, shading, and alignment field labels.

Note: When you have multiple dimensions on the rows or columns shelves, the field labels appear adjacent to each other in the table. Each field label is separated from the others with a forward slash symbol. Specify a different separator in the **Format** pane.

Format Numbers and Null Values

You can specify the format for numeric values that are displayed in your viz, including measures, dimensions, parameters, calculated fields and axis labels. When specifying a number format, you can select from a set of standard formats, such as number, currency, scientific and percentage.

You can also define a custom number format with the option to include special characters.

When a measure contains null values, you can use formatting to handle the null values in a different way, such as replacing nulls with zeros or hiding them.

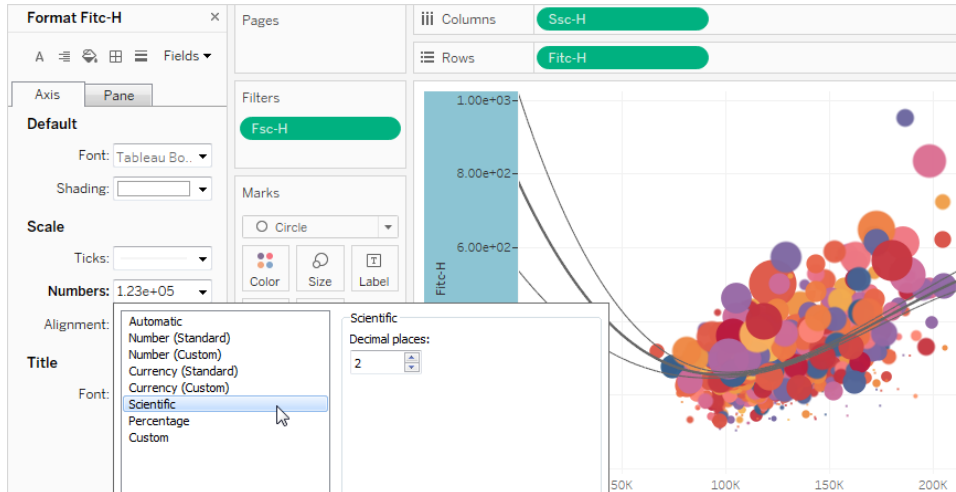

For Tableau Desktop

Specify a number format

1. Right-click (control-click on Mac) a number in the view and select **Format**.
2. In the **Format** pane, click the **Numbers** drop-down menu.

3. Select a number format.

Some formats require additional settings. For example, if you select **Scientific**, you must also specify the number of decimal places.

Here are the number formats and associated options available in Tableau.

NUMBER FORMAT

Automatic: format is automatically selected based on either the format specified by the data source or the data contained in the field.

Number (Standard): format is based on locale selected.

Number (Custom): format is customised to your choice.

FORMAT OPTIONS

None.

Locale: number format changes based on the geographical location selected.

Decimal Places: the number of decimal places to display.

Negative Values: how negative values are displayed.

Units: the number is displayed using the specified units. For example, if the number is 20,000 and the units are thousands, the number will be displayed as 20K.

Currency (Standard): format and currency symbol is based on locale selected.

Currency (Custom): format and currency symbol is customised to your choice.

Scientific: numbers are displayed in scientific notation.

Percentage: numbers are displayed as a percentage with the percent symbol. The value of 1 is interpreted as 100% and 0 as 0%

Custom: format is based entirely on what is specified in the format options.

Prefix/Suffix: characters that precede and follow each displayed number.

Include thousands separators: whether the number shows separators every thousand (example: 100,000 vs. 100000).

Locale: currency format based on the geographical location selected.

Decimal Places: the number of decimal places to display.

Negative Values: how negative values are displayed.

Units: the number is displayed using the specified units. For example, if the number is 20,000 and the units are thousands, the number is displayed as 20K.

Prefix/Suffix: characters that precede and follow each displayed number.

Include thousands separators: whether the number shows separators every thousand (example: 100,000 vs. 100000).

Decimal: the number of decimal places to display.

Decimal: the number of decimal places to display.

Custom: type in the format you want to use, including special characters (optional). See "Define a custom number format" in this topic for details.

Define a custom number format

To apply a custom number format in your viz:

1. Right-click (control-click on Mac) a number in the view and select **Format**.
2. In the **Format** pane, click the **Numbers** drop-down menu and select **Custom**.
3. In the **Format** field, define your formatting preferences using the following syntax: `Positive number format;Negative number format;Zero values.`

When defining your number format code, keep in mind that:

- You can specify the formatting for up to three types of numbers in the following order: positive numbers, negative numbers and zeros.
- Each number type must be separated by a semicolon (;).
- If you specify only one number type, the format for that type is used for all numbers.
- If you specify two number types, the format for the first type is applied to positive numbers and zeros, while the format for the second type is applied to negative numbers.
- If you skip types in your number format code, you must include a semicolon (;) for each of the missing types.

Custom number format examples

Refer to the following table for examples of commonly used custom number format codes that you can use in your viz.

The syntax has three portions: `<positive number format>;<negative number format>;<zero format>` separated by semicolons.

| USE CASE | NUMBER CODE SYNTAX | EXAMPLE OUTPUT |
|---------------------------|--|--|
| Show only positive values | <code>#,##; ;</code> (note a blank space after the 2nd and 3rd semicolon) | Positive values: 1,234 Negative values: (only the blank space displays) Zero values: (only the blank space displays) |
| Show only negative values | <code>;-#,##;</code> | Positive values: (nothing is displayed) Negative values: -1,234 Zero values: (nothing is displayed) |

| | | |
|-----------------------------------|--|--|
| Show only zero values | ::0; | Positive values: (nothing is displayed) Negative values: (nothing is displayed) Zero values: 0 |
| Hide zero values | #,###;-#,###;; | Positive values: 1,234 Negative values: -1,234 Zero values: (nothing is displayed) |
| Show negative values in brackets | #,###;(#,###);; | Positive values: 1,234 Negative values: (1,234) Zero values: (nothing is displayed) |
| Add a character prefix to a value | \$\$,###.##;-\$\$,###.##;\$0; | Positive values: \$1,234.56 Negative values: -\$1,234.56 Zero values: \$0 |
| Add a character suffix to a value | ##%;-##%;0%; | Positive values: 12% Negative values: -34% Zero values: 0% |
| Add text descriptors | "\$"#,##" Surplus";"\$"-##" Shortage";"\$"0; | Positive values: \$1,234 Surplus Negative values: \$-1,234 Shortage Zero values: \$0 |

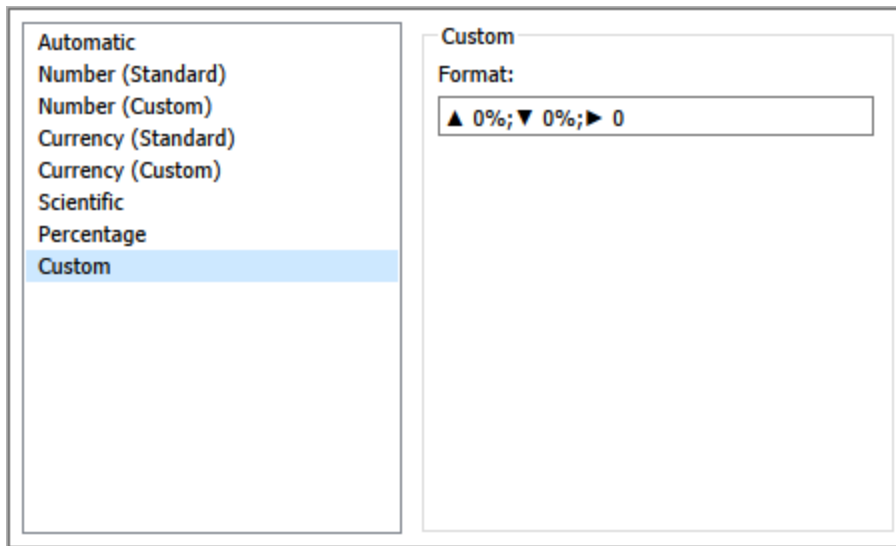

There are several ways to customise your number format to meet your needs. For more code guidance and examples, see [Review guidelines for customising a number format](#) in the Microsoft Knowledge Base.

Note: There are slight deviations between the options described by Microsoft and those available in Tableau. For example, custom number formats that align text within columns aren't relevant in Tableau. Additionally, custom number formats to colour code text aren't applicable because you can apply colour to text using the Marks card. (For more information on applying colour, see [Control the Appearance of Marks in the View](#).) Be sure to only use custom number formats that apply in Tableau.

Include special characters in a custom number format

One of the benefits of custom number formatting is the ability to include special characters or symbols. Symbols can make it easier to quickly understand comparisons between measures and calculations in your viz.

For example, let's say you want to show a month-over-month comparison of profits for three of your company's top-selling products. Rather than using the standard label to show that the profit for these products changed +5%, -2% and 0% from last month, you can set the custom number format as follows to show these changes as ▲5%, ▼2% and ►0.

Set the default number format for a field

Right-click (control-click on Mac) the field in the **Data** pane and select **Default Properties > Number Format**.

In the subsequent dialog box, specify a number format to be used whenever the field is added to the view. The default number format is saved with the workbook. It's also exported when you export the connection information.

Note: Formatting numbers using the **Format** pane overrides any number formatting applied elsewhere.

Format a measure as currency

The view in the following image shows profit over time. Notice that the profit figures on the vertical axis aren't formatted as currency.

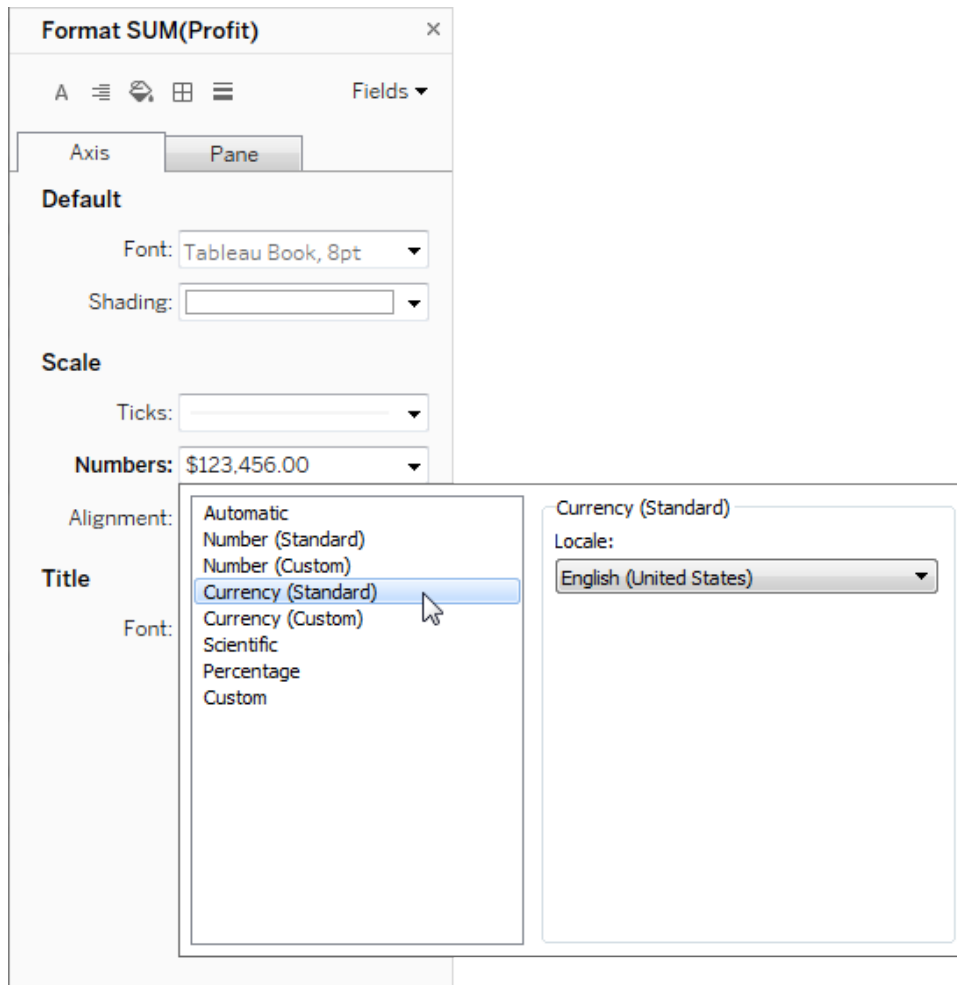

To format the numbers as currency:

1. Right-click the **Profit** axis and choose **Format**.

2. On the **Axis** tab in the **Format** pane, under **Scale**, select the **Numbers** drop-down list, and then select one of the following:

Currency (Standard) to add a dollar sign and two decimal places to the figures.

Currency (Custom) to specify the number of decimal places, how to show negative values, the units, whether to include a prefix or suffix, and whether to include a separator character.

Use locale to specify number formats

By default, Tableau uses your computer's locale and language settings to format numbers. But you can explicitly set a different locale in the **Format** pane.

The following steps show how to set Swiss German currency, using the same view as in the previous section.

1. Right-click the **Profit** axis and select **Format**.
2. On the **Axis** tab, under **Scale**, select the **Numbers** drop-down list and then select **Currency (Standard)**.

3. In the **Locale** drop-down list, items appear in a **Language (Country)** format. For this example, select **German (Switzerland)**. The view updates to show the sales figures as Swiss Francs, formatted for the German language.

Tip: You can change the default currency setting so that every time you drag the **Profit** measure to a view it uses the settings you want. In the **Data** pane, right-click **Profit** (or other monetary measure) and select **Default Properties > Number Format**. Then format the field as shown above.

Format null values

When a measure contains null values, they're usually plotted in a view as zero. However, sometimes that changes the view and you'd rather just suppress null values altogether. You can format each measure to handle null values in a unique way.

To format null values for a specific field:

1. Right-click the field in the view that has the null value (Control-click on a Mac) and choose **Format**.
2. Go to the **Pane** tab.
3. In the **Special Values** area, specify whether to show the null value using an indicator in the lower right corner of the view, plot it at a default value (such as zero for number fields), hide the value but connect the line, or hide and break the line to indicate that a null value exists.

Format SUM(Profit)

Fields ▾

Axis Pane

Default

Font: Tableau Book, 8pt ▾

Alignment: Automatic ▾

Numbers: \$123,456 ▾

Totals

Font: Tableau Medium, 8pt ▾

Alignment: Automatic ▾

Numbers: \$123,456 ▾

Grand Totals

Font: Tableau Medium, 8pt ▾

Numbers: \$123,456 ▾

Special Values (eg. NULL)

Text: (Blank)

Marks: Show at Indicator ▾

- Show at Indicator
- Show at Default Value
- Hide (Connect Lines)
- Hide (Break Lines)

4. If you specify text in the **Text** field, it appears in the view for a null value when mark labels are turned on. See [Show and Hide Mark Labels](#).

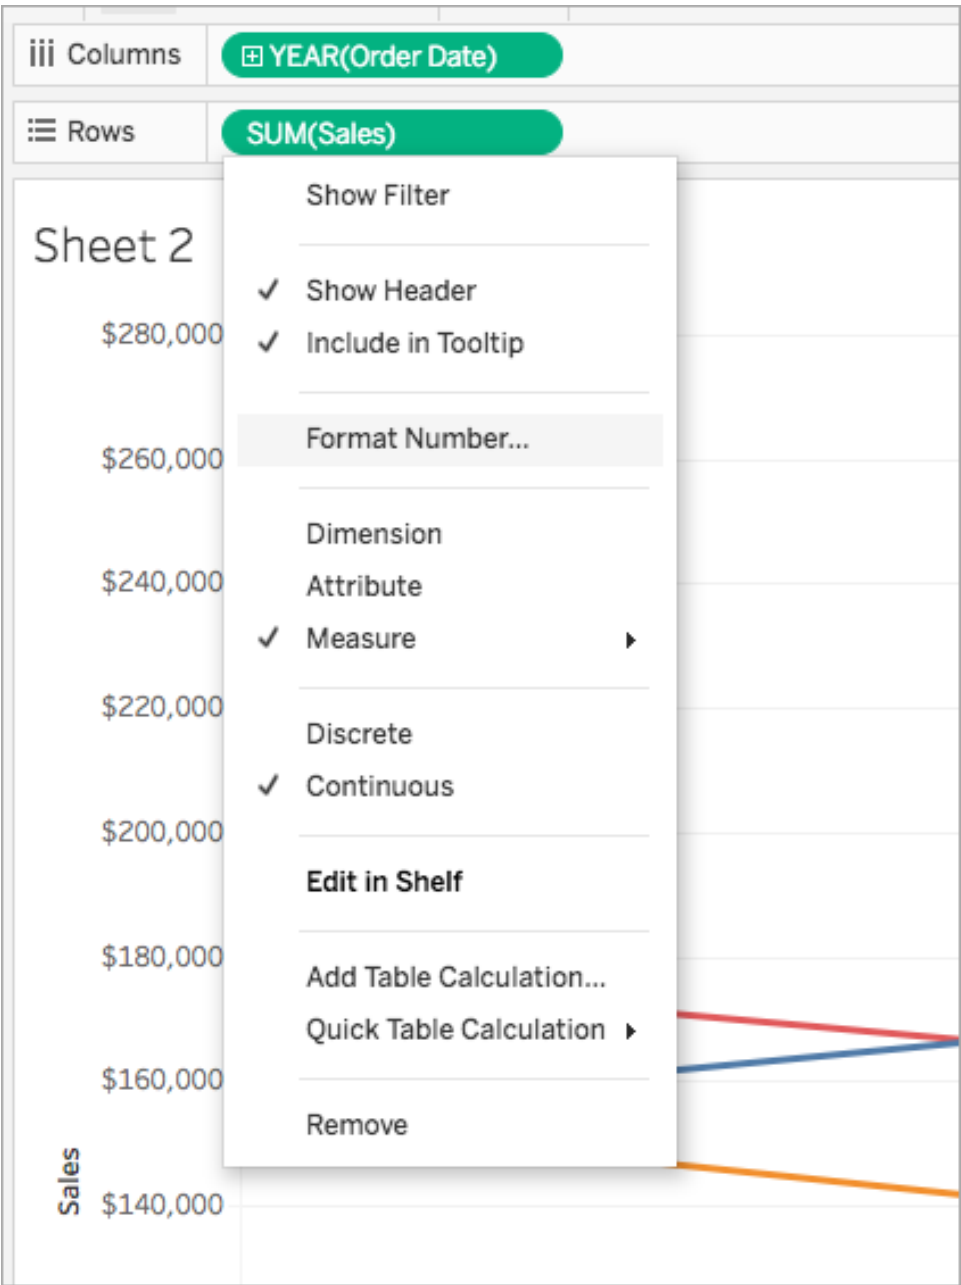

Note: The Special Values area isn't available for dimensions or discrete measures.

For Tableau Server or Tableau Cloud

Specify a number format

When authoring a view on the web, you can specify the number format for a field used in the view.

1. In web editing mode, right-click a measure in the view and select **Format Number**.

2. In the dialog box that appears, select a number format.

Some formats provide additional settings. For example, if you select **Currency**, you can also specify the number of decimal places, as well as the units, and whether or not to include separators, such as commas.

In this example, Sales is formatted as a Currency with zero decimal places and thousand (k) units. Sales numbers in the view update with these settings. Labels and tooltips update as well.

Here are the number formats and associated options available in Tableau.

| NUMBER FORMAT | FORMAT OPTIONS |
|--|--|
| Automatic: format is automatically selected based on either the format specified by the data source or the data contained in the field. | None. |
| Number (Custom): format is customised to your choice. | <p>Decimal Places: the number of decimal places to display.</p> <p>Units: the number is displayed using the specified units. For example, if the number is 20,000 and the units are thousands, the number is displayed as 20K.</p> <p>Include separators: whether the number shows separators every thousand (example: 100,000 vs. 100000).</p> |
| Currency (Custom): format and currency symbol is customised to your choice. | Decimal Places: the number of decimal places to display. |

Units: the number is displayed using the specified units. For example, if the number is 20,000 and the units are thousands, the number is displayed as 20K.

Include separators: whether the number shows separators every thousand (example: 100,000 vs. 100000).

Percentage (Custom): numbers are displayed as a percentage with the percent symbol. The value of 1 is interpreted as 100% and 0 as 0%

Scientific (Custom): numbers are displayed in scientific notation.

Decimal Places: the number of decimal places to display.

Decimal Places: the number of decimal places to display.

Resize Tables and Cells

You can change the size of the rows, columns and cells that compose a table. The best way to resize your table depends on the view type and the table components you want to resize.

Use commands to resize rows and columns

1. From a worksheet in Tableau Desktop, Select **Format > Cell Size**.
From a worksheet in Tableau Cloud or Tableau Server, expand the Fit menu and select **Cell Size**.

2. Choose the **Taller**, **Shorter**, **Wider** or **Narrower** command. To quickly apply these commands, see [Shortcuts for resizing rows and columns \(Tableau Desktop\)](#) on page 3457.

For example, in the view below, we used the **Wider** and **Taller** commands to make the view more readable.

| | | Order Date | | | | | | | |
|-------------|---------|------------|----------|----------|----------|----------|----------|----------|----------|
| | | 2011 | | | | 2012 | | | |
| Segment | Region | Q1 | Q2 | Q3 | Q4 | Q1 | Q2 | Q3 | Q4 |
| Consumer | Central | \$6,116 | \$8,324 | \$30,149 | \$22,727 | \$6,759 | \$14,559 | \$13,726 | \$14,619 |
| | East | \$1,683 | \$14,985 | \$21,136 | \$38,700 | \$1,683 | \$14,985 | \$21,136 | \$38,700 |

| | West | \$2,397 | \$6,866 | \$8,241 | \$18,704 | \$2,249 | \$5,227 | \$6,576 | \$2,568 |
| Home Office | Central | \$2,249 | \$5,227 | \$6,576 | \$2,568 | \$545 | \$2,000 | \$750 | \$11,242 |
| | East | \$545 | \$2,000 | \$750 | \$11,242 | \$30,684 | \$665 | \$467 | \$5,035 |
| | South | \$30,684 | \$665 | \$467 | \$5,035 | \$5,013 | \$3,551 | \$6,744 | \$6,402 |
| | West | \$5,013 | \$3,551 | \$6,744 | \$6,402 | | | | |

Note: For a given field, all members will have the same width and the same height. You can't resize individual field members.

Manually resize rows and columns

To manually resize the widths or heights of row and column headers or axes:

1. Place your cursor over the vertical or horizontal border of a header or axis.
2. When you see the resize cursor , click and drag the border left and right or up and down.

Resize an entire table

You can increase or decrease the size of the entire table by selecting **Bigger** or **Smaller** on the **Cell Size** menu. For example, to increase the width of the columns and the height of the rows for the view shown below, you can select **Cell Size > Bigger**. This option increases both the width and height of the panes in a visually appropriate way. Notice that the size of the row headers increases horizontally when you resize the table.

Resize cells

Any table you can create in Tableau has the cell as its basic component. For a text table, the cell is what you would expect. It is the intersection of a row and a column, and is where the text is displayed.

However, depending on the view you construct, identifying the cell is not always possible or useful, such as in the case of a scatter plot.

Manipulating cells to enhance your data view is useful when dimensions are the inner fields on both the **Rows** and **Columns** shelves. In this case, there are two shortcuts you can select on the **Format > Cell Size** menu:

- **Square Cell** – Adjusts the view so the cell has a 1:1 aspect ratio. This results in a square cell, which is useful for heatmaps.
- **Text Cell** – Adjusts the view so the cell has a 3:1 aspect ratio. This is useful for text tables.

For example, you can see the text table below with **Square Cell** and **Text Cell** applied. **Text Cell** enforces a cell aspect ratio of 3:1 and results in a compact table that is easy to read.

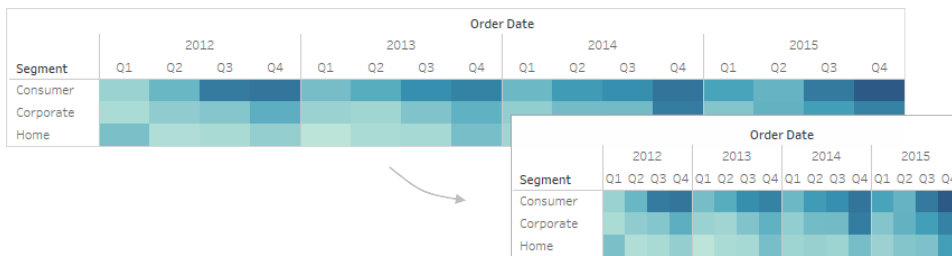

Square Cell

Text Cell

The left screenshot shows the Tableau interface with 'YEAR(Order Date)' on the Columns shelf and 'Segment' on the Rows shelf. The right screenshot shows a zoomed-in view of the resulting table.

| Segment | 2011 | 2012 | 2013 | 2014 |
|-------------|-----------|-----------|-----------|-----------|
| Consumer | \$266,097 | \$266,536 | \$296,296 | \$332,473 |
| Corporate | \$128,435 | \$128,757 | \$206,943 | \$242,011 |
| Home Office | \$89,716 | \$75,239 | \$105,235 | \$159,463 |

The heatmap shown below is modified by selecting **Square Cell** on the **Format > Cell Size** menu. This enforces a cell aspect ratio of 1:1 and results in a compact table that is easy to analyse. You can also use the **Size** slider on the **Marks** card to adjust the size of each mark.

After changing the cell size, you can use **Ctrl+B** and **Ctrl+Shift+B** to decrease or increase the table size while maintaining the cell aspect ratio. On a Mac, the keystrokes are **Command-B** and **Shift-Command-B**.

Define Table Structure

In addition to the standard formatting, there are some other settings that define the table structure. You can modify these settings by selecting **Analysis > Table Layout > Advanced** to open the Table Options dialog box. There you can specify the aspect ratio, the default number format, row and column attributes and the default label orientation for labels along the bottom of

the view. While these settings apply to the whole view, some can be overridden using the **Format** pane.

Set the aspect ratio

The aspect ratio refers to the ratio of the pane width to the pane height. You can choose to constrain the aspect ratio to a specified amount or not constrain it at all. An unconstrained axis range can be useful because it means that the axes don't have to be the same length.

Anytime you manually resize a row or column, you are unconstraining the aspect ratio. The aspect ratio setting only applies to views containing continuous axes on both the row and column shelves. Nominative axes are not affected by the aspect ratio settings.

Set the default number format

You can define the number of decimal places to appear by default for numbers in the view. If you select **Automatic**, Tableau automatically decides the number of decimal places based on the data in the field. If you select **Manual**, you can decide to show up to 16 decimal places.

Set row attributes

Select from the following row attributes:

- **Maximum levels of row labels:** determines the number of fields that can be added to the Rows shelf before the headers are combined on the same level.

For example, if you set Maximum levels of row labels to 3 and place 5 discrete fields on the Rows shelf, then the first, second and third row headers will appear in the same header, separated by commas (they will be combined at the same header level).

| Columns | | SUM(Sales) | | | | |
|---------------------------------------|---------------|---------------|--------|-------|------|-------------|
| Rows | | Customer Name | Region | State | City | Postal Code |
| Sheet 22 | | | | | | |
| State | City | Postal Code | | | | |
| Aaron Bergman, Central, Oklahoma | Oklahoma City | 73120 | | | | |
| Aaron Bergman, Central, Texas | Arlington | 76017 | | | | |
| Aaron Bergman, West, Washington | Seattle | 98103 | | | | |
| Aaron Hawkins, East, New York | New York City | 10035 | | | | |
| | Troy | 12180 | | | | |
| Aaron Hawkins, East, Pennsylvania | Philadelphia | 19134 | | | | |
| Aaron Hawkins, South, Mississippi | Gulfport | 39503 | | | | |
| Aaron Hawkins, West, California | Los Angeles | 90004 | | | | |
| | San Francisco | 94109 | | | | |
| | | 94122 | | | | |
| Aaron Smayling, Central, Texas | Austin | 78745 | | | | |
| Aaron Smayling, East, New York | New York City | 10035 | | | | |
| Aaron Smayling, South, North Carolina | Jacksonville | 28540 | | | | |
| Aaron Smayling, South, Virginia | Arlington | 22204 | | | | |
| Aaron Smayling, West, California | Pasadena | 91104 | | | | |
| | San Francisco | 94110 | | | | |

In this example, Customer Name, Region, State, City and Postal Code are the 5 discrete fields on the Rows shelf. Maximum levels of row labels is set to 3. In the resulting view, Customer Name is combined with Region and State in the first column.

- Maximum levels of horizontal row labels: determines the number of fields that can be placed on the Rows shelf before headers are automatically oriented vertically rather than horizontally when the table doesn't fit the view.

Set column attributes

Select from the following column attributes:

- **Maximum levels of column labels:** determines the number of fields that can be placed on the Columns shelf before Tableau begins to combine the labels. For example, if you set Maximum levels of column labels to 8 and place 9 discrete fields on the Columns shelf, then the first and second column headers will appear in the same header, separated by a comma (they will be combined at the same header level).
- **Show innermost level at bottom of view when there is a vertical axis:** displays the innermost level of column headers at the bottom of the view (as opposed to the top) when a vertical axis is added to the view.
- **Default orientation of labels at bottom of view:** determines whether labels at the bottom of the view are oriented horizontally or vertically by default. You can toggle between the horizontal and vertical options by pressing Ctrl + L on your keyboard (Command-L on a Mac).

Create Custom Colour Palettes

Tableau Desktop comes with colour palettes that have been carefully designed to work well together and effectively apply colour to data in many situations, such as on maps, heatmaps, bar charts, etc. You can also create and use your own custom colour palettes by modifying the **Preferences.tps** file that comes with Tableau Desktop. For example, you can create a custom categorical palette that matches your company's brand.

About the preferences file

You can add as many custom palettes as you like to your **Preferences.tps** file, each with as many colours as you want. Although there isn't a limit to how many colours can be added to each custom palette, the Edit colours dialog box only shows 20 colours. If you need to manually assign more than 20 colours to data items, you may want to create several custom palettes with 20 or fewer colours in each palette.

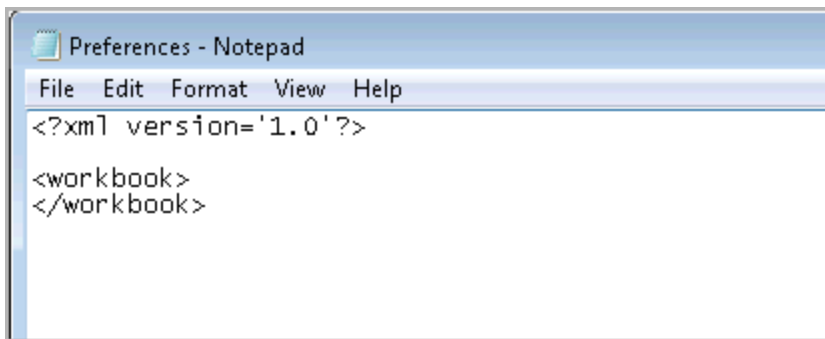

When you modify **Preferences.tps** to add colours, use the standard HTML format for the new colours (hex code #RRGGBB or Red Green Blue format). When you save the workbook and restart Tableau Desktop, the colour palette names you added to **Preferences.tps** appear in the **Select Colour Palette** drop-down list (Edit Colour dialog). You can use a custom palette like you would any other.

Tableau doesn't test or support custom colour palettes, so be sure to back up your workbooks before you continue. Also, there is no guarantee that custom colour palettes you create will work with future Tableau Desktop upgrades.

Note: When you edit your **Preferences.tps** file, be sure to use straight quotation marks (' ' or " ") to delimit the palette name and type, not curly quotation marks (" " or ' ').

Edit the preferences file

The **Preferences.tps** file is located in the My Tableau Repository folder that is created when you install Tableau Desktop, likely located in Documents. The preferences file is a basic XML file that you can open in a text editor to modify. An unedited preferences file looks like this:

To edit your preferences file:

1. Go to the My Tableau Repository folder in your Documents directory, and open the **Preferences.tps** file with a text editor.
2. Between the opening and closing `workbook` tags, insert opening and closing `preferences` tags so that it looks like this:

```
<?xml version='1.0'?>
<workbook>
<preferences>
</preferences>
</workbook>
```

Note: If your **Preferences.tps** file already has preferences tags, you don't need to add them again.

3. Follow one of the next procedures to create a custom colour palette by inserting `color-palette` tags between the `preferences` tags. For example:

```
<?xml version='1.0'?>
<workbook>
<preferences>
<color-palette name="MyColors" type="regular">
<color>#1e4c56</color>
<color>#cba94b</color>
</color-palette>
</preferences>
</workbook>
```

Colour palettes can be categorical (`type="regular"`), sequential (`type="ordered-sequential"`) or diverging (`type="ordered-diverging"`).

4. To add more palettes, insert another set of `color-palette` tags.

```
<?xml version='1.0'?>
<workbook>
<preferences>
<color-palette name="MyColors" type="regular">
<color>#1e4c56</color>
<color>#cba94b</color>
</color-palette>
<color-palette name="MoreColors" type="regular">
<color>#ffe96f</color>
<color>#799a0d</color>
</color-palette>
</preferences>
</workbook>
```

5. You must restart Tableau Desktop to see the new colour palettes.

Create a categorical palette

A categorical colour palette contains several distinct colours that can be assigned to discrete dimension members. For example, when you put a discrete dimension such as **Region** on the **Colour** card, the categorical colour legend is used.

In the preferences file, a categorical palette is `type="regular"`.

Build a custom categorical colour palette

The following is an example of what to add between the `preferences` tags to add a categorical colour palette. Note that the `type` attribute is specified as `regular`, which identifies this palette as a categorical palette.

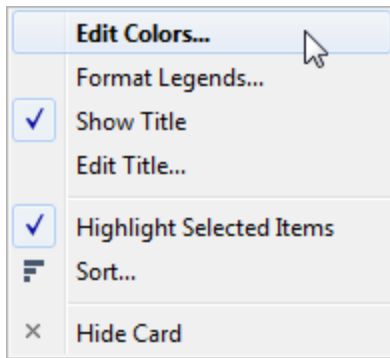

To create a custom categorical colour palette:

1. In the **Preferences.tps** file, between the 'preferences' tags, paste the following. Be sure to use straight quotation marks, not curly quotation marks, to delimit the name and type of palette.

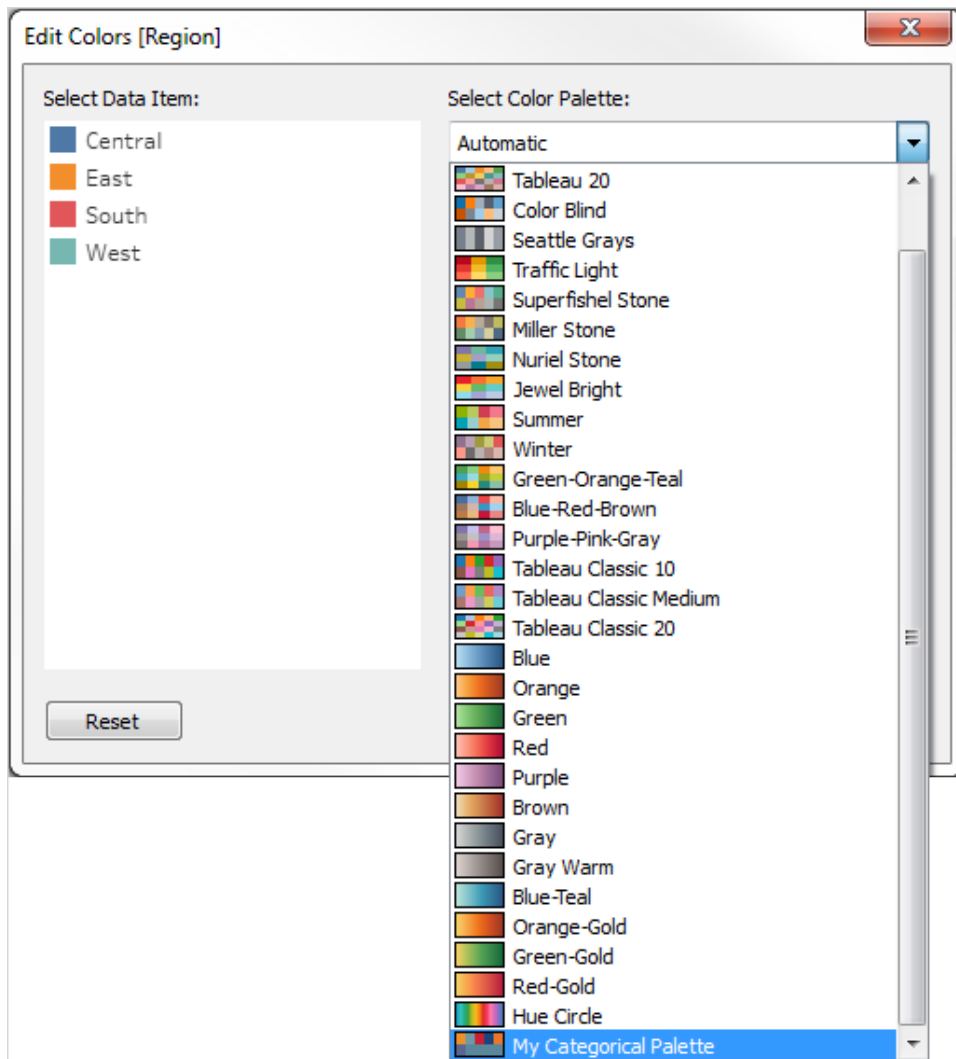

```
<color-palette name="My Categorical Palette" type="regular">
<color>#eb912b</color>
<color>#7099a5</color>
<color>#c71f34</color>
<color>#1d437d</color>
<color>#e8762b</color>
<color>#5b6591</color>
<color>#59879b</color>
</color-palette>
```

2. Save the **Preferences.tps** file and then restart Tableau Desktop.
3. Open a data source, such as the **Superstore - Sample** data source.
4. From the **Data** pane, drag a discrete dimension, such as **Region**, to **Colour**.

5. Click the colour legend menu arrow and select **Edit Colours**.

6. In the Edit Colours dialog box, from the palette drop-down list, select your new custom palette.

7. Click the **Assign Palette** button to assign the custom colours to each respective field.

8. Click **OK**.

Create a sequential palette

Another type of palette is the sequential colour palette. This type of colour palette is used for continuous fields, typically for measures. Typically, a sequential palette shows a single colour, varying in intensity.

You must specify at least the two end colours in the sequential colour range. Tableau will extrapolate the shades in between.

Build a custom sequential colour palette

The following is an example of what to add between the `preferences` tags to add a sequential colour palette. Note that the `type` attribute is specified as `ordered-sequential`, which identifies this palette as a sequential palette.

To create a custom sequential colour palette:

1. In the **Preferences.tps** file, between the `preferences` tags, paste the following. Be sure to use straight quotation marks, not curly quotation marks, to delimit the name and type of palette.

```
<color-palette name="My Sequential Palette" type="ordered-sequential">
```

```
    <color>#eb912b</color>
    <color>#eb9c42</color>
    <color>#ebad67</color>
    <color>#eabb86</color>
    <color>#eacba8</color>
    <color>#ebd8c2</color>
  </color-palette>
```

2. Save the **Preferences.tps** file and then restart Tableau Desktop.
3. Open a data source, such as the **Superstore- Sample** data source.

4. From the **Data** pane, drag a measure (such as **Sales**) to **Colour**.
5. Click the colour legend menu arrow, and select **Edit Colours**.
6. In the Edit Colours dialog box, from the palette drop-down list, select your custom palette.
7. If you want each colour gradation to be defined within a box, select the **Stepped Colour** check box, and in the **Steps** text box, type the number of colour steps you want to display in the bar.
8. Click the **Advanced** button.
9. Select the **Start** check box, and in the text box, type the low end number you want for the continuum.
10. Click the **Apply** button to see the result, and make adjustments as needed. The colour will range from high to low intensity (or the reverse) based on the order you specify in the **Preferences.tps** file. The default for sequential colour palettes in Tableau is to make the high end of the continuum intense and the low end pale, though selecting the **Reversed** check box will do the opposite.

Create a diverging colour palette

The third type of colour palette is a diverging colour palette. Instead of a gradient from one extreme to the other, a diverging palette is like two sequential palettes that share a colour in the

middle but have different extremes. This type of palette shows two ranges of values using colour intensity (how dark or light) to show the magnitude of the number, and the actual colour (orange or blue) to show which range the number is from. Diverging palettes are most commonly used to show the difference between positive and negative numbers.

Build a custom diverging colour palette

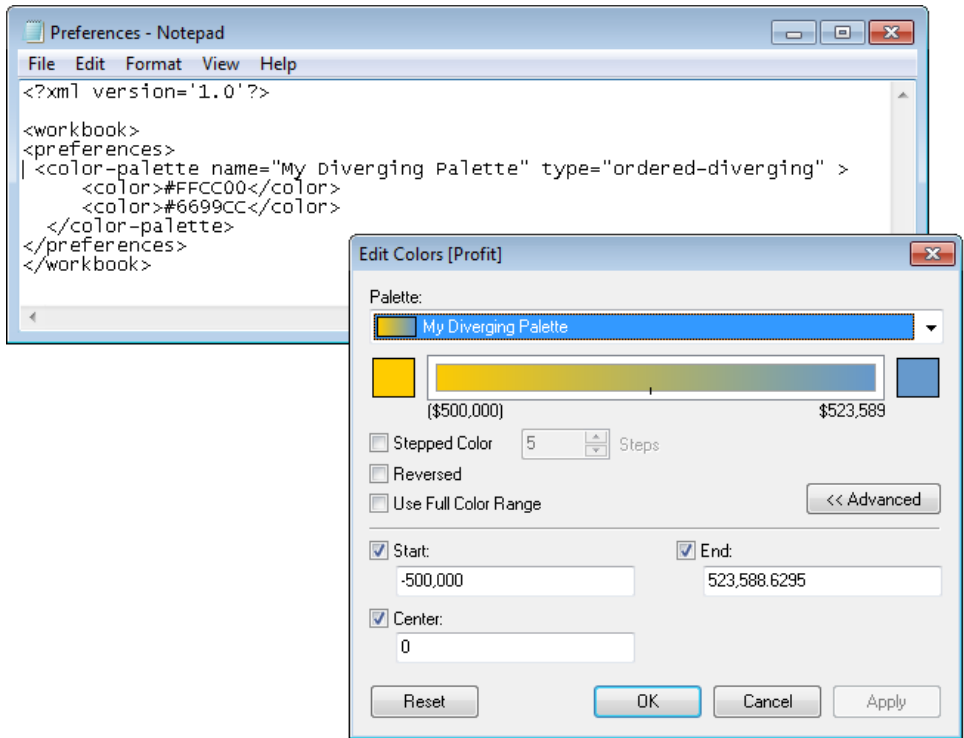

The following is an example of what to add between the `preferences` tags to add a diverging colour palette. Note that the `type` attribute is specified as `ordered-diverging`, which identifies this palette as a diverging palette.

To create a custom diverging colour palette:

1. In the **Preferences.tps** file, between the `preferences` tags, paste the following. Be sure to use straight quotation marks, not curly quotation marks, to delimit the name and type of palette.

```
<color-palette name="My Diverging Palette" type="ordered-diverging">
<color>#eb912b</color>
<color>#59879b</color>
</color-palette>
```

2. Save the **Preferences.tps** file and then restart Tableau Desktop.
3. Open a data source, such as the **Superstore - Sample** data source.
4. Click the **Assign Palette** button. The colours in the palette are used in the order they appear in the Preferences file.

Use discontinued (classic) colour palettes

In version 10.0, Tableau created new colour palettes, updated some existing ones (such as Tableau 10 and Tableau 20), and discontinued others. If you want to keep using a colour palette that was discontinued, you can edit your **Preferences.tps** file to add the hex values for the palette. You can add as many colour palettes as you like.

Hex values for discontinued colour palettes

The table below lists discontinued colour palettes, along with the XML code and hex values you can use in your **Preferences.tps** file to restore them. If you use the code as-is, palette names will start with **Classic** to indicate that they're from before version 10.0. In many cases, there are updated versions of colour palettes that have been discontinued.

| Version 9.x palette name | Version 9.x HEX Values |
|-----------------------------|---|
| Tableau 10 | <code><color-palette name="Classic 10" type="regular"></code> |

| | |
|---|--|

Use Custom Formatting Themes

Tableau comes installed with many formatting options so that you can customise your visualisations and dashboards to suit your needs. If you use the same formatting for many workbooks, or if you have special fonts and colours that work better for your business, you can use a custom formatting theme to save time. Custom themes quickly apply your formatting choices to the entire Tableau workbook.

You can add a custom theme to your Tableau workbook by importing a JSON file that specifies your formatting choices. Likewise, if you're viewing a workbook and you want to use the same theme on another workbook, you can export the custom theme file.

Note: This feature is available only in Tableau Desktop 2025.1.

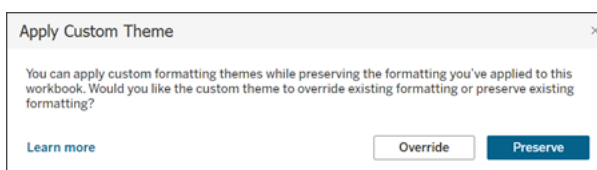

Import a custom theme

1. Open Tableau Desktop and create a worksheet.
2. From the toolbar, select **Format**.
3. Select **Import Custom Theme...**

4. Select a JSON file to import and select **Open**.

A dialog appears with options to **Override** or **Preserve** any existing formatting edits that you've made.

You can choose to have the custom theme override all formatting changes made to your Tableau workbook before importing the custom theme. You can also choose to keep changes made through the formatting pane before importing the custom theme.

Note: If you choose to have the custom theme override existing formatting edits, it will only override style changes that you have included in the JSON file. It also will not override style changes made through the rich text editor.

Override: The custom theme file will override any formatting done to your Tableau workbook.

Preserve: The custom theme file will preserve any formatting done to your Tableau workbook.

5. Select **Override** or **Preserve**.

Your custom theme imports and applies formatting to your workbook.

Export a custom theme

You can export a custom theme in two ways: You can export the custom theme file, or you can export a workbook with a custom theme applied. When you export a theme, the export file includes the formatting choices made on the worksheet you selected. For example, if you have different formatting choices on two different worksheets within a workbook, the custom theme file you export will reflect the formatting choices on the worksheet you selected when you exported the file. Only style elements that are supported and present in the custom theme file will be exported.

Export a JSON file that contains a custom theme

1. From the toolbar, select **Format**.

2. Select **Export Custom Theme...**

3. Navigate to the folder where you'd like to save the custom theme file and press **Save**.

You can now find the custom theme file locally. This theme file can be imported to and used with other workbooks.

Export a workbook with a custom theme applied

1. From the toolbar on a worksheet, select **File** and then choose **Save As**.
Alternatively, you can select **Export Packaged Workbook**.
2. Save the workbook as a .twb or a .twbx file.

When you reopen the workbook in Tableau, the custom theme will be applied.

Create the JSON theme file

A JSON file is where the styles in your custom theme are defined. You can create a file using your favourite text editor, making sure to include the style elements you want for your custom theme. Use the example file as a template for creating your file.

There are many third-party resources that can help you validate your file, such as <https://www.jsonschemavalidator.net>.

Copy the JSON schema file needed to validate your theme file [here](#).

Elements to include in the custom theme file

Your custom theme file should contain a version, base theme, style elements, style attributes and formatting choices.

Version

The first line of the custom theme file should contain the version. As of Tableau 25.1, the version number is 1.0.0, and the line should look like this: "version": "1.0.0".

The version number may be updated in future versions of Tableau.

Base-theme

The second entry of the custom theme file should contain the base-theme. The base theme corresponds to existing workbook themes available in Tableau and is based on different versions of Tableau Desktop. Any formatting styles specified in the JSON theme file will be applied on top of the base theme.

| Base theme | Corresponds with | Entry in the theme file |
|------------|---|-------------------------|
| Smooth | Tableau Desktop Versions 10.x and newer | "base-theme": "smooth" |
| Clean | Tableau Desktop Versions 8.0.x – 9.3.x | "base-theme": "clean" |
| Modern | Tableau Desktop Versions 3.5 – 7.0. | "base-theme": "modern" |
| Classic | Tableau Desktop Versions 1.0 – 3.2 | "base-theme": "classic" |

For more information on workbook themes, see [Upgrade or change your workbook theme \(Tableau Desktop only\)](#) on page 2925

Style elements

The style elements specify at what level the formatting choices will be applied. For example, all fonts, filter titles or just tooltip fonts. See the style elements table for a list of available elements to specify.

Style attributes

The style attributes specify the part of the style element that you'd like the formatting choices to be applied to. For example, font-color and font-size for the All style element.

Be sure to check the list of attributes for the style element you're using. For example, while the highlighter style element supports a background colour style attribute, the highlighter-title element does not.

Formatting choices

The formatting choices specify what you'd like to apply to the style element and style attribute. For example, a font colour, font family and font size. The formatting choice must be entered as a string or an integer, depending on the style attribute. Colours must be entered as a hex colour code, such as #FF0000.

A **string** input type contains text.

An **integer** input type contains whole numbers.

Example custom theme file

```
{  "version": "1.0.0",
  "base-theme": "smooth",
  "styles": {
    "all": {
      "font-color": "#d16302",
      "font-family": "Tableau Bold"
    },
    "worksheet": {
      "font-color": "#d16302",
      "font-family": "Tableau Bold",
      "font-size": 14
    },
    "worksheet-title": {
      "font-color": "#d16302",
      "font-family": "Tableau Bold",
      "font-size": 14
    },
    "view": {
      "background-color": "#ffb370"
```

```

    }
  }
}

```

Style elements supported with custom themes

This table contains a list of supported style elements and their corresponding supported style attributes. While not all style elements available in Tableau are currently supported for custom themes, we will be adding more style elements in future releases. When you import a custom theme file, its style elements will apply to all worksheets in the workbook.

| Style Element | Description | Style Attributes | Input Type | Formatting Choice |
|-----------------|---|------------------|------------|---|
| all | Formats all fonts across the entire workbook. | font-color | String | String that follows the format of a hex colour code, such as #FF0000. |
| | | font-family | String | String with a maximum length of 50 characters. |
| worksheet | Formats the worksheet default font. | font-color | String | String that follows the format of a hex colour code, such as #FF0000. |
| | | font-family | String | String with a maximum length of 50 characters. |
| | | font-size | Integer | Integer with a minimum value of 1 and a maximum value of 99. |
| worksheet-title | Formats the work- | font-color | String | String that follows the |

Troubleshoot importing custom theme files

Some of my style elements aren't applied

Invalid font type

Fonts can only be displayed if they come installed with Tableau or if the font is present in your environment.

Formatting was applied through the rich text editor

If you've applied formatting updates through the rich text editor rather than through the formatting pane, the formatting will remain if you've chosen to override existing formatting when applying the custom theme. This happens because of the style system formatting.

Can't import the theme file

The theme file contains an error

The error message will give you the location of the error (for example, font colour). Locate the style element in the style element table and make sure your entry in the style element matches the input type guidelines. For example, colours are string data types and must follow the formatting of a hex colour code, such as #FF0000.

There are many third-party resources that can help you validate your theme file, such as <https://www.jsonschemavalidator.net>.

Copy the JSON schema file needed to validate your theme file [here](#).

The theme file size is too large

The maximum allowed file size is 15000 bytes (or 15 KB). Reduce the file size and try again.

The theme file path is too long

The file path can't exceed 256 characters in length. Reduce the length of the file path and try again.

The theme file name contains invalid characters

The file name can only contain alphanumeric characters, dots, dashes, spaces and underscores. Remove any invalid characters in the file name and try again.

Optimise Workbook Performance

When we mention *performance*, we mean the speed with which you can work in Tableau. It might mean the speed of data analysis, such as working in Tableau Desktop on a large corporate database that you are accessing remotely. Or, it could refer to the speed of loading views or dashboards that you access on your desktop from Tableau Server.

If you are working with small data volumes, many of the recommendations in this section are optional for you. Your workbook performance is probably as speedy as you expect. But if you work with hundreds of millions of records, designing an efficient workbook is critically important to the speed at which you can work. We recommend that you review the topics and tips in this section before you start building your first view.

Making performance improvements almost always means making trade-offs. For example: Do you sacrifice speed to make sure you have the most current data? Is it important to include *all* the data for analysis, or will a speedier subset do? The bigger and more complicated the data, the longer it takes to interpret and render. But there are things you can do to accelerate the process. Think of fine-tuning your workbook performance as working on a puzzle with multiple pieces. Pick and choose from the topics in this section to find the pieces that solve your particular puzzle.

The topics in this section on performance discuss the big picture and then drill down to specific functionality. It starts with databases, data and extracts, and then focuses on things that affect your data source, your workbooks, your calculations and visualisations. The next set of topics discuss how to record and analyse workbook performance. Finally we look at how to reduce upload times to a Tableau server.

[Designing Efficient Workbooks](#) whitepaper on [tableau.com](#)

[Designing Efficient Workbooks](#) (1 hour) and [Best Practices for Dashboard Performance](#) (50 minutes) free, video presentations

[The Tableau Performance Optimisation Flowchart](#), [The Tableau Performance Checklist](#) and the [Tableau Performance Checklist blog series](#) on the [InterWorks blog](#).

General tips

This general list of considerations is a start in learning how to approach optimising workbooks. It comes from the TL;DR page in the [Designing Efficient Workbooks](#) whitepaper.

- The cleaner your data is and the better it matches the structure of your questions, the faster your workbooks will run and the happier your life will be. Only connect to the data that you need for analysis.
- Extracts are a quick and easy way to make most workbooks run faster. If you don't need real-time data and aren't working over billions of rows of data, you should try them.
- The majority of slow dashboards are caused by poor design – in particular, too many charts on a single dashboard, or trying to show too much data at once. Keep it simple. Allow your users to incrementally drill down to details, rather than trying to show everything then filter (guided analysis).
- Don't work with data you don't need – both in terms of the fields you reference as well as the granularity of the records you return. Use filters, hide unused fields and aggregate.
- While reducing the data, make sure you use filters efficiently.
- Strings and dates are slow, numbers and Booleans are fast.
- There is no silver bullet for inefficient workbooks. Start by looking at the performance recorder to understand where the time is going. Long-running queries? Lots of queries? Slow calculations? Complex rendering? Use this insight to focus your efforts in the right direction.
- Upgrading to the newest version may boost performance without needing anything else.
- If it is slow in the data source, it will be slow in Tableau Desktop. If it is slow in Tableau Desktop, it will (almost always) be slow in Tableau Server.
- Performance tuning is highly individualised to the context of your environment, data, analysis and workbook. What works in one situation may not work in another test and iterate to see what works in your specific case.

Workbook Optimiser

The Workbook Optimiser is a tool that identifies whether a workbook follows certain performance best practices. These guidelines are limited to what can be parsed from the workbook's metadata and evaluated by a rules engine algorithm. Not all of its recommendations are applicable to or

appropriate for every workbook. There are many aspects of performance that aren't captured by the Optimiser, some of which can offer easy wins. For more information, refer to [Streamline your workbook](#) on page 3059 and the whitepaper [Designing Efficient Production Workbooks](#).

Run the Workbook Optimiser

In Tableau Desktop

The Workbook Optimiser is available from the Server menu or the publishing dialog.

1. From the **Server** menu, click **Run Optimiser**.
2. The workbook is automatically evaluated against the guidelines, and results display in one of three categories: Take action, Needs review or Passed (or Passed and ignored).
 - You may see fewer than three categories. If no guidelines fall into a category, it doesn't display.
 - Expand each category to see the guidelines. You can also expand each guideline for more information about why it's a recommendation. Some have additional information specific to your workbook.
 - You can choose to address any or none of the guidelines. As running the Optimiser is a voluntary step in the publishing process, it doesn't prevent you from being able to publish.
3. To close the dialog and go back to the workbook, click Close.
4. To close the dialog and go back to (or open) the publishing dialog, click Publish.

In web authoring

The Workbook Optimiser is available from the publishing menu and publishing dialog in web authoring.

Optimiser categories

The Optimiser breaks down its guidelines into three categories: take action, needs review and passed.

Take action indicates that updating the workbook to follow these best practices has minimal to no impact on the functionality of the workbook. There's probably no reason to avoid making these changes.

Needs review indicates that following these best practices may involve modifying the workbook in more involved ways, such as restructuring a data source or simplifying a dashboard.

- For these guidelines, use your best judgement to determine what is possible or practical to address.
- Some recommendations may involve a lot of effort for minimal performance gain and aren't worth it.
- It may be useful to use the Performance Recorder to get a performance benchmark.
- Some may be deliberate choices you've made.

As the author, you're the final authority on what makes a workbook as efficient as possible.

Remember that some best practices should be broken to effectively deliver content. Always weigh the goal of the workbook against changes to improve performance.

Passed indicates the guidelines are met and the workbook is already following best practices in that area. But remember, there are many aspects of performance that aren't captured by the Optimiser. This category is renamed **Passed and ignored** if any guidelines are ignored for the workbook.

Ignore a guideline

Guidelines aren't always applicable to your situation. Perhaps you're publishing a template workbook for others to use and need to preserve unused fields and data sources. You don't want the optimiser to continue to notify you about those guidelines.

It's possible to ignore a guideline for a workbook.

1. From a specific guideline, click the **Ignore** button.
 - The guideline is muted and moves to the **Passed and ignored** section. Even if you run the optimiser again, that guideline won't appear in the Take action or Needs review section.
2. To resume evaluating the guideline, find its row in the **Passed and ignored** section and click the **Ignore** button again.
 - The optimiser runs again and the guideline is evaluated. It continues to be checked each time the optimiser runs.

Autofix a guideline

Some suggestions from the workbook optimiser can be implemented without user input. For these guidelines, there's a button to autofix the rule. If the button doesn't appear you must manually address the issue.

From a specific guideline, click the Autofix button.

- The recommended action (such as closing an unused data source) is taken behind the scenes and the guideline moves to the Passed section.
- If the autofix fails for any reason, you'll be notified and prompted to resolve the issue manually.
- If the button isn't available, that guideline cannot be autofixed and must be addressed manually.

The guidelines

Every guideline contains a “consider” statement that suggests a potential way to address the performance impact. These are necessarily general and may not apply in every situation. These suggestions are a starting point only; always frame your decisions in the context of your environment and the goals of your workbook.

Note: Not all suggestions are possible to perform in the browser and may require [editing in Tableau Desktop](#) instead.

Navigate to a guideline by letter: [A](#) . [B](#) . [C](#) . [D](#) . [E](#) . [F](#) . [G](#) . [H](#) . [I](#) . [J](#) . [K](#) . [L](#) . [M](#) . [N](#) . [O](#) . [P](#) . [Q](#) . [R](#) . [S](#) . [T](#) . [U](#) . [V](#) . [W](#) . [X](#) . [Y](#) . [Z](#)

Calculation length

From the Workbook Optimiser

Sample output message: The calculation **My calculation** is 600 characters long

Computing the results of complex calculations can impact performance.

Consider breaking the calculation apart and moving whatever is possible to the database, or using Tableau Prep to create the calculations prior to analysis.

Additional information

Complex and long calculations can either be written in a single calculation or nested (with some components written as stand-alone calculations that are used in the larger calculation). Building a calculation with nested components may make it easier to troubleshoot and maintain, but it can add complications and additional processing. If possible, pushing these components back to the data source may aid performance.

Comments in calculations count against the length, so this guideline may be triggered by a long comment rather than a long and complex calculation.

Calculation uses multiple data sources

From the Workbook Optimiser

Sample output message: The data source **Supply Chain** includes 17 calculations using fields from another data source.

When calculations use fields from multiple data sources, Tableau can't use any optimisations and must compute the calculation locally.

Consider using Tableau Prep to create the calculation and using an extract.

Additional information

By moving the cross-database calculation to the data layer, the processing can be performed before the user even requests the dashboard. See [Join your data \(Prep\)](#) and [Create level of detail and rank calculations](#) for more information.

Under some conditions, a parameter may trigger this guideline. If a calculation is indicated that doesn't use multiple data sources, check to see if it has a parameter and if that parameter can be simplified.

Dashboard size not fixed

From the Workbook Optimiser

Sample output message: The dashboard **Q3 analytics** isn't fixed-size.

Fixed-sized dashboards can be cached because they're a predictable size. Using automatic dashboard sizing means the results depend on the user's screen, and therefore the dashboard must be rendered every time. Rendering dashboards more often comes with a performance hit.

Consider using fixed dashboard sizing.

Additional information

Although responsive elements are a best practice in web design, letting your dashboard resize can distort the layout of the content in addition to the performance impact of re-rendering. For Tableau visualisations, it's best to use a [fixed dashboard size](#) and use [device-specific dashboards](#) to support different devices and screen sizes.

Filter uses conditional logic

From the Workbook Optimiser

Sample output message: The filter **Sample Type** uses conditional logic.

Dimension filtering can be done in various ways, such as on a list of values, by wildcard matching or using conditional logic. Conditional logic can be slow.

Consider changing the filter to not use conditional logic. If necessary, make sure your logic tests for the most frequent outcome first and use ELSEIF or CASE when possible.

Additional information

For more information on filtering, see [Filter Your Data](#).

Filter uses "Only Relevant Values"

From the Workbook Optimiser

Sample output message: The filter **Sample Type** uses "Only Relevant Values".

When a filter uses "Only Relevant Values", the interactive filter control only shows options that are applicable given the current state of the view. Every time a change is made to other filters, the list of values to be displayed must be requeried, which has a performance impact.

Consider using dashboard filter actions instead. If the end-user benefit is valuable enough that this feature should be used, consider extracting the data and optimising the extract.

Additional information

There are situations where using "Only Relevant Values" is necessary to avoid an unwieldy filter list. Instead of using interactive filters in that situation, try using [action filters](#). For example, consider a dashboard that has cascading filters for Category, Sub-Category and Product ID, where Product ID is set to show "Only Relevant Values". Removing that restriction would expand the list of products significantly. Rather than using filters, you can build simple visualisations (such as a bar chart of Category and Sub-Category) and use it as a filter. The user clicks on a bar and the action filter is applied to the rest of the visualisations on the dashboard. For more information, see [Dashboard Actions](#).

Live data connections

From the Workbook Optimiser

Sample output message: The data source **Supply Chain** isn't an extract.

Tableau extracts are designed to be as efficient as possible for use with analytics. Using extracts is one of the easiest ways to improve performance due to the data source. Extracts also have many native features for optimisation.

Consider extracting the data source.

Additional information

In some instances, taking an extract may put undesirable strain on the Tableau Server or Tableau Site's resources. Work with your Tableau administrator to determine the best course of action.

The whitepaper [Designing Efficient Workbooks](#) has extensive information about extracts and how to use them for performance. (You may need to sign in to access the whitepaper.)

Multiple connections in a data source

From the Workbook Optimiser

Sample output message: The data source **Supply chain** uses multiple data connections.

Data sources that include multiple connections can't be computed locally.

Consider combining the data sources in Tableau Prep and using an extract for analysis.

Additional information

See [Join your data \(Prep\)](#) for more information.

Nested calculations

From the Workbook Optimiser

Sample output message: The calculation **My Calculation** references another calculation.

Nesting calculations can add complications and additional processing, especially with IF statements and other performance-intensive functions.

Consider pushing the calculations to the data source or materialise them in an extract.

Additional information

This rule may be triggered for a calculation that isn't in the viz itself but is referenced by a calculation in the viz. For example, imagine four fields:

1. **Points earned** (a field in the data source)
2. **Quiz score** = [Points earned]*10
3. **Curved grade** = [Quiz score]*1.05
4. **Letter grade** = IF [Curved grade] >= 90 THEN "A" ELSEIF [Curved grade] >= 80 THEN "B" ELSEIF [Curved grade] >=70 THEN "C" ELSEIF [Curved grade] >=60 THEN "D" ELSE "F" END

Quiz score is a non-nested calculation that only references a field. Both **Curved grade** and **Letter grade** are nested calculations because they contain references to other calculations. Even if only **Letter grade** is used in the viz, **Curved grade** also triggers the nested calculation rule because it's in use inside **Letter grade**.

For more information on materialising calculations in an extract (Compute Calculations Now), see [Materialise Calculations in Your Extracts on page 947](#).

For more information about building calculations in Tableau Prep, see [Calculations in Tableau Prep](#).

Non-materialised calculations

From the Workbook Optimiser

Sample output message: The data source **Supply Chain** hasn't been pre-computed.

Computing the results of a calculation can impact performance.

Consider pushing calculations to the data source when possible. If using an extract, materialise calculations to pre-compute their results.

Additional information

Pre-compute the data and calculations either in an extract or your back-end data source. By moving this additional processing to the data layer, the processing is completed before the user even requests the dashboard.

Taking an extract of your data often boosts performance, though there are trade-offs in data freshness and some functionality. See [Extract Your Data on page 925](#) for more information about options for extracts and [Materialise Calculations in Your Extracts on page 947](#) for more information on materialising calculations.

Extract your data: Right-click on the data source's name at the top of the Data pane and select **Extract Data**. In the configuration dialog, choose **Compute Calculations Now**.

Number of data sources

From the Workbook Optimiser

Sample output message: The workbook contains 17 data sources.

Each data source contributes to the amount of time Tableau spends loading and rendering a workbook.

Consider combining data sources if possible, especially when the level of granularity is the same or they support the same analysis.

Additional information

See [Relate Your Data on page 628](#) for more information on combining data sources, or consider using Tableau Prep.

However, be wary of over-combining data sources. Workbooks perform best when each type of analysis is built off a well-designed data source. If it's hard to combine your data sources, this could be a sign that the analysis should be split into multiple workbooks, each with a more targeted purpose.

To split your analysis across multiple workbooks, try one of these methods:

- Save a copy of the workbook and delete unnecessary sheets, dashboards and data sources from each one. See [Streamline your workbook](#) for more information.
- Copy specific sheets into a new workbook. This may be more efficient because copying a dashboard into a new workbook carries over only what is needed for that dashboard.

However, not all formatting options are transferred. See [Copying Information Between Workbooks on page 3103](#) for more information.

Number of filters

From the Workbook Optimiser

Sample output message: The sheet **Classroom Distribution** contains 17 filters.

Excessive filters on a view create a more complex query.

Consider reducing the number of filters and using filter actions wherever possible. Not all types and formats of filters are created equal in terms of performance, so consider optimising necessary filters.

Additional information

The whitepaper [Designing Efficient Production Workbooks](#) has an entire section on filters that goes into much more detail. In brief:

- Reduce the overall number of filters
- Filters applied to multiple worksheets trigger multiple queries with every change
- Limit use of **Show only relevant values**. Using an extract helps optimise this feature if it's needed.
- Avoid high cardinality include/exclude filters
- Use the **Apply** button to prevent multiple refreshes as the user interacts with the filter
- Filter on fields that are present in the view
- Use continuous date filters rather than discrete date filters
- Context filters shouldn't be used purely to boost performance

Filter actions are an efficient way to guide the user through a dashboard. See [Filter Actions on page 1396](#) for more information.

Number of layout containers

From the Workbook Optimiser

Sample output message: The dashboard **Q3 analytics** contains 42 layout containers.

Layout containers can complicate dashboard rendering.

Consider removing unnecessary layout containers and simplifying the dashboard design.

Additional information

For more information about layout containers and the Layout pane, see [Group items using layout containers on page 2734](#).

Number of LOD calculations

From the Workbook Optimiser

Sample output message: The workbook contains 42 LOD calculations.

Computing the results of complex calculations can impact performance. Often, LODs are used on the fly to address issues of granularity in the data source that could be handled prior to analysis.

Consider tailoring the data source to the analysis to avoid the need for as many LODs.

Additional information

Level of Detail calculations are powerful tools, but they're expensive. Make sure you're only using them when necessary.

Production databases are designed to handle significant query loads and are a great option for moving processing out of Tableau. FIXED LOD calculations can sometimes be performed by the database. Tableau Prep also supports FIXED LOD calculations. See [Create level of detail and rank calculations](#) for more information.

Number of views in a dashboard

From the Workbook Optimiser

Sample output message: Dashboard **Q3 analytics** contains 17 views

A dashboard must load all elements before it can be displayed. The more views a dashboard contains, the longer it takes to load. Although it often involves a redesign, reducing the number of views in a dashboard is often the best way to boost its efficiency.

Consider streamlining the dashboard to be as effective and simple as possible by reducing the number of views, filters and other elements. Start with anything that can be removed immediately. See [Streamline your workbook](#) for other ways to reduce clutter in your dashboard

Additional information

If a more substantial redesign is needed, remember that not all views have an equal impact on performance. Focus on sheets with the most marks, filters or other complexity. A good strategy can be to limit the initial dashboard to summary information and only provide more details when the user requests them. There are many strategies for this sort of guided drill-down, including:

- Use action filters. See [Filter Actions on page 1396](#) for more information.
 - Hide detailed views in a container using a layout container with a show/hide button. See [Show and hide objects by clicking a button on page 2701](#) for more information.
 - Break the dashboard into multiple dashboards and use navigation buttons. See [Detailed options for Navigation and Download objects on page 2700](#) for more information
-

Number of workbook sheets

From the Workbook Optimiser

Sample output message: The workbook contains 42 visible sheets

The overall size of a workbook impacts how long it takes to be processed and displayed. All visible sheets must be loaded before Tableau can display a workbook or view. Reducing the number of sheets can help speed up load time.

Consider reducing the number of sheets in the workbook by closing unneeded sheets, hiding sheets that are used in a dashboard or splitting the analysis into multiple workbooks.

Additional information

Delete sheets that aren't necessary for the analysis: right-click on the sheet tab along the bottom of the workbook and select Delete.

Hide sheets in use: Worksheets used in a dashboard or story can't be deleted, but they can be hidden. See [Manage Sheets in Dashboards and Stories on page 2812](#) for more information.

- Hide all a dashboard's sheets: Right-click the dashboard tab at the bottom of the workbook and select Hide All Sheets.
- Hide a specific sheet: Right-click the sheet tab at the bottom of the workbook and select Hide.

If all sheets are needed, decide if the analysis can be split into multiple workbooks, each with a more targeted purpose.

- Save a copy of the workbook and delete unnecessary sheets, dashboards and data sources from each one. See [Streamline your workbook](#) for more information.
- Copy specific sheets into a new workbook. This may be more efficient because copying a dashboard into a new workbook carries over only what is needed for that dashboard. However, not all formatting options are transferred. See [Copying Information Between Workbooks on page 3103](#) for more information.

Unused data sources

From the Workbook Optimiser

Sample output message: The data source **Supply Chain** isn't used in the workbook.

Each data source contributes to the amount of time Tableau spends loading and rendering a workbook.

Consider closing data sources that aren't in use.

Additional information

If any data sources aren't being used, close them: right-click on the data source's name at the top of the Data pane and select **Close**.

Unused fields

From the Workbook Optimiser

Sample output message: The data source **Supply Chain** contains 42 fields that aren't being used.

Hiding unused fields prevents them from being unnecessarily queried and reduces the size of extracts.

Consider hiding any fields that aren't being used, regardless of whether the data source is an extract.

Additional information

Hide unused fields

- In Tableau Desktop: open the drop-down menu at the top of the Data pane and select **Hide All Unused Fields**.
 - In web authoring: right-click on an unused field and select **Hide**. There's no way to bulk hide unused fields in web authoring. If hiding fields individually is prohibitive, consider [editing in Tableau Desktop](#) instead of working in the browser.
-

Uses data blending

From the Workbook Optimiser

Sample output message: The sheet **Classroom Distribution** uses data blending.

Data blending performance is driven by the number of unique members in the linking fields.

Consider using relationships when possible. If a blend is required, try to use low cardinality linking fields.

Additional information

There are [several ways to combine data](#) from multiple sources. [Data blending](#) sends two separate queries to two separate data sources and displays the results together in the viz. These queries are at the level of the [linking fields](#) and the results are merged in memory in Tableau. Large query results require more processing to generate the final viz.

Tip: If you're not using data blending but the Workbook Optimiser failed this rule, check if the workbook is using [cross data source filtering](#). Filtering across data sources suffers from similar performance issues around field cardinality.

Uses date calculations

From the Workbook Optimiser

Sample output message: The data source **Supply Chain** contains 17 date calculations.

Date logic can be complicated. Minimise the number of date calculations and conversions you have to do in Tableau.

Consider using DATEPARSE and MAKEDATE before other methods, and try to use built-in functions like DATEDIFF() when possible. If filtering on a date, use relative date filters or a continuous date filter instead of a discrete filter.

Additional information

Computing calculations in Tableau can have a significant performance impact, especially [date functions](#). Consider taking an extract and [materialising calculations](#), or pushing calculations to your data source. For more information about building calculations in Tableau Prep, see [Create Calculations in Tableau Prep](#).

Note: If a date calculation is nested in another calculation, the optimiser flags the nested date calculation, even if the parent calculation is the field used in the viz.

Uses grouping

From the Workbook Optimiser

Sample output message: The data source **Supply Chain** uses 17 grouped fields

Tableau's native grouping functionality loads the entire domain of the field, which can have a performance impact.

Consider using a calculated field with a CASE statement or sets instead of groups.

Additional information

In the testing performed for the [Designing Efficient Workbooks](#) whitepaper, grouping with CASE and sets performed better than the native group functionality.

The **CASE** function can be used to create groups. Imagine a scenario where the data involved a deck of cards. There's a field for the card value (2–10, J, Q, K, A) but the analysis should compare face cards to number cards. The case statement to make that grouping could be

```
CASE [Value]
  WHEN "J" THEN "Face card"
  WHEN "Q" THEN "Face card"
  WHEN "K" THEN "Face card"
  ELSE "Number card"
END
```

Sets have the added benefit of set actions, which make sets more powerful and flexible than traditional grouping. For more information, see [Create Sets on page 1101](#) and [Set Actions on page 1444](#).

Streamline your workbook

Remove what you can

Thoughtfully reducing complexity is key to good performance. A low-impact place to start is to remove elements that aren't in use.

Workbook

- **Delete sheets:** Right-click on the sheet tab along the bottom of the workbook and select Delete.
- **Hide sheets:** Right-click on the sheet tab along the bottom of the workbook and select Hide.

Worksheets

- **Remove parameters, sets, groups:** Right-click on the item in the Data pane and select Delete.
- **Delete calculations:** Right-click on the calculation in the Data pane and select Delete.
- **Remove filters:** Right-click on the field on the filter shelf and select Remove. Note that removing the quick filter interface (open the filter menu and select Hide Card) will not delete the filter itself.

Dashboards

- **Remove layout containers:** Open the Layout pane and expand the Item hierarchy. Right-click on each layout container (tiled, horizontal or vertical) and select Remove Container.
- **Remove filters or legends:** Select a filter or legend and open the drop-down menu and select Remove from Dashboard.
- **Remove device layouts:** On the Dashboard pane, open the menu for the device layout and select Delete Layout.

Data sources

- **Close data sources:** Right-click on the data source's name at the top of the Data pane and select Close.
- **Hide unused fields:** Open the drop-down menu at the top of the Data pane and select Hide All Unused Fields.
- **Use data source filters:** Right-click on the data source's name at the top of the Data pane and select Edit Data Source Filters > Add
- **Configure the extract:** Right-click on the data source's name at the top of the Data pane and select Extract Data. In the dialog, you can:
 - Use extract filters to limit how much data is pulled into the extract
 - Aggregate data for visible dimensions to reduce unnecessary granularity
 - Hide all unused fields to drop them from the extract

Break up the workbook

If a workbook contains multiple sheets or dashboards for different analytical purposes, consider splitting it into multiple workbooks, each with a more targeted purpose.

- **Option 1:** Save a copy of the workbook and delete unnecessary sheets, dashboards and data sources from each one. See above for some examples.

- **Option 2:** Copy out specific sheets into a new workbook. This may be more efficient because copying a dashboard into a new workbook carries over only what is needed for that dashboard. However, not all formatting options will be transferred. See [Copy Sheets and Data Sources](#) for more information.

General suggestions

These suggestions are pulled from the whitepaper [Designing Efficient Production Workbooks](#).

- **Limit the data** by adding a data source filter, dropping unnecessary columns or aggregating to the appropriate level.
- **Extracts solve many problems.** Changing from a live connection to an extract will make most workbooks run faster. If you're not running extracts, this is the first place to start, even just as a test to rule out other data issues.
- **Simple is fast.**
- **Move complexity to the data layer.**
 - Use an extract
 - Use a fixed dashboard size
 - Upgrade to the latest version of Tableau
 - Limit the data. Data volume is the single most significant factor in performance.

Know Your Data at the Database Level

Understanding the impact that certain factors in the design of your database have on Tableau performance might give you information you can use to work with your database team to optimise data at the database level.

Enable support for referential integrity

Databases that support referential integrity support the Tableau Assume Referential Integrity feature, which improves the performance of inner joins. Joins cost time and resources to process on the database server. When you join multiple tables in a data source, Tableau uses functionality that is generally invisible to the user, called *join culling*. Join culling queries only the relevant tables instead of all tables defined in your join. Join culling only occurs where referential integrity is defined between tables. For more information, see [Assuming Referential Integrity for Joins](#) on page 812.

Make sure database permissions support creating temp tables

Does your database grant users permission to create and drop temporary tables, also known as temp tables, and does the environment have sufficient spool space for the queries being run? Tableau creates temp tables to help improve performance and add functionality. The temp tables temporarily hold information specific to a connection. If the creation of temp tables in the database is restricted, the overall performance of workbooks and views isn't as fast as it could be.

Create indexes for tables

Index the tables in your relational database. To successfully index your data set, identify the fields that you frequently filter on and add them to the index. If you have a field that you use as a context filter often, consider setting it as your primary index. If you are working with Access tables that have more than 200,000 rows of data, consider setting indexes on the tables. You can learn how to do this by searching for “index” in the Access online help. You can officially store 2 GB of data (approximately 1-2 million rows) in an Access database, but it performs poorly well below this limit.

Many database management system (DBMS) environments have management tools that will look at a query and recommend indexes that would help.

Break up your data

You can often improve performance if you partition a large database table into multiple smaller tables. For example, you can create a cluster of Access tables that addresses specific subsets of your data.

Use a database server

If you have a lot of data, you might consider storing it in a database server, such as Oracle, MySQL or Microsoft SQL Server. The Professional Edition of Tableau can connect to these larger database servers.

Test Your Data and Use Extracts

You probably have no control over the hardware, processing power, and disk space that your database runs on. Or how many people access the database at any given time, how many

services are running, or how robust the network is. But you can test the *raw performance* of the data before you begin to build a workbook, so that you understand the environment you're working in. And there are things you can do to affect the performance of the workbooks you create, starting with how you choose to connect to your data: the drivers you use, and whether your connection type is *live* or *extract*.

Test as close to the data as possible

A good way to test the raw performance of the data is to install Tableau Desktop on the computer where the data resides and to run some queries. This eliminates external factors such as network bandwidth and latency from performance results, and help you to understand the raw performance of the query in the data source.

Additionally, you can use the *localhost* name for the data instead of the DNS name to help determine if environmental factors such as slow name resolution or proxy servers are slowing performance.

Connect with native database drivers

When you connect to data with native database drivers, you will often experience significantly faster performance than when you connect to the same data with ODBC drivers. When you use native database drivers, make sure that you're using the latest version. Database vendors are always working to improve their drivers. For a list of drivers, see [Drivers and Activation](#) on the Tableau website.

Work with extracts instead of live data

Depending on your data, you can choose between a live or extract connection on the data source page. A *live* connection is a direct connection to your data. A Tableau data *extract* is a compressed snapshot of data stored locally and loaded into memory as required to render a Tableau visualisation. Extracts are designed to use all parts of your computer's memory optimally.

There are several reasons to use an extract, but the main performance-related reason is if your query execution is slow. The extract data format is designed to provide a fast response to analytic queries. In this case, you can think of the extract as a query acceleration cache.

For more information about Tableau extracts, see [Extract Your Data on page 925](#). Another reference is a three-part blog post about extracts that starts with the first post, [Understanding Tableau Data Extracts](#).

Reduce the amount of data

When you create an extract, use filters to exclude data that you don't need. Also, ask yourself if you need all of the records in a data source, or if you can limit the extract to a representative sample. For more information, see [Extract Your Data on page 925](#).

Hide unused fields

Hidden fields are not included when you create an extract. Use the **Hide All Unused Fields** option to hide unnecessary fields before you create an extract. This makes the extract smaller, which improves performance. For more information, see [Hide or Unhide Fields on page 1068](#).

Optimise extracts

The **Compute Calculations Now** option materialises calculations in your extract, meaning that certain calculations are computed in advance and their values are stored in the extract. Depending on the complexity of the calculations used in your extract, this can potentially speed up future queries.

To materialise calculations, select a data source on the **Data** menu and then select **Extract > Compute Calculations Now**. For more information, see [Materialise Calculations in Your Extracts on page 947](#).

Use extracts for file-based data

In general it's best practice to import file-based data – text files such as CSV, Microsoft Excel spreadsheets, and Microsoft Access files, as well as statistical files like SPSS, SAS, and R – into Tableau. This makes queries perform much faster and also results in a much smaller file to store the data values.

If your data is a large text or Excel file, using an extract not only improves performance but also makes more functionality available to you. Note that if you connect Tableau to a large text file, you will be prompted to extract the data if Tableau discovers that the file is too large to perform well.

Avoid using custom SQL

In most cases, custom SQL runs slower than queries created by Tableau. Tableau cannot perform query optimisations on custom SQL. But in cases where you must use custom SQL, use an extract so that the query runs only once. For more information, see [Connect to a Custom SQL Query](#) on page 868.

Design for Performance While You Build a View

You're connected to your data, and you've built your data source. The next step is to begin building a view in Tableau. There are a few things to keep in mind as you build your workbook so that it will perform faster while you're building it, as well as after it is created.

Use the Describe field to get to know your data

Rather than dragging a dimension out onto the rows shelf so that you can eyeball the data – which requires Tableau to render the data as a crosstab, one of the slowest visualisation types – use the **Describe field** option. Right-click the field in the **Data** pane to view a description of the data type as reported by the data source, as well as a sample of the dimension member values.

Keep workbooks a reasonable size

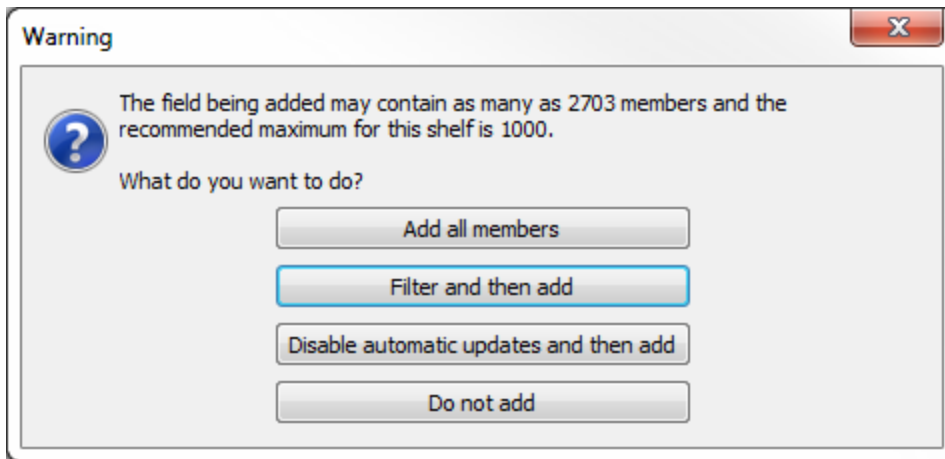

The fewer worksheets and data sources in a workbook, the faster it will perform. If you have a big topic to explore and are tempted to put everything into a single monolithic workbook, reconsider. Notice if your workbook starts to slow down with the addition of a new view and additional queries. If the performance starts to suffer as you enlarge the scope of your workbook, think about breaking your workbook into separate files.

Turn off Automatic Updates

When you place a field on a shelf, Tableau generates the view by automatically querying the data. If you are creating a dense data view, the queries might be time-consuming and significantly degrade system performance. In this case, you can turn off queries in Tableau while you build the view. You can then turn queries back on when you are ready to see the result. For more information, see [Turn off Automatic Updates to Boost Performance](#) on page 3077.

Look for warnings

Tableau displays a performance warning dialog box when you attempt to place a large dimension (with many members) on any shelf. The dialog box provides four choices, as shown below. If you choose to add all members, then you might experience a significant degradation in performance.

You might also see a warning when you attempt to create too many panes in a table. In this case, Tableau warns you that the requested table "contains more than the recommended maximum number of panes". It is best not to display more than the recommended number of panes, in part because you won't get a useful view.

Create Efficient Calculations

When your data doesn't provide all the information you need to answer your questions, you can create calculated fields to help with your analysis.

Within a calculated field you can define a hardcoded constant (such as a tax rate), do very simple mathematical operations like subtraction or multiplication (for example, revenues minus cost), use more complex mathematical formulas, perform logical tests (IF/THEN, CASE), do type conversions, send expressions to external services such as R, and much more.

There are different calculation types in Tableau:

Basic and aggregate calculations: These types of calculations are generated as part of the query to the underlying data source and are calculated in the database. In general, basic and aggregate calculations scale very well, and there are many database tuning techniques that can improve their performance.

Table calculations: These calculations are calculated by Tableau on the query result set. While this means more work for Tableau, table calculations are generally done over a much smaller set of records than are in the original data source. If table calculation performance is a problem (possibly because the result set returned to Tableau is very large) consider pushing some aspects of the calculation back to the data source layer. One way to do this is to aggregate the data and then perform the calculation on the aggregated data.

Level of detail (LOD) expressions: LOD expressions are generated as part of the query to the underlying data source and are calculated in the database. They are expressed as a *nested select*, so they are dependent on database performance. A table calculation or blending might perform better than a LOD expression, or vice versa.

If you suspect performance is slow due to a LOD expression, you might try replacing it with a table calculation or a data blend to see if performance improves. For an example, see Example 2 in [Tableau's Order of Operations on page 161](#).

LOD expressions can be affected by join culling, so look at [Assuming Referential Integrity for Joins on page 812](#) if your queries run slowly when you use LOD expressions.

For more information, see the Tableau White Paper [Understanding Level of Detail \(LOD\) Expressions](#).

Use parameters for conditional calculations

A common technique in Tableau is to show a parameter control so users can select a value that determines how a calculation is performed. Typically, to give the user easy-to-understand options, it makes sense to create the parameter as a string type. But numerical calculations are much faster than string calculations, so take advantage of the **Display As** feature of parameters: that is, show text labels but use underlying integer values for the calculation logic. For more information, see [Create Parameters on page 1131](#).

Convert date fields

Users often have date data that is not stored in native date formats. For example, a date might be a string or a numeric timestamp. You can use the DATEPARSE function if your data supports it – this function is available for non-legacy Microsoft Excel and text file connections, MySQL, Oracle, PostgreSQL, and Tableau data extract data sources. Otherwise, parse the field into a date string such as “2012-01-01”. ISO strings are preferred because they are not locale-specific. Then pass the value to the DATE function. If the originating data is a numeric field, converting it first to a string and then to a date is very inefficient. It is much better to keep the data as numeric and use

DATEADD and date literal values to perform the calculation. The performance gains can be significant with large data sets. See [Date Functions on page 2067](#) for more information about these functions.

Use CASE logic statements

When working with complex logic statements, CASE statements may be faster than IF or ELSEIF statements.

Remember that ELSEIF is faster than ELSE IF, because a nested IF computes a second IF statement rather than being computed as part of the first.

For more information, see the whitepaper [Designing Efficient Workbooks](#).

Aggregate measures

If the views you create are slow, make sure you are working with aggregated measures. With disaggregated data, you might be trying to view many rows of data at once. You can reduce the number of rows by aggregating the data. To do this, select **Analysis > Aggregate Measures**.

Calculation tips

There are lots of little things you can do that can improve calculation performance.

- Distinct counting values is one of the slowest aggregation types in almost all data sources. Use the COUNTD aggregation sparingly.
- Using parameters with a wide scope of impact (for example, in a custom SQL statement) can affect cache performance.
- Filtering on complex calculations can potentially cause indexes to be missed in the underlying data.
- Script functions like RAWSQL and SCRIPT_* for integrating with external services can be slow, particularly if there are lots of values that need to be passed back and forth from the DBMS/R server.
- Use NOW only if you need the time stamp level of detail. Use TODAY for date level calculations.
- Remember that all basic calculations are passed through to the underlying data—even literal calculations like label strings. If you need to create labels (for example, for column

headers) and your data is very large, create a simple text/Excel file data source with just one record to hold them so they don't add overhead on the big data source.

Make Visualisations Faster

You've put in a lot of work to make your visualisation – view, dashboard or story – make a point or tell a story. You don't want to lose your audience while you wait for the visualisation to load. By following the guidelines in this topic, you can improve the speed of your visualisations.

Reduce the scope

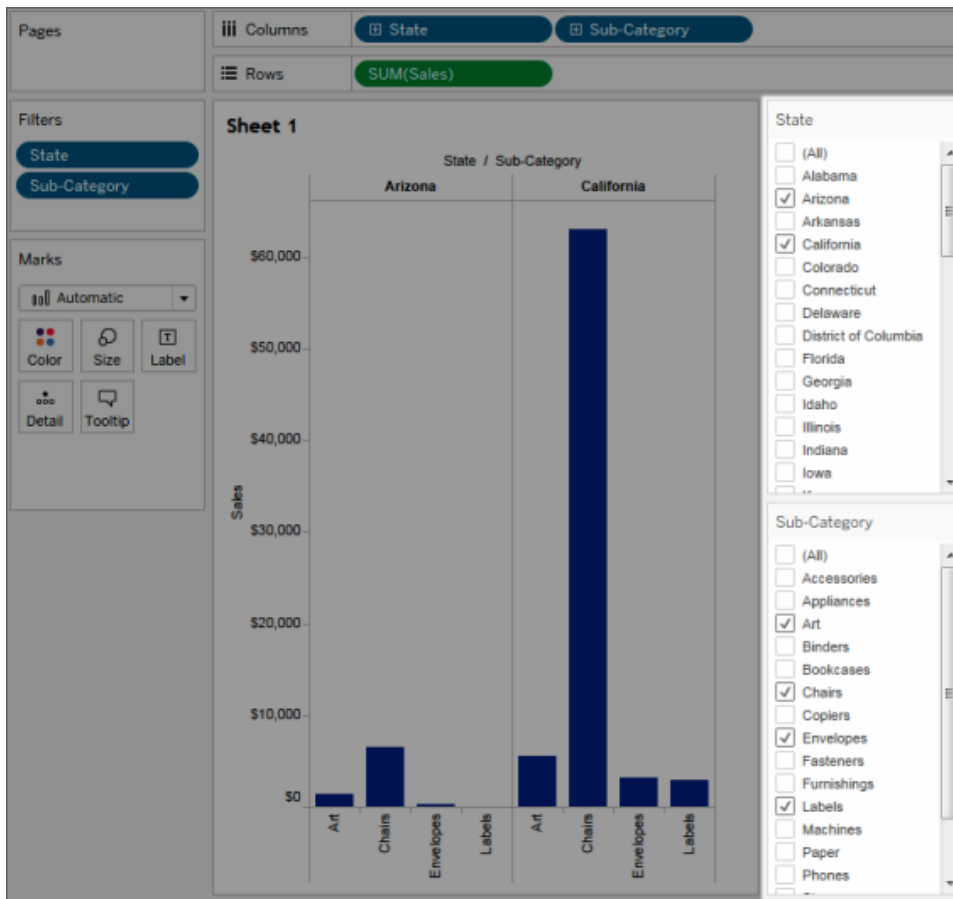

Whether you're creating a view, dashboard or story, it's tempting to pack a lot of information into your visualisation because it's so easy to add more fields and calculations to the view and more sheets to the workbook. But the result can be that the visualisation becomes slower and slower to render.

Remember that each worksheet runs one or more queries against the data, so the more sheets, the longer it takes to render the visualisation.

Take advantage of the fact that Tableau is designed to deliver interactive visualisations to your users, and spread the data out across multiple visualisations, if you can. Be strategic when designing your visualisation – the fewer sheets and data sources, the faster your visualisation will perform.

Limit the number of filters you show in the view

Filters that you show in your view (formerly called quick filters) are a very powerful feature of Tableau that you can use to create rich, interactive visualisations for your users. See the filters highlighted on the right in the following screenshot:

When you add an interactive filter to a view, each filter in the view requires a query in order to populate the options. If you add a lot of interactive filters to your dashboard, it can cause the dashboard to take a long time to render.

Also, when you use “show relevant values” on a filter, it requires a query to update the shown values each time other filters are changed. Use this feature sparingly.

Reduce the number of marks on the view

While there is no hard and fast rule on what defines “too many marks”, be aware that more marks means that more processing power and memory is required to render them. You can find the number of marks by looking at the lower left of the Tableau Desktop window in the status bar. Watch out for large crosstabs and for maps with complex custom polygons. Keep in mind that too many data points on a view can also reduce the visual analytics value by causing information overload.

To avoid this problem, compile related views and connect them with action filters so that you can go from an overview to a more granular view as you explore the data. Make sure that you remove any unneeded dimensions from the **Detail** shelf. You can also try displaying your data in different types of views to see what's most effective.

Zoom without filtering

When users zoom in on a visualisation with a large number of marks, Tableau doesn't filter out the marks you can't see. What changes is the view of the data, not the total number of marks. If you only need a subset of the data, filter out the data you don't need.

Record and Analyse Workbook Performance

Your workbook is done and you're wondering if its performance is taking a little longer than it should. To find out what's slowing it down, you can use a performance recording to evaluate your workbook. This is an especially good idea if you plan to share or publish the workbook.

The Performance Recording feature in Tableau records performance information about key events as you interact with a workbook. You can then view performance metrics in a workbook that Tableau creates to analyse and troubleshoot different events that are known to affect performance:

- Query execution
- Compiling query
- Geocoding
- Connections to data sources
- Layout computations
- Extract generation
- Blending data
- Server rendering (Tableau Server only)

Tableau support may ask that you create a performance workbook as they work with you to diagnose performance issues.

Create a performance recording in Tableau Desktop

To start recording performance, follow this step:

Help > Settings and Performance > Start Performance Recording

To stop recording and view a temporary workbook containing results from the recording session, follow this step:

Help > Settings and Performance > Stop Performance Recording

You can now view the performance workbook and begin your analysis.

Click **File > Save** to save the workbook to the location you choose. If you're sending the recording to Tableau Support, save this workbook as a packaged workbook (.twbx) file, and then send it.

Interpret a performance recording workbook

A performance recording workbook contains two main dashboards: Performance Summary and Detailed Views. The Performance Summary dashboard provides a high-level overview of the most time-consuming events. The Detailed Views dashboard provides a lot more detail and is intended to be used by advanced users when building workbooks. The **Detailed Views** dashboard is only visible when the performance recording workbook is opened using Tableau Desktop.

Performance Summary

The **Performance Summary** dashboard contains three views: **Timeline**, **Events** and **Query**.

Timeline

The uppermost view in the performance summary recording dashboard shows the events that occurred during recording, arranged chronologically from left to right. The bottom axis shows elapsed time since Tableau started, in seconds.

In the Timeline view, the **Workbook**, **Dashboard** and **Worksheet** columns identify the context for events. The **Event** column identifies the nature of the event, and the final column shows each event's duration and how it compares chronologically to other recorded events:

Events

The middle view in a performance summary dashboard shows the events, sorted by duration (greatest to least). Events with longer durations can help you identify where to look first if you want to speed up your workbook.

Different colours indicate different types of events. The range of events that can be recorded is:

- Computing layouts

If layouts are taking too long, consider simplifying your workbook.

- Connecting to data source

Slow connections could be due to network issues or issues with the database server.

- Compiling query

This event captures the amount of time spent by Tableau in generating the queries. Long compile query times indicate that the queries generated are complex. The complexity may be due to too many filters, complex calculations or generally due to a complex workbook. Examples of complex calculations include, lengthy calculations, LOD calculations or nested calculations. Try simplifying the workbook, using action filters or moving calculations to the underlying database.

- Executing query

- For live connections, if queries are taking too long, it could be because the underlying data structure isn't optimised for Tableau. Consult your database server's documentation. As an alternative, consider using an extract to speed performance.
- For extracts, if queries are taking too long, review your use of filters. If you have a lot of filters, would a context filter make more sense? If you have a dashboard that uses filters, consider using action filters, which can help with performance.

- Generating extract

To speed up extract generation, consider only importing some data from the original data source. For example, you can filter on specific data fields, or create a sample based on a specified number of rows or percentage of the data.

- Geocoding

To speed up geocoding performance, try using less data or filtering out data.

- Blending data

To speed up data blending, try using less data or filtering out data.

- Server rendering

You can speed up server rendering by running additional VizQL Server processes on additional machines.

Query

If you click on an **Executing Query** event in either the **Timeline** or **Events** section of a performance summary dashboard, the text for that query is displayed in the Query section.

If you are connected to a published data source, the query text is displayed in XML. If you are connected to the data source directly, the query is displayed in SQL like shown below:

Query

```
SELECT "State"."ID" AS "ID",
       "StateSynonyms"."Name" AS "State_Name",
       "State"."ParentID" AS "State_ParentID"
FROM "StateSynonyms"
INNER JOIN "State" ON (("State"."ID" = "StateSynonyms"."ParentID") AND ("State"."MapCode" = "StateSynonyms"."MapCode"))
```

If it makes sense, you can use the query text to work with your database team on optimising at the database level. Sometimes the query is truncated and you'll need to look in the Tableau log to find the full query. Most database servers can give you advice about how to optimise a query by adding indexes or other techniques. See your database server documentation for details.

Sometimes for efficiency, Tableau combines multiple queries into a single query against the data. In this case, you may see an **Executing Query** event for the Null worksheet and zero queries being executed for your named worksheets.

Detailed Timeline

This view is the detailed version of the **Timeline** view that shows all events and separating individual items that were grouped in the **Timeline** view. It is intended to be used by advanced

users during workbook designs.

Detailed Views

The **Detailed Views** dashboard contains **Depth**, **Exclusive CPU**, **Inclusive CPU** and **Elapsed Time** views.

Depth

The **Depth** view is the uppermost view in the **Detailed Views** dashboard and provides insight into what happens when a request is made. This view is the most useful when filtered to a single user request. Examples of user requests are: loading a view, selecting a mark or changing a filter.

Each bar on the depth view represents a single activity. An activity is a unit of work that is done as part of processing a user request. A single user request results in multiple activities. The length of each bar on the depth view is proportional to the elapsed time for the activity that the bar represents.

High level activities appear at the top of the view. Activities lower down are child activities generated by high level activities.

Hovering over each bar provides additional details about the activity and also highlights the corresponding row in the **CPU** and **Elapsed Time** view described in the next section.

In order to narrow down on what parts of the request took the most time, investigate long running activities at the highest levels.

CPU and Elapsed Time

The **CPU** and **Elapsed Time** views appear lowermost in the **Detailed Views** dashboard. You can toggle between **Exclusive CPU**, **Inclusive CPU** and **Elapsed Time** views by clicking on the radio buttons.

| | |
|--|--|
| Select a View <input checked="" type="radio"/> Exclusive CPU <input type="radio"/> Inclusive CPU <input type="radio"/> Elapsed Time | - Exclusive CPU time is useful for identifying activities that consume majority of the CPU - Inclusive CPU time is useful for identifying high level activities that consume majority of the CPU (either themselves or due to activities that they sponsor) - Elapsed time is useful for identifying activities that took the most wall clock time |
|--|--|

While the **Depth** view can help in quick visual identification of long running activities, it may not necessarily highlight activities that happen multiple times with each instance taking a small amount of time. The **Exclusive CPU**, **Inclusive CPU** and the **Elapsed Time** views provide aggregate statistics for each activity. The number of times an activity took place is shown in the **Count** column and the total amount of time taken by a single activity is shown using the bar chart.

Reduce Upload Times to Tableau Server

You've created your workbook and analysed its performance recording to make sure that it's been optimised for speed. Now you're ready to publish the workbook to Tableau Server. It isn't always possible to reduce upload times to Tableau Server, but here are some considerations to keep in mind.

Avoid publishing packaged workbooks

It is a best practice to publish workbooks (.twb files) and data sources separately, rather than publishing them together as packaged workbook (.twbx files). This may not make your initial uploads of workbooks and data sources any faster than publishing them together, but it makes republishing workbooks faster (if you don't have to also republish data sources), and it makes data sources available online for new workbooks. For data sources that are extracts, it also allows you to schedule automated refreshes.

Make extracts smaller

For Tableau extracts, you can help speed uploads by making your extract smaller. As you create extracts, consider:

- Removing unused fields from extracts.
- Making extracts smaller with sampling and filtering.
- Aggregating data for visible dimensions.

[Extract Your Data on page 925](#)

[Publish a Data Source](#) on page 3143

Turn off Automatic Updates to Boost Performance

When you place a field on a shelf, Tableau generates the resulting view by querying the data source. When you create a complex data view that involves many fields, these queries can be time-consuming. To improve performance, you can turn off automatic updates while composing a view, and then query the data source when you're done.

Automatic updates for worksheets

To turn off updates for worksheets, click the **Pause Auto Updates** button  on the toolbar. You can also toggle automatic updates on and off by pressing F10 (Option-Command-0 on a Mac) on your keyboard.

While automatic updates are off, you can update the view at any time by clicking the **Run Update**

 button on the toolbar, or by pressing F9 (Shift-Command-0 on a Mac).

Identifying invalid states when automatic updates are off

It's possible to enter an invalid state when automatic updates are turned off. When this happens, the view is desaturated and invalid commands are disabled. The view and commands become available again when you click **Run Update** on the toolbar.

For example, the view below has automatic updates turned off. When we changed the aggregation for Profit from a summation to an average, the view became desaturated to indicate that the current view is invalid.

Automatic updates for filters

When you change a filter, even when you turn off automatic updates for worksheets, Tableau continues to query the data source to update the view. When you work with a large data set, this continuous query action can degrade performance, so Tableau also gives you an option to pause automatic updates for filters. If you pause automatic updates for filters, you can make as many changes as you need without having to wait for Tableau to update the filter each time.

To pause automatic updates for filters, click the drop-down arrow on the **Pause Auto Updates** button on the toolbar and select **Auto Update Filters** to clear the tick .

To resume automatic updates for filters, click the drop-down arrow on the **Pause Auto Updates** button on the toolbar and select **Auto Update Filters** again. You can also click the **Run Update**

button on the toolbar to manually update the view at any time.

How Automatic Updates Affect Dashboards and Stories

You configure automatic updates on a per-view basis. This means that you can have a dashboard where some views update automatically, and others don't. Similarly, you can have a story where some story points update automatically, and others don't. But when dashboards or stories are published to Tableau Server, automatic updates affect either none of the contributing views in a story or dashboard, or all of the views.

Save Your Work

You can save your work at any time while analysing or interacting with data in Tableau.

For Tableau Desktop

In Tableau Desktop, there are several ways to save your work:

- **Automatically save a workbook** – Automatically saves the workbook in the same location as the original file. In the event of a crash, a recovered version is available.
- **Save a workbook** – Saves all open worksheets.
- **Save a packaged workbook** – Saves the workbook along with all referenced local file data sources and images into a single file.
- **Save a bookmark** – Saves the current worksheet.

You can share workbooks and bookmarks with your co-workers, provided they can access the relevant data sources that the workbook uses. If your co-workers do not have access to the data sources, you can save a packaged workbook.

Custom fields such as binned measures, calculated fields, groups, and sets are saved with workbooks and bookmarks.

Automatically save a workbook

Tableau Desktop automatically saves your work for you every few minutes – no more losing hours of work if Tableau Desktop closes unexpectedly. This feature is enabled by default, but you can turn it off from the toolbar under **Help > Settings and Performance > Enable Autosave**.

Note: If you don't see this option, your System Administrator may have disabled this feature.

If Tableau crashes, a recovered version of the workbook is automatically created with a .twbr extension and saved in the same location as the original file or in your **My Tableau Repository/Workbooks** folder. New workbooks are saved with the name "Book1" plus a numeric ID. When you reopen Tableau, a recovery dialog box shows a list of the recovered files that you can select and open to continue in your flow.

You can also delete unwanted files from this same dialog box.

For more information about how to turn this feature on or off during installation, see [Before You Install](#) in the Tableau Desktop Deployment guide.

Save a workbook

When you open Tableau Desktop, it automatically creates a new workbook. Workbooks hold the work you create and consist of one or more worksheets. Each worksheet contains a particular view of your data.

To save a Tableau workbook:

1. Select **File > Save**.
2. Specify the workbook file name in the **Save As** dialog box.

By default, Tableau saves the file with the .twb extension. By default, Tableau saves your workbook in the **Workbooks** folder in your My Tableau Repository. You can find this repository in your Documents folder. However, you can save Tableau workbooks to any directory you choose.

Tableau file names cannot include any of the following characters: forward slash (/), backslash (\), greater-than sign (>), less-than sign (<), asterisk (*), question mark (?), quotation mark ("), pipe symbol (|), colon (:), or semicolon (;).

To save a copy of a workbook you have open:

- Select **File > Save As** and save the file with a new name.

Save a packaged workbook

Packaged workbooks contain the workbook along with a copy of any local file data sources and background images. The workbook is no longer linked to the original data sources and images. These workbooks are saved with a .twbx file extension. Other users can open the packaged workbook using Tableau Desktop or Tableau Reader, and do not need access to the data sources that the workbook includes.

To learn more about how to save your workbook as a packaged workbook, see [Packaged Workbooks](#) on page 3084.

Save a bookmark

You can save a single worksheet as a Tableau bookmark. When you save the bookmark, Tableau creates a snapshot of the worksheet. Bookmarks can be accessed from any workbook using the Bookmarks menu. When you open a bookmarked worksheet, it adds the worksheet to your workbook in the state that it was in when it was bookmarked. It will never update or change automatically. Bookmarks are convenient when you have worksheets that you use frequently.

To save a Tableau bookmark:

1. Select **Window > Bookmark > Create Bookmark**.
2. Specify the bookmark file name and location in the Create Bookmark dialog box.

Tableau saves the file with a .tbm extension. The default location is the Bookmarks folder in the Tableau Repository. However, you can save bookmarks to any location you choose. Bookmarks that are not stored in the Tableau repository do not appear on the **Bookmark** menu.

You can organise bookmarks into folders in the same way you organise files or documents. This can be useful when you have a large number of bookmarks to manage. For example, you might organise bookmarks based on employee name, product types, or sales results. You can organise bookmarks by creating a new folder, renaming an existing folder, renaming existing bookmark files, and so on.

Delete bookmarks the same way as you would delete any other file on your computer. After you delete a bookmark from the Bookmarks folder in the Tableau Repository, it is removed from the **Bookmarks** menu the next time you start Tableau.

Note: While bookmarks are generally a snapshot of the worksheet and include the data connection, formatting, etc., a bookmark does not include parameter values and the current page setting on the Pages shelf.

For web authoring

When creating, editing and interacting with views on Tableau Server or Tableau Cloud, there are a couple of different ways for you to save your work:

- **Save a workbook** - saves a workbook in the project you specify.
- **Save a copy of a workbook** - saves a copy of the workbook in the project you specify.
- **Save changes as a custom view** - saves changes as a custom view, which is related to the original view and updates when the original view is updated.

Save a workbook

When you create a new workbook or edit an existing workbook on Tableau Server or Tableau Cloud, you can save your work at any time.

To save a workbook:

- In web editing mode, select **File > Save**.

Note: If the workbook has never been saved, you must select **File > Save As**.

Save a copy of an existing workbook

Sometimes you don't want to overwrite an existing view with your changes. In cases like these, you can save a copy of an existing workbook. When you do this, the existing workbook remains unchanged, and a copy of it is created for you to edit as you wish.

Note: When you save a copy of an existing workbook, it is not updated when the original workbook is updated or republished. It is also not deleted when the original view is deleted. If you would like to create a view that updates with the original, see the [Save changes as a custom view on the facing page](#) section

To save a copy of a workbook:

1. In web editing mode, select **File > Save As**.
2. In the Save Workbook dialog box that opens, do the following:
 1. For **Name**: Enter a name for the workbook.
 2. For **Project**: Select the project in which you would like to save the workbook.
 3. (Optional) Select **Show sheets as tabs** to display all worksheets, dashboards, and stories in the workbook as separate tabs.
 4. Click **Save**.

Note: The person who published the data source to Tableau Server or Tableau Cloud may have also set up credentials for accessing the published data source included in the workbook you are about to save. These authentication options should appear in the Save Workbook dialog box. For more information, see the authentication types in the [Set Credentials for Accessing Your Published Data](#) topic.

Save changes as a custom view

If you notice you are making the same changes to a view every time you open it, you might want to consider saving the changes as a custom view. This option is not available in web editing mode, but can be accessed when you open a view to interact with it.

A custom view does not change the original, but is related to it. If the original view is updated or republished, the custom view is also updated.

You can also choose whether your custom views are visible to other users (public), or only to you (private).

For more information about custom views and how to create them, see [Use Custom Views on page 3323](#).

See Also

[Use Custom Views on page 3323](#)

Packaged Workbooks

Workbooks often reference external resources. For example, workbooks might reference background images or local file data sources such as Excel files, Access files, and Tableau extract files (.hyper).

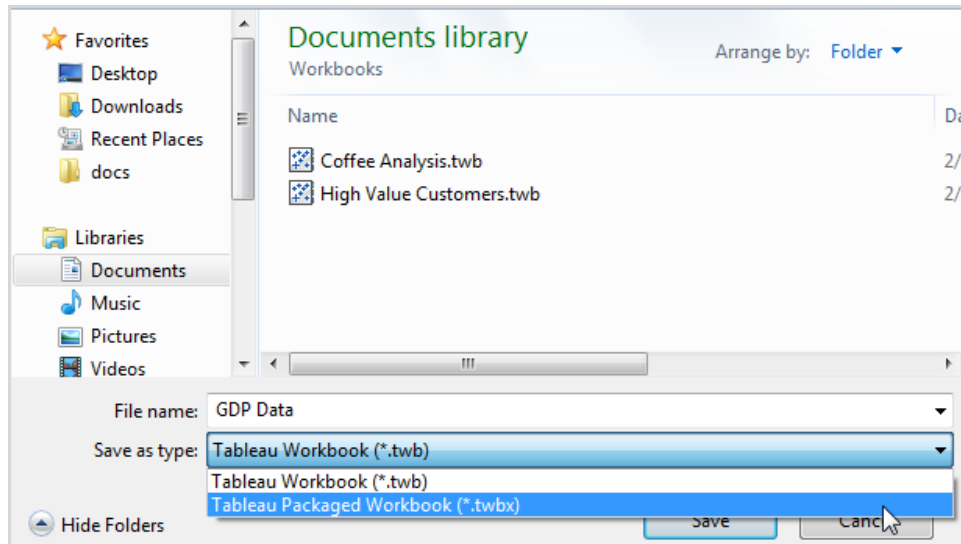

When you save a workbook, links to these resources are also saved. The next time you open the workbook, the views are automatically updated with any changes that may have occurred to the data and images. In most cases, you will want to save the workbook in this way. But if you plan to share the workbook with someone who does not have access to the referenced resources or to Tableau Server, you might want to save a packaged workbook instead.

Packaged workbooks contain the workbook along with a copy of any local file data sources and background images. The workbook is no longer linked to the original data sources and images. These workbooks are saved with a .twbx file extension. Other users can open the packaged workbook using Tableau Desktop or Tableau Reader.

Note: The content of the .twbx file is stored in plain text. All data, including filter values that may give semantic clues to the data, will be readable by anyone who opens the file.

Create a .twbx with file-based data sources

1. Select **File > Save As**.
2. Specify a file name for the packaged workbook in the Save As dialog box.
3. Select **Tableau Packaged Workbooks** on the **Save as type** drop-down list.

4. Click **Save**.

The default location is the **Workbooks** folder of the Tableau repository. However, you can save packaged workbooks to any directory you choose.

The following files are included in packaged workbooks:

- Background images
- Custom geocoding
- Custom shapes
- Local cube files
- Microsoft Access files
- Microsoft Excel files
- Tableau extract files (.hyper)
- Text files (.csv, .txt, etc.)

If you are sharing packaged workbooks that contain Microsoft Excel or Access 2007 data sources, the people opening the workbook must either have Microsoft Excel and Access 2007 or the Office 2007 Data Connectivity Components installed on their computers. The data connectivity components are available on the Tableau [Tableau Drivers](#) page.

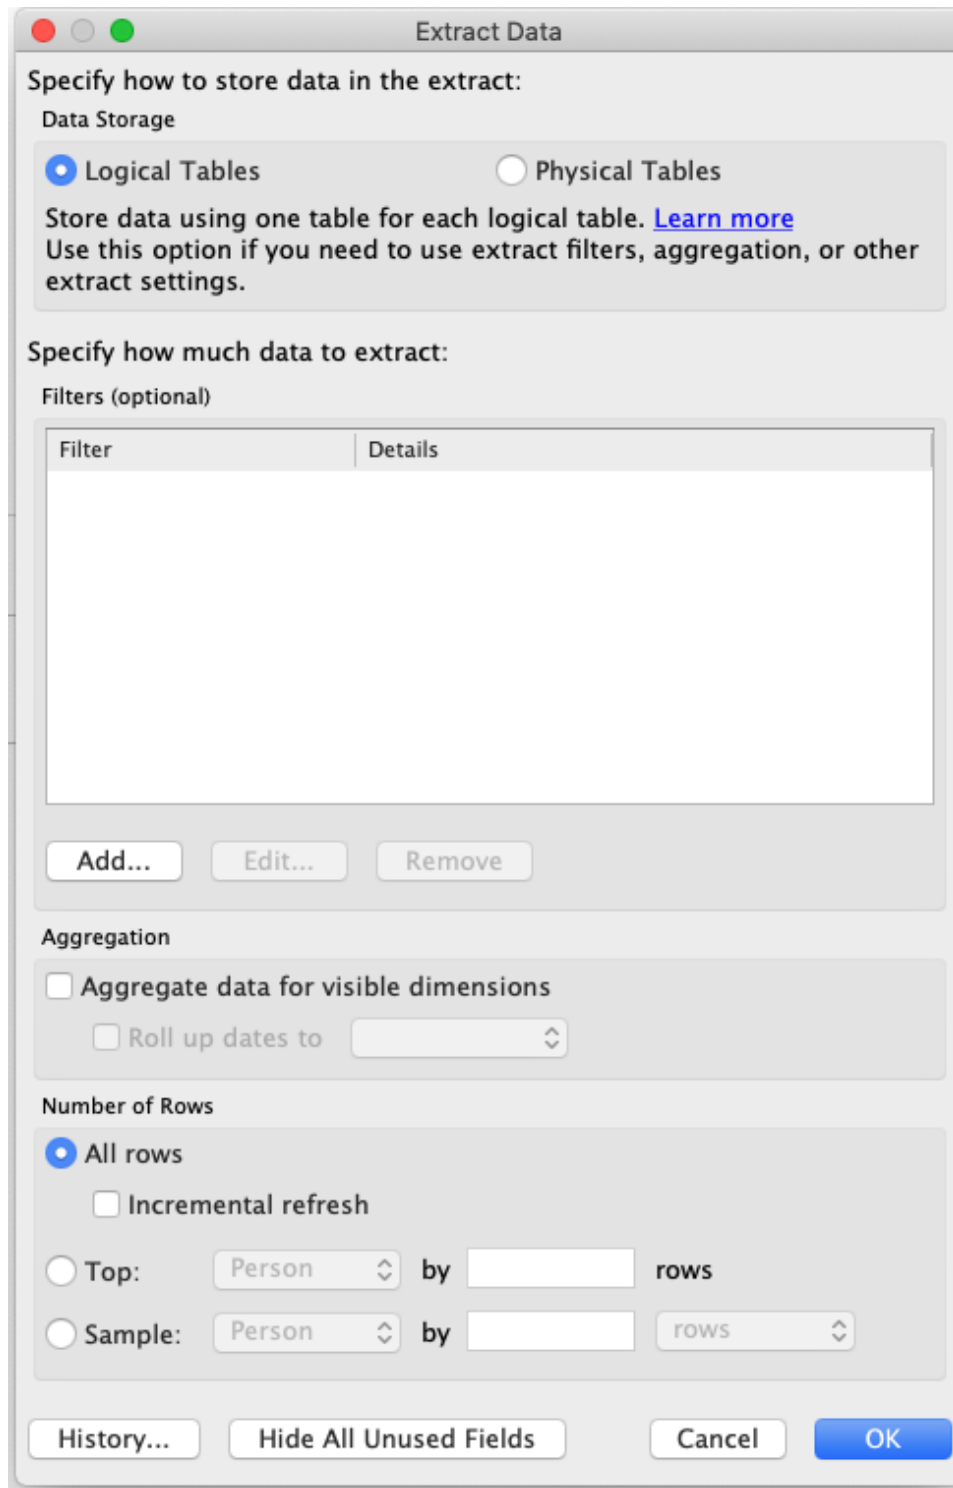

Create a .twbx with non-file-based data sources

If the workbook contains connections to enterprise data sources or other non-file-based data sources, such as Microsoft SQL, Oracle, or MySQL, the data must be extracted from the data sources for it to be included in a packaged workbook (.twbx).

1. In the workbook, right-click the data source in the Data pane and choose **Extract Data**.

2. In the Extract Data dialog box, click the **Extract** button to extract all data from the data source.

The image shows the 'Extract Data' dialog box in Tableau. It is a standard macOS-style window with a title bar and three colored window control buttons (red, yellow, green) in the top-left corner. The dialog is organized into several sections. The first section, 'Specify how to store data in the extract:', has a sub-header 'Data Storage' and two radio buttons: 'Logical Tables' (selected) and 'Physical Tables'. Below these is a text block explaining the 'Logical Tables' option, including a 'Learn more' link. The second section, 'Specify how much data to extract:', has a sub-header 'Filters (optional)' and a table with two columns: 'Filter' and 'Details'. The table is currently empty. Below the table are three buttons: 'Add...', 'Edit...', and 'Remove'. The third section, 'Aggregation', has a checkbox 'Aggregate data for visible dimensions' which is unchecked. Below it is another unchecked checkbox 'Roll up dates to' followed by a dropdown menu. The fourth section, 'Number of Rows', has a radio button 'All rows' (selected), an unchecked checkbox 'Incremental refresh', and two options: 'Top:' and 'Sample:'. Each of these options has a dropdown menu (currently showing 'Person'), the word 'by', another dropdown menu (empty), and the word 'rows'. At the bottom of the dialog are four buttons: 'History...', 'Hide All Unused Fields', 'Cancel', and 'OK'.

Extract Data

Specify how to store data in the extract:

Data Storage

☒ Logical Tables ☐ Physical Tables

Store data using one table for each logical table. [Learn more](#)
Use this option if you need to use extract filters, aggregation, or other extract settings.

Specify how much data to extract:

Filters (optional)

| Filter | Details |
|--------|---------|
|--------|---------|

Add... Edit... Remove

Aggregation

☐ Aggregate data for visible dimensions

☐ Roll up dates to

Number of Rows

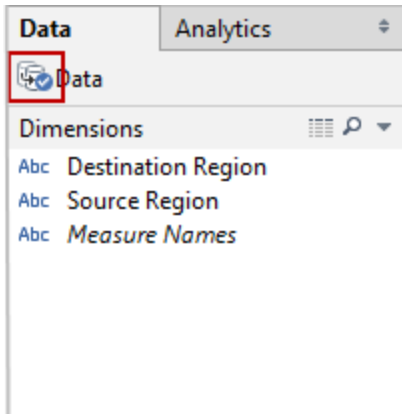

☒ All rows ☐ Incremental refresh

☐ Top: Person by rows

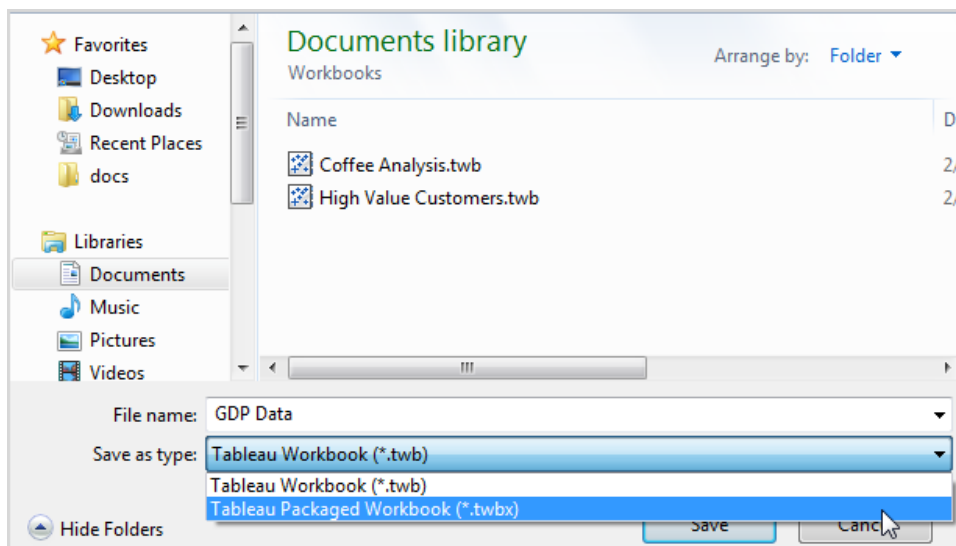

☐ Sample: Person by rows

History... Hide All Unused Fields Cancel OK

After the extract completes, the data source icon changes to indicate that an extract is active for that data source. Instead of a single cylinder, there are two cylinders connected by an arrow.

3. **Optional:** Repeat the above steps for each data source in the workbook.
4. Select **File > Save As**.
5. From the **Save as type** drop-down menu, select Tableau Packaged Workbook (*.twbx).

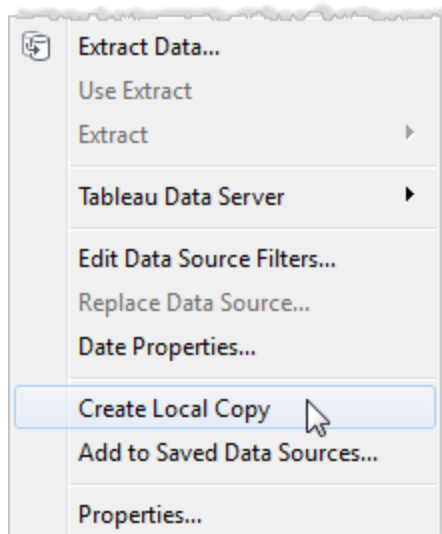

After the extracts have been created for all non-file-based data sources and the packaged workbook has been saved, you can send your workbook.

Create a .twbx with Tableau Server data sources

If the workbook contains connections to a published Tableau Server data source, you must download a local copy of the Tableau Server data source, take an extract of it, and then replace the connection to the local copy for it to be included in a packaged workbook (.twbx).

1. In the workbook, right-click the published data source in the Data pane, and then select **Create Local Copy**.

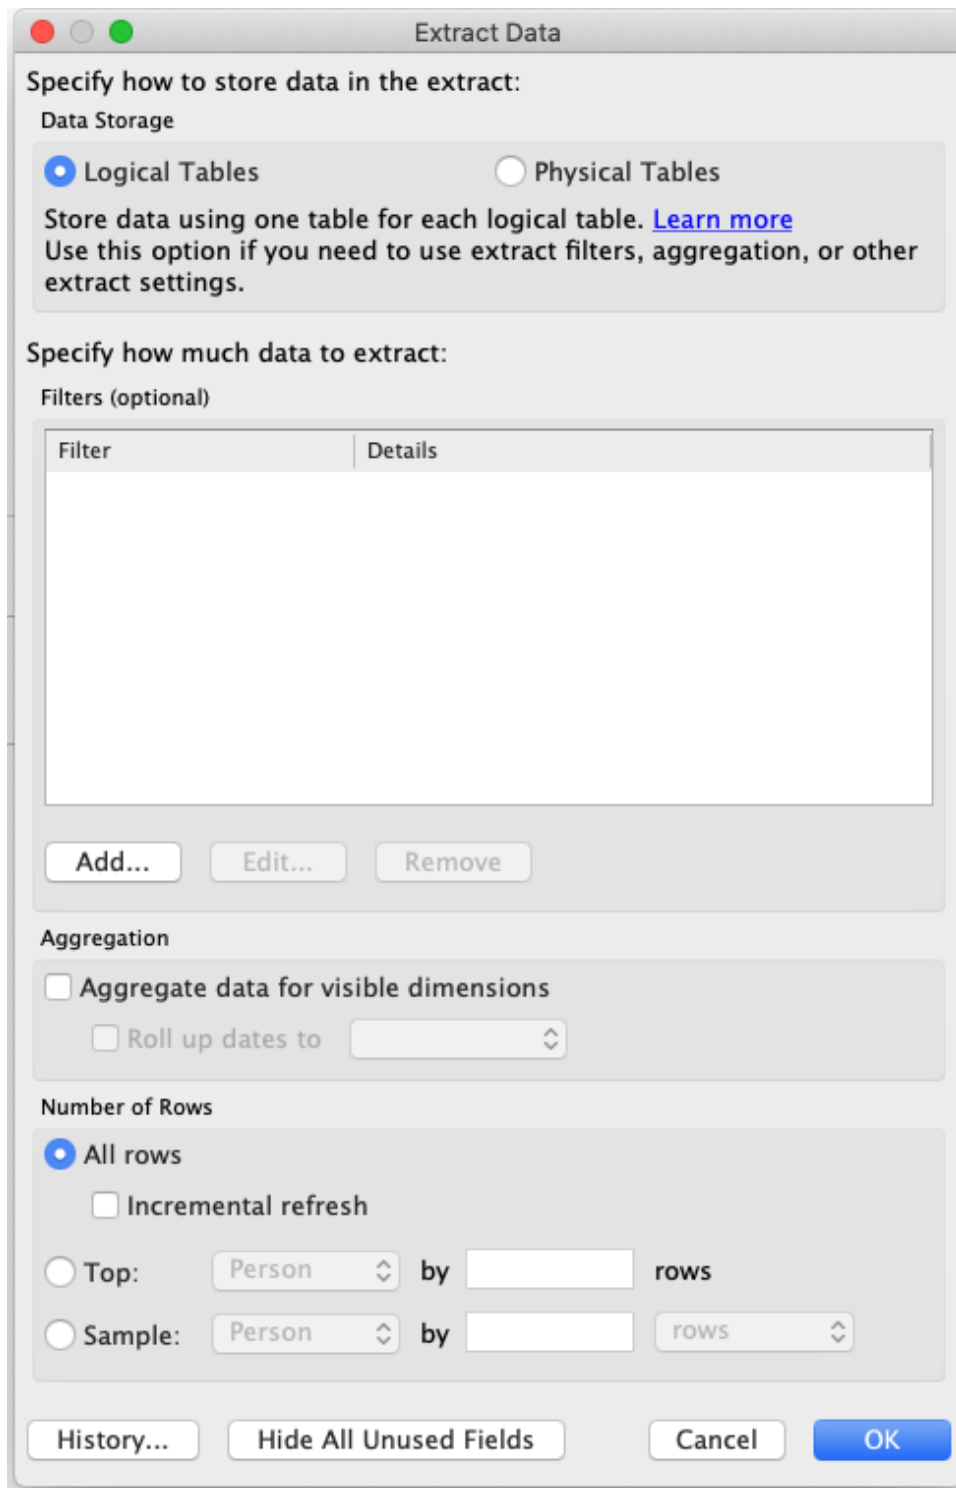

A copy of the published data source is added to the Data pane.

2. Right-click the local copy, and select **Extract Data**.
Note: If the local copy is a published extract you can skip this step.

3. In the Extract Data dialog box, click the **Extract** button to extract all data from the data source. Creating an extract of the data source allows the person you are sharing the

workbook with to have access to a copy of the data source.

The 'Extract Data' dialog box is used to configure how data is stored and extracted. It includes sections for Data Storage, Filters, Aggregation, and Number of Rows.

Extract Data

Specify how to store data in the extract:

Data Storage

☒ Logical Tables ☐ Physical Tables

Store data using one table for each logical table. [Learn more](#)
Use this option if you need to use extract filters, aggregation, or other extract settings.

Specify how much data to extract:

Filters (optional)

| Filter | Details |
|--------|---------|
|--------|---------|

Aggregation

☐ Aggregate data for visible dimensions

☐ Roll up dates to

Number of Rows

☒ All rows

☐ Incremental refresh

☐ Top: by rows

☐ Sample: by rows

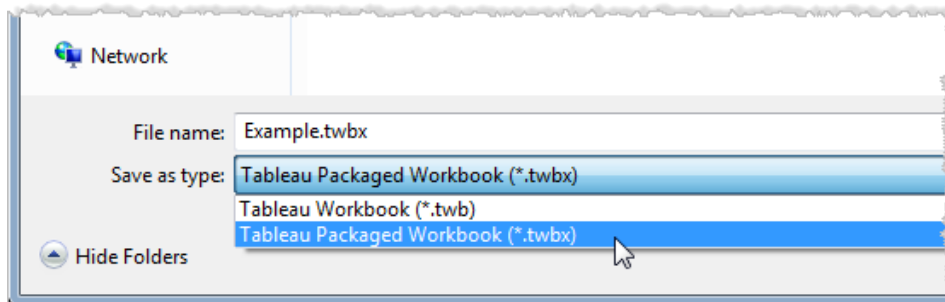

4. In the Data pane, right-click the published data source, and then select **Replace Data Source**.

5. Verify that the published data source will be replaced by the local data source, and then click **OK**.

6. Right-click the published data source, and then click **Close**.
7. Select **File > Save As**.
8. From the **Save as type** drop-down menu, select Tableau Packaged Workbook (*.twbx).

After the local copy and extract of the local copy is created and the packaged workbook saved, you can send your workbook.

Unpackage a .twbx

Packaged workbooks can be unpackaged.

On a Windows or macOS computer, rename the file with a .zip extension (for example, from myfile.twbx to myfile.zip) and then double-click it.

When you unpackage a workbook, you get a regular workbook file (.twb), along with a folder that contains the data sources and images that were packaged with the workbook.

Save Workbooks with Tableau Public

If you want to share your data discoveries with the world outside of your organisation, you can save your workbook to Tableau Public, a free cloud service. On Tableau Public, anyone can interact with your views, or download your workbooks or data sources. For information, go to the [Tableau Public website](#).

Important: Workbooks and data published to your Tableau Public profile are not private and are freely accessible to anyone. To work offline or use private data, you can save workbooks locally with the free Tableau Desktop Public Edition.

Save a workbook to Tableau Public

1. With your workbook open in Tableau Desktop Professional or Public Edition, select **Server > Tableau Public > Save to Tableau Public**.

Note: This option is available only if you've created a viz that contains at least one field.

2. Sign in using your Tableau Public account.

If you don't have an account, select the link to create a new one.

3. Type a name for the workbook and click **Save**.

When you save a workbook to Tableau Public, the publishing process creates an extract of the data connection.

Tip: The title becomes part of your view's metadata. Use a unique title that will help others find it when they search. (The title shown in the image is a good example of how *not* to name your workbook.)

After the workbook is published, you are redirected to your account on the [Tableau Public website](#).

On your profile page on Tableau Public, do any of the following to customise your profile:

- Hover the pointer over a viz to get access to actions such as selecting it as your featured viz, or hiding, downloading or deleting it.
- Hover the pointer over a viz and then select **View** to open the viz's home page. There you can select **Edit Details** to customise metadata such as workbook name and description, add a permalink, and change other settings.
- To get a link to share on social media or code to embed in a web page, display a view, and then click **Share** at the bottom of the view. (You can get links and embed code for other Tableau Public users' views this way, too.)

Save a workbook locally with Tableau Desktop Public Edition

With the free [Tableau Desktop Public Edition](#), you can choose to either save workbooks to Tableau Public or save workbooks locally. Local saving allows you to work offline until you're ready to share your work on Tableau Public, and it gives you the option to work with private data that can't be shared on Tableau Public.

Revert a Workbook to the Last Saved Version

You can revert a workbook at anytime to undo all of the changes you've made to it since you last saved it.

To revert to the last saved version of a workbook:

- In Tableau Desktop, select **File > Revert to Saved**, and then select **Revert** in the warning dialog box that opens.
- In web authoring mode, select **File > Revert**.

The Revert command is only available for workbooks (.twb) that do not have connections to Extract data sources.

Auto-save Workbooks

In Tableau Cloud, Autosave saves the edits that you make to a new or existing workbook while you work.

How does Auto-save work?

As soon as you start making changes to a new or existing workbook, we'll start to autosave the changes to a private draft version of your workbook. When you're ready to share your changes with others, use **Publish** to replace the last published revision with your draft.

Note: Auto-save doesn't automatically save every type of change, such as specific types of assets. In these cases, you'll see a notification that you must **Publish** your workbook to save your edits.

Workbook file size

Auto-save is available for workbooks that are smaller than 5 MB. You must **Publish** to manually save changes for larger workbook files.

What if multiple users edit the same workbook?

When more than one user works on the same workbook, each user's edits are associated with and saved to their own private draft. When you begin to edit a workbook, you'll receive a notification if the version you're working from has a published revision from another user. You're then offered a choice to either discard your draft and edit the current revision or to resume editing your private draft.

Warning: You won't receive a notification if another user publishes a revision after you've begun your edits to your private draft. If another user publishes their draft before you publish your version, your changes will overwrite theirs.

You can check the workbook **Revision History** to see when the workbook was last published. From the revision history, you can choose to **Preview** a revision or **Restore** a previous revision. For more information, see [Work with Content Revisions](#).

If you choose to discard your draft to edit the current revision, the draft and associated asset files that were uploaded are deleted. To retain assets and edits that you made in your private draft, you can manually incorporate the edits of other users into your private draft. Then, publish the workbook with both sets of changes.

Permissions requirement

Auto-save is available to Creators and Explorers (can publish) with web editing capabilities at the workbook level. If a user has web editing capabilities at the view level only, Auto-save won't be turned on.

Export Views from Tableau Desktop to Another Application

There are several ways to get views and workbooks out of Tableau Desktop and into a presentation, report, or web page.

Note: If you're using Tableau Cloud or Tableau Server, instead see [Download Views and Workbooks on page 3417](#) and [Link to a PNG, PDF or CSV of a View on page 3416](#).

Copy a view as an image

You can quickly copy an individual view as an image and paste it into another application, such as Microsoft Word or Excel. If you're using Tableau Desktop on macOS, a TIFF (Tagged Image File Format) image is copied to the clipboard. On Windows, a BMP (Bitmap) image is copied.

1. Select **Worksheet > Copy > Image**.
2. In the Copy Image dialog box, select the elements you want to include in the image. If the view contains a legend, under Image Options, select the legend layout.
3. Click **Copy**.
4. Open the target application and paste the image from the clipboard.

Export a view as an image file

To create an image file that you can reuse, export the view rather than copy it. You can choose BMP, JPEG, PNG or SVG image file formats on macOS or Windows. Note, however, that SVG substitutes Tableau fonts (Tableau Regular, Tableau Semibold, etc.) with a similar font.

1. Select **Worksheet > Export > Image**.
2. In the Export Image dialog box, select the elements you want to include in the image. If the view contains a legend, under Image Options, select the legend layout.
3. Click **Save**.
4. In the Save Image dialog box, specify a file location, name and format. Then click **Save**.

Export as a PowerPoint presentation

When you export a workbook to Microsoft PowerPoint format, selected sheets become static PNG images on separate slides. If you export a story sheet, all story points export as separate slides. Any filters currently applied in Tableau are reflected in the exported presentation.

Tip: To optimise a dashboard for PowerPoint, on the Dashboard tab, choose **Size > Fixed Size > PowerPoint (1600 x 900)**.

To export a workbook to PowerPoint:

1. Select **File > Export as PowerPoint**.
2. Select the sheets you want to include in the presentation. (Hidden sheets can also be included.)

The exported PowerPoint file reflects the file name of your workbook, and the title slide states the workbook name and the date the file was generated.

Tip: Choose **File > Page Setup** to show or hide titles, views, legends and captions for an individual sheet. (These options in the Show section aren't available for dashboards.)

Export to PDF

To create a vector-based file that embeds the Tableau fonts, print to PDF. After customising the layout of page elements using the **File > Page Setup** dialog, choose **File > Print to PDF**. For detailed instructions, see [Print Views from Tableau Desktop on page 3107](#)

Export Data from Tableau Desktop

You can export the data in a Tableau data source, including all or part of the records from your original data. Alternatively, you can export only the portion of data used to generate the view.

Note: If you're using Tableau Cloud or Tableau Server, instead see [Download Views and Workbooks](#) on page 3417 and [Link to a PNG, PDF or CSV of a View](#) on page 3416.

Export data in the data source

After you join tables from one or more connections and make general customisations (for example, create a calculated field, pivot fields, create groups, apply data source or extract filters, etc.) to your Tableau data source, you might want to share or reuse the data in its new form. You can do this using one of the methods listed below.

- [Export your data to .csv file](#) below
- [Extract your data](#) on the facing page
- [Export the data source](#) on the facing page

Note: The export may exclude some table calculations and level of detail expressions.

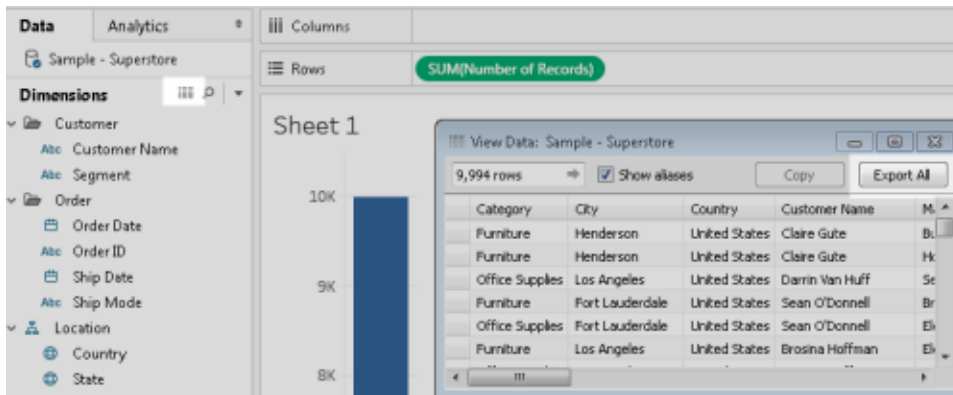

Export your data to .csv file

Because the .csv format is one of the most simple structured formats for data, it is supported by a wide range of tools, databases, and programming languages. Exporting your data in the Tableau data source using this format creates an independent data set and can be a convenient and flexible way to share your data with others.

There are two primary ways you can export your data in the data source to a .csv file in Tableau: from the Data Source page and from the view.

- **From the Data Source page:** On the Data Source page, select **Data > Export Data to CSV** to export all the data in your data source to .csv file.
- **From the view:** On the sheet tab, drag a field to the Columns or Rows shelf, click the

View Data icon in the Data pane, and click the **Export All** button.

Extract your data

Another way to export all of your data or a subset of your data in the data source is to create an extract (.hyper) file. An extract functions as an independent data set, which you can use to connect directly from Tableau. For more information, see [Extract Your Data on page 925](#).

Export the data source

After you connect to your data, you can export and save your data source as a Tableau data source (.tds) file. Saving the data source creates a shortcut to your remote data and allows you to avoid having to create a new connection to a specific data set each time. For more information, see [Save Data Sources on page 975](#).

Export data used in the view

After you create a view, you can also export just the data used to generate that view.

The fields that are exported come from the fields on the shelves of the sheet. However, fields that function as external filters, in other words, the fields that appear only on the **Filters** shelf, are not included in the export. If you want to include other fields with the exported data without changing the baseline view, you can place those fields on the **Detail** shelf.

The various methods for exporting the data used to generate the view is listed below.

- [Export data in the view to Microsoft Access or .csv on the next page](#)
- [Export crosstab of data in the view to Excel on the next page](#)
- [Copy data in the view to clipboard on page 3101](#)
- [Copy crosstab of data in the view to clipboard on page 3102](#)

Export data in the view to Microsoft Access or .csv

Export the data that is used to generate the view as an Access database (Windows only) or .csv file (Mac only).

1. In Tableau Desktop, select **Worksheet > Export > Data**.
2. Select a location and type a name for your Access database or .csv file.
3. Click **Save**.

If you're on Windows, the Export Data to Access dialog box displays to give you the option to immediately use the new Access database and continue working in Access without interrupting your work flow.

Export crosstab of data in the view to Excel

You can export directly to Excel the data used to generate the view formatted as a crosstab. When you export your view as a crosstab, Tableau automatically opens the Excel application and pastes a crosstab version of the current view into a new Excel workbook.

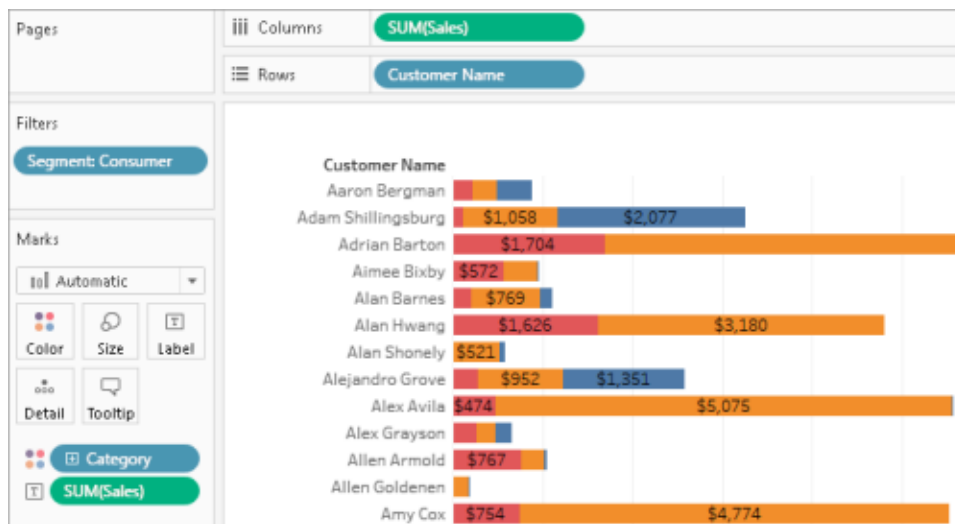

Although this option provides a direct method for exporting your data to another application, performance of the export can be affected because it is simultaneously copying and formatting the data. If the view you are exporting contains a lot of data, a dialog box opens asking whether you want to export the formatting. In this case, if you choose to exclude the formatting from the export, performance of the export might improve.

- In Tableau Desktop: select **Worksheet > Export > Crosstab to Excel**.
If you're using a Mac, this option opens a dialog box where you can save the file. You must then manually open the file in Excel.
- In Tableau Server or Tableau Cloud, open a view or dashboard and select **Download > Crosstab**.
Select which sheets from the workbook to export data from.

Copy data in the view to clipboard

Copy the data used to generate the view so that you can paste it into another application.

1. Create a view.

2. Select **Worksheet > Copy > Data**.
3. Open another application, such as Word, and paste the data into the document.

In this example, the fields placed on the Columns, Rows, and Colour shelves are copied into the document. However, the **Customer Segment** field is not copied because it is an

external filter because it appears only on the Filters shelf.

| Category | Customer Name | Sales |
|-----------------|--------------------|---------|
| Furniture | Aaron Bergman | \$391 |
| Furniture | Adam Shillingsburg | \$2,077 |
| Furniture | Adrian Barton | \$1,280 |
| Furniture | Aimee Bixby | \$16 |
| Office Supplies | Aaron Bergman | \$274 |
| Office Supplies | Adam Shillingsburg | \$1,058 |

Copy crosstab of data in the view to clipboard

You can copy a crosstab version of a view so that you can paste or transfer the data into another application. The pasted data always appears as a crosstab, even if the initial view of the data in Tableau did not use a crosstab format.

Copying a crosstab is restricted by some general conditions:

- You must copy all records in the view. You cannot copy a subset of records.
- This option is valid for aggregated views only. It cannot be used on disaggregated views of data because a crosstab is by definition an aggregated view of data. This means the **Aggregate Measures** option on the Analysis menu must be selected in order for copying a crosstab to work properly.
- You cannot copy a crosstab if the view contains continuous dimensions such as continuous dates and times.
- Other restrictions may apply depending on the data in your view.

After the general conditions are met, copy the crosstab.

1. Create a view.

2. Select **Worksheet > Copy > Crosstab**.
3. Open another application, such as Excel, and paste the crosstab.

| | A | B | C | D | E |
|---|--------------------|-----------|------------|------------|---|
| 1 | | Category | Category | Category | |
| 2 | Customer Name | Furniture | Office Sup | Technology | |
| 3 | Aaron Bergman | \$391 | \$274 | \$222 | |
| 4 | Adam Shillingsburg | \$2,077 | \$1,058 | \$120 | |
| 5 | Adrian Barton | \$1,280 | \$11,489 | \$1,704 | |
| 6 | Aimee Bixby | \$16 | \$379 | \$572 | |
| 7 | Alan Barnes | \$131 | \$769 | \$213 | |

Copying Information Between Workbooks

Individual sheets, dashboards and stories can be copied and pasted between workbooks in Tableau Desktop(although not in web authoring). This feature allows you to easily copy an analysis or port a data source into another workbook. It is also possible to import an entire workbook into your current workbook.

What gets copied or saved with selected sheets

When you copy, save or export selected sheets, the data source or sources that are used on that sheet are also copied. This includes any calculations, parameters, sets, etc. Custom shapes and colours are also included. If the sheet being copied is a dashboard or story, all of the sheets that are used on that dashboard are also copied, whether they are hidden or not.

Custom colours and shapes will be available in the copied or imported sheet but will not be added to your Tableau Repository. If you would like these to persist for other workbooks, refer to [Create Custom Colour Palettes on page 3009](#) and [Use custom shapes](#).

If you are trying to copy formatting between sheets, see [Copy and paste worksheet formatting](#).

How Tableau handles duplicate items

When you paste or import sheets from a different workbook, some items might already exist in the destination workbook, or some items might have the same name in both places. If Tableau encounters an exact duplicate item in the Data pane, such as a calculation, it does not paste or import that item into the destination workbook. However, if an item in the Data pane has the same name but is defined differently, Tableau imports and renames it.

Tableau also pastes or imports sheets and data sources with duplicate names – whether only the name is identical, or their names and contents are identical – and it renames the newer copy.

Copy and paste sheets between workbooks

Copying and pasting sheets is a quick way to combine information from different workbooks or create a new workbook. It is also useful workaround to [replace a data source](#) for a single sheet rather than all sheets that use the data source. You can copy one or more sheets from the tabbed sheet view, filmstrip view or sheet sorter view. Use Shift + click or Ctrl + click to select multiple sheets.

To copy and paste a worksheet using the filmstrip view, do the following:

1. Open a workbook and click the **Filmstrip** button in the status bar.

2. Select the thumbnails of the sheets you want to copy, then right-click (Control-click on Mac) and select **Copy**.

Tableau copies the information in the file format (.twb or .twbx) of the workbook.

3. Open the destination workbook, or create a new workbook. Right-click (Control-click on Mac) on the tab for any sheet, and select **Paste**.

Pasted sheets are placed after existing worksheets, dashboards, and stories.

Note: The **Paste** option is not available when the active sheet is a story.

4. Save the changes.

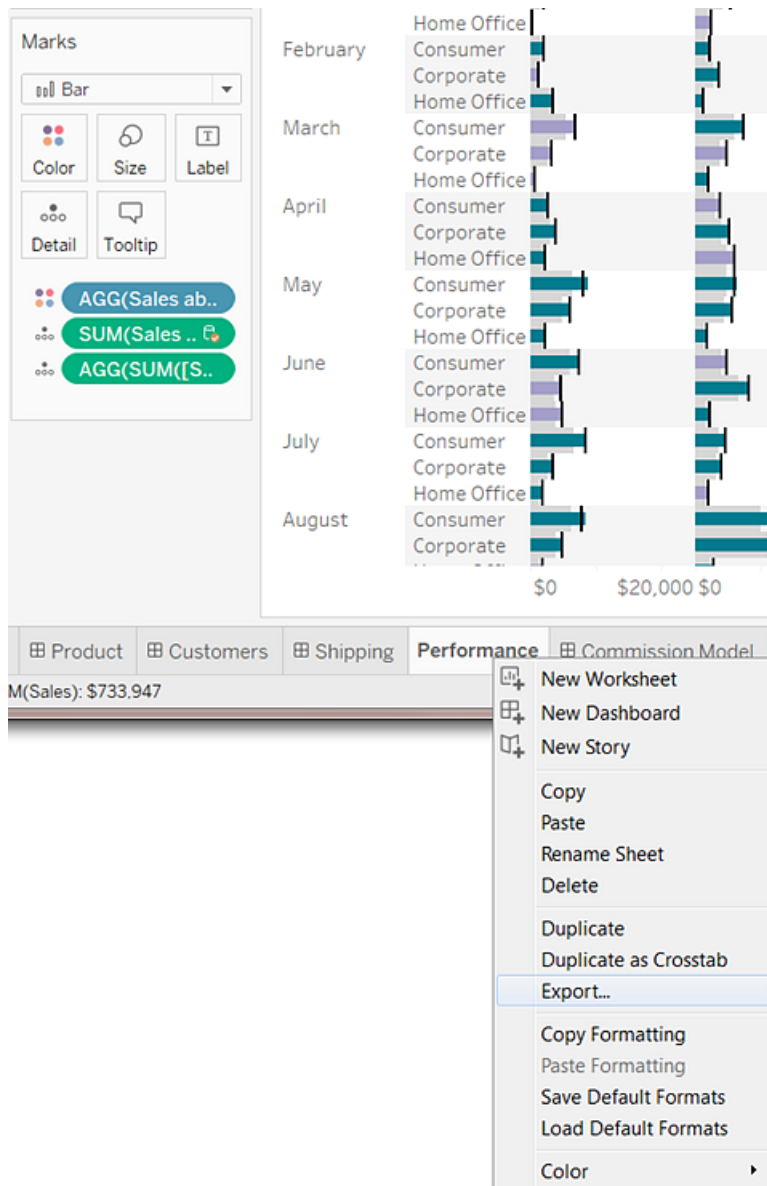

Export and import sheets between workbooks

If you want to extract a subset of information from a larger workbook to maintain as a standalone file, you can export or save selected sheets to a new workbook. You can then import that workbook into an existing one to incorporate its sheets and other objects into the existing workbook.

Note: These steps describe how to share your work among Tableau workbooks. You can also export views to use outside of Tableau. For information, see [Export Views from Tableau Desktop to Another Application](#) on page 3096.

1. Open the workbook that contains the sheets you want to export to a new file.
2. Using the tabbed worksheet, filmstrip view, or sheet sorter view, right-click (Control-click on Mac) the sheet tab or thumbnail view, and then select **Export** to export a single sheet. Use Shift + click or Ctrl + click to select multiple sheets.

3. In the Save As dialog box, specify the file format you want to save (.twb or .twbx), select the location for the new workbook file, give it a name, and then click **Save**.

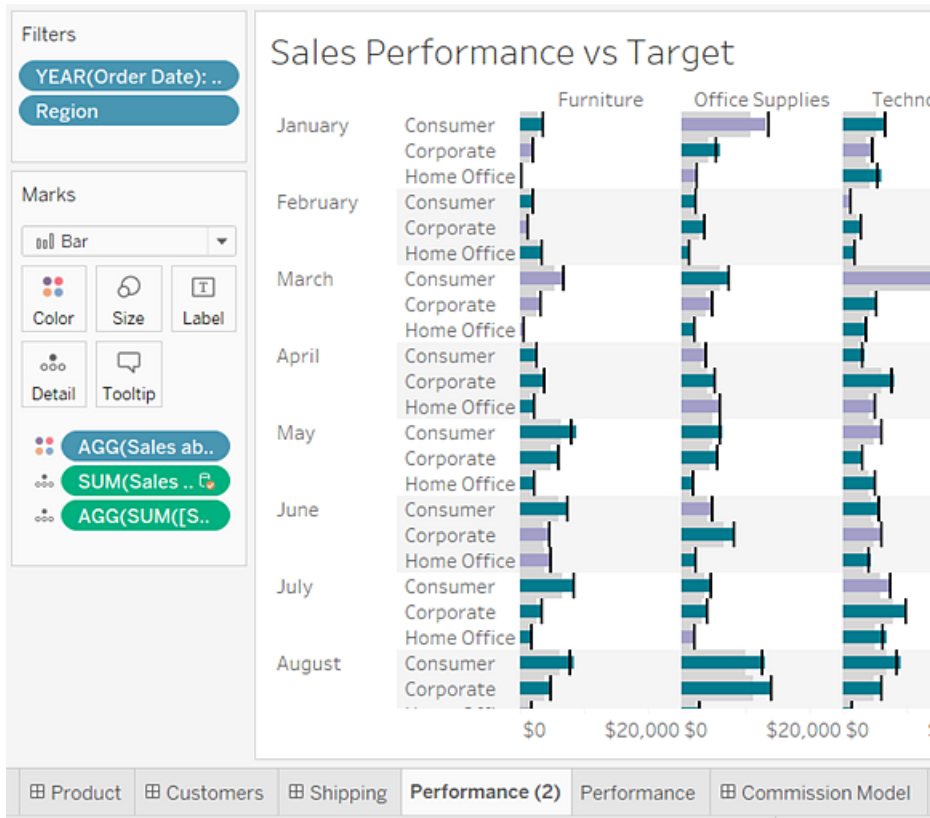

Import an entire Tableau workbook

After you save or export selected sheets to a new workbook (.twb) file, you can import the information into another workbook.

1. With the existing workbook open, select **File > Import Workbook**.
2. Select the workbook that contains the sheets you saved from another workbook, and click **Open**.

The following image shows the result of importing a workbook that contains a sheet with the same name as a sheet in the existing workbook. Tableau adds a number after the name of the imported sheet.

Print Views from Tableau Desktop

Before printing, specify how you want the printed page to look using the Page Setup dialog box. Then print to a printer or PDF.

Set up the page

You can apply different page setup options for each worksheet in a workbook. For example, worksheets can print with titles showing or hidden, with unique page orientation, and more.

To begin, select **File > Page Setup**.

General settings (available for individual sheets, not dashboards)

- **Show** - Show or hide the title, view, caption, colour legend, shape legend, size legend and map legend.
- **Headers and Breaks** - Control the appearance of these table elements.
 - Repeat headers and legends on each page – adds table row and column headers at the top of each printed page when a view breaks across several pages.
 - Break pages on pane boundaries – prevents page breaks in the middle of a table cell.
- **Pages Shelf** - If the view uses the Pages Shelf, specify whether to print the current page or all pages.

Layout settings

- **Legend Layout** - If you include one or more legends, select how you want the legends to appear on the printed page.
- **Margins** - Specify top, bottom, left, and right margins by typing values into the text boxes.
- **Centring** - Optionally, select whether to centre the view horizontally or vertically – or both – on the page.

Print Scaling settings

These settings affect only printed documents, not exported images or PDFs. However, the page orientation settings are used as the default when you publish the workbook to Tableau Cloud or Tableau Server.

- **Print Scaling** - Scale a view to fit within a single page or print across multiple pages. Select from the following options:
 - Automatic – Scales the view automatically based on the paper size.
 - Scale to – Scales the view to the specified percentage of its original size.
 - Fit to – Scales the view to fit within the specified area. Select the number of printed pages across and down. For example, if you have a really wide view that is not very tall, you can specify three pages across by one page down.

- **Page Orientation** - Specify how you want the view oriented on the printed page. Select from the following options:
 - Use Printer Setting – Use the page orientation that is already specified by the printer.
 - Portrait – Presents the view so that it is oriented vertically on the printed page.
 - Landscape – Presents the view so that it is oriented horizontally on the printed page.

The following diagram shows the difference between portrait and landscape page orientations.

Print a view

After you have configured the [Page Setup](#) settings, select **File > Print**. The following options in the Print dialog box are unique to Tableau.

Show Selections

When this option is selected any selections you've made in the views will be maintained while printing.

Change the Print Range

When you print from a workbook with multiple worksheets, each worksheet represents one or more printed pages, depending on the page setup.

Select from the following print ranges:

- **Entire Workbook** - Prints all the worksheets in the workbook.
- **Active Sheet** - Prints only the sheet currently displayed in the workbook.
- **Selected Sheets** - Prints the selected sheets.

You can select multiple worksheets in a workbook by holding down the CTRL or Shift keys (or the ⌘ key on a Mac) while clicking the worksheet tabs that you want to select.

Print to PDF

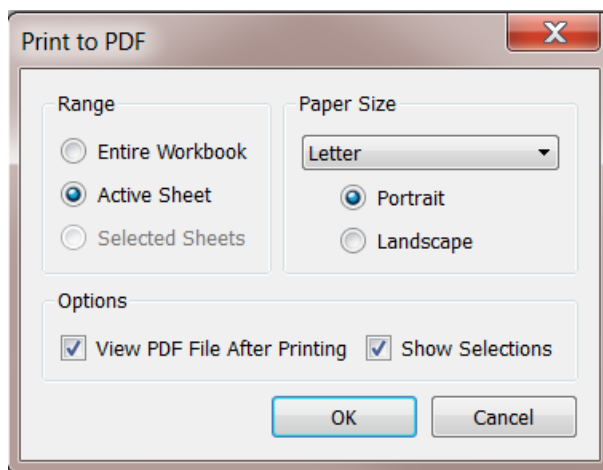

Note: If you're using Tableau Cloud or Tableau Server, instead see [Download Views and Workbooks on page 3417](#) and [Link to a PNG, PDF or CSV of a View on page 3416](#).

In Tableau Desktop, you can save views as PDF files rather than printing them as hard copies. You do not need to have Adobe Acrobat installed on your computer.

When you print an individual sheet to PDF, filters in the view are not included. To show filters, create a dashboard containing the sheet and export the dashboard to PDF.

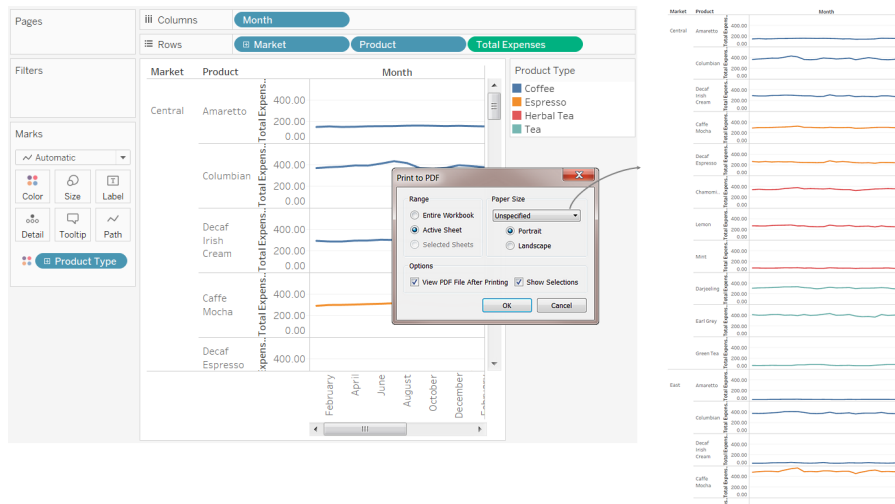

Print to PDF using a Windows computer

1. Specify **page setup** options for each sheet in your workbook.
2. Select **File > Print to PDF**.

3. In the Print to PDF dialog box, select the print Range:

- Entire Workbook - Publishes all the sheets in the workbook.
 - Active Sheet - Publishes only the sheet currently displayed in the workbook.
 - Selected Sheets - Publishes the selected sheets. To select multiple sheets in a Tableau workbook, hold down the Ctrl key as you select sheet tabs along the bottom of the Tableau workbook.
4. Select a **Paper Size**. If you select Unspecified, the paper size will expand to the necessary size to fit the entire view on a single page.

5. Select **View PDF File After Printing** if you want to automatically open the PDF after creating it. This option is only available if you have Adobe Acrobat Reader or Adobe Acrobat installed on your computer.
6. Select whether to **Show Selections**. When this option is selected the selections in the views are maintained in the PDF.
7. Click **OK** and specify where you want to save the PDF. Then click **Save**.

Print to PDF using a Mac computer

1. Specify **page setup** options for each sheet in your workbook.
2. Select **File > Print**.
3. In the Print dialog box, click **Show Details** to select a print range:
 - Entire Workbook - Publishes all the sheets in the workbook.
 - Active Sheet - Publishes only the sheet currently displayed in the workbook.

- **Selected Sheets** - Publishes the selected sheets. To select multiple sheets in a Tableau workbook, hold down the Command key as you select sheet tabs along the bottom of the Tableau workbook.

4. Click **PDF > Save as PDF**.

5. Specify where you want to save the PDF, then click **Save**.

Publish Data Sources and Workbooks

Suppose you create a view that exposes a new range of questions in the data you're using, and you want to share this analysis with other people using this data. Or maybe you are your team's Data Steward, in charge of building the data models approved for use by analysts, and meeting your organisation's requirements for security, compliance, performance and so on.

You can share your work with the rest of your team by publishing it to Tableau Server or Tableau Cloud. After it's published, you and your team can access it through your web browser or the Tableau mobile app. Publishing data sources can also help you to centralise data management.

In other resources

For the steps on how to publish, see the following topics:

- [Publish a Data Source](#) on page 3143
- [Comprehensive Steps to Publish a Workbook](#) on page 3120
- [Upload Workbooks to a Tableau Site](#) on page 3234

Note: If you do not have Tableau Cloud or Server, you can share analysis on Tableau Public, a free cloud service. As the name suggests, views published to Tableau Public are publicly accessible. For more information, see public.tableau.com.

Why publish

You can publish data sources and workbooks when you want to widen the audience for your data analysis within your organisation. By publishing you can begin to do the following:

- Collaborate and share with others
Allow people in your organisation to view, interact with, download, subscribe to, share, edit and save published views, even if they do not use Tableau Desktop. Incorporate views into blog posts or websites.
- Centralise data and database driver management

Create and publish data models that everyone can use. Centralised data management allows for sharing a single source for your Tableau data. All workbooks connected to the published data reflect updates to it.

In addition, when you publish and connect to data on the server, people connecting to the data from Tableau Desktop do not need to install and maintain database drivers on their own computers.

- Support mobility

Access your data from a different computer or location, through a web browser or the Tableau Mobile iOS app. Sign in to your organisation's Tableau Server from a private network offsite.

What you can publish

Content types you can publish include:

- **Data sources:** You can publish data sources that others can use to build new workbooks. A data source can contain a direct (or live) connection to your database or an extract you can refresh on a schedule.

For information, see [Best Practices for Published Data Sources](#) on page 3137.

- **Workbooks:** Workbooks contain your views, dashboards and stories, and data connection. You can include local resources, such as background images and custom geocoding, if they reside in a location that the server or other Tableau users cannot access.

Who can publish

To publish to Tableau Server or Tableau Cloud, your server or site administrator must grant you the following capabilities:

- A *site role* of **Creator** (formerly Publisher) on the site you're publishing to.
- **View** and **Save** capabilities set to **Allowed** on the project into which you publish.

If you use Tableau Desktop and are not sure whether you can publish to a server, or you are having trouble publishing, see your Tableau administrator. If you're an administrator, see [Content Access and Ownership](#) in the Tableau Server help (or the [Tableau Cloud version](#)) for more information about site roles and permissions.

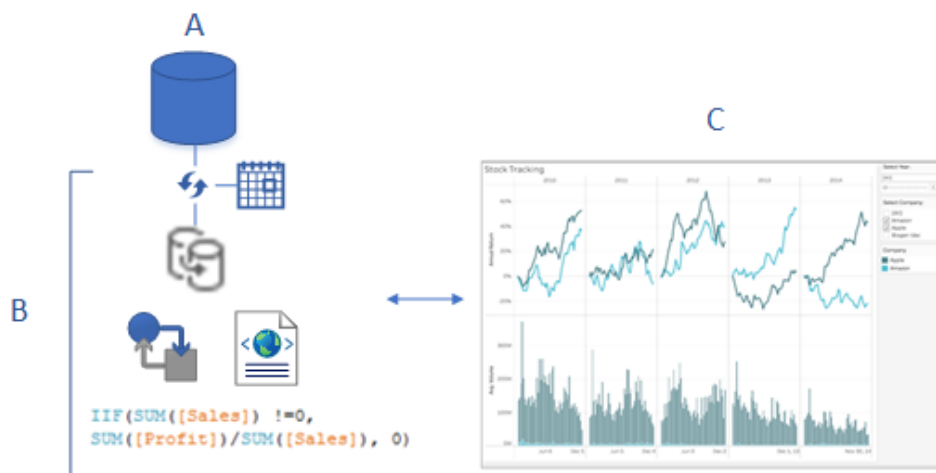

Prepare for Publishing a Workbook

When you publish a workbook, you need to make a decisions that determine how others will access the views and the data behind them. You also need to take into account the experience you and others will have of interacting with the views on the server. Before you publish your workbook, use the information in this topic to help you make these decisions and improve the performance of the workbook.

Note: If you have a Tableau site administrator, check with them on whether your organisation already has publishing guidelines that have already answered these questions.

What makes up a typical published workbook

During the publishing process, you select settings that determine how the pieces that make up the workbook interact with each other. The following image shows a simplified overview of the structure of a workbook.

- A. The underlying (original) data that you connected to when you created the workbook. When you publish, you specify whether to include credentials for accessing this data, or whether to require users to enter credentials to access it.
- B. The Tableau data source. This is where the action is. It contains the XML metadata that describes how to access the underlying data (A), field customisations or calculations you made in Tableau, when to refresh the extract if there is one.

In this image, the data is embedded in the workbook, and it contains an extract connection and refresh schedule, some calculations, and so on.

- C. A view showing data from B, which you want to make available for your colleagues to edit or interact with on the server. When you publish, you can select the sheets – which include views, dashboards, and stories – you want to share.

Decide how to access the data and keep it up-to-date

During the publishing steps, you need to answer the following questions about the data connection. For help with the answers, see [Best Practices for Published Data Sources on page 3137](#).

- Will you publish with a live connection to the data, or will you create an extract?

If you publish live connections to Tableau Cloud, see [Authorise Access to Data Published to Tableau Cloud on page 3156](#).

- Do you want to publish the workbook's connections as separate, standalone Tableau data sources (and then connect the workbook to the published data); or embed the data into the workbook?

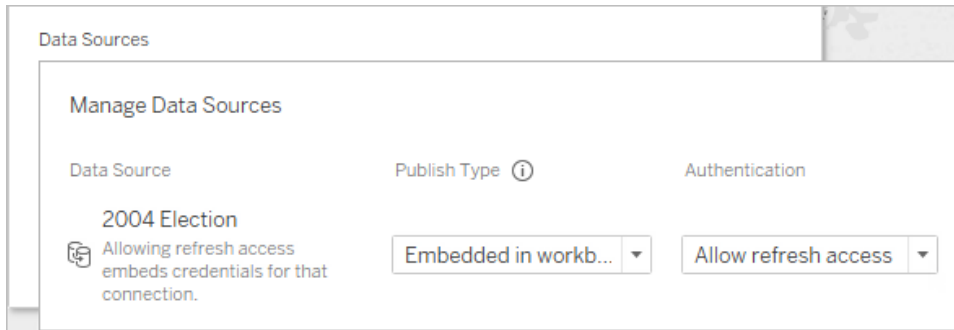

Tip: If the workbook already connects to a Tableau data source, you keep the existing connection. That means you've just answered this question.

- Do you want the workbook to show the data when other users open the workbook, or do you want to require them to provide database credentials? (Either way, they must also have access to the site and project you publish to.)

This can be complicated depending on the data the workbook connects to. In many cases, [the simple path to data](#) described below works great. If it doesn't work for you (or you're not sure), see [Set Credentials for Accessing Your Published Data on page 3153](#).

The simple path to data authorisation

When you go through the publishing steps, you specify how your workbook users will access the data the workbook connects to. You do this in the **Data Sources** section of the Publish Workbook dialog box.

Depending on the connection type, the simple path might work for your environment. You would do one of the following:

For a connection to a Tableau data source: Keep the existing connection and embed the password.

For other data connections:

1. Before you open the Publish Workbook dialog box, create an extract and include only the data you need for the workbook.
2. In the Publish Workbook dialog box, embed the extract in the workbook and select **Allow refresh access**. The latter embeds the credentials in the connection.
3. After you specify remaining settings and click Publish, set up a refresh schedule.

For the complete steps, see [Comprehensive Steps to Publish a Workbook](#) on page 3120.

Scenarios where data authorisation requires some extra effort

The simple path doesn't work best for every situation. Some reasons you might need to divert from it include:

- Instead of embedding data into workbooks, your existing policies mandate publishing data sources separately and connecting workbooks to the Tableau published data sources.

This requires a few more steps than embedding the data; however, where there is a choice between the two, publishing data separately and managing it on the server is considered a better practice.
- You added a user filter to enforce row-level security. In this scenario, publishing live connections is more common, and other steps are required to secure the filter.
- You're publishing to Tableau Server, and you use SAP HANA or Impala single sign-on, or your workbook connects to data that can use impersonation-based authorisation

(SQL Server or Kerberos-enabled data).

- Other reasons that have to do with your organisation's data security or authorisation policies, which your IT staff can help you with.

Even if whatever you decide turns out to be not the best path, you can easily correct it by republishing. In some cases, your site administrator can change the settings on the server directly.

Assess the workbook performance and ease of use

Keep performance and interaction best practices in mind as you build workbooks you want to publish. If changes take a long time to display while you're working in Tableau Desktop, they will take as long or longer to display on the server. Simple steps you can take that can have a big impact include limiting the number of marks you add to a view, limiting the number of views you add to a dashboard, and removing unused fields from your data source.

For additional tips, see the following topics:

- [Make Visualisations Faster on page 3069](#)
- [Design for Performance While You Build a View on page 3065](#)
- [Designing Efficient Workbooks](#), starting with "Writing Efficient Workbooks" on page 6. This Tableau white paper requires that you sign in to the Tableau website using a free Tableau ID. This is the same ID that you use for the Tableau community forums.

Simple Steps to Publish a Workbook

When you want to share a workbook with your colleagues, you can publish it to Tableau Server or Tableau Cloud with a few simple clicks. There, other people can view it, interact with it, and even edit it if their server permissions allow.

Before you publish your workbook, make sure you know the following:

- The name of the server and how you sign in to it. If your organisation uses Tableau Cloud, you can click the Quick Connect link.
- Any publishing guidelines your Tableau administrator might have, such as the name of the project you should publish to.

Publish your workbook

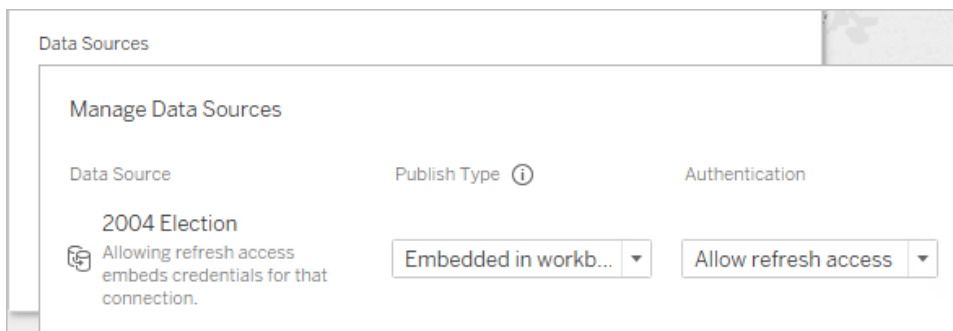

1. With the workbook open in Tableau Desktop, click the **Share** button in the toolbar.

If you're not already signed in to Tableau Server or Tableau Cloud, do so now. If you don't have a site yet, you can create one on Tableau Cloud.

2. In the Publish Workbook dialog box, select the project to publish to.
3. Name the workbook according to whether you're creating a new one or publishing over an existing one.
4. Under Data Sources, select **Edit**. For **Authentication**, select **Allow refresh access** or **Embed password**.

For some data connections, only one authentication option appears. If **None** shows, leave it set to that.

1. Click **Publish**.

If this is your first time publishing a workbook, test it on the server and work out any glitches before letting other users know the workbook is available.

For more details, see these topics:

- [Comprehensive Steps to Publish a Workbook](#) on the next page
- [Publish a Data Source](#) on page 3143
- [Set Credentials for Accessing Your Published Data](#) on page 3153

Let others know the workbook is available on the server

1. Make sure your colleagues can access the site and project you published to.
2. Send them [a direct link to your workbook](#).
3. After they sign in, the workbook opens for viewing, interacting or editing.

Comprehensive Steps to Publish a Workbook

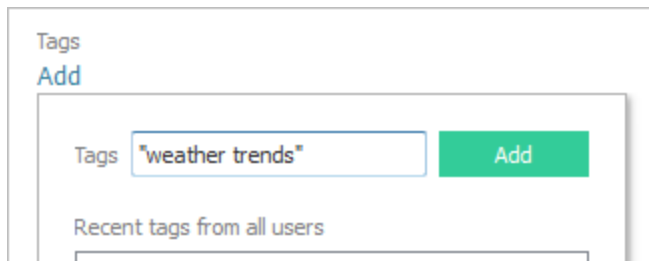

1. In Tableau Desktop, open the workbook you want to publish.
2. Select **Server > Publish Workbook**.

If the **Publish Workbook** option doesn't appear on the **Server** menu, make sure a worksheet or dashboard tab is active (not the Data Source tab).

If necessary, sign in to a server. For Tableau Cloud, enter <https://online.tableau.com>. For more information, see [Sign in to Tableau Server or Tableau Cloud on page 193](#).

3. In the **Publish Workbook** dialog box, select the project, enter a name for the workbook, and add search tags.

Tags help users find related workbooks when they browse the server. Separate tags using a comma or space. To add a tag that contains a space, put the tag in quotation marks.

4. For **Permissions**, accept the default project settings.

Generally, a site admin manages permissions on the server. If you think your workbook is an exception, work with your administrator to determine the best course of action. See

[Set Permissions as You Publish a Data Source or Workbook on page 3150](#).

5. For **Data Sources**: select **Edit** to change whether the data is embedded in the workbook or published separately, or how people authenticate with data sources.
 - If you're publishing an extract and want to set up a refresh schedule, you must select **Embed password** or **Allow refresh access**.

- If your workbook connects to a Tableau data source, we recommend embedding the password. If you instead choose to prompt users, they need extra permissions on the data source.

For more information, see [Set Credentials for Accessing Your Published Data on page 3153](#).

6. Configure **Variable publishing options** below that are available for this workbook.
7. Click **Publish**.
8. (Optional) Set up a refresh schedule for each extract you have published.

The publishing workflow guides you through these steps. For some data types you publish to Tableau Cloud, the publishing process starts Tableau Bridge on your computer.

For more information, see [Schedule Extract Refreshes as You Publish a Workbook on page 3164](#).

Variable publishing options

The following options appear when they're appropriate for the workbook.

Show or hide sheets

By default, Tableau Desktop publishes all sheets in a multiple-sheet workbook. In the **Sheets** section of the Publish Workbook dialog box, you can specify which sheets to include. Hiding sheets is useful when you want to publish a dashboard or story without showing the worksheets that were used to create it.

Important: Hiding sheets isn't a security measure. Anyone who has the **Download Workbook/Save a Copy** capability can access the hidden sheets. Other editing permissions can also allow access to hidden sheets. For more information, see [Content Access and Ownership](#) in Tableau Server Help.

Show sheets as tabs

If you select multiple sheets to show, you can specify how users navigate them.

- Select the **Show Sheets as Tabs** tick box to provide tab-based navigation.

- Clear the tick box to allow people to open only one view at a time.

How sheet tabs are configured also impacts permissions. When a workbook shows sheets as tabs, workbook-level permission rules are applied to the sheets. When the sheets aren't shown as tabs, any changes made to workbook permissions don't apply to the individual sheets (aka views). View-level permissions must be set independently. See the [Set Content Permissions](#) tab in the [Permissions](#) topic for more information.

Show selections

Use Show Selections to highlight a particular portion of the view when others open the workbook. Make your selections in Tableau Desktop before you start the publishing process.

Include external files

In general, if your views contain information that isn't available on the server, you can use **Include External Files** during publishing. With this option, you can include a local flat file. However, the availability of this option depends on whether you're publishing to Tableau Server or Tableau Cloud.

For Tableau Server

If you're publishing content that references data or images on a mapped drive, you can select **Include External Files** when you publish. Alternatively, you can change the connection

information so that the workbook references the UNC path to the data. For example, you could change **D:\datasource.xls** to **\\filesrv\datasource.xls**.

For Tableau Cloud

You can publish a workbook connected to on-premises data, such as Excel, or text private network data, such as Excel files and SQL Server data, which Tableau Cloud can't connect to directly. Check to see if the connections in the data source are supported by Tableau Bridge. For more information, see [Supported Connectors](#).

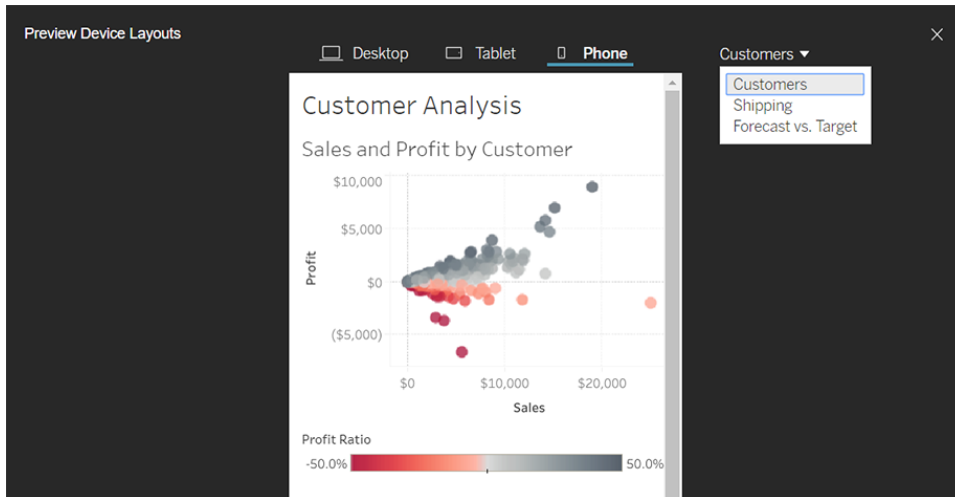

Do one of the following:

- If all the connectors are supported by Tableau Bridge, you can ignore the **Include External Files** tick box, but you must use Bridge to keep the data fresh. For more information, see [Use Tableau Bridge to Keep Tableau Cloud Data Fresh](#).
- If one of the connections in the data source isn't supported by Tableau Bridge, you can select the **Include External Files** tick box. Tableau Cloud can then refresh the data that can be connected to directly. File-based data can't refresh and its data remains static in this case
- For flat files (Excel, .csv, .txt), you can skip ticking Include External Files. A shadow extract is created and the view should display properly.

Preview device layouts

To see how your designs appear on mobile devices, click **Preview device layouts** in the browser when publishing is complete. Then choose a device type above the viz, and a specific dashboard from the menu on the right.

If you don't like a device preview, open the workbook in Tableau Desktop, [adjust device layouts](#), and republish.

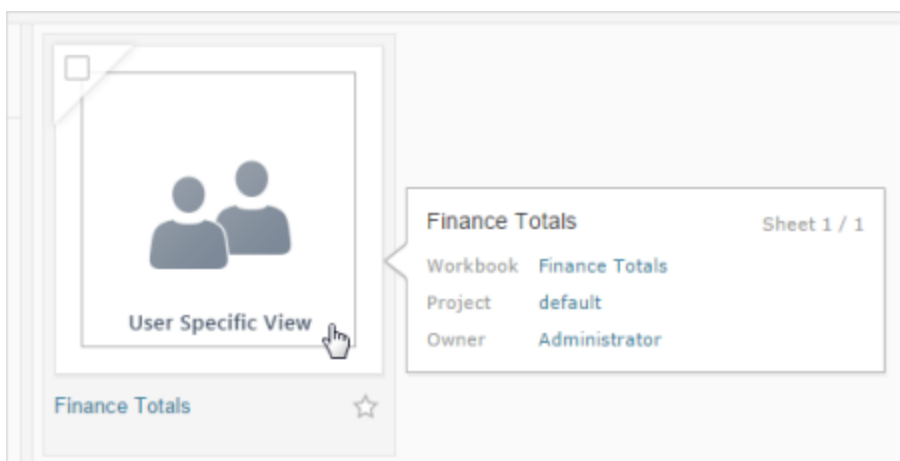

Choose how to generate thumbnails for workbooks with user filters

On the server, users can browse Tableau content with a thumbnail view. These thumbnail images are based on workbook sheets. If your workbook contains user filters, you can specify which user's filter to use when creating the thumbnails. For example, if you want the thumbnail to show all regions of a sales forecast, generate thumbnails based on a user who can see all regions.

In the following scenarios, a generic image appears in place of the view thumbnail.

- The user you select doesn't have permission to see the data.
- The data is from a Tableau Server data source that uses data source filters, user calculations, impersonation or other user references.

To learn more about user filters, see [Restrict Access at the Data Row Level](#) on page 3166.

Publish Views to Salesforce

Bring your views from Tableau Cloud or Tableau Server right to your Salesforce ecosystem by publishing views to a CRM Analytics app or Salesforce Lightning page.

For more information, see [Publish Tableau Content to CRM Analytics](#) in Salesforce Help.

Prerequisites

See a complete list of [prerequisites](#) in Salesforce Help, including required licences, account setup, and permissions.

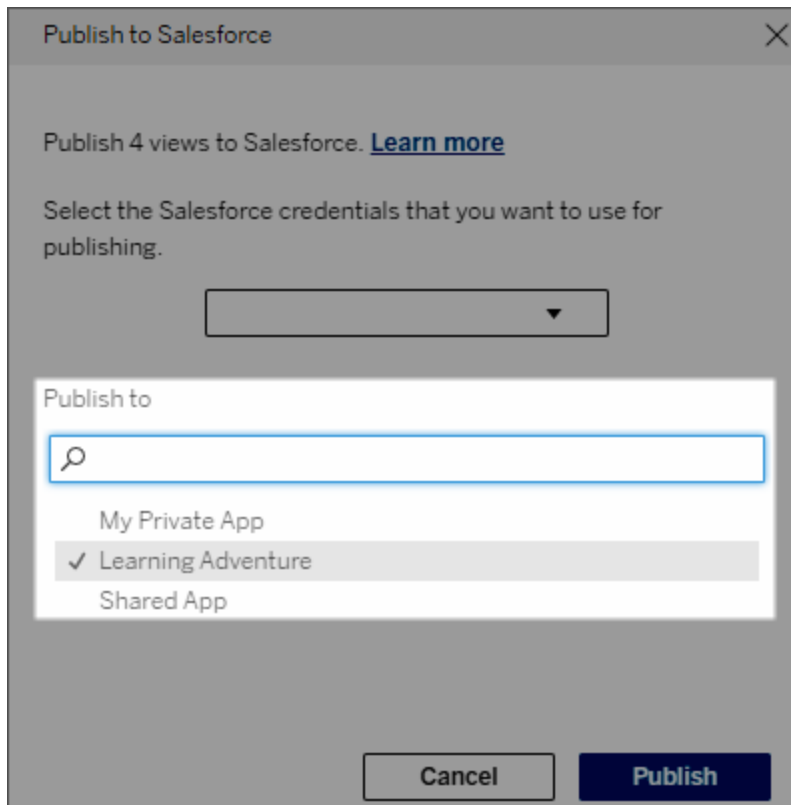

Publish a view to Salesforce

Select one or more views, including dashboards, sheets and stories. Then, choose a destination from a list of CRM Analytics apps to which you have access to edit or manage.

1. Select the view that you want to publish to Salesforce.

Note: You can select a maximum of 25 views at a time to publish to Salesforce.

2. For **Actions**, select **Publish to Salesforce**.
3. Select the Salesforce credentials that you want to use for publishing.
4. Select the destination app that you want to publish to. You can only see apps that you can edit or manage with the signed-in Salesforce user.

5. Click **Publish**.

Who can see the published view in Salesforce?

When you publish a view to Salesforce, anyone with access to the selected CRM Analytics app or Lightning page can see that the content exists. However, only those signed in with existing Tableau permissions can see the view.

Visual Segment Creation to Data Cloud

Segmentation enables data analysts to curate relevant portions of data from their analyses in Tableau and seamlessly transfer them to [Salesforce Data Cloud](#). Once in Data Cloud, marketing professionals can use various platforms (such as [Data Cloud for Marketing](#)) to quickly take high-impact steps to boost marketing campaigns with ease.

About segmentation

Overview and examples

Segmentation that starts in Tableau provides a way for analysts to visually explore their audience (typically customers) and send data about relevant portions of the target population to Data Cloud. From Data Cloud, marketers can publish to other Salesforce clouds or platforms for further analysis and action.

To better understand the benefits of segmentation and how it works, let's consider a likely use case. A data analyst reviewing an analysis of data about a recent marketing campaign in Tableau identifies a segment with lower engagement than the overall campaign audience. The data analyst knows this is an important subset of the overall data that the marketing team will want to address. So, the data analyst sends this low-engagement segment to Data Cloud.

From Data Cloud, a member of the marketing team (or marketer) can access the segment to get a filtered view of the campaign data related to the low-engagement group. With a focused snippet of the overall data, it's easier for the marketer to determine the actions they need to take to improve engagement.

With an action plan in mind, the marketer publishes the segment on Salesforce Marketing Cloud or a similar platform where they created the original campaign.

In this example and similar scenarios, the data analyst benefits from the robust analysis capabilities in Tableau while efficiently handing off their findings to the marketer. The marketer benefits from accessing a targeted view of data that's relevant to them that they can manage and send to the marketing tools they're already using. Most importantly, the customers benefit from marketing campaigns that effectively reach them.

Workflow

With segmentation, you can streamline the collaboration between data analysts working in Tableau and marketers working in Data Cloud and connected marketing platforms. The typical workflow looks like:

1. The data analyst uses a viz in Tableau to analyze and identify a subset of the customer data that's relevant, meaningful and actionable to marketers.
2. The data analyst creates a segment of their audience data from their Tableau viz and sends it to Data Cloud.
3. The marketer accesses the segment from Data Cloud. From there, they create a plan for acting on the segment data, and send it to their activation target. The activation target is

typically a marketing platform or tool that the marketing team uses to manage marketing campaigns, such as [Data Cloud for Marketing](#).

4. The marketer launches the marketing campaign from the activation target, and analyses the campaign results from their platform of choice.

Learn more

To learn more about segmentation, check out these helpful resources:

- [Segmentation](#) (Salesforce Help) – Get a comprehensive review of segmentation and activation on Data Cloud.
- [Segmentation and Activation module](#) (Trailhead) – Learn how to create, filter and activate marketing segments with Data Cloud.
- [Segmentation Filter Examples](#) (Salesforce Help) – For common use cases for segmentation and get inspiration for creating your own segments.
- [Data Cloud and the Ethical Use of Data trailmix](#) (Trailhead) – Learn how you can use ethical practices when building marketing segments in Data Cloud.

Requirements for segmentation

Licence requirements

To create a segment in Tableau, data analysts need a Creator licence for Tableau Cloud.

To publish a segment in Data Cloud, marketers need:

- Developer, Enterprise, Performance or Unlimited Salesforce edition
- Segmentation and Activation add-on licence for Data Cloud
- Standard Data Cloud permission set and the appropriate marketing-specific permissions (see [Data Cloud Standard Permission Sets](#) for more information)
- (Recommended) [Data Cloud for Marketing](#), for activating segments
- (Optional) The Ad Audiences add-on licence for Data Cloud, for activating segments to advertising platforms

Data requirements

Data sources and connections

To create a segment, your [data source](#) must use a single [direct connection to live data](#) (no extracts) and your viz must use a single data source. Published data sources, multiple

connections and multiple data sources aren't supported.

Data model configuration

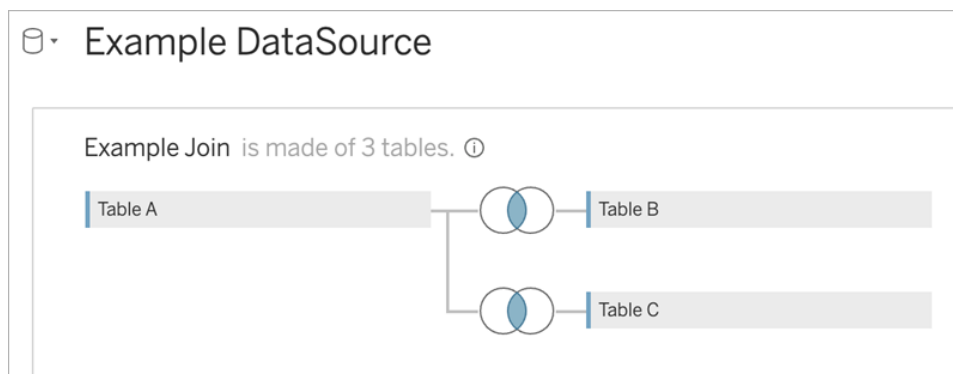

When configuring your data model in Data Cloud, be sure to:

- Connect to a Profile DMO, and have the Profile DMO set as the left-most table in the Data Source tab
- Use only one **primary key**

When configuring your data model in Tableau, be sure to:

- Use a table that's used only one time in the data source
- Only use a single table in the logical layer (multiple logical tables aren't supported)
- Avoid including unions or custom SQL tables
- Only use joins between DMOs that match existing Data Cloud relationships
- Use linear joins between DMOs in which each object is only joined to a single object (rather than joining multiple objects to the same object)

For example, instead of:

Do this:

- Use join expressions that only include fields (calculations and multiple joins from a single table aren't supported) and the equals operator (other operators aren't supported)

When connecting your data model in Tableau to your data model in Data Cloud, you can recreate any necessary portions of the model using [Tableau joins](#).

Authentication

To create segments in Tableau, you must allow Tableau to connect to Data Cloud using the Salesforce Data Cloud connector. If the Data Cloud connector isn't already configured on your Tableau site, [follow these steps](#).

In the connected app, add the following scopes:

- Perform ANSI SQL queries on Customer Data Platform data (cdp_query_api)
- Manage Customer Data Platform profile data (cdp_profile_api)
- Manage Customer Data Platform Ingestion API data (cdp_ingest_api)
- Perform segmentation on Data Cloud data (cdp_segment_api)

User permissions requirements

To create a segment, work with your Salesforce admin to confirm that you have access to the following application programming interfaces (APIs):

- Write access for the [Create Segment API](#)
- Read access for the [Data Cloud Metadata API](#)

Field requirements

When you create a segment, use fields in your filters that are either existing database fields (rather than fields created by Tableau), or [groups](#). Fields that are cast to other data types might cause errors.

The following types of fields aren't supported in segment filters:

- Measures with MEDIAN, PERCENTILE or ATTR aggregations
- Table calculations
- Calculations
- Bins
- Groups based on sets, calculations or combined fields
- Tableau-generated fields, such as:

- Metadata fields (measure names/values)
- Generated map-related fields (latitude and longitude)
- Table type fields (count of object or logical table)
- Calculated insights
- Clusters

Filter requirements

When you create a segment, multiple filters are applied based on your configuration. Segment filters can include a combination of data source filters, context filters, view filters and filters based on your viz selection.

Use quantitative filters for:

- A measure (with or without aggregation)
- A range of dates

Use categorical filters for segments with individual values selected.

The following types of filters aren't supported in segments:

- Categorical filters with a top, wildcard or condition filter
- Relative to current date filters with anything other than date and year for next/last N
- Relative to current date filters with anything other than date, month and year for the current period
- Date filters with Month/Day/Year
- Date filters with date truncation
- Date filters with a datetime exact comparison to another datetime

Relative date filters with a specified anchor date are supported.

Create a segment using engagement data

To create a segment from Tableau to Data Cloud using engagement data, you must configure the correct modelling in Tableau using join clauses.

Use joins within a single logical table and join on the same field as defined in the relationships in the Data Model tab in Data Cloud.

For example, to create a segment using Email Engagement data for the Unified Individual in Tableau, configure your data model and map the relationships as shown.

Note: This example is for illustrative purposes only. Data in your Data Cloud instance might use different relationships.

Create a segment in Tableau

1. In Tableau, select the desired portion of the data in your viz, and then right-click and select **Publish Segment to Salesforce**.

2. Configure your segment in the **Create Segment for Data Cloud** dialog.

Segment name is required. The name must start with a letter and can only contain alphanumeric characters and underscores. The name can't contain consecutive underscores or end with an underscore, and spaces aren't allowed. In Data Cloud, the segment name displays as the name that you specify in the **Segment name** field plus a timestamp of when you create the segment.

When you add filters in the dialogue, the filter field names appear under **Rules**.

You can hover over a rule to learn more about it, such as the filter or mark selection that the rule was built on. Multiple rules might filter on the same field, but learning more about a rule's origins can help you identify any duplicates.

As you add each filter, a segment population count displays. The population count represents the count of individual data points (typically customers) who meet your filter criteria. You can use the population count to verify that your segment is working as expected by confirming that the count is the same in Tableau and Data Cloud. Tableau counts all individual records in your viz, but the segment only counts distinct individuals. To

see distinct individuals in a Tableau viz that matches the segment count, use the Count Distinct (COUNTD) aggregated function.

When you add rules, the **Description** is pre-populated with details about them. You can edit the description as needed, but there's a 255-character maximum. A description is optional, but it can make it easier to find the segment in Data Cloud.

3. Click **Create**. When the segment is created, a confirmation message appears with a link to view the segment in Data Cloud.

If you receive an error after clicking on **Create**, confirm that you meet the [requirements to publish to Data Cloud](#) and [check the status of your organisation's Salesforce instance](#).

4. In the confirmation message, click **View in Data Cloud**.

For segments created in Tableau, you can modify the **Segment Name**, **Description** and **Publish Schedule** in Data Cloud. To do so, click **Edit Properties**.

You can't revise a segment's rules after you publish it. Instead, you must [delete the segment in Data Cloud](#) and create a new one in Tableau.

5. From Data Cloud, your marketing team can [publish the segment to the appropriate activation targets](#).

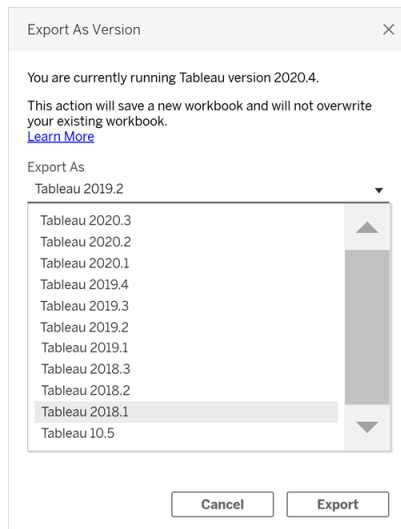

Make Workbooks Compatible with Older Versions

You can downgrade workbooks to share them with people using older versions of Tableau products.

Important: When you downgrade to an older version, any features or functionality that aren't available in that version are removed for compatibility. Additionally, any calculated fields created in the newer version that use functions unavailable in the older version will have to be manually corrected or removed upon downgrade.

Export to an earlier version from Tableau Desktop

1. In Tableau Desktop select **File > Export As Version** and select the version that you want to downgrade to. (The earliest version you can export is Tableau Desktop 10.5.)

2. Save the workbook to your My Tableau Repository or a selected folder.

Downgrade a workbook when publishing to Tableau Server

If you're using a newer version of Tableau Desktop with an older version of Tableau Server, you can downgrade to the older Tableau Server version when you choose **Server > Publish Workbook**. A warning message appears indicating that workbook will be downgraded when published:

The screenshot shows the 'Publish Workbook to Tableau Server' dialog box. It has a title bar with a close button. The main area contains several sections: 'Project' with a dropdown set to 'Default'; 'Name' with a text field containing 'Sales and profit by region'; 'Description' with an empty text area; 'Tags' with an 'Add' button; 'Sheets' with 'All' and 'Edit' buttons; 'Permissions' with a lock icon and text 'Permissions are locked by the site administrator or project leader Vi'; 'Data Sources' with '1 embedded in workbook' and an 'Edit' button; and 'More Options' with three checked checkboxes: 'Show sheets as tabs', 'Show selections', and 'Include external files'. At the bottom, there is a red warning message: 'Warning: Server is running an older version than your copy of Tableau Desktop. The workbook will be downgraded on the server and may lose some functionality. All datasources must be embedded in the workbook.' and a green 'Publish' button.

If you later open the downgraded workbook in the newer version of Tableau Desktop, you'll see a message like the one shown below. You may then need to add back the features that were removed when the workbook was downgraded.

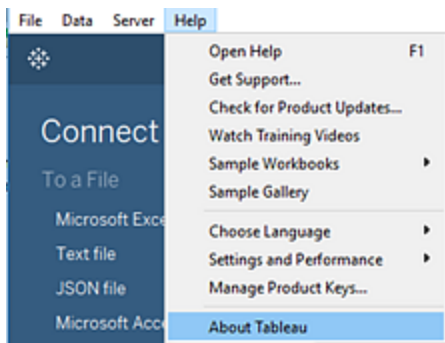

Note: Data sources are not downgraded during publishing.

Download an older version from Tableau Cloud or Tableau Server

If you're using Tableau Cloud or Tableau Server, you can download a workbook to be opened in an older version of Tableau Desktop.

1. To identify which version of Tableau Desktop you're using, select **Help > About Tableau** from the top menu.

2. In Tableau Server or Tableau Cloud, open the view you'd like to download.
3. Click the **Download** button, and then click **Tableau Workbook**.
4. Select the version that you want to export to. (The earliest version you can download is Tableau Desktop 10.5.)

For more information, see [Download Views and Workbooks](#) on page 3417.

Additional compatibility resources

In the Tableau Deployment Guide, check out [Make Workbooks Compatible Between Versions](#) to learn more about how different versions of Tableau products interact.

Best Practices for Published Data Sources

Publishing data sources to Tableau Cloud or Tableau Server is integral to maintaining a single source for your data. Publishing also enables sharing data among colleagues; including those who don't use Tableau Desktop, but have permission to edit workbooks in the web editing environment.

Updates to a published data source flow to all connected workbooks, whether the workbooks themselves are published or not.

What makes up a published data source

A Tableau data source consists of the following:

The data connection information that describes what data you want to bring in to Tableau for analysis. When you connect to the data in Tableau Desktop, you can create joins, including joins between tables from different data types. You can rename fields on the Data Source page to be more descriptive for the people who work with your published data source.

An extract, if you decide to create one. Guidelines for when to create an extract are included below, as well as in the additional resources.

Information about how to access or refresh the data. The connection also includes access information. Examples of this type of information include:

- The path to an original Excel file.
- Embedded credentials or OAuth access tokens for accessing the data directly.
- Alternatively, no credentials, so that users are prompted to enter them when they want to access the data (whether it's to view a workbook that connects to it, or to connect a new workbook to it).

For more information, see [Set Credentials for Accessing Your Published Data on page 3153](#).

Customisation and cleanup that helps you and others use the data source efficiently. When you're working with your view, you can add calculations, sets, groups, bins and parameters; define any custom field formatting; hide unused fields; and so on.

All of these refinements become part of the metadata contained in the data source that you publish and maintain.

Preparing a data source for publishing

When you publish a data source, consider these best practices:

- Create the connection for the information you want to bring into Tableau and do any customisation and cleanup that will help you and others use the data source efficiently.

- If appropriate, create an extract of the data you want to publish. For more information, see the following section, [When to use an extract below](#).
- Develop a data source naming convention.
 - After publishing a data source, you can rename it in Tableau Cloud or Tableau Server. To rename a published data source, choose the **More actions** menu next to the name of your data source. Then, choose **Rename** and enter the new name. You can also use the [Update Data Source REST API](#) to rename a published data source. Be sure to use a well-considered naming convention to help other users of the data deduce which data source to connect to.
 - When a published data source is renamed, all workbooks that use that data source will use the new name after the next data source refresh is complete. Like renaming workbooks, renaming a published data source isn't saved in the revision history of a data source.
 - You can add and edit captions for your data source, but changing the caption doesn't change the name of the underlying published data source. If you edit the underlying published data source name, the caption isn't updated. But don't worry – the correct data source is still referenced. You'll see the updated underlying published data source name in the **Data Source** tab.
- Consider designating the following roles among your Tableau users:
 - A data steward (or team) who creates and publishes the data sources for the Tableau community, which meet your organisation's data requirements.
 - A site administrator who manages published content, extract refreshes and permissions on the server you publish to (Tableau Server or Tableau Cloud).

Central management helps to avoid data source proliferation. Authors who connect to managed data can be confident that the answers they find in it reflect the current state of the business.

When to use an extract

Under the following conditions you might be required or choose to publish an extract instead of connecting live.

Publishing data to Tableau Cloud that it cannot reach directly

Tableau Cloud in the cloud cannot reach data sources that you maintain on your local network. Depending on the connection, you might be required to publish an extract and set up a refresh

schedule using Tableau Bridge.

Some cloud-hosted data sources always require extracts. These include Google Analytics, Salesforce.com, Oracle, OData and some ODBC data sources. You can set up refresh schedules for some of these data sources directly on Tableau Cloud; for others, you use Tableau Bridge.

Web data connector data sources always require extracts. If you connect to the data source using standard user name and password authentication, you can refresh it using Tableau Bridge. If you connect to the WDC data source using OAuth authentication, you will need to use an alternative method to refresh it.

For more about how Tableau Bridge supports both extract and live connections to data Tableau Cloud cannot reach directly, see [Use Tableau Bridge to Expand Data Freshness Options](#) in the Tableau Cloud Help.

Improving performance

Even if the server supports live connections to your data, an extract might make more sense. For example, if the database is large or the connection slow, you can extract a subset that includes only the pertinent information. The extract can be easier and faster to work with than connecting live.

In cases where you can use a live connection or an extract that you refresh on a schedule, you might want to experiment with both options to see which works best for you.

Enabling functionality the data source does not inherently support

For example, suppose you want to use the Median function with SQL Server data.

To learn more about creating data extracts, see [Extract Your Data on page 925](#).

Publishing data separately or embedded in workbooks

You can publish data sources as standalone resources that workbooks connect to, or you can publish workbooks with the data sources included within them.

When you publish a workbook, if any connection specifies anything other than a Tableau data source published to the same project, the data is published as part of the workbook (sometimes referred to as *embedded* in the workbook).

When data is embedded in a workbook:

- Access to the data source is limited to the workbook in which you published it. Neither you nor other users can connect to that data from another workbook.
- You can set up extract refresh schedules as you do for data sources that you publish separately.

Each way of publishing has its advantages. The table below shows a few common points of comparison. It is not a comprehensive list, and these are generalisations. How these and other factors apply to you are specific to your environment.

| Published separately | Embedded in workbook |
|--|--|
| Publishing data sources is a step toward centralising data management. You can create policies geared toward minimising data source proliferation and helping people find the right data for the work they do. | Each embedded data source has a separate connection to the data. Each has the potential to show something different than the other at any given time (and data source proliferation is common). |
| Meant to be shared; becomes available for other Tableau users to connect to. | Data is available only inside the workbook; it is not available for other Tableau Desktop users to connect to. |
| Without content management and self-service guidelines, seeing a long list of data sources to connect to can be confusing to users who rely on the data to do their work, and is more difficult to manage on the server. | Users create their own connections, and they know exactly what data they're getting. |
| Someone who changes a shared data source might be uncertain or unaware of the effects that those changes have on connected workbooks. | Changing the data requires opening the workbook, where you can see the result of the change. |
| Even if effects of data source changes on connected workbooks are planned, updating those connected workbooks is cumbersome. | Same as above; however, if multiple workbooks use similar data and need to be updated, it might be worth connecting to a published data source instead. |

| Published separately | Embedded in workbook |
|---|--|
| Extracts can be refreshed on a schedule. You set up one refresh schedule for the extract, and all workbooks that connect to it always show the most current data. | <p>Embedded extracts that aren't refreshed can be useful for showing snapshots in time.</p> <p>If you want to keep the data fresh, each workbook must have its own refresh schedule.</p> |
| Generally helps you to optimise performance on the server or site. | Performance might be affected when the server contains multiple workbooks that connect to the same original data, and each workbook has its own refresh schedule. |

Keeping extracts up-to-date

When you publish a data source with an extract, you can refresh it on a schedule. The way you schedule refreshes depends on the data source type and whether you're publishing to Tableau Server or Tableau Cloud.

For more information, see the following topics:

- [Keep Data Fresh](#) on Tableau Cloud
- [Keep Data Fresh](#) on Tableau Server

Publish a Data Source

When you are ready to make a data source available to other users, you can publish it to Tableau Server or Tableau Cloud. If the data source is in a workbook that you published to Tableau Server or Tableau Cloud, you can make it available by saving it, provided it's an embedded Excel or text file. For details, see [Publish a Data Source on the Web on page 3229](#).

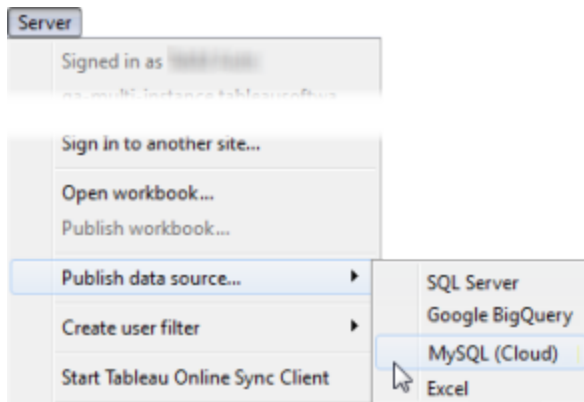

Note: If you haven't yet read about best practices for creating data sources and when to create an extract, see [Best Practices for Published Data Sources on page 3137](#).

General publishing steps

The following steps give an overview of the publishing workflow you will use regardless of the type of data or the server you publish to. Below these steps you can find supplemental information for authentication types and [using Tableau Bridge](#).

1. Select **Server > Publish Data Source**.

If your workbook is connected to multiple data sources, select the one you want from the Publish Data Sources submenu.

2. If you're not already signed in to Tableau Server or Tableau Cloud, sign in now.

How you sign in depends on how your administrator has set up your environment. For information, see [Sign in to Tableau Server or Tableau Cloud on page 193](#).

3. In the **Publish Data Source** dialog box, do the following:

- For **Project**, select the project you want to publish to and enter the data source name.
- For **Description** and **Tags**, add a description and tags that will help you and other users find it.

Separate tags using either a comma or a space. To add a tag that contains a space, put it in quotation marks (e.g., "Sales Quotes").

- For **Refresh Schedule**, if publishing an extract, you have the option to select a refresh schedule to ensure that your extract data stays fresh. If you choose not to select a schedule here, you can select a schedule from Tableau Server after publishing.

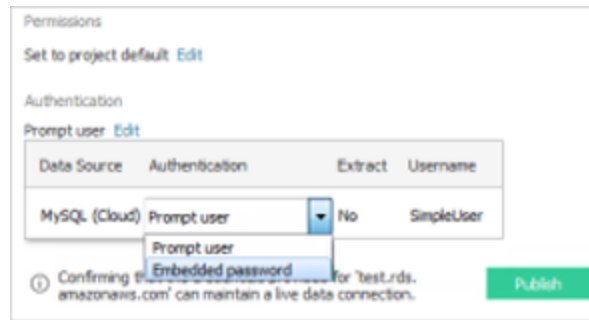

Note: This option is not available when publishing from the Data Source page or to Tableau Cloud.

- For **Permissions**, accept the default project settings.

Generally a site administrator manages permissions on the server. If you think your data source is an exception, work with your administrator to determine the best course of action, and see [Set Permissions as You Publish a Data Source or Workbook on page 3150](#).

- For **Authentication**, if you need to provide credentials to access your data, you can specify how authentication should be handled when the data is published to

the server.

The options available for accessing the data source depend on the type of data you publish and whether you are publishing to Tableau Server or Tableau Cloud.

Information appears at the bottom of the dialog box to let you know whether you need to take further action, such as adding Tableau Cloud to your data provider's authorised list.

For information about the authentication types, see [Set Credentials for Accessing Your Published Data](#) on page 3153.

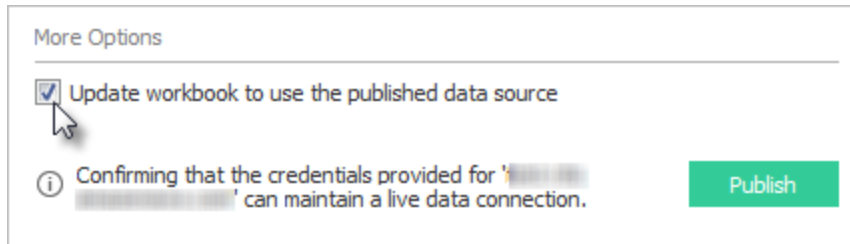

4. If you are publishing file-based data that is on a Windows mapped drive, or using images that will not be available from the server, select **Include external files**.

When you include external files, copies of the files are put on the server as part of your data source. Copies of files are also put on the server and included as part of the data source when you publish extracts of multi-connection data sources that contain a connection to file-based data such as Excel. For more information about the implications of publishing extracts of multi-connection data sources, see [Join Your Data](#) on page 796

If you do not want to publish the external files to the server, change the connection information so that the data source references a full UNC path. For example, rather than connecting to D:\datasource.xls, you would connect to \\filesrv\datasource.xls.

5. By default, during the publishing process, Tableau updates the workbook connection to use the new published data source. It also closes the local data source.

To continue using the local data source instead, clear the **Update workbook to use the published data source** check box.

Note: If you select **Undo** after publishing the data source, Tableau will revert to using the local data source, but the data source will remain published. In addition, Tableau does not replace a local data source when you publish a cube (multidimensional) data source to Tableau Server. (Tableau Cloud does not support publishing cube data sources.)

6. Click **Publish**.

After publishing is complete, your web browser opens Ask Data for the data source, where you can ask questions to automatically create vizzes. For more information, see [Automatically Build Views with Ask Data on page 1011](#).

7. (Optional) Set up a refresh schedule on the server. For more information, see the following topics:

- [Schedule Refreshes on Tableau Server](#)
- [Schedule Refreshes on Tableau Cloud](#)
- Schedule Refreshes Using Tableau Bridge - see the section below.

Publish on-premises data (Tableau Cloud only)

To keep data sources that connect to on-premises data fresh after publishing to Tableau Cloud, Tableau Bridge is required. Tableau Cloud relies on Bridge to facilitate the connection between it and data accessible only from inside a private network.

As part of the publishing process, Tableau Cloud will automatically detect if Bridge is needed. If Bridge is needed, your publishing workflow might differ from the publishing process described above.

Refer to one of the following topics depending on the type of data source you're publishing:

- If publishing a data source that uses an extract connection, see [Set up a Bridge Refresh Schedule](#) in the Tableau Cloud Help. If publishing a data source that connects to a private

cloud database, see [Set up schedules for private cloud-based data sources](#).

- If publishing a data source that uses an live connection, see [Publish a Bridge Data Source with a Live Connection](#) in the Tableau Cloud Help. If publishing a data source that connects to a private cloud database, see [Publish private cloud-based data sources](#) to ensure Bridge is used to facilitate the data freshness tasks.

Publish with a Web Data Connector

To publish a web data connector data source, you need to *import* the web data connector to the server before you can set up a refresh schedule. You can do this only on Tableau Server.

You can refresh some web data connector data sources on Tableau Cloud, using Tableau Bridge.

For information, see [Web Data Connectors in Tableau Server](#) in the Tableau Server Help or [Connectivity with Tableau Bridge](#) in the Tableau Cloud Help.

Hidden fields in workbooks

Workbooks connected to a published data source respect the state of hidden fields in the published the data source.

- If you create a new workbook that uses a published data source with hidden fields, those fields remain hidden in the workbook and cannot be used in calculations, sets, groups, and other object creation.
- If you work with an existing workbook that uses a published data source with hidden fields, those hidden fields are displayed in red in the workbook to indicate that the fields, and therefore the views and calculations that use those fields, are invalid.

You can address this issue in one of the following ways:

- Show (unhide) the relevant fields in the data source, and then republish the data source.
- Update the relevant workbooks to exclude the hidden fields.

For information, see [Hide or Unhide Fields on page 1068](#).

Edit a Published Data Source

Imagine that you've published a data source and your team is using the data source across a number of workbooks. This is a good start, but you have some changes in mind that will make your data source great. Before you implement these changes, you want to see how your proposed changes look in Tableau. And most importantly, you need to test your changes to ensure they won't negatively impact any existing workbooks that use the data source.

Editing a published data source allows you to test changes and make improvements to your data source while maintaining it as a single source of data.

Note: Only users with a site role of Creator can edit publish data sources in the browser.

Edit and test changes

Whether you're creating a new published data source or editing an existing published data source, you can create joins and edit the schema from the Data Source page without leaving your browser. Then use the Scratchpad to test your changes, create folders, organise hierarchies and rename fields and aliases before publishing your data source. While editing your data source, you'll have all the same features and functionality that you have when authoring in Tableau Cloud. For more information, see [Web Authoring and Tableau Desktop Feature Comparison](#).

To edit a published data source:

1. From the Start or Explore page, navigate to the data source you want to edit.
2. Click **Edit Data Source**.

3. Click the **Data Source** page to make joins or edit the schema.

4. Click the **Scratchpad** sheet.
5. From the **Data** pane, create folders, organise hierarchies, rename fields and their aliases or update metadata that are saved with the published data source.
6. Drag and drop fields onto the scratchpad to make sure your changes are working as expected.
7. Click **Publish**.

Just like you can with workbooks, you can also **Publish As** if you want to make a copy of the data source.

Note: Personal Spaces don't support published data sources.

Roll back changes

To revert to the last version of the published data source:

1. Navigate to the data source that you want to revert.
2. Click **File**.
3. Choose **Revert to Published**.

This reverts to the latest published version of that data source.

Understand supported connections

Editing published data sources doesn't support:

- Tableau Bridge connectors in Tableau Cloud.
- Data sources that use embedded passwords in Tableau Cloud and Tableau Server.

Also, the Data Source page isn't available for published data source connection types that aren't supported, including but not limited to .hyper file types. To see which connection types are supported, see [Creators: Connect to Data on the Web on page 3218](#).

Learn about permissions

To edit a published data source, you'll need a Creator licence that has Save or Save As permissions for data sources in the respective folder. For more information, see [Permissions](#).

Edit data sources published by a flow

If you make edits to a data source that was published by a flow, the changes will be overwritten during the next scheduled flow. Instead, edit the data source in the flow. For more information, see [Publish a Flow to Tableau Server or Tableau Cloud](#).

Set Permissions as You Publish a Data Source or Workbook

As the publisher of a workbook or data source, you may be able to set permissions as part of the publishing process. Permissions allow or deny other users access to published content on Tableau Server or Tableau Cloud. For example, who can interact with views in a workbook, download a copy of a data source and so on.

Note that permissions are different than access to the data source. Accessing some data types requires signing in using a database name and password or embedding database credentials into the connection. For information, see [Set Credentials for Accessing Your Published Data on page 3153](#).

When possible, it is best to use the default permission rules for the project where you are publishing your content. If you are publishing to a [locked project](#), you won't be able to modify the permissions. But if you are publishing content into a customisable project and there is a reason your content should have unique permissions, you can set permission rules during publishing.

About setting permissions during publishing

When you start the publishing process, the dialog box shows the permissions that will be applied. By default, the content you publish follows the permission rules of project you are publishing to.

Permissions
Same as project (Default) Edit

More Options

☒ Update workbook to use the published data source

i Requires creating an extract on publish. Publish

When you change permissions in the publishing dialog box, you are setting unique permission rules for the content you're publishing. This means changes to the permission rules for the project will not impact your content. Depending on your environment, this might be as you intend, or it might conflict with the guidelines your administrator has set and have unintended consequences.

Tips for deciding whether to set permissions on content

- **Learn your organisation's practices**

Consult with your Tableau administrator to learn the guidelines for your organisation. It's common (and recommended) practice for an administrator to lock permissions to the project. If you work in such an environment, you will not be able to set unique permissions for your content. And be aware, even if you set permissions during publishing, the person who manages permissions on the server might change these settings afterwards.

- **Know the consequences of setting explicit permissions**

In addition to the potential conflicts described earlier, unique permissions on some content requires extra maintenance to keep track of which content has exceptions, and which exceptions are applied.

- **Publish quickly by accepting the default permissions settings**

If necessary, you or your administrator can update permissions on the server afterwards, where you have a more comprehensive view into the effects of your changes.

How to set permissions during publishing

1. In the publishing dialog box, next to the summary that indicates the current settings, click **Edit**.

2. In the popup that appears, do one of the following:
 - To set custom capabilities or assign a role explicitly, select an existing user or group and click **Edit**, or click **Add**.
 In the **Add/Edit Permissions** dialog box, make your changes.
 Click **Apply** to save changes and keep the dialog box open to configure another user or group. Click **OK** to close the dialog box.
 - To remove a permission rule, select the user or group, and then click **Remove**.

Assign permission templates

When you publish content, you can assign any of the following **templates** to a selected user or group:

- **View:** Allows the user basic access to the content, such as filtering a workbook or connecting to a data source.
- **Explore:** Allows the user all capabilities from the View template as well as additional functionality, such as web editing a workbook or downloading a data source.
- **Publish:** Allows the user the ability to overwrite the content (such as via web editing and saving over the original). This will also give them ownership of the content.
- **Administer:** Allows the user the ability to manage the content, such as deleting it and setting permissions.

Set Credentials for Accessing Your Published Data

When you publish a workbook to Tableau Cloud or Tableau Server, you can publish the data source it connects to as part of the workbook (*embedded* into the workbook), or as a separate, standalone data source. In addition, if the data source you're publishing requires authentication, you can customise how credentials are obtained.

The type of authentication to your data source is independent on how people sign in to your Tableau Cloud or Tableau Server site. For example, to give people direct access to the data in a workbook, you would embed a database user's credentials into the data source's connection. But anyone viewing the workbook would still need to be able to sign in to the site on Tableau Cloud or Tableau Server to open your workbook.

This topic describes how to set authentication on data connections as part of the publishing process.

Note: This topic doesn't apply to connections to that don't require authentication, such as text files or Excel files.

Set the authentication type

For many types of connection, you can embed a database user's name and password, or use single sign-on (SSO). Specific exceptions are described later in this topic.

The following steps describe how to set authentication as part of publishing a data source or workbook. You can do this for each connection in the data source.

1. In the Publish Workbook dialog box, go to the **Data Sources** area, which lists the workbook's connections, and select **Edit**.
2. In the **Manage Data Sources** popup, after you decide whether to publish the data source separately or as part of the workbook, select an authentication type for each connection in the data source. The available authentication types depend on the connection type, and they can include one or more of the following:
 - **Prompt user:** Users must enter their own database credentials to access the published data when the view or workbook loads.
 - **Embedded password:** The credentials you used to connect to the data will be saved with the connection and used by everyone who accesses the data source or workbook you publish.
 - **Server run as account:** A single Kerberos service account is used to authenticate the user. On Windows this is the account that Tableau Server runs as. On Linux it can be any Kerberos account.
 - **Viewer credentials:** The viewer's credentials are passed through to the database using SSO (usually Kerberos).
 - **Impersonate with embedded account or Impersonate with server Run As service account:** Impersonation using embedded credentials connects with the embedded credentials and then switches to the viewer's identity (only for databases that support this). Impersonation using the Run As service account is similar but first, connects with the Kerberos service account before switching to the viewer's identity.
 - **Refresh not enabled or Allow refresh access:** These options appear when you publish an extract of cloud data such as from Salesforce, and database credentials are needed to access the underlying data. **Allow refresh access** embeds the credentials in the connection, so that you can set up refreshes of that extract on a regular schedule.

Important: How you want to keep extracted data fresh is also a factor:

- If you want to set up an automatic refresh schedule, you must embed the password in the connection.
- If you're publishing a cloud data connection to Tableau Cloud, the publishing steps alert you if you must add Tableau Cloud to the data provider's authorised list.
- You can't publish an extract that's created from a Kerberos-delegated, row-level-secure data source.

Dropbox, OneDrive connections

For Dropbox and OneDrive, when you publish a data source or workbook and select **Embedded password**, Tableau creates a saved credential and embeds it in the data source or workbook.

Workbook connections to Tableau data sources

When you publish a workbook that connects to a Tableau Cloud or Tableau Server data source, rather than setting the credentials to access the underlying data, you set whether the workbook can access the published data source it connects to. Regardless of the original data type, the choice for server data sources is always **Embedded password** or **Prompt users**.

If you select to prompt users, a user who opens the workbook must have **View** and **Connect** permissions on the data source to see the data. If you select embed password, users can see the information in the workbook even if they don't have View or Connect permissions.

Virtual connections

As of Tableau Cloud and Tableau Server 2022.3 and Tableau Desktop 2022.4, when you publish Tableau content like a data source or workbook that uses a virtual connection and select **Embed password** or **Embed credentials**, the viewer of the content will have your permissions to connect to and query the virtual connection. However, any data policies associated with the virtual connection are always evaluated using the viewer's identity – not yours.

For example, you publish a workbook that uses a virtual connection. To let viewers of the workbook connect to and query data by way of the virtual connection, you embed your permissions to connect to and query the virtual connection. Then, any data policies associated with the virtual connection prevent the viewers of the workbook from accessing any sensitive data.

When evaluating whether the tables in a virtual connection can be viewed and accessed, the identity of the content creator is used. However, when evaluating any data policies associated with the tables in a virtual connection, the viewer's identity is used. And the content creator can only ever embed connect permissions to the virtual connection – not edit permissions.

If you choose not to embed permissions, then only users with permissions to access the workbook or data source and with connect permissions to the virtual connection can access the workbook or data source.

The embed password and embed credentials options for virtual connections don't work in Tableau Cloud 2022.2, Tableau Server 2022.1 and Tableau Desktop 2022.3 and earlier. If you select these options before you upgrade to 2022.3 (for Tableau Cloud and Tableau Server) or

2022.4 (for Tableau Desktop), the options will work as expected after you upgrade. Then, you're able to embed your permissions for querying a virtual connection.

- If you publish to Tableau Server, see [Edit Connections](#) in the Tableau Server Help.
- If you publish to Tableau Cloud and the workbook connects to Salesforce, Google Analytics, Google Sheets, Google BigQuery, OneDrive, Dropbox and QuickBooks Online data, see [Refresh Data Using Saved Credentials](#) in the Tableau Cloud Help.
- If you're a Tableau Server administrator looking for more information about authentication, see the Tableau Server help topics "Authentication" ([Windows](#) | [Linux](#)) and "Data Connection Authentication" ([Windows](#) | [Linux](#)).

Authorise Access to Data Published to Tableau Cloud

The information in this topic applies to you if you publish workbooks or data sources to Tableau Cloud that contain live connections to cloud data – for example, Amazon, Google, Salesforce.com.

As a security measure, cloud-based data providers might require you to supply authorised IP addresses from which external applications request access to your data. A request from an IP address that is not explicitly approved could be rejected. To ensure live connections you publish to Tableau Cloud remain uninterrupted, add Tableau Cloud to your data provider's allowlist.

The table below lists [Hyperforce](#) IP addresses Tableau Cloud uses based on the pod your site resides on. You can see the pod in the URL that appears after you sign in to Tableau Cloud.

The table below lists IP addresses for each pod. It also lists Hyperforce VPCE IDs to use when your Tableau Cloud data resides in the same region as your Tableau Cloud instance. You can see the pod in the URL that appears after you sign in to Tableau Cloud.

Notes:

- In addition to enabling communication over the Tableau Cloud IP range, you might need to enable access over the appropriate database port (for example, 80 or 443) depending on the communication type (HTTP or HTTPS).
- IP addresses are dedicated to and controlled by Salesforce.

IP addresses for Tableau Cloud

Hyperforce IP addresses are added periodically and will require your data provider's allowlist to be updated. Site admins will receive an email notification alerting them when new IP addresses become available.

You can also stay informed of new IP addresses using *one* or *both* options:

- **Option 1 – periodically review the IP address table below:** At least 30 days before the IP addresses are enabled, the IP address table below is updated.
- **Option 2 – automate IP address updates using the JSON text file:** Salesforce recommends that your data provider's allowlist mirror the <https://ip-ranges.salesforce.com/ip-ranges.json> text file at all times by automating the IP address updates. New IP addresses are added to the text file at least 30 days before they're enabled.

In the text file, the IP address for your pod is listed by the Hyperforce region that your pod resides in. To determine the Hyperforce region, refer to the 'Pod' and the associated 'Hyperforce Region' columns in the table below. For example, if your pod name is 'prod-ca-a', your Hyperforce region is 'ca-central-1'. In the <https://ip-ranges.salesforce.com/ip-ranges.json> text file, search for 'ca-central-1' for the appropriate IP address to include in your data provider's allowlist.

Notes:

- When new IP addresses become available, a new version of the text file that contains both new and existing IP addresses replaces the previous text file.
- The text file version is indicated by the "createDate" (in UTC).
- Salesforce recommends that you make a copy of the previous version of the text file for your records.
- Not all regions will receive new IP addresses at the same time.

IP addresses

About the Hyperforce migration

Between August 2024 and March 2025, Tableau Cloud sites were migrated to Salesforce's [Hyperforce](#). This move enhances broader compliance, improves security and privacy, increases regional availability and ensures future scalability, delivering these benefits more quickly and reliably worldwide.

Previous IP addresses

The migration to Hyperforce resulted in a change to Tableau Cloud IP addresses. The old IP addresses are provided below for reference and to assist you in identifying and removing any inactive IP addresses from your data provider's allowlist.

For active IP addresses, see the table [above](#).

IP addresses before Hyperforce migration

| Location | | Hyperforce Region | Pod (Pod Name) | IP Address before Hyperforce Migration |
|--------------|-----------|-------------------|--------------------|--|
| Asia Pacific | Australia | ap-southeast-2 | prod-apsoutheast-a | 3.25.37.32/28 |
| | Japan | ap-northeast-1 | prod-apnortheast-a | 18.176.203.96/28 |
| Canada | Quebec | ca-central-1 | prod-ca-a | 3.98.24.208/28 |
| Europe | Germany | eu-central-1 | dub01 | 34.246.74.86 |

| | | | | |
|-------------------------|---|-----------|-------------------------|---------------------------------|

| | | | us-west-2b (UW2B) | 34.214.85.34 34.214.85.244 |
| United States - East | Virginia | us-east-1 | prod-useast-a | 3.219.176.16/28 |
| | | | prod-useast-b | 3.219.176.16/28 |
| | | | us-east-1 (useast-1) | 50.17.26.34 52.206.162.101 |

VPCE IDs for Tableau Cloud

After the migration to Hyperforce, some new requirements apply when accessing Tableau Cloud data stored in an Amazon S3 bucket.

When the data is *in the same region* as your Tableau Cloud instance:

- You *must* use a VPC endpoint (VPCE) instead of IP source addresses to control access to your S3 data.

VPC endpoints are private connections between a virtual private cloud (VPC) and a resource (your data in S3). Using an endpoint is a better solution because an IP address can change over time.

When the S3 bucket is *in a different region* from the Tableau Cloud site:

- You need to use the IP addresses to control access to the S3 bucket.

This applies to both the S3 connector and the Snowflake connector when the Snowflake instance is on AWS in the same region as the Pod and **Internal stage protection is enabled** in the Snowflake instance.

IP addresses and VPCE IDs

| Location | | Hyperforce Region | Pod (Pod Name) | IP Address and Range/VPCE ID |
|--------------|-----------|-------------------|--------------------|--|
| Asia Pacific | Australia | ap-southeast-2 | prod-apsoutheast-a | 141.163.192.0/23 vpce-071ca855ea8cc1154 |
| | Indonesia | ap-southeast-3 | prod-apsoutheast-c | 141.163.212.0/24 vpce-05825e2ebed977018 |
| | Japan | ap-northeast-1 | prod-apnortheast-a | 141.163.208.0/23 vpce-045516807606e4738 |

Tableau Bridge connections to Tableau Cloud

To facilitate connections between on-premises data and Tableau Cloud, Tableau Bridge uses common port 443 to make outbound requests to Tableau Cloud. For more information, see [Network access](#) section in the Install Tableau Bridge topic.

See also

[Keep Data Fresh](#) (Tableau Cloud Help)

Use Bridge to Keep Data Fresh

For data sources or virtual connections data that Tableau Cloud can't reach directly, you can use Tableau Bridge to keep data fresh. For example, use Bridge when your data source connects to data hosted behind a firewall.

Note: If a data source connects to underlying data hosted in the cloud and is accessible from the public internet, connections run from Tableau Cloud directly.

What is Bridge

Tableau Bridge is client software that runs on a machine in your network. The client works in conjunction with Tableau Cloud to keep data sources that connect to private network data, which Tableau Cloud can't reach directly, up to date. Private network data includes on-premises data and private network cloud data.

How does it work

Tableau Bridge functions like a conduit between private network data, such as Excel files and SQL Server data, and Tableau Cloud. The client communicates with Tableau Cloud through an outbound encrypted connection to enable connectivity between data behind a firewall and your Tableau Cloud site.

For more information about how Bridge communicates with Tableau Cloud, see [Tableau Bridge Security](#).

Who can use it

Although any authorised user of Tableau Cloud can use Bridge, Bridge is optimised for users that perform the following functions in an organisation: site admins and data source owners.

Site admins, or users who have the Site Administrator or Site Administrator Creator role on Tableau Cloud, install and manage Bridge clients. For more information, see [Plan Your Bridge Deployment](#).

Content owners, or users who have the Creator or Explorer (can publish) role on Tableau Cloud, typically publish and manage their own content. Content owners use Bridge to facilitate the live and extract connections between Tableau Cloud and private network data.

- For **live connections**, Bridge is detected automatically as part of the data source or virtual connection publishing process. Support for live connections are enabled through pooling.

More about data sources: Users see the option to publish the data source with a live connection during the publishing process. This option is available when live connections are supported for relational or cloud databases accessible only from inside the network.

After the user publishes the data source, an available client in the pool facilitates the live queries. That's all there is to it.

To get started, users publish a data source to Tableau Cloud and select the option to maintain a live connection. Or publish a workbook, then specify a live connection. For more information about publishing data sources, see [Publish a Bridge Data Source with a Live Connection](#).

Note: If publishing a data source that connects to a private cloud database, follow the steps described at [Publish private cloud-based data sources](#) to ensure Bridge is used to facilitate the data freshness tasks.

- For **extract connections**, users can set up refresh schedules for data sources or virtual connections. For more information, see [Set Up a Bridge Refresh Schedule](#).

Note: If publishing a data source that connects to a private cloud database, follow the steps described at [Set up schedules for private cloud-based data sources](#) to use Bridge facilitated refresh schedules.

Schedule Extract Refreshes as You Publish a Workbook

When you publish workbooks that connect to extracts, you can set up a schedule for updates (refreshes) for those extracts, so the views in those workbooks stay current.

The ways you can set up and manage extract refresh schedules depends on where you publish and on the original data type.

- When you publish to **Tableau Server**, the schedule runs and is managed on the server.
- When you publish to **Tableau Cloud**:
 - If extracts are from cloud data (for example, Google Analytics or Salesforce), schedules run and are managed on Tableau Cloud.
 - If extracts are from on-premises or web data connector (WDC) data, you set up and manage refresh schedules using Tableau Bridge.

Note: In many organisations a server content manager or administrator manages all refresh schedules. We recommend that, before you publish, you find out from your administrator whether they have guidelines for these schedules.

Set up a schedule as you publish content

During the publishing process, after you click the **Publish** button, the scheduling options appropriate for your data types and publishing destination appear.

If you are publishing a multi-connection data source, you need to set a refresh schedule for each extract connection in the data source.

To use refresh schedules with connections to a database that requires you to sign in to it, you must store (embed) a database user's credentials with the connection. For more information, see [Set Credentials for Accessing Your Published Data on page 3153](#).

Publish and refresh on Tableau Cloud

For the subtleties around refreshing each type of data you publish to Tableau Cloud, see [Keep Data Fresh](#). Here are examples of things you need to know:

- If your workbook connects to cloud data, add Tableau Cloud to your cloud data provider's authorised list (allowlist). The IP address range for your site location is listed in [Authorise Access to Data Published to Tableau Cloud on page 3156](#).
- Tableau Bridge starts during the publishing process if your data source or workbook connects to on-premises data.

Tableau Bridge supports standard database authorisation and cannot refresh data you connect to through OAuth. To learn more, see [Use Tableau Bridge to Expand Data Freshness Options](#).

- When you publish a multi-connection data source to Tableau Cloud, if any one connection requires using Tableau Bridge, you must use Bridge to refresh *all* connections in the data source.

For example, say you publish a data source with an extract connection to a MySQL data hosted in the cloud, and a live connection to an on-premises SQL Server database. Although Tableau Cloud supports refreshing hosted MySQL data, in this case, you would need to use the Bridge client to keep both the SQL Server and MySQL connections fresh.

For information about using both live and extract connections in a data source, see [About working with multi-connection data sources](#).

Refreshing web data connector extracts

When you publish a workbook with a web data connector (WDC) data source, you must *import* the web data connector to Tableau Server before you can set up a refresh schedule. You can do this only on Tableau Server. For information, see [Web Data Connectors in Tableau Server](#) in the Tableau Server Help.

For information about refreshing web data connector data sources published to Tableau Cloud, see [Use Tableau Bridge to Expand Data Freshness Options](#) in the Tableau Cloud Help.

Restrict Access at the Data Row Level

When you share workbooks with others by publishing them to Tableau Server or Tableau Cloud, by default, all users who have access to the workbooks can see all of the data shown in the views. You can override this behaviour by applying a type of filter that allows you to specify which data "rows" any given person signed in to the server can see in the view.

This approach for securing data at the row level applies to data sources with live connections and extract data sources whose tables are stored as multiple tables. For more information about storing extract data using multiple tables, see [Extract Your Data on page 925](#).

Note: For information on the alternatives you can use to implement row-level security in Tableau, see an [Overview of Row-Level Security Options in Tableau](#) in the Tableau Server Help.

For additional related information, see the whitepaper [Best Practices for Row_Level Security with Entitlement Tables](#).

How user-based filtering works

Suppose you created a quarterly sales report for a set of products over several years, in different geographic regions.

When you publish this report, you want to allow each regional manager to see only the data relevant to his or her region. Rather than creating a separate view for each manager, you can apply a *user filter* that restricts access to the data based on users' characteristics, such as their role.

Restricting access to data in this way is referred to as *row-level security* (RLS). Tableau offers the following approaches to row-level security:

- **Create a user filter and map users to values manually on page 3169.**

This method is convenient but high maintenance, and security can be tentative. It must be done per-workbook, and you must update the filter and republish the data source as your user base changes.

- **Create a dynamic filter using a security field in the data on page 3171.**

Using this method, you create a calculated field that automates the process of mapping users to data values. This method requires that the underlying data include the security information you want to use for filtering.

The most common way to do this is to use a reference ("look-up", "entitlements" or "security") table that contains this information. For example, if you want to filter a view so that only supervisors can see it, the underlying data must be set up to include usernames and specify each user's role.

Because filtering is defined at the data level and automated by the calculated field, this method is more secure than mapping users to data values manually.

Adding user filters to data sources

The two methods in the previous section describe ways to add filters to data embedded in workbooks. If multiple workbooks connect to the same data, instead of wrangling filters on each workbook, you can filter the data source, and then connect the workbooks to the data source after you publish it.

Workbooks that connect to your filtered data source expose only the data the user signed in to the server is allowed to see. In addition, all connected workbooks show data refreshes as they occur.

Extracts vs. live connections with user filters

Generally, when using one of the methods described above, RLS with extracts are faster to create and have better performance than RLS with data sources that use live connections.

Requirements for RLS with extract data sources

As mentioned earlier, the first requirement to using RLS with extracts is that the data in the extract should be stored using multiple physical tables. You can configure your extract to have its data stored using multiple physical tables by following [Extract Your Data on page 925](#).

In addition to the above requirement, there are some additional considerations to make if you plan to use RLS with your extract. Because extract data stored using multiple tables do not support extract filters and some other functionality that help reduce the amount of data in the extract, you might consider using one of the following suggestions:

- Connect to data using custom SQL
- Connect to a database view that already has the appropriate level of filtering

For more information about these suggestions, see [Extract Your Data on page 925](#).

Recommended practices for RLS with extract data sources

To effectively perform RLS with extracts, Tableau recommends keeping the number of tables (or database views or custom SQL queries) in your extracts to two. In other words, Tableau recommends that the tables in your extract be comprised of the following types of tables:

- A data table – this is the table that contains all the data you want to show.
- A reference table – this is the "look-up" or "entitlements" table that contains the user information and the security groups the users belong to.

By minimising the tables in your extract to these two, you ensure that the only join that Tableau has to perform is between these two tables and thus avoid any duplication of data or "join explosion."

- [Overview of Row-Level Security Options](#) in Tableau in the Tableau Server Help

Create a User Filter and Secure it for Publishing

Prerequisites

To implement row-level security (RLS) with a live data source, follow the steps below.

To implement RLS with an extract, there are some extra steps and considerations. For more information see [Requirements for RLS with extract data sources on the previous page](#).

Note: For information on the alternatives you can use to implement RLS in Tableau, see an [Overview of Row-Level Security Options in Tableau](#).

Create a user filter and map users to values manually

User-based filtering is one option to help secure your data source or workbook using RLS. This procedure is best for a small and fairly static set of users or groups, and only a small number of workbooks that need user filters.

1. In Tableau Desktop, open the workbook and connect to the data you want to filter.
2. Navigate to the worksheet that you want to apply a filter to.
3. Select **Server > Create User Filter**. Then select the field you want to use for filtering the view, such as **Region**.
4. If prompted, sign in to your server or site.
5. In the **User Filter** dialog box, name the filter. We'll use **Regional Managers**.
6. Select a user or group on the left, then indicate which values on the right they should be able to see. Repeat this process for each user or group, and click **OK** when you're done mapping users to values.

For this example, Andrew Allen is set up to see the East region.

7. After you create the user filter, it appears in the **Sets** area of the Data pane.
8. Drag the user filter to the **Filters** shelf. The filter becomes a context filter, and the view adjusts to show data that you are allowed to see.

To test or fine-tune the filter:

- If the view appears as a blank canvas, you need to allow yourself or a group you are a member of to see a region. In the **Sets** area of the **Data** pane, open the drop-down menu on the user filter, and then select **Edit Set**.
- To preview how the filter works in the published view, in the lower-right corner of the workbook, open the **Filter as User** menu, and select the user or group from the list.

Note: Previewing is not available if the workbook connects to a published data source.

- To return to viewing the workbook as yourself, in the top right corner of the **Filter as User** menu, select **Reset**.
- To copy the mapping selections you set on one user or group to another (rather than manually mapping the same settings), see [Copy selected field values from one user to another on page 3175](#).

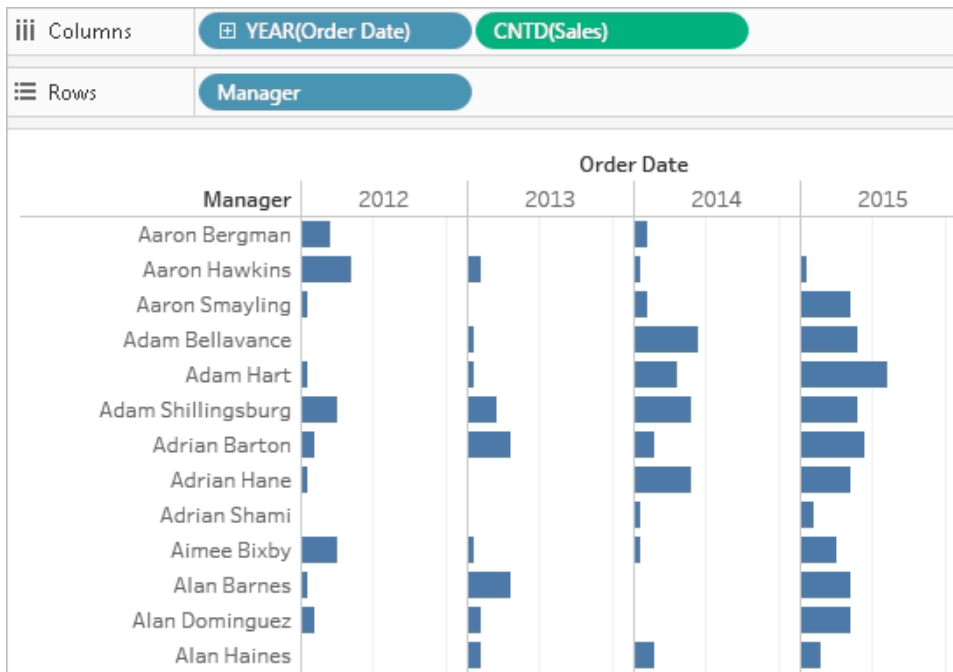

Known Limitations

If using Tableau Desktop and a published data source, note that calculations containing both an LOD expression and a user function can't be computed properly in Tableau Desktop. These calculations are stripped out.

Important: When you publish the workbook, you need to take additional steps to make sure users cannot edit the workbook and remove the filter. For information, see [Secure user filters on published content on page 3174](#).

Create a dynamic filter using a security field in the data

The steps below are based on the following view, which shows annual sales performance for a list of regional managers.

As described in [Restrict Access at the Data Row Level](#) on page 3166, this approach requires the database to contain the field you want to use for filtering.

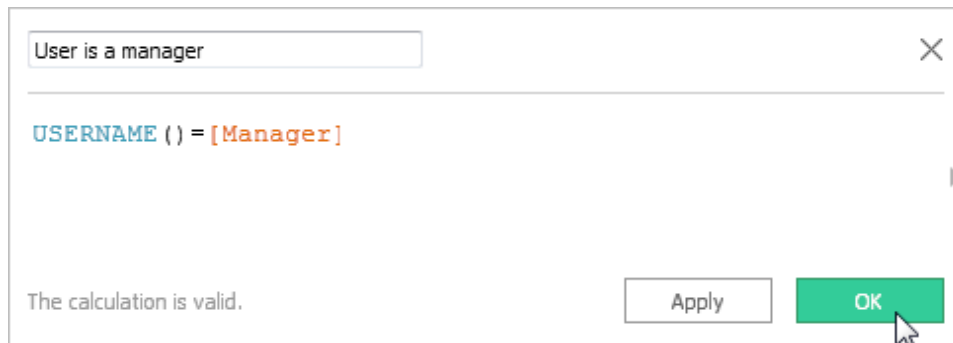

For this example, the data includes a *reference table* called **People**, which contains two columns: Region and Manager. Names in the Manager field match Tableau Cloud or Tableau Server user names, and we'll use this field for filtering.

You can follow along using the Superstore data that comes with Tableau Desktop, although the fields and values do not match exactly.

Connect to the data and set up the user filter

1. In Tableau Desktop, open the workbook and connect to the data you want to filter. In this example, we use a table called **Orders**.
2. Double click the Orders table to open the join canvas. Add the reference table (**People**) with a left join. For this example, join on the field **Region**.
3. On the worksheet, select **Analysis > Create Calculated Field**, and create the following field, named "User is a manager".

```
USERNAME() = [Manager]
```

This calculation returns TRUE if the user name of the person signed in to the server exists in the manager column of the People table.

4. Add the **User is a manager** field to the **Filters** shelf.
5. In the **Filter** dialog box, select **True**, and then click **OK**.

This sets the filter so that only people who are managers can see the data in the view. If you are not listed in the Manager field, your view while authoring might appear as a blank canvas.

6. See how the view looks to a particular person: in the lower-right, open the **Filter as User** menu, and select someone you know is a manager.

Important: As with a manual user filter, you need to take steps to [Secure user filters on published content on the next page](#).

Filter a data source

Rather than maintain user filters and special permissions on each published workbook, you can filter a data source, and then publish the data source to make it available as a shared, one-to-many resource for anyone who uses that data.

This procedure builds from the dynamic-filter approach described in this topic.

1. Complete the steps in [Create a dynamic filter using a security field in the data on page 3171](#).
2. In the lower-left area of Tableau Desktop, select the **Data Source** tab.
3. In the upper-right area of the **Data Source** page, under **Filter**, click **Add**.

4. In the **Edit Data Source Filters** dialog box, click **Add**, add the calculated field you created for the dynamic filter (**User is a manager**), and set the filter to **True**. Click **OK** until you get back to the **Data Source** page.

Global filters and data source filters

When you create a data source filter, any global filters that use that data source are automatically displayed in the **Edit Data Source Filters** dialog box to make it easy for you to promote a global filter to a data source filter. To promote the global filter to a data source filter, click **OK**.

If you promote a global filter to a data source filter, that global filter will no longer be visible in worksheets of the workbook (because it becomes a data source filter).

Note: Be aware that you do not need to select a global filter in the **Edit Data Source Filters** dialog box to promote it. When you click **OK**, all global filters in the list will be promoted. To prevent a global filter from being promoted to a data source filter, select the global filter in the **Edit Data Source Filters** dialog box and then click **Remove**.

Secure user filters on published content

When you publish a workbook or data source with user filters, you need to set permissions to make sure that users opening your workbook or connecting to your Tableau Server data source cannot remove the filter, thereby gaining access to all of the data.

Notes

- Before publishing, we recommend that you consult with your Tableau administrator regarding any existing policies in your organisation, particularly for setting permissions.

See also [Set Permissions as You Publish a Data Source or Workbook](#) on page 3150.

- This information applies to publishing data sources with live connections and extracts whose data is stored as multiple tables.

Permissions settings

To secure user filters, the following capabilities must be set to **Deny**, either during publishing, or afterward on the server.

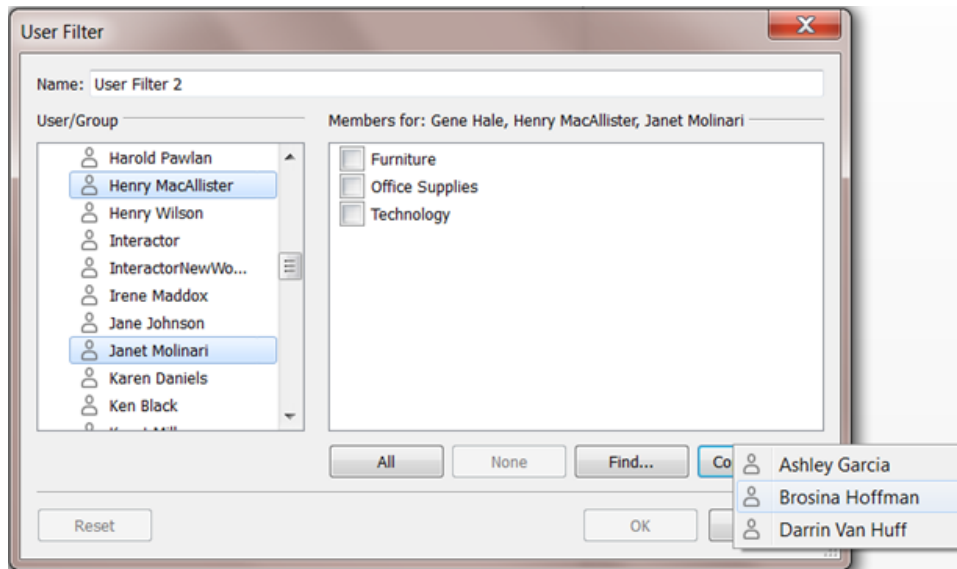

| Workbooks | Data sources |
|---|--|
| <ul style="list-style-type: none">• Web Edit• Download/Save a copy• Set Permissions | <ul style="list-style-type: none">• Save• Download• Set Per-missions |

Copy selected field values from one user to another

When you're creating a user filter manually, after you map a user or group to data values (members), you might want to map another user or group in the same way. You can do this by copying and pasting the settings.

1. In the **Data** pane, under **Sets**, select a user filter. Click the drop-down arrow and select **Edit Set**.
2. In the **User Filter** dialog box, select the user or group on which you want to paste settings from another user or group.

3. Click **Copy From**, and select the user or group whose settings you want to copy.

Recycle Bin

The Recycle Bin allows Site Administrators, Server Administrators and authors with Explorer (can publish) or Creator licences to restore previously deleted projects, workbooks and data sources.

You can access the Recycle Bin from the Home page of your Tableau site. Expand the side pane and then select **Recycle Bin**. If you don't see Recycle Bin, the feature must be turned on by your administrator.

What content is stored in the Recycle Bin?

When the Recycle Bin is turned on, the following content types will temporarily move to the Recycle Bin after deletion:

- Workbooks (including revision history, views, embedded credentials, embedded data sources and extracts)
- Data sources (including extracts and embedded credentials)
- Projects (including contained workbooks and data sources)

However, when you delete and restore workbooks, data sources and projects, some elements of the original content will be lost, including:

- Custom views
- Subscriptions
- Data-driven alerts
- Permissions
- Aggregated statistics about the deleted item (view and usage counters)
- Tags
- Favourite information (if the item was favourited)

Tip: If you don't see something that you expect to be in the Recycle Bin, verify that the correct **Content Type** is selected.

Content: Notes and best practices

- When deleted, supported content types keep their original names. The Restore action will fail if the project you restore to already has an item with the same name. To resolve this issue, restore into a different project, rename the just-restored content and then move the content into the desired location.
- Workbooks and data sources stored in the Recycle Bin still take up space on a site. If a workbook or data source uses an extract, that extract size is still counted against the site quota.
- When deleted, supported content types do not change their owner. Users who originally owned content are still considered to be an owner.
- On restore, restored Items will take on the default permissions set for the container that you restore to. When restoring critical content, the operating user should verify that permissions are set as necessary. The Restore operation will not restore original content permissions.

Projects: Notes and best practices

Projects can contain a variety of content or nested projects. Note the following about projects when the Recycle Bin is turned on.

Note: Recycle Bin respects hierarchy for nested projects on the original delete action and when restoring content. For example, you can delete an entire project branch from the root project to send the root and all nested projects to the Recycle Bin, and you can restore an entire project branch from the Recycle Bin if you restore the root project (and all of the nested projects are still in the Recycle Bin). However, hierarchy is not respected when you delete content from the Recycle Bin. To delete all of the projects from an original project branch from the Recycle Bin, you'll need to delete each project individually.

Example project: Project A includes 2 workbooks (A and B), a data source and a flow.

- When a project is initially deleted and sent to the Recycle Bin, all content from that project that is compatible with the Recycle Bin is stored individually. For Project A, you'll see a project, Workbook A, Workbook B and a data source in the Recycle Bin. Other types of content, like flows, are deleted immediately and can't be recovered.

- All compatible content from a project can be restored or deleted individually. For example, you can permanently delete Workbook A from Project A, leaving only a project, Workbook B and the data source in the Recycle Bin.
- If you restore a project, all compatible content that is still stored in the Recycle Bin at the time will also be restored. For Project A, if you've already deleted Workbook A and then restore Project A, the project will restore with only Workbook B and a data source.
- If you delete a project from the Recycle Bin, only the project is deleted. For example, if you delete Project A from the Recycle Bin, Workbook B and the data source remain in the Recycle Bin until they are individually deleted, restored or until the storage time expires.

Example project: Project A includes Workbook A, Workbook B, a data source and a nested Project B that includes Workbook C.

- If a deleted project contains nested projects, any nested projects that are still stored in the Recycle Bin at the time will be restored if the top-level project is restored. For example, restoring the root Project A restores the top-level Project A, Workbook B, a data source, Project B and Workbook C to the selected restore location
- Nested projects in the Recycle Bin can be restored independently from their top-level project. If a nested project is restored independently, and then the top-level project is later restored, the top-level project is restored without any content from the nested project. For example, if you restore Project B independently and then later restore Project A, Project A will be restored with the top-level project, Workbook B and the data source. The restored Project B will no longer be nested within Project A.

Example project: Project 1 (P1) is a project branch that includes 4 nested projects (P2-P3-P4-P5).

Scenario: You initially delete P1 and send the whole branch (the root P1 and the nested P2-P3-P4-P5) to the Recycle Bin.

- From the Recycle Bin, you can delete any individual project from the original hierarchy (P1-P2-P3-P4-P5).
- Deleting nested projects from the Recycle Bin will disrupt the original project hierarchy.
 - If you delete P3, then P1, P2, P4 and P5 remain in the Recycle Bin. However, P4 is no longer connected to P2. The original single project branch is now divided into two branches: P1-P2 and P4-P5.

- With P3 deleted, if you then restore P1, the Restore action will also restore P2, but will leave P4 and P5 in the Recycle Bin.
- With P3 deleted, if you restore P4, the Restore action will also restore P5, as P4 is now considered the root for P5.vvv
- You can restore any of the originally nested projects individually.
- You can't remove a whole project hierarchy from the Recycle Bin. You must delete each project individually.

Restore content from the Recycle Bin

You can restore content from the Recycle Bin to a project within the storage time frame configured by the administrator.

1. From the Home page, expand the side pane and then select **Recycle Bin**.
2. For **Content Type**, select **Workbooks**, **Projects** or **Data Sources**.
3. Select the **More actions** menu for the content that you want to restore, and then select **Restore**.
4. Select a project as the restore location.
5. Select **Restore**.

Delete content from the Recycle Bin

You can permanently delete content from the Recycle Bin before the end of the storage time frame configured by the administrator. This action can't be undone.

1. From the Home page, expand the side pane and then select **Recycle Bin**.
2. For **Content Type**, select **Workbooks**, **Projects** or **Data Sources**.
3. Select the **More actions** menu for the content that you want to permanently delete, and then select **Delete**.
4. Select **Delete**.

Turn on the Recycle Bin

Administrators can turn on the Recycle Bin for a Tableau site in the Tableau [site settings](#).

1. From the General tab, scroll to the Recycle Bin section.
2. Select the tick box for **Allow Recycle Bin for this site**.
3. Select the number of days that the content is stored in the Recycle Bin. You can choose 1, 7 or 30 days.

Important: Content is permanently deleted after the selected number of days.

4. Select **Save**.

Turn off the Recycle Bin

Warning: If an administrator turns off the Recycle Bin, any content stored in the Recycle Bin will be permanently deleted.

Administrators can turn off the Recycle Bin for a Tableau site in the Tableau [site settings](#).

1. From the General tab, scroll to the Recycle Bin section.
2. Clear the tick box for **Allow Recycle Bin for this site**.
3. Select **Save**.

Contact your administrator

The Recycle Bin can only be turned on and configured by a Tableau Site Administrator or Server Administrator. To see contact information for your administrator, from the Home page, select the **Show help menu** icon, and then select **Contact Tableau Administrator**.

What Can I Do with a Tableau Site?

Your Tableau site is a private workspace on the web where you can share data insights and collaborate with your colleagues. With certain access levels, you can connect to data and create workbooks right on the web, or connect to data sources and workbooks built in Tableau Desktop. Your site role sets what you're able to do in your Tableau site.

What is a site?

A Tableau site is a place for your team to publish data sources and workbooks to share with each other.

In Tableau-speak, we use site to mean a collection of users, groups, and content (workbooks, data sources) that's walled off from other sites (collections of users, groups and content).

As a site user, you might be able to sign in to one site, or you might be able to sign into multiple sites, depending on the access your administrator gives you. After you sign in, you can see projects and content that you can access.

How does my site work with Tableau Desktop?

Tableau Desktop and your Tableau site are built to work together. In Tableau Desktop, you can connect to data and build workbooks, stories and dashboards. When you want to share insights with others, you can publish workbooks and data sources to your Tableau site.

In your Tableau site, you can view, interact with, and edit those published views. You can also use your Tableau site to find and edit workbooks in Tableau Desktop.

What can I do on the web?

Your site role and content permissions determine what you can see and do with Tableau on the web. Starting in 2018.1, your Tableau site role can be Creator, Explorer, or Viewer. For in-depth details on each site role, see the capability grid on [Tableau Pricing](#).

Not sure what your site role is? To check, select the icon in the top right corner of the site with your initials or profile picture and select **My Account Settings**. **Site Role** tells you if you are a Creator, Explorer or Viewer.

In general:

Creators can:

- Make new connections to data in the browser
- Upload workbooks (.twb and .twbx files)
- Build and publish data sources and workbooks from the browser or Tableau Desktop
- Open and edit published workbooks in the browser or Tableau Desktop
- Create new data flows and edit an existing flow
- Use Dashboard Starters (Tableau Cloud only)
- Everything else that Explorers and Viewers can do

Explorers* can:

- Connect to published data sources on the site to create new workbooks
- Save new workbooks in Personal Space
- Download workbooks or other content in Personal Space, including data.
- Edit and analyse data in published workbooks (Save and Save As options vary based on permissions. If Save As is available, workbooks can be saved in Personal Space.)
- Create data alerts
- Create subscriptions for others
- Everything that Viewers can do

*The user level Explorer (can publish) is an Explorer who can publish new content from Tableau Desktop to a site and create and publish new content from an existing published data source, but cannot connect to external data or create new data sources.

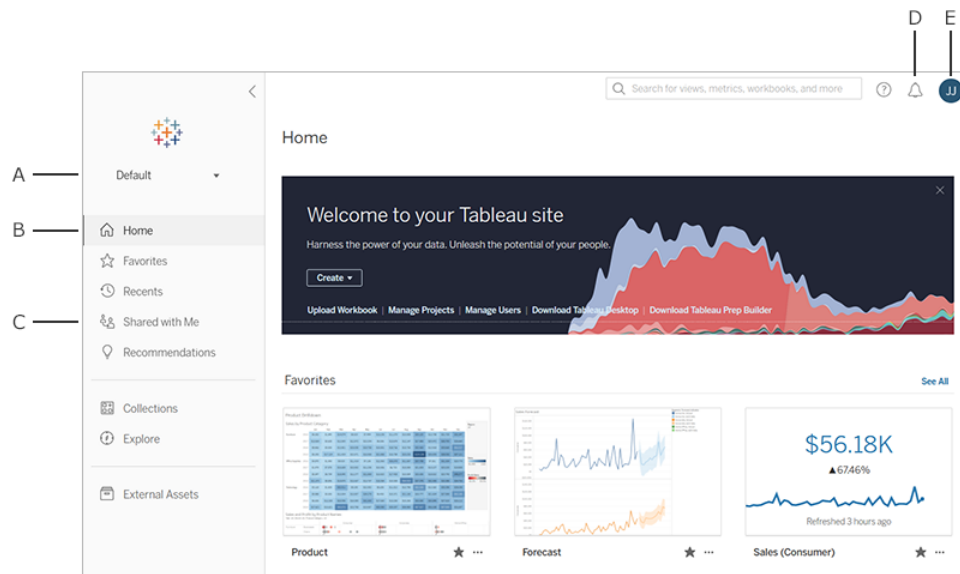

Viewers can:

- Create custom views and see published and custom views others have created
- Explore the data in a view using filters and legends, sorting and tooltips
- Share, comment on and download content (options vary based on permissions)

For more details, see [What Can I Do with a Tableau Web View?](#)

Tour Your Tableau Site

When you sign in to Tableau Server or Tableau Cloud, the first page you see looks similar to the following example.

- **A - Site picker**(if you have access to more than one site)
- **B - Home**
- **C - Navigation menu**
- **D - Notifications**
- **E - Your content and account settings**

Note: You might see additional features if your site is licensed for Data Management, which includes Tableau Catalog, Tableau Prep Conductor and other data management features. When Tableau Catalog is enabled, you can see an External Assets page, view data lineage information and more. You can also see virtual connections listed as another Tableau content type. To learn more, see [Use Data Management in the Tableau Cloud or Tableau Server help](#).

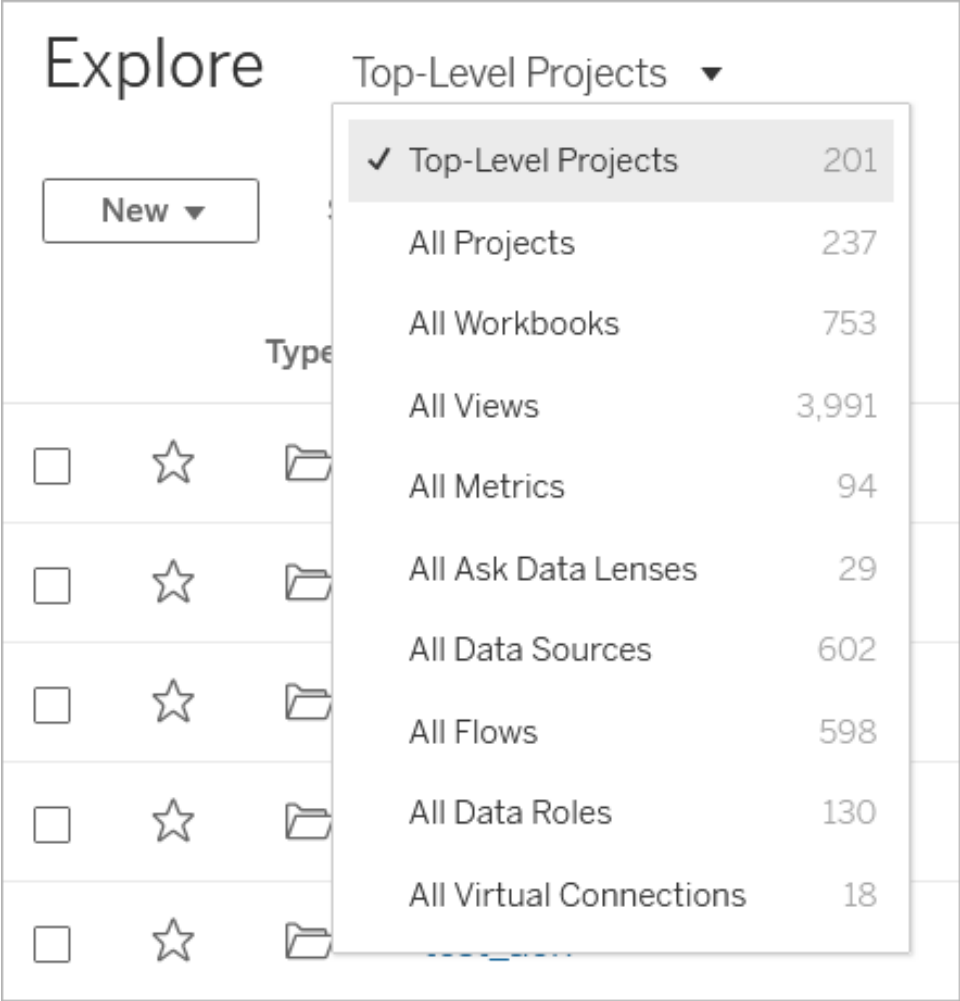

Browse and find content

To see all of the content you have access to across your Tableau site, from the navigation menu, click **Explore**. Your site role and permissions determine the content that you can see and the options that are available.

- **A** - Content type menu
- **B** - Quick search
- **C** - Your account and settings

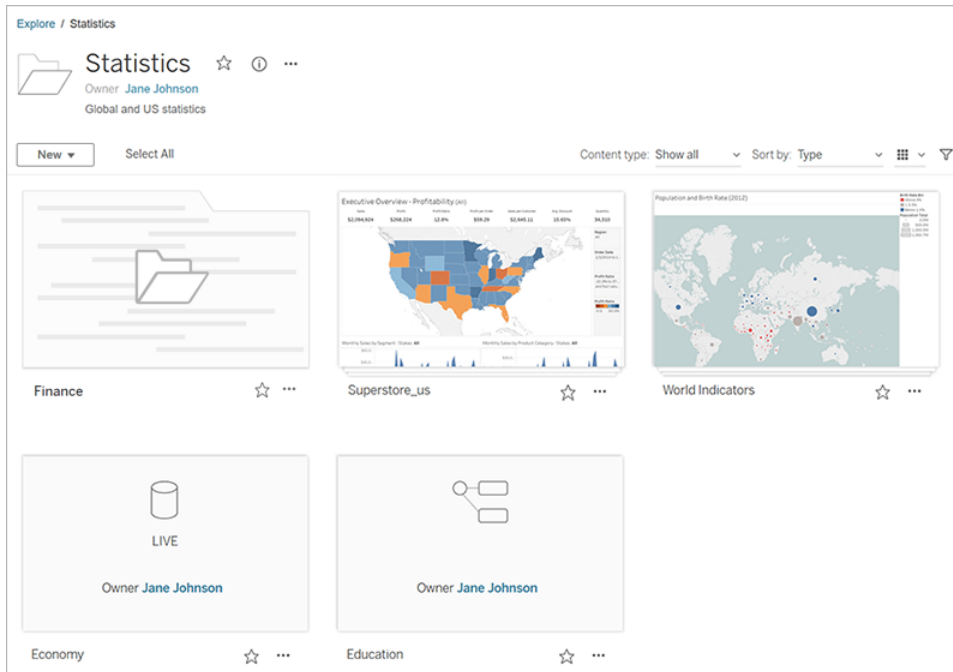

By default, Explore shows **Top-Level Projects**. To see other types of content, select them from the drop-down content type menu.

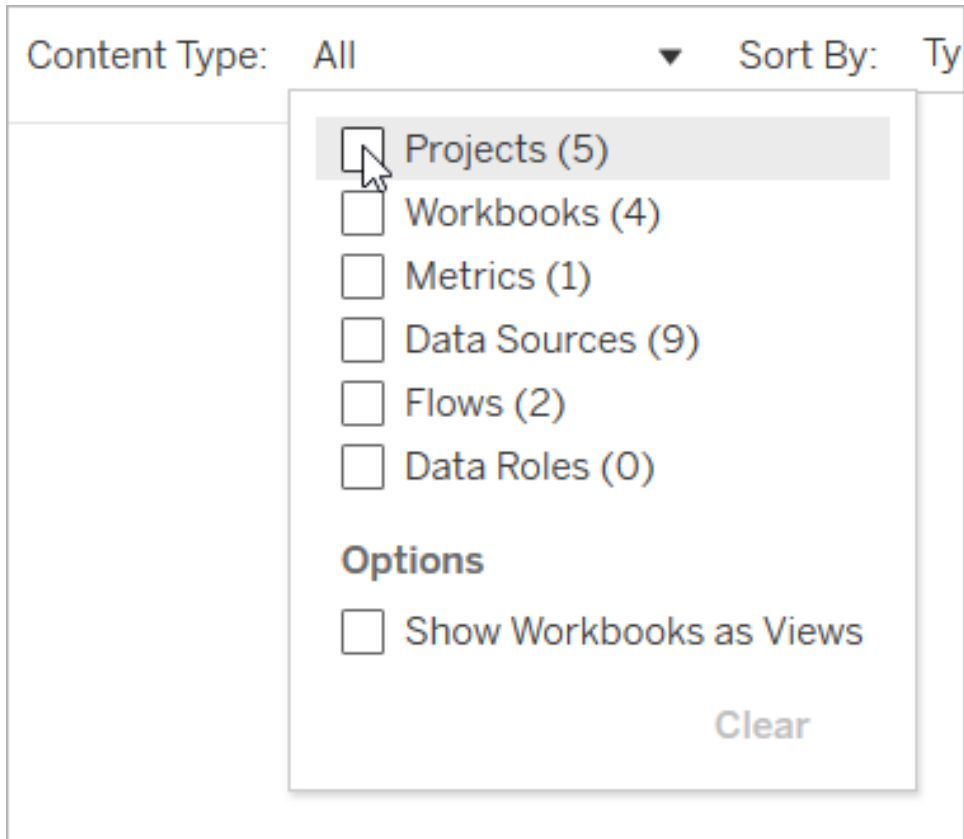

Projects

Projects provide a way to organise the content on your site. Top-level projects can contain other (nested) projects, forming a hierarchy that you navigate like the file system on your computer.

When you open a project, you see all of the content that project contains on a single page, including any nested projects.

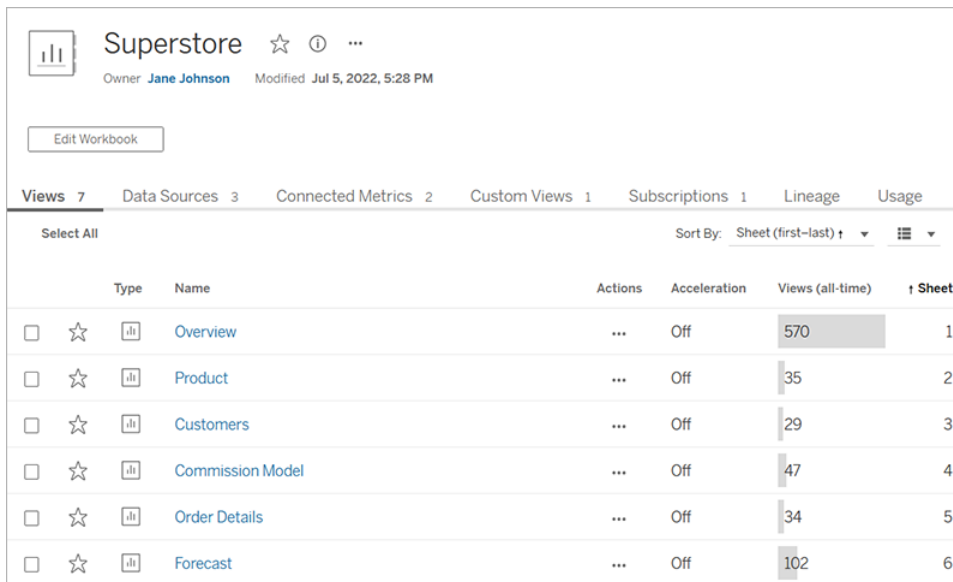

To see only specific content types in a project, click the **Content Type** drop-down menu and select the content types you want to see. You can select the **Show Workbooks as Views** option to see all of the individual views and custom views within a workbook displayed on the project page.

Workbooks

A workbook page shows the views included in the workbook, the data sources used by the workbook, metrics created from the views in the workbook, custom views, user subscriptions to either the workbook or to individual views, lineage data (if Tableau Catalogue is enabled) and usage statistics.

For more information about creating workbooks, see [Creators: Get Started with Web Authoring](#) on page 3202.

Views

A view page displays options for interacting with the view, including sharing, subscribing and editing. The options available in the toolbar vary depending on the site configuration and your permissions.

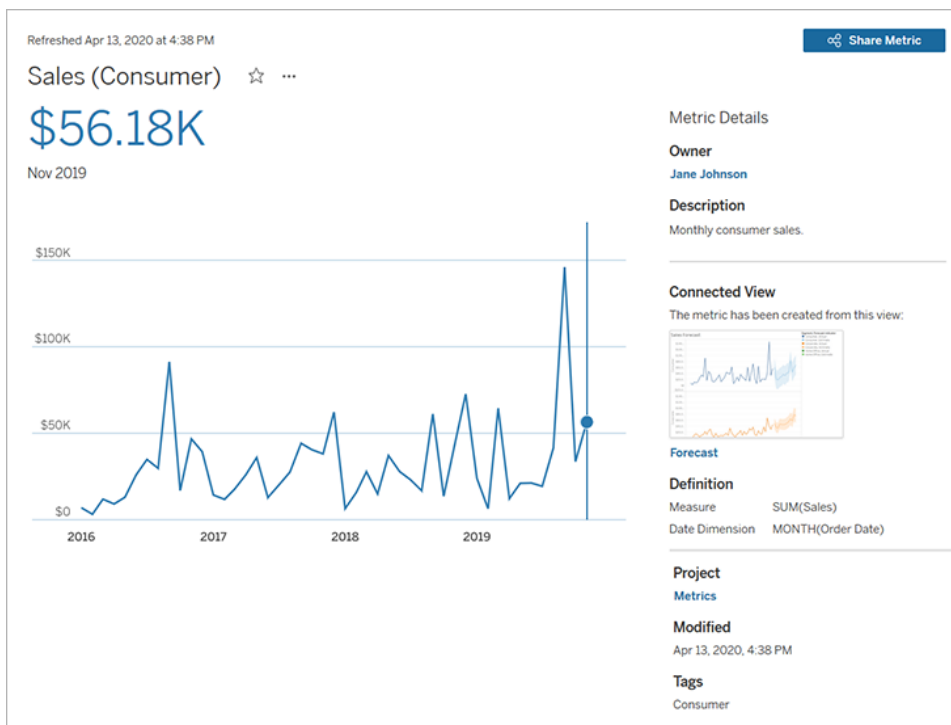

When a workbook is published from Tableau Desktop with the **Show sheets as tabs** option selected, you can see each sheet by clicking the tabs below the view toolbar.

For more information about working with views, see [What Can I Do with a Tableau Web View?](#) on page 3271.

Metrics

A metric page shows the current value for the metric, the time the metric last refreshed and details about the metric, such as the owner, description and definition. If the metric has a date dimension as part of its definition, it will show a timeline that displays historical values for the metric.

For more information about metrics, see [Create and Troubleshoot Metrics \(Retired\)](#) on page 3239.

Retirement of the legacy metrics feature

Tableau's legacy metrics feature was retired in Tableau Cloud in February 2024 and in Tableau Server version 2024.2. In October 2023, Tableau retired the ability to embed legacy metrics in Tableau Cloud and in Tableau Server version 2023.3. With Tableau Pulse, we've developed an improved experience to track metrics and ask questions of your data. For more information, see [Create Metrics with Tableau Pulse](#) to learn about the new experience and [Create and Troubleshoot Metrics \(Retired\)](#) for the retired feature.

Data sources

A data source page shows connections to databases or file-based data, as well as the workbooks connected to the data source. If the data source is an extract, the page shows scheduled extract refreshes.

You can use **Ask Data** to investigate your data directly from the data source page. Type a question and instantly get a visualisation as an answer. For more information, see [Automatically Build Views with Ask Data on page 1011](#).

The screenshot shows the Tableau interface for a data source named 'Stock Data'. The page has a breadcrumb trail 'Explore / Default / Stock Data'. Below the title, it shows the owner 'Jaman', the type 'Unencrypted Extract', and the last refresh time 'Mar 25, 2019, 8:50 AM'. A 'New Workbook' button is present. The 'Ask Data' tab is active, showing a search bar and a list of suggested questions. The left sidebar contains a 'Data' section with a search bar and a list of categories: Industry, Sector, Investor, Market, Order DS, Stock, Stock Name, and Stock Ticker. The main area displays suggested questions like 'by Sector', 'Equity at least 1,070', and 'sort Sector in alphabetical order'.

When viewing a list of data sources, to see connection and authentication details, from the **Show As** menu, select **Connections**.

Ask Data lenses

An Ask Data lens provides a curated subset of data from a data source, making it easier for you to find relevant answers to your questions. For more information, see [Create Lenses that Focus Ask Data for Specific Audiences](#) on page 1031.

Data roles

A data role page shows custom data roles published to your site or server. You can create custom data roles in Tableau Prep Builder using the field values in your data set and publish them to Tableau Server or Tableau Cloud to share with others. You can use data roles to validate field values when cleaning your data.

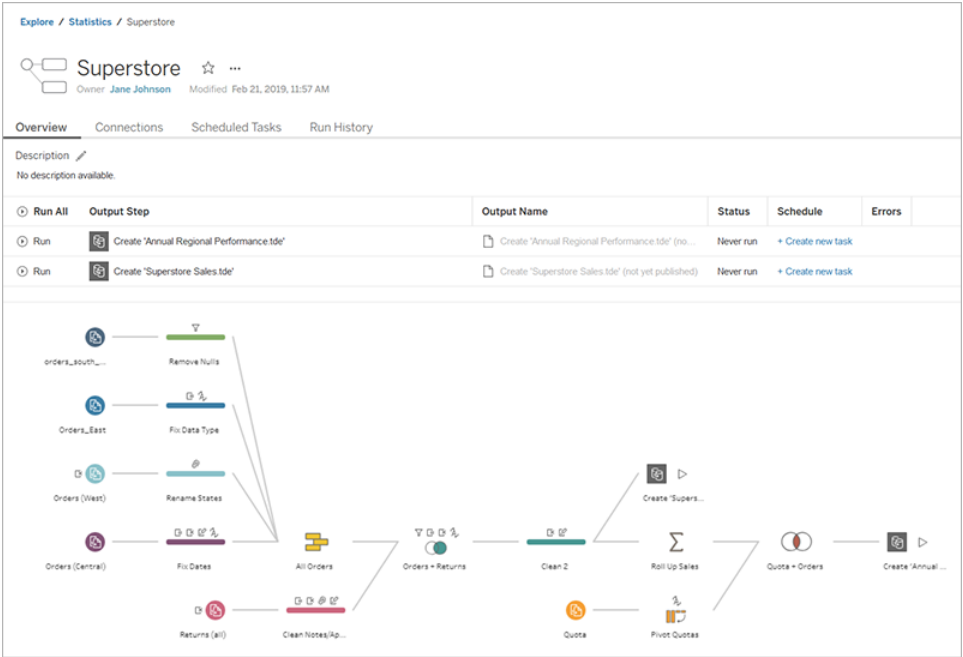

The screenshot shows the Tableau Prep interface for a data role named 'city-datarole'. At the top, there is a breadcrumb trail: 'Explore / Default / city-datarole'. Below this, the role name 'city-datarole' is displayed with a star icon and a menu icon. The owner is listed as 'Jane Johnson' and the modification date is 'Jun 25, 2019, 5:37 PM'. The 'Definition' tab is selected, showing an 'About' section with 'Role Type' (Synonyms), 'Dictionary' (Shipping), and a 'Description' field that says 'No description available.' Below this, a 'Values (531)' section is shown with a search bar labeled 'Search Values'. A table lists the first three values: 'Aberdeen', 'Abilene', and 'Akron'.

| Name |
|----------|
| Aberdeen |
| Abilene |
| Akron |

For more information about creating and using data roles to clean data, see [Use Data Roles to Validate Your Data](#) in the Tableau Prep online help.

Flows

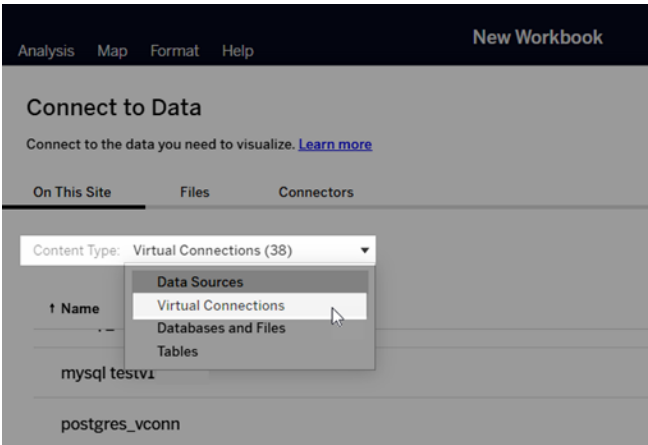

The flow page enables you to view, edit, monitor and maintain your flow and run it on demand. If you have a Data Management licence with Tableau Prep Conductor enabled, you can schedule your flow to run or set up linked tasks to run multiple flows one after the other.

For more information about working with flows, see [Keep Flow Data Fresh](#) in the Tableau Prep help.

Virtual connections

Virtual connections provide a central access point to data. You can use a virtual connection to create a data source, workbook or flow. You can trust that the data is fresh because the extract refresh schedule has already been set. And you can share content freely, knowing that you won't put security at risk because data policies that apply row-level security are always enforced. For more information, see [Use a Virtual Connection in the Tableau Cloud](#) or [Tableau Server](#) help.

Access important content quickly

In addition to browsing content in projects, take advantage of the following areas of your site to keep track of the items that are important to you:

- **Personal Space** – a private location for Explorers and Creators to save or edit work. For more information, see [Create and Edit Private Content in Personal Space on page 3229](#).
- **Favourites** - Add any type of content to your favourites.
- **Recents** - See the views, metrics and flows you have most recently accessed.
- **Shared with Me** - Find items that other users have sent you.
- **Collections** - Create your own collection of related items, or access collections made by other users. For more information, see [Organise Items in a Collection on page 3293](#).

View content as list or grid

You can display content as a list or as a grid of thumbnails by clicking the **View As** icons.

Here's the list view:

| New ▾ | | Select All | Content Type: All ▾ | Sort By: Type ▾ | Grid View ▾ | Filter ▾ |
|------------------------------|------------------|------------|---------------------|-----------------|------------------------|----------|
| Type | Name | Actions | Value | Owner | | |
| <input type="checkbox"/> ☆ 📁 | Finance | ... | | Jane Johnson | Dec 11, 2018, 11:50 AM | |

Tableau Desktop and Web Authoring Help

-  indicates a view
-  indicates a metric
-  indicates an Ask Data lens
-  indicates a data source
-  indicates a data role
-  indicates a flow
-  indicates a virtual connection

And here's the grid view:

In grid view, you can hover over thumbnails to see details about the content.

Sort content

To sort items, click the **Sort By** drop-down menu. You can sort by characteristics such as name, owner, number of views, and creation date.

This example shows the sort options for number of page views.

| Content type: Views | | | | | Sort by: Views (1 month) ↓ | |
|---------------------|------------------|-------|--------------|--|----------------------------|---------|
| Views (1 month) | Workbook | Sheet | Owner | | | |
| 6 | World Indicators | 3 | Jane John | | Order | 2:54 PM |
| 5 | World Indicators | 7 | Jane John | | ✓ 1 month | 2:54 PM |
| 4 | Regional_us | 3 | Jane John | | 3 months | |
| 3 | Superstore_us | 6 | Jane John | | 12 months | |
| 3 | Superstore_us | 3 | Jane John | | All-time | |
| 2 | Regional_us | 6 | Jane Johnson | | Sort | |
| | | | | | Name | |
| | | | | | ✓ Viewed by users | |
| | | | | | Workbook | |
| | | | | | Sheet | |
| | | | | | Project | |
| | | | | | Owner | |
| | | | | | Modified | |

You can also sort a list by clicking the column heading. An arrow indicates the order: ascending (up arrow) or descending (down arrow).

| ↓ Views (1 month) ▾ | Workbook | Sheet |
|---------------------|------------------|-------|
| 6 | World Indicat... | 3 |
| 5 | World Indicat... | 7 |
| 4 | Superstore_us | 6 |
| 3 | Regional_us | 3 |
| 3 | Superstore_us | 3 |
| 2 | Regional_us | 6 |

Identify and navigate sites

Each site on Tableau Server and Tableau Cloud has a name and an ID.

On Tableau Server, if only one site exists, that site is named **Default**. When you're signed in to the **Default** site, the browser URL looks something like this:

`https://server-name/#/home`

If you have access to multiple sites, you select one when you sign in.

On Tableau Cloud or an instance of Tableau Server running multiple sites, the browser URL includes **`#/site/`** followed by the site ID. If the URL doesn't include **`/site/`**, then you're signed in to the **Default** site.

The following URL shows an on-premises Tableau Server site whose site ID is **finance**:

`https://localhost/#/site/finance/home`

Once signed in, you can navigate to another site by selecting it from the site picker. If you have access to only one site, you will not see the site picker.

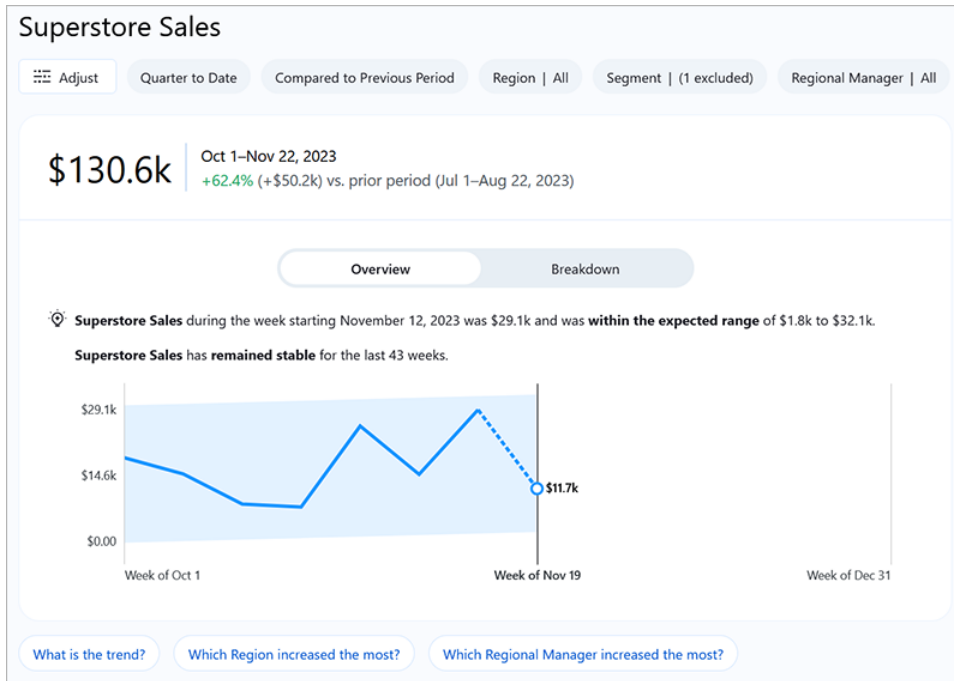

Tableau Pulse

Available for Tableau Cloud, Tableau Pulse helps you to stay up to date with your data by providing insights about metrics. You can follow metrics to receive a digest with changes to your data via email or Slack, and you can visit a metric's details page on Tableau Cloud to ask questions of the data and learn more.

Metrics in Tableau Pulse are based on data sources published to your Tableau site, but Tableau Pulse metrics are separate from the other content on your site and don't appear in projects under Explore. To access Tableau Pulse, from the navigation menu, select **Pulse**. For more information, see [Create Metrics with Tableau Pulse](#).

Creators: Get Started with Web Authoring

There's a lot you can do with Tableau on the web. As a Creator, you can connect to data directly to power your analytics, create stunning data visualisations, and share those insights with others. In this guide, we'll cover the Tableau Cloud environment, connecting to and preparing your data for analysis, creating a workbook and sharing those insights with others.

Not sure what your user level is? To check, select the icon in the top right corner of the site with your initials or profile picture and select **My Account Settings**. **Site Role** tells you if you are a Creator, Explorer or Viewer.

Step 1: Sign in and explore projects on the facing page

Step 2: Create a new workbook and connect to data on
page 3204

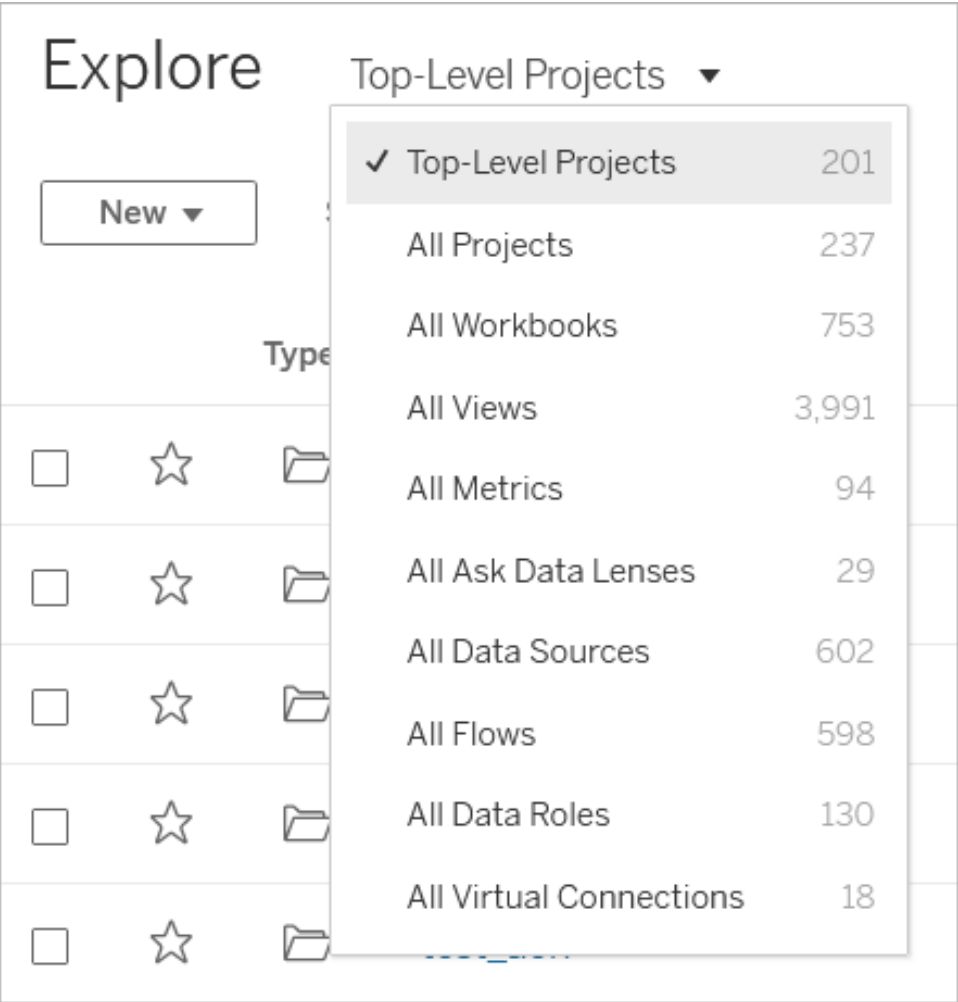

Step 3: Prepare your data on page 3206

- Step 4: Author a view on page 3208
- Step 5: Present your work on page 3215
- Step 6: Save your work on page 3217
- Step 7: Collaborate and share your findings on page 3218

Step 1: Sign in and explore projects

To get started, enter your user name and password to sign in to your Tableau site. Then, from the navigation pane, click **Explore** to see all the content you have access to across the site.

Initially, you will see **Top-Level Projects**. You can browse these projects or select other content types.

Workbooks, data sources, data roles and flows can be saved to locations called projects. Projects can also contain nested projects. Much like folders on your desktop, projects are a way to sort and manage content in your site. If you've been invited to an existing site, you may see projects created by your teammates.

In addition to projects, you can privately save workbooks to a location called Personal Space. You can use Personal Space to create or explore workbooks and move them to a project when you're ready to share with others. For more information, see [Create and Edit Private Content in Personal Space](#) on page 3229.

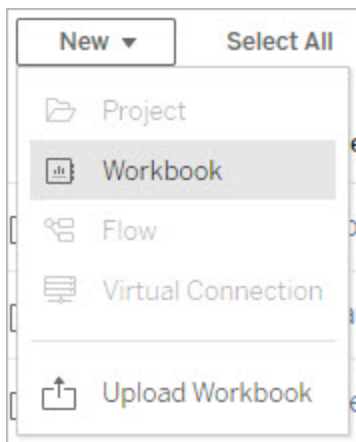

Both Personal Space and a default project are places for you to use for explorations if other projects are not available to you.

Starting in 2019.3, Tableau Catalog is available with Data Management in Tableau Server and Tableau Cloud. When Tableau Catalogue is enabled in your environment, in addition to navigating and connecting to data from Explore, you can navigate and connect to more kinds of data, like databases and tables, from External Assets. For more information about Tableau Catalog, see "About Tableau Catalog" in the [Tableau Server](#) or [Tableau Cloud](#) Help.

Step 2: Create a new workbook and connect to data

In some way, you'll need to connect to data in order to analyse it and build a workbook. As a Creator, Tableau lets you connect to data sources directly on the web, or you can connect to data sources [published to Tableau Cloud through Tableau Desktop](#).

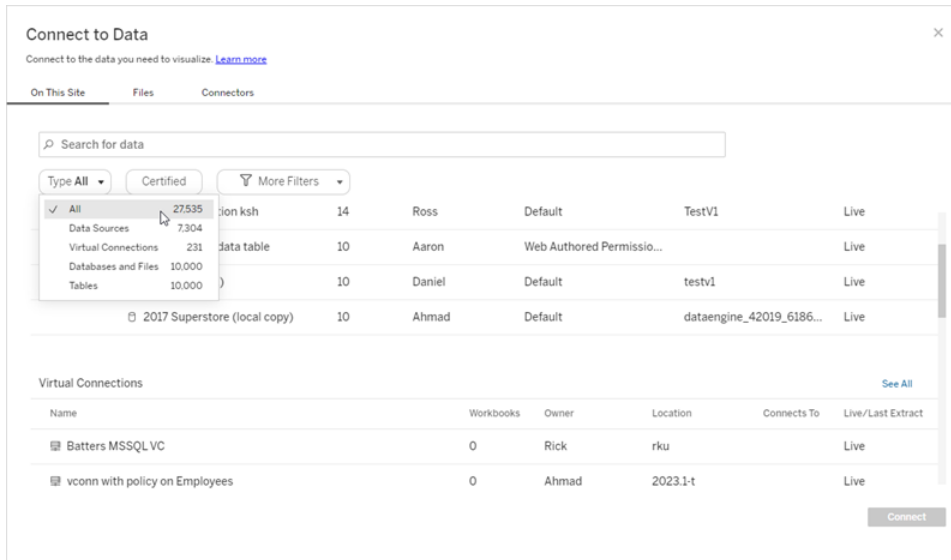

To begin, click the **New** button and select **Workbook**.

The **Connect to Data** dialog displays a scrollable list of mixed content that's popular. If you have a Data Management licence, you can connect to data with a virtual connection, and if you have

Data Management with Tableau Catalogue enabled, you can also connect to external assets, like databases, files and tables.

The responsive search field shows a list of suggestions that updates as you enter text. Filter search results by type of data, certification status or other filters that depend on the type of data selected. For example, some types of data may allow you to filter based on tags, connection type, data quality warnings or other criteria. Older versions of the dialog look and function slightly differently, but the overall function is similar.

You can connect to the data that will power your workbook in several ways:

- Connect to published data sources from the **On This Site** tab.
If you have a Data Management licence, you can connect to data with a virtual connection, and if you have Data Management with Tableau Catalogue enabled, you can also connect to external assets, like databases, files and tables.
- Upload Excel or text-based data sources from the **Files** tab.
- Connect to server or cloud data sources from the **Connectors** tab.
- On Tableau Cloud, quickly author and analyse data from LinkedIn Sales Navigator, Oracle Eloqua, Salesforce, ServiceNow ITSM and Marketo from the **Dashboard Starters** tab.

To learn more about connecting to data on the web, see [Creators: Connect to Data on the Web](#).

Tableau Catalogue users create workbooks from external assets

When you have Data Management with Tableau Catalog enabled, you can create a new workbook when you're making a Catalog-supported connection from the External Assets page:

And from database and table pages:

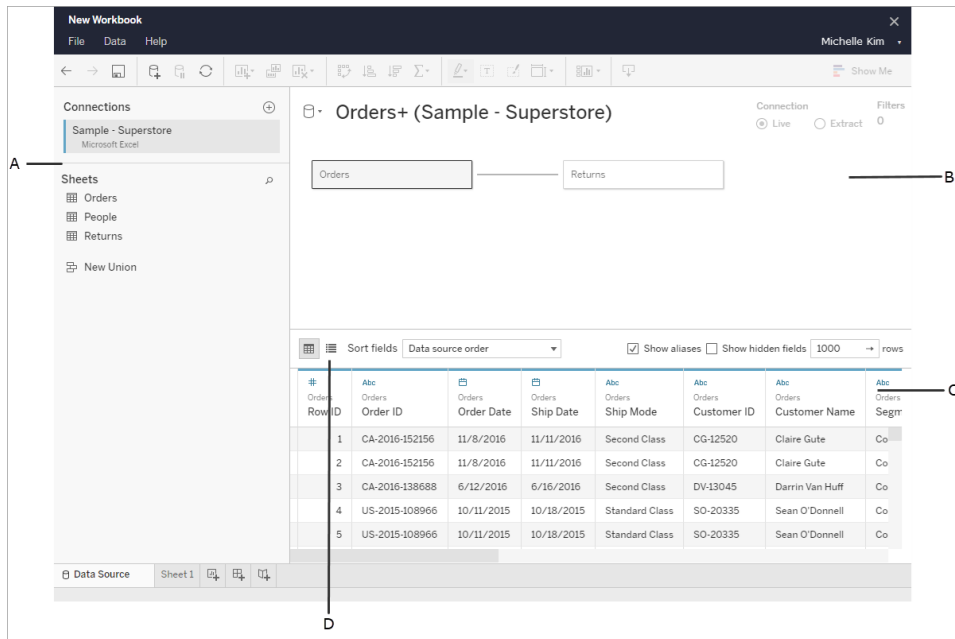

If Catalogue doesn't support the connection, **New Workbook** doesn't appear.

Step 3: Prepare your data

After you have connected to data, use the data source page to prepare your data for analysis.

Parts of the data source page

There are four areas of the data source page:

- A. **Left pane:** Displays details about your data. For file-based data, the left pane might display the file name and the worksheets in the file. For relational-based data, the left pane might display the server, the database or schema and the tables in the database.
- B. **Canvas:** When connected to most relational and file-based data, you can drag one or more tables to the canvas area to set up your Tableau data source for analysis.
- C. **Data grid:** You can use the data grid to review the fields and the first 1,000 rows of the data contained in the Tableau data source.
- D. **Metadata grid:** The button takes you to the metadata grid, which displays the fields in your data source as rows so you can look at its structure.

You can prepare your data for analysis in the data source page by:

- Renaming your data source
- Cleaning your data using the Data Interpreter
- Setting text file options
- Relating your data
- Editing data columns

To learn more about preparing your data for analysis on the web, see [Creators: Prepare your Data on the Web](#).

Once your data is ready for analysis, click on **Sheet 1** at the bottom of the screen to be taken to the Tableau workspace to build a view.

Step 4: Author a view

You've connected to data, you've set it up for analysis, and now you're ready to create a visual analysis of your data. Tableau calls this a **view**. If you've used Tableau Desktop before, the workspace area is very similar.

Workspace area

This is the layout of the Tableau workspace:

- A. **Workbook name.** A workbook contains sheets. A sheet can be a worksheet, a dashboard, or a story. For more information, see [Workbooks and Sheets](#).
- B. **Pages shelf, Filters shelf, Marks card** - Drag fields to the cards and shelves in the workspace to add data to your view. For more information, see [Shelves and Cards](#).

- C. **Columns and Rows shelf** - Drag fields to the cards and shelves in the workspace to add data to your view. For more information, see [Shelves and Cards](#).
- D. **Toolbar** – Use the toolbar to access commands and analysis and navigation tools. See the [Tableau Toolbar Button reference](#).
- E. **View** – This is the workspace where you create your data visualisations.
- F. **Side Bar** - In a worksheet, the side bar area contains the Data pane and the Analytics pane.
- G. Go to the **data source** page. For more information, see [Creators: Preparing Data on the Web](#).
- H. **Sheet tabs** - Tabs represent each sheet in your workbook. This can include worksheets, dashboards and stories.

Starting in Tableau 2020.2: For each table or folder in the Data pane, a grey line separates dimensions (above line) and measures (below line). The **Dimensions** and **Measures** labels are no longer used in the Data pane.

Different ways to start building a view

Every time you drag a field into the view or onto a shelf, you are asking a question about that data. The question will vary depending on where you drag various fields, the types of fields, and the order in which you drag fields into the view.

For every question you ask, the view changes to represent the answer visually - with marks (shapes, text, hierarchies, table structures, axes, colour).

In the worksheet, the columns from your data source are shown as fields on the left side in the **Data** pane. The **Data** pane contains a variety of different kinds of fields, organised by table.

When you build a view, you add fields from the **Data** pane. You can do this in different ways. For example:

- Drag fields from the **Data** pane and drop them onto the cards and shelves that are part of every Tableau worksheet.

- Double-click one or more fields in the **Data** pane.

- Select one or more fields in the **Data** pane and then choose a chart type from **Show Me**, which identifies the chart types that are appropriate for the fields you selected. For more information, see [Show Me](#).

Filtering data

You might want to filter your data to only display a certain amount in your view. You can filter your data in a number of ways, including:

When you add fields to the filter Shelf, an interactive filter appears in the view. You can then select the items you want to include or exclude in the view.

- To create a filter in Tableau on the web, drag a dimension, measure or date field to the filter shelf.

When you add a field to the filters shelf, an interactive filter appears in the view. You can select items you want to include or exclude from the view, or select a range of values.

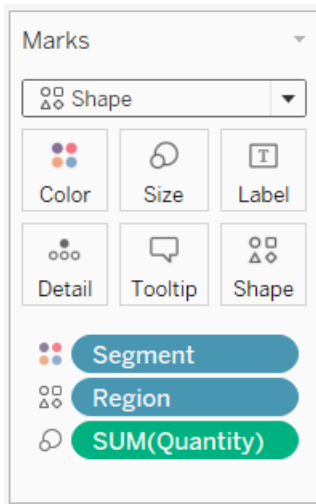

- You can also interact with a published view by selecting a single mark (data point) or click and drag in the view to select several marks. On the tooltip that appears, you can select Keep Only to keep only the selected marks in the view, or select Exclude to remove the selected marks from the view.

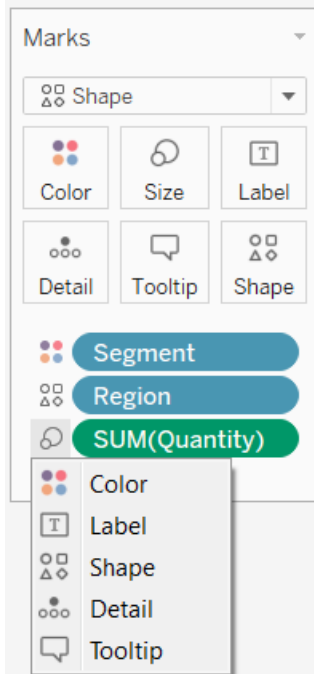

For more information about filtering in Tableau, including Tableau's order of operations, see [Filter Data from Your Views](#).

Using the Marks card

You can use the Marks card to add context and details to the marks in your view. You use the Marks card to set the mark type, and to encode your data with colour, size, shape, detail and text.

After you add a field to the Marks card, you can click the icon next to the field to change the property it is using. You can also click the property buttons in the Marks card to change those settings.

Many properties can have multiple fields. For example, you can add multiple fields to Label, Detail, Tooltip and Colour. Size and Shape can only have one field at a time. For more information, see [Mark Properties Reference](#).

Undo your work

Tableau is extremely flexible and very forgiving. As you build a view, if you ever take a path that isn't answering your question, you can always undo to a previous point in your exploration.

- To undo or redo, click undo ⬅ or redo ➡ on the toolbar.

You can undo all the way back to the last time you opened the workbook. You can undo or redo an unlimited number of times.

Build and edit views on the web

There are many ways to explore data in Tableau. For instructions on building specific chart types on the web, see [Edit Tableau Views on the Web](#) on page 3236, or for more features available to help you build a visualisation in Tableau, see [Build and Explore Data Views](#).

Step 5: Present your work

There are several ways to tell a story or persuade others with the data insights you've found in your views.

Format your work

You can format almost everything you see on a workbook, including parts of a view, your workbook's fonts and graph lines.

- [Learn about visual best practices](#)
- [Format parts of a view](#)
- [Create Custom Colour Palettes](#)
- [Format Text and Numbers](#)
- [Format at the workbook level](#)

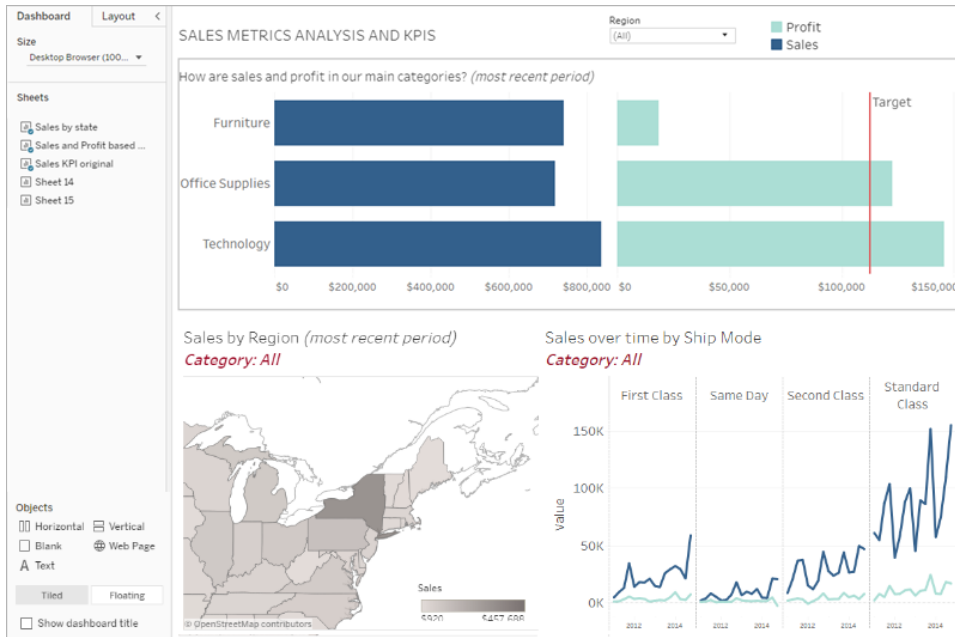

Dashboards

A **dashboard** is a collection of several worksheets and supporting information shown in a single space so you can compare and monitor different data simultaneously.

To open a new dashboard sheet and start creating a dashboard, click the New Dashboard icon at the bottom of the workbook:

The Dashboard area appears on the left and lists the sheets in your workbook. You can add one or more views to a dashboard, add objects like web pages, blank space and layout containers, or interactivity to associate different views on your sheet.

- [Learn more about dashboards](#)
- [Learn about tips and tricks from dashboard experts](#)

Stories

A **story** is a sheet than contains a sequence of worksheets and dashboards that work together to convey information. You can use stories to make a compelling case by showing how facts are connected, and how decisions create stories to tell a data narrative, provide context, demonstrate how decisions relate to outcomes or make a compelling case with your data.

[Create a story](#) or [learn more about stories](#).

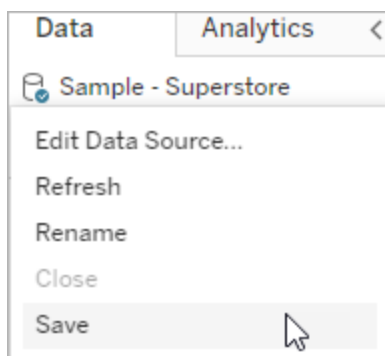

Step 6: Save your work

You can save your workbook at any time by selecting **File > Save As**. Your workbook will save to the folder it was created in.

You can also save your data source to create another workbook later, or enable members of your team to use that data for their own analysis.

To save a data source, hover over the data source name in the Data tab in the workspace until an arrow appears. Select the arrow and select **Save**.

Note: When you save a data source on the web, it will appear as a published data source in the **Connect to Data** window as well as in the **Data Sources** section.

When you're finished, select **File > Close** to exit the workspace.

Step 7: Collaborate and share your findings

There are a number of ways to share your work and stay up-to-date.

Collaborate

Other Creators or Explorers in your organisation can edit or update your workbooks and views if they have been given access to the project where the workbook is located. Access is controlled by your site's administrator, who can set project permissions, move content between projects and change a user's role. If you've saved your data source, those users can connect to your data and use it to create new workbooks.

Share Views and Insights

Every view or workbook saved to your site can be shared via links in email and other applications, or can be embedded directly into web pages, wikis and web applications.

To see a view, users must have permission to access it in Tableau Server or Tableau Cloud.

Learn how to:

- [Share web views](#) (link to a view or embed a view).
- [Subscribe to Views](#) to receive a snapshot of it by email at regular intervals.
- Create [Data-Driven Alerts](#) to receive email notifications when data reaches important thresholds.
- [Comment on views](#) to share a conversation with other users.
- [Embed views and dashboards](#) into webpages.
- [Download views or workbooks](#).

Creators: Connect to Data on the Web

Before you can create a workbook and build a view on the web to analyse your data on the web, you must connect to your data. Tableau supports connecting to data sources on the web

published through Tableau Desktop, or connecting to data directly through Tableau Cloud, Tableau Server or Tableau Public.

Starting in 2019.3, Tableau Catalog is available as part of the Data Management offering for Tableau Server and Tableau Cloud. When Tableau Catalog is enabled in your environment, in addition to navigating and connecting to data from Explore, you can navigate and connect to more types of data, like databases and tables, from Tableau Catalog. For more information about Tableau Catalog, see "About Tableau Catalogue" in the [Tableau Server](#) or [Tableau Cloud](#) Help. Starting in 2021.4, Data Management includes virtual connections, a central access point to data. For more information, see "About Virtual Connections and Data Policies" in the [Tableau Server](#) or [Tableau Cloud](#) help.

Open the Connect to Data page

On the web, you use the Connect to Data page to access data to connect to. After you sign in to Tableau Server or Tableau Cloud, you can open this page two ways:

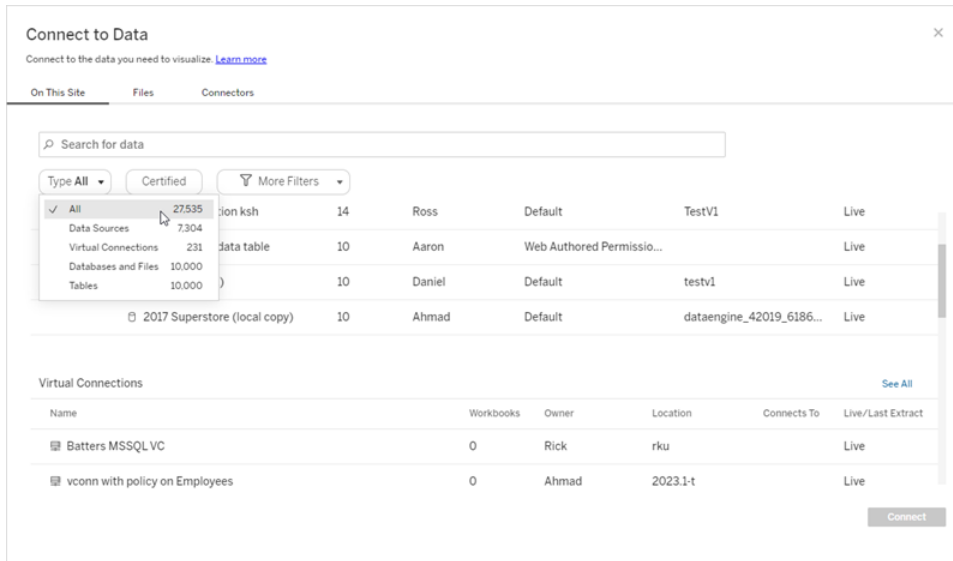

- **Home > New > Workbook**
- **Explore > New > Workbook**

If you're on Tableau Public, you can open this page from your author profile:

- **My Profile > Create a Viz**

The **Connect to Data** dialog displays a scrollable list of mixed content that's popular. If you have a Data Management licence, you can connect to data with a virtual connection, and if you have Data Management with Tableau Catalogue enabled, you can also connect to external assets, like databases, files and tables.

The responsive search field shows a list of suggestions that updates as you enter text. Filter search results by type of data, certification status or other filters that depend on the type of data selected. For example, some types of data may allow you to filter based on tags, connection type, data quality warnings or other criteria. Older versions of the dialog look and function slightly differently, but the overall function is similar.

On the Connect to Data page, the tabs you see depend on the product you have.

Tableau Server

On Tableau Server, select from the following tabs to connect to data: On this site, Files and Connectors.

Connect to data On this site

1. Select **On this site** to browse to or search for published data sources.
2. Select the data source under **Name** and click the **Connect** button.

Note: In addition to connecting to data sources, when you have Data Management, you can use **On this site** to connect to data using a virtual connection. When Tableau Catalogue is enabled, you can also connect to databases, files and tables.

Connect to files

Tableau supports uploading Excel, text-based data sources (.xlsx, .csv, .tsv), and spatial file formats that only require one file (.kml, .geojson, .topojson, .json and Esri shapefiles and Esri File Geodatabases packaged in a .zip) directly in your browser. In the **Files** tab of the **Connect to Data** pane, connect to a file by dragging and dropping it into the field or clicking **Upload from Computer**. The maximum file size you can upload is 1 GB.

Use connectors

From the **Connectors** tab, you can connect to data housed in a cloud database or on a server in your enterprise. You must supply connection information for each data connection that you make. For example, for most data connections, you must supply a server name and your sign-in information.

Supported Connectors contains information on how to connect Tableau to each of these connector types to set up your data source. If the connector you need doesn't appear in the Connectors tab, you can connect to data through Tableau Desktop and publish your data source to Tableau Cloud or Tableau Server for web authoring. Learn more about how to **Publish a Data Source** in Tableau Desktop.

When Tableau successfully connects to your data, the Data Source page opens so that you can prepare the data for analysis and begin building your view. To learn more, see **Creators: Prepare Data on the Web**.

**Google BigQuery needs OAuth when creating data sources from the web. Learn more about how server administrators can [Set up OAuth for Google](#).

***Teradata web authoring currently doesn't support query banding functionality. See [Teradata](#) for details.

‡Supports virtual connections if you have Data Management. See [About Virtual Connections and Data Policies](#) in the Tableau Server help for details.

Tableau Catalog Supported Connectors

Tableau Catalogue supports making a connection with a subset of the data connectors that Tableau Server supports. If a data source, database, file or table is greyed out, you can't connect from Tableau Server. You can, however, connect from the Tableau Desktop **Connect** pane, if you have the correct permissions.

Tableau Cloud

On Tableau Cloud, select from the following tabs to connect to data: On this site, Files, Connectors and Dashboard Starters.

Connect to data On this site

1. Select **On this site** to browse to or search for published data sources.
2. Select the data source under **Name** and click the **Connect** button

Note: In addition to connecting to data sources, when you have Data Management, you can use **On this site** to connect to data using a virtual connection. When Tableau Catalogue is enabled, you can also connect to databases, files and tables.

Connect to files

Tableau supports uploading Excel or text-based data sources (.xlsx, .csv, .tsv) directly in your browser. In the **Files** tab of the Connect to Data pane, connect to an Excel or text file by dragging and dropping it into the field or clicking **Upload from Computer**. The maximum file size you can upload is 1 GB.

Use connectors

From the **Connectors** tab, you can connect to data housed in a cloud database or on a server in your enterprise. You must supply connection information for each data connection that you make. For example, for most data connections, you must supply a server name and your sign-in information.

Supported Connectors has information on how to connect Tableau to your data using connectors. If the connector you need doesn't appear in the Connectors tab, you can connect to data through Tableau Desktop and publish your data source to Tableau Cloud or Tableau Server for web authoring. Learn more about how to **Publish a Data Source** in Tableau Desktop.

Note: If you're unable to connect to your data from Tableau Cloud, check to see if the database is publicly accessible. Tableau Cloud can only connect to data that's accessible from the public internet. If your data is behind a private network, you can connect using Tableau Bridge. To learn more, see **Publishers: Use Tableau Bridge to Keep Tableau Cloud Data Fresh**.

Tableau Cloud Connectors

| | | |
|--------------------------------|-------------------------|-----------------------------|

*For more information about using OAuth 2.0 standard for Google BigQuery, OneDrive and Dropbox connections in Tableau Cloud, see [OAuth Connections](#).

**Teradata web authoring currently doesn't support query banding functionality. See [Teradata](#) for details.

‡Supports virtual connections if you have Data Management. See [About Virtual Connections and Data Policies](#) in the Tableau Cloud help for details.

§Tableau Cloud doesn't support SSL using Google Cloud SQL.

Tableau Catalog Supported Connectors

Tableau Catalog supports making a connection with a subset of data connectors that Tableau Cloud supports. If a data source, database, file or table is greyed out, you can't connect from Tableau Cloud. You can, however, connect from the Tableau Desktop **Connect** pane, if you have the correct permissions.

Use Dashboard Starters

On Tableau Cloud, you can author and analyse data from LinkedIn Sales Navigator, Oracle Eloqua, Salesforce, ServiceNow ITSM and QuickBooks Online using Dashboard Starters. On

the **Dashboard Starter** tab, from the list of pre-built designs, select an option and click **Use Dashboard**. See [Dashboard Starters for Cloud-based Data Sources](#) for details.

Tableau Public

On Tableau Public, you can connect to data by uploading a supported file.

Connect to files

Tableau supports uploading Excel or text-based data sources (.xlsx, .csv, .tsv) directly in your browser. In the **Files** tab of the Connect to Data pane, connect to an Excel or text file by dragging and dropping it into the field or clicking **Upload from Computer**. The maximum file size you can upload is 1 GB.

If you don't have a data set, check out the free [sample data sets](#) on the Tableau Public website.

Use connectors

From the **Connectors** tab, you can connect to data housed in a cloud database. You must supply connection information for each data connection that you make. For example, for most data connections, you must supply your sign-in information.

[Supported Connectors](#) has information on how to connect Tableau to your data using connectors. If the connector you need doesn't appear in the Connectors tab, you can connect to data through Tableau Desktop and create a data extract.

Note: If you're unable to connect to your data from Tableau Public, check to see if the database is publicly accessible. Tableau Public can only connect to data that's accessible from the public internet.

Tableau Public Connectors

Google Drive

OData

After you connect

When Tableau connects to your data, the Data Source page opens so that you can prepare the data for analysis and begin building your view. To learn more, see [Creators: Prepare Data on the](#)

Web.

Keep data fresh in web authoring

Update uploaded files in Tableau Cloud or Tableau Server: If you manually upload a file (Excel or text) for web authoring, Tableau can't refresh the file automatically. To update your data, select "Edit Connection" to upload a new version of the file.

In Tableau Public, go to your viz and click **Request Update**. You can also keep your data fresh automatically by selecting "Keep this data in sync" in Tableau Desktop Public Edition.

Update file-based published data sources in Tableau Cloud: If you have a published data source in Tableau Cloud (published through Tableau Desktop) that uses file-based data, you can keep it fresh using Tableau Bridge. For more information, see [Expand Data Freshness Options by Using Tableau Bridge](#).

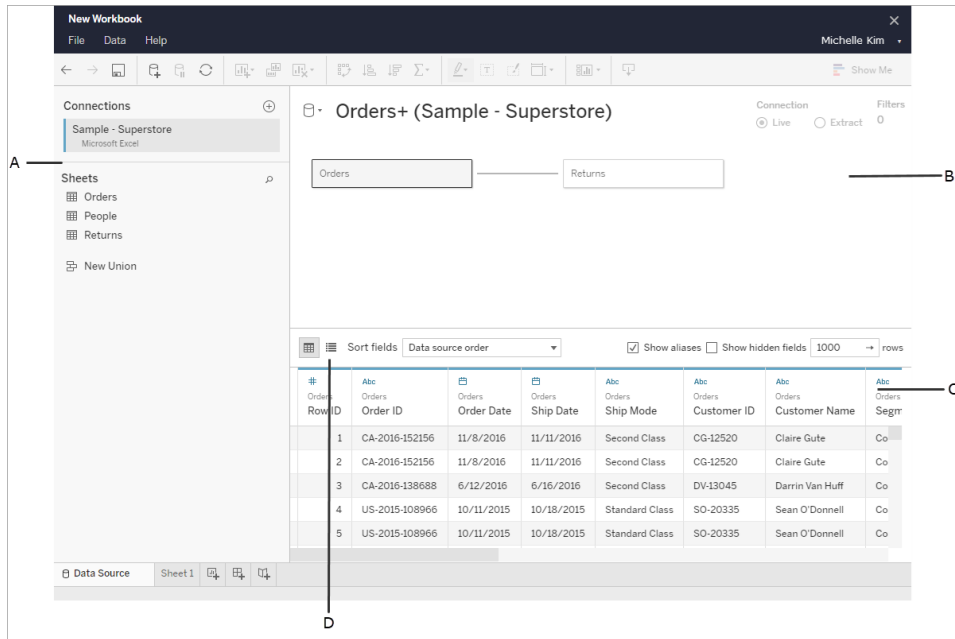

Prepare Data on the Web

After you connect to data in Tableau Cloud or Tableau Server, you can use the Data Source page to set up your data source and prepare your data for analysis. Having data that is formatted in a way Tableau likes is crucial to building a view or doing analysis in Tableau, and communicating the right information to the right people.

This article describes preparing your data in the browser with Tableau Cloud or Tableau Server. Although Tableau supports many of the same functionality for preparing your data for analysis in the browser as Tableau Desktop, for specific differences between the two, see [Web Authoring and Tableau Desktop Feature Comparison](#) on page 3425.

Note on keeping your data fresh: If you connect to a published **flat file** (Excel or text), that data will not be refreshed even if it's modified. If your data is in an **on-premises server** and is published to the web through Tableau Desktop, it will be rendered as an extract and won't be refreshed. If you need to keep data published through Tableau Desktop fresh on the web, you can use Tableau Bridge. To learn more about these requirements, see [Keep Data Fresh](#) and [Use Bridge to Keep Data Fresh](#) on page 3163

Tour the Data Source page

There are four parts of the data source page:

A: Left pane

Displays details about your data connection. For example, for Excel-based data, the left pane shows your Excel workbook name, and sheets contained in that workbook. For databases, the left pane displays the server, the database or schema and tables in the database.

B: Canvas

When connected to most relational and file-based data, you can drag one or more tables to the canvas area to join tables for analysis.

In the canvas, you can also join tables from the same or multiple data sources

C: Data grid

You can use the data grid to review or rename fields, create calculations, preview your changes and more.

D: Metadata grid

Select the metadata grid button to see the fields in your data source as rows. This view is helpful in understanding the structure of your data source.

Set up data sources

After you connect to your data, use the Data Source page to set up the data source and prepare your data for analysis. There are many optional configurations that you can make before you begin your analysis. The configurations that you make on the Data Source page creates the data source that Tableau uses to interpret and interact with your data.

Plan the Data Source on page 602

Relate Your Data on page 628

Connect to a Custom SQL Query on page 868

Join Your Data on page 796

Union Your Data on page 852

Convert a Field to a Date Field on page 889

Pivot Data from Columns to Rows on page 897

Clean Data from Excel, CSV, PDF and Google Sheets with Data Interpreter on page 902

Edit and sort fields in the data grid

You can make changes to your fields in the data grid. You can rename your fields, group them, create aliases, create calculated fields, change data type and convert to a measure.

Publish a Data Source on the Web

You can save data sources to share or reuse from your published workbooks on Tableau Server. To do this, you'll need to have the specific permissions to edit the workbook and publish on Tableau Server. For more about publishing permissions, see [Who can publish content](#) in the Tableau Server Help.

If your data source uses a large extract, this publish step might take a few minutes.

1. On Tableau Server, open a workbook in web authoring.
2. Click the tab for any worksheet.
3. From the **Data** pane, click the drop-down menu for the data source you want to share, and click **Save as Published Data Source**.

Note: After the data source is published to the web, you will not be able to edit or view the data model.

Create and Edit Private Content in Personal Space

Personal Space is a private location for all Explorers and Creators to save content to when working in a Tableau Site. Content saved in Personal Space can't be shared with other users but can be moved to a project when you're ready for others to see it. Within Personal Space, you can create a new workbook or save a workbook to Personal Space as a separate copy. You can also move existing content you own into Personal Space for editing, then move it back to a project later. Explorers can download workbooks in Personal Space, including all data included in the workbook.

Privacy in Personal Space

Content saved to your Personal Space is only visible to you and site administrators. Site administrators can't directly access any user's Personal Space or edit content in someone else's Personal Space, but they can view and manage Personal Space workbooks. Personal Space workbooks appear in administrator search results and as a workbook location on the Explore page. In addition, the permissions menu is unavailable when a workbook is in Personal Space because the workbook is private.

Tableau Catalogue and Personal Space

Starting in 2019.3, Tableau Catalog is available with Data Management in Tableau Server and Tableau Cloud. For more information, see "About Tableau Catalog" in the Tableau Server or Tableau Cloud Help.

When Tableau Catalog is enabled in your work environment, the information about workbooks you save in your Personal Space is indexed by Catalog. These workbooks are included in lineage counts. However, only you can see the workbooks. Furthermore, users who browse through the lineage tool see Permissions required instead of information about workbooks in your Personal Space.

Collaboration tools

When a workbook is in Personal Space, some functionality is disabled, including share, metrics, comments, alerts and subscriptions. Existing alerts and subscriptions to you will continue running, but alerts and subscriptions to others will fail, since the content is now private. Metrics can't be created in Personal Space but will continue to work if a connected workbook is moved there. (The legacy Metrics feature was retired in February 2024 for Tableau Cloud and in Tableau Server version 2024.2. For more information, see [Create and Troubleshoot Metrics \(Retired\)](#).)

These limitations are removed when the workbook is moved or saved to another location. For example, if a workbook contains comments and moves to Personal Space, existing comments are hidden. Comments are restored when the workbook is moved to another location.

Extract refreshes in Personal Space

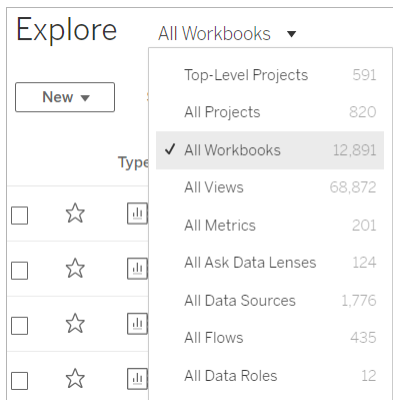

To limit resource consumption, existing extract refreshes continue to run if they've been scheduled, but new extract refreshes can't be scheduled while a workbook is in Personal Space.

Find content in Personal Space

You can access Personal Space from the left navigation menu to see all your Personal Space content or create a new workbook, and you can save to Personal Space when creating or editing a workbook anywhere on the site.

You can also see workbooks in Personal Space from the Explore page when All Workbooks is selected, and you can filter down to Personal Space content.

Publish a workbook to Personal Space

Personal Space works much like a private project for you to publish a new or existing workbook to from Tableau Cloud, Tableau Server or Tableau Desktop.

Publish a workbook to Personal Space on Tableau Server or Tableau Cloud

1. With the workbook open, select **File > Publish As**.
2. Under Location, select **Personal Space**.

Note: Explorers can only save workbooks to Personal Space and may not see a location selection dialog.

Publish a workbook to Personal Space from Tableau Desktop

Starting in 2023.1, you can publish a workbook to Personal Space from Tableau Desktop.

1. With the workbook you want to publish open in Tableau Desktop, select **Server > Publish Workbook**.
2. Under Project, select **Personal Space**.
3. Under Data Sources, select **Edit**.
4. In the Manage Data Sources popup under Publish type, select **Embedded in workbook** for all data sources. You must embed data sources when publishing from Tableau Desktop, because you can't publish data sources separately to Personal Space.
5. Fill out the remainder of the publishing options as usual. For more information, see [Comprehensive Steps to Publish a Workbook](#).

Move workbooks to Personal Space

You can move an existing workbook to Personal Space if you are the owner of the workbook and there is room in your Personal Space. Personal Space storage limits are set by administrators.

To move a workbook to Personal Space:

- Select a workbook, then click the **Actions** drop-down menu.
- Select **Move**.
- Under Location, Select **Personal Space**.

Note: Explorers can only save workbooks to Personal Space and may not see the move action or location selection dialog.

For more information, see [Perform actions](#) in the Manage Web Content help topic.

When you move an existing workbook or data source to Personal Space, tools like share, alerts and subscriptions become hidden. Existing extract refreshes continue to run if they've been scheduled, but users can't schedule new extract refreshes within their Personal Space.

Existing subscriptions and alerts also continue but can't be edited from Personal Space and will fail if other users are recipients. Existing connected metrics will continue to refresh, but the connected view will not be visible to other users.

Move workbooks from Personal Space

When you move a workbook out of Personal Space, collaboration tools like share, alerts and subscriptions become visible, and any existing comments reappear.

Upload Workbooks to a Tableau Site

Most workbooks you encounter in a Tableau Cloud or Tableau Server site are created and published to the web using Tableau Desktop, or are created directly on the web. When Desktop is unavailable, you can upload Tableau workbooks and Tableau packaged workbooks directly to your Tableau Cloud or Tableau Server site if you have a Creator and Explorer (can publish) site role.

Upload a new workbook to a Tableau site

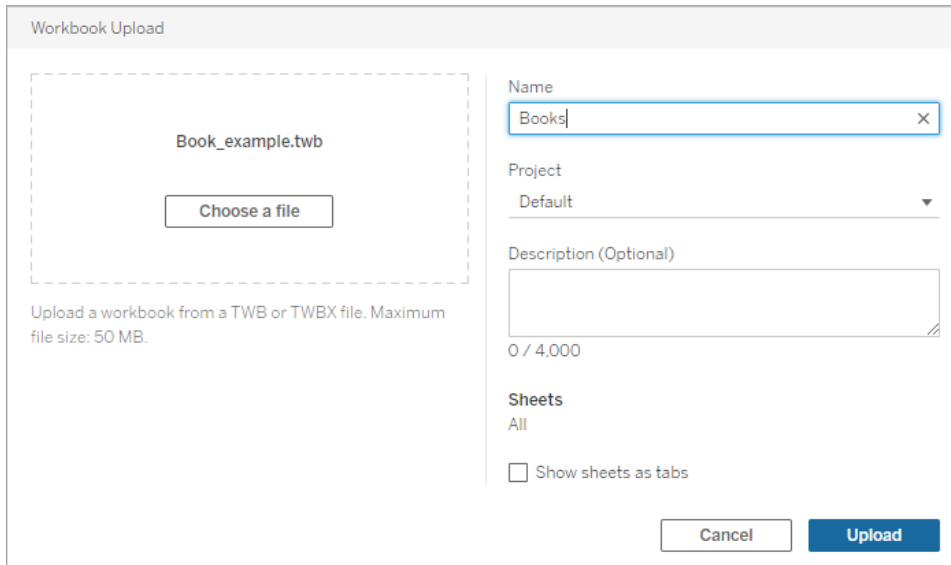

To upload a workbook:

1. Sign in to a site on Tableau Cloud or Tableau Server.
2. From the Home or Explore pages, select **New > Workbook Upload**.

3. In the dialog that opens, do either of the following:
 - Select **Choose a file** to select a .twb or .twbx file from your computer
 - Drag and drop a file into the upload area of the dialog.

Files must be 50 MB or smaller to be uploaded.

The 'Workbook Upload' dialog box is shown. On the left, there is a dashed box containing the text 'Book_example.twb' and a 'Choose a file' button. Below this, it says 'Upload a workbook from a TWB or TWBX file. Maximum file size: 50 MB.' On the right, there are several fields: 'Name' with a text input containing 'Books' and a close button; 'Project' with a dropdown menu showing 'Default'; 'Description (Optional)' with a text area showing '0 / 4,000'; 'Sheets' with a dropdown showing 'All'; and a checkbox for 'Show sheets as tabs' which is currently unchecked. At the bottom right, there are 'Cancel' and 'Upload' buttons.

4. In the Name field, enter a name for your workbook. By default, the workbook will retain the name of the file.
5. Choose a project where your workbook will be published, or leave as is to publish the workbook to the Default project.

Note: You'll see a warning if the project already contains a workbook with the same name. You can override an existing workbook, or update the **Name** field to something else.

6. Optionally, add a workbook description or select **Show sheets as tabs** to provide tab-based navigation.

How sheet tabs are configured also impacts permissions. When a workbook shows sheets as tabs, workbook-level permission rules are applied to the sheets. When the sheets are not shown as tabs, any changes made to workbook permissions do not apply to the individual sheets (aka views). View-level permissions must be set independently. For more information, see the [Set Content Permissions](#) tab in the [Permissions](#) topic for more information.

7. Select **Upload**.

If the workbook is overwriting an existing workbook, confirm that you'd like to overwrite, or select **Cancel** to rename.

8. When the workbook uploads successfully, you're directed to the first sheet of the workbook.

Note: Uploading publishes every sheet in the workbook. To limit publishing to specific sheets, use Tableau Desktop to upload.

Permissions and data source connections

To upload a workbook, you must have permission to publish to the site and the project.

If your workbook uses an embedded data source that requires a password, you can embed credentials after you publish the workbook.

To edit the data source connection after uploading and publishing a workbook:

- Open the workbook for editing, select the Data Source tab, and select Edit Connection.
- From the Data Sources tab, select the Actions menu (...) and select Edit Connection.

Edit Tableau Views on the Web

If you can see the **Edit** button when you are looking at a view in Tableau Cloud or Tableau Server, that means you can make changes to it. Depending on your access level and permissions, you can:

- Edit an existing published workbook and add worksheets for views, dashboards, and stories.
- Create and edit a new workbook based on a published data source.
- Edit an existing workbook and add worksheets in the browser, or by opening the workbook in Tableau Desktop.
- Connect to different published data sources while editing. For details, see [Connect to Published Data Sources while Web Editing](#).

For more information about how to build different types of charts and views in Tableau, see [Build Charts and Analyse Data on page 1009](#).

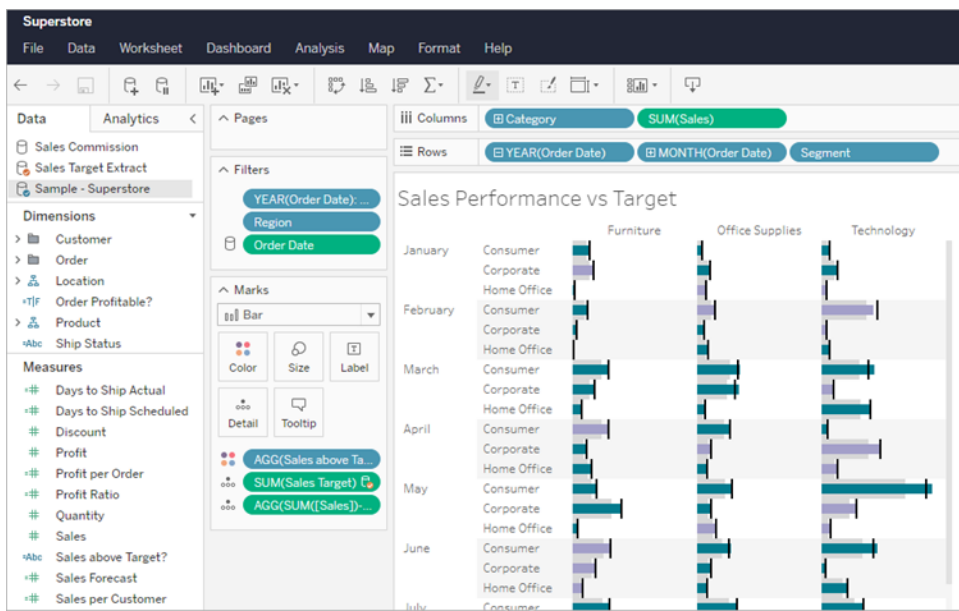

Note: Editing a view on a mobile device, either with a mobile web browser or the Tableau Mobile app, is not supported. You must use a desktop web browser.

Edit a published view

1. Sign in to a site, then either open the workbook that contains the view you want to edit, or show **All Views** from the Explore page.
2. Open the view.
3. Click **Edit** in the view toolbar.

When you click **Edit**, the view opens in web authoring mode.

Now you can edit the view.

Note: If you have Tableau Desktop version 2021.2 or later, you can also open the workbook in Tableau Desktop and edit there. Select the Edit in Desktop icon  in the authoring toolbar to open, then publish the workbook to the site when you're finished.

To learn how to build a chart or dashboard, see **Step 4** in [Creators: Get Started with Web Authoring](#) and [Explore and Analyse Data in a View](#).

4. The **Save** options available to you will vary depending on your permissions set by your Tableau site administrator.
 - To close the view without saving your changes, select **File > Close**.
 - To save your work in the current workbook, select **File > Publish**.
 - To save your work as a new workbook, select **File > Publish As**. Creators can select a location to save the workbook, either in a project or to their private Personal Space. Explorers can only save to Personal Space. For more information about Personal Space, see [Create and Edit Private Content in Personal Space on page 3229](#).

Note: If you edited a workbook in Tableau Desktop and want to publish your changes, select **Server > Publish Workbook** and select **Publish**. The workbook's location and name will be populated in the **Publish** dialog.

Create a new workbook on the web from a published data source

1. Sign in to a site on Tableau Cloud or Tableau Server.
2. Either open the project that contains the data source you want to use, or show **All Data Sources**.
3. Click the ... next to the data source name to open the actions menu, then click **New Workbook**.

A new, blank workbook opens in the Tableau Server web editing environment.

Create and Troubleshoot Metrics (Retired)

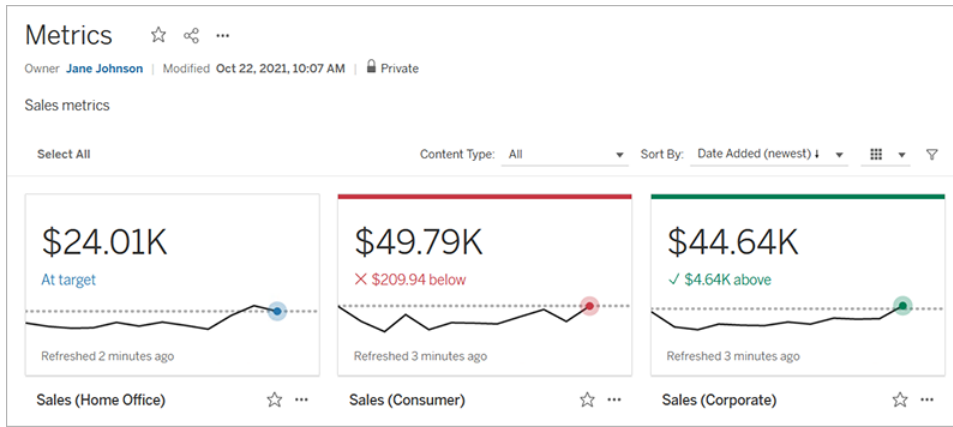

Retirement of legacy metrics

This article is about Tableau's legacy metrics feature, which was retired in Tableau Cloud in February 2024 and in Tableau Server version 2024.2. In October 2023, Tableau retired the ability to embed legacy metrics in Tableau Cloud and in Tableau Server version 2023.3.

Tableau Pulse introduces a new way to track metrics. With Tableau Pulse, the metrics you create are used to generate insights about your data. These data insights are sent directly to users who follow the metrics, so they can learn about changes to their data in their flow of work. For more information, see [Create Metrics with Tableau Pulse](#).

If you have legacy metrics that you want to keep, note the data source, measure and time dimension for those metrics and recreate them in Tableau Pulse. Legacy metrics won't be automatically migrated to Tableau Pulse.

Metrics provide a fast way to stay informed about your data. Because metrics update automatically and display their current value in the grid and list view of your content, you can check all the key numbers you care about in seconds.

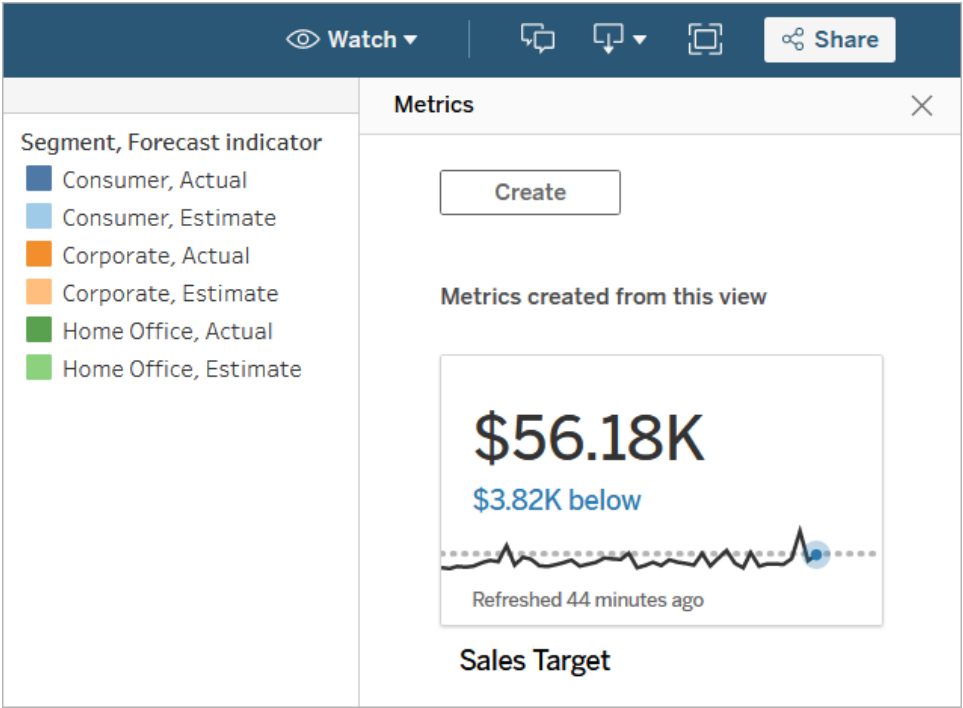

At their most basic level, metrics show the value of an aggregate measure, like the sum of sales. More complex metrics can include timelines, comparisons and statuses that provide an easy-to-understand indicator of how you're performing relative to a prior point in time or a value you have defined.

If you have a set of dashboards that you regularly check, create metrics for the numbers that you want to monitor then track them in one place by adding them to your favourites or a collection, or by creating them in the same project. That way, you don't need to load and filter the dashboards unless you want to dig deeper into your data.

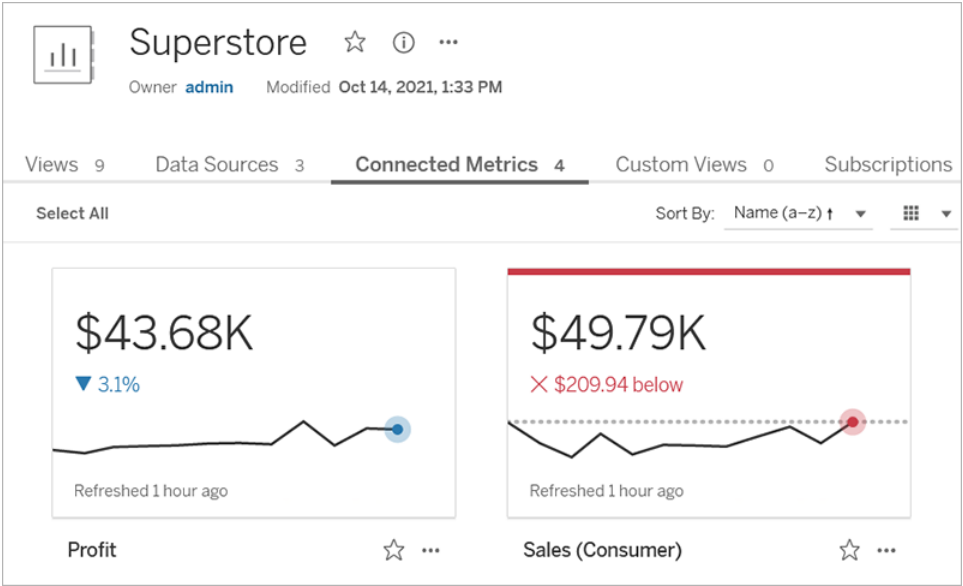

Find metrics on your site

There are a few ways to find metrics on your Tableau site. To browse all the metrics that you have permission to view, navigate to the Explore page, then select **All Metrics** from the content type menu.

If you're looking for metrics related to a particular view or workbook, check the connected metrics for that content. To see connected metrics for a view, open the view, then click **Watch > Metrics** in the view toolbar. The metrics displayed are ordered from the newest creation date to the oldest.

To see connected metrics for all the views in a workbook, navigate to the workbook, then click the **Connected Metrics** tab. You can sort these metrics using the Sort By menu.

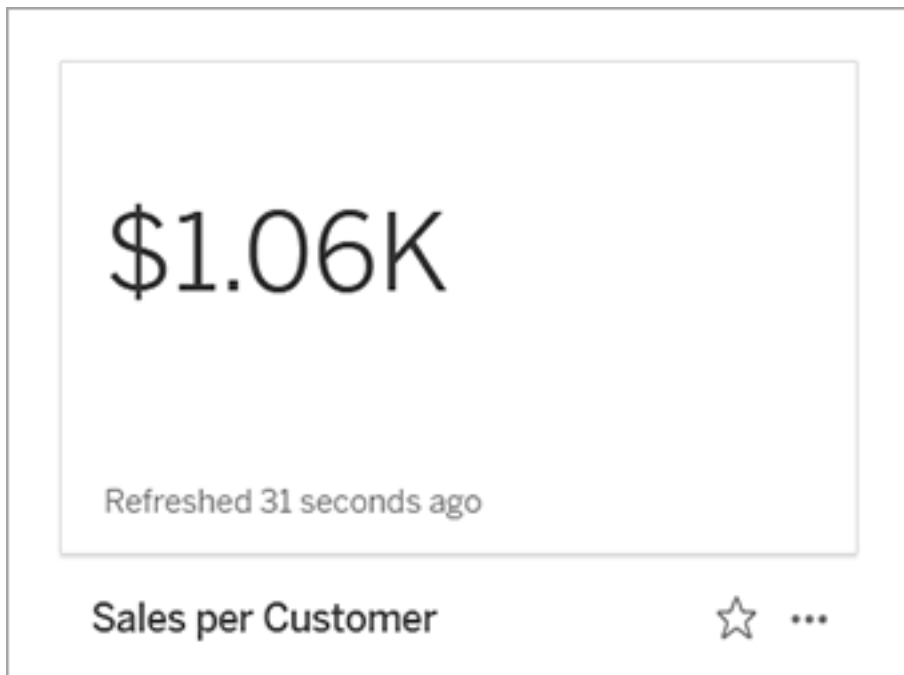

Components of a metric

The only data required to define a metric is an aggregate measure. Metrics are created from a mark in a view, and the measure associated with that mark defines the metric. The measure must be aggregated because an unaggregated mark will not change over time. For information about dimensions and measures in Tableau, see [Dimensions and Measures, Blue and Green](#).

A metric can optionally be defined by a date dimension, and you can configure a comparison and a status for your metric. Each of these components will add context to the data presented on the metric card.

Metrics that have only a measure defining them will appear as a single number. This number will update when the data updates, but there will be no timeline on the card.

Timeline

When you select a mark to define a metric, if the mark has a date dimension associated with it, that dimension becomes part of the metric definition. Metrics with a date dimension show a timeline, and you can configure the historical comparison for the metric. By default, the historical comparison is to the previous mark.

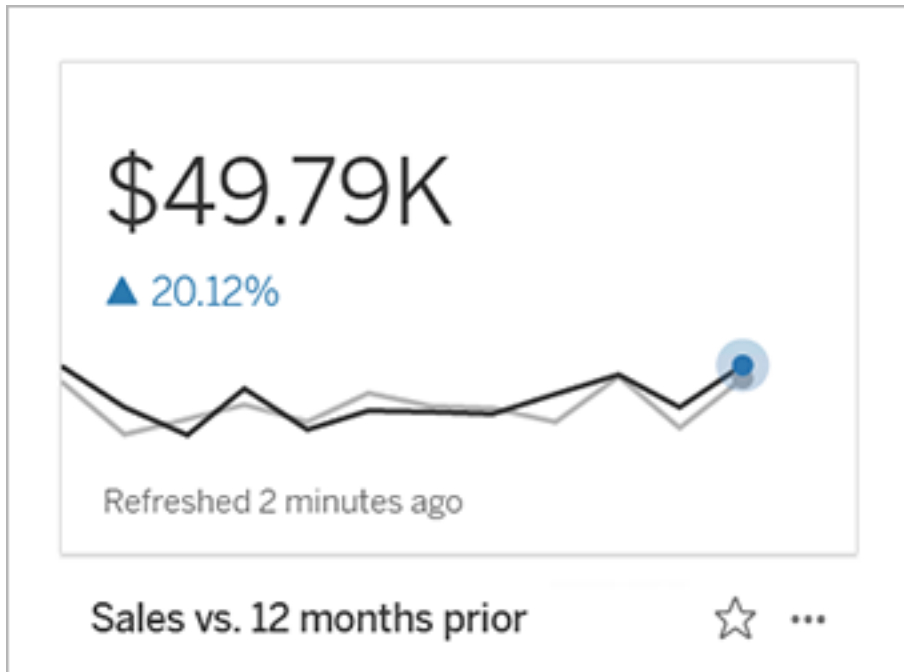

When you open a metric's details page, the timeline shows the value of the measure based on the granularity of the date dimension, for example, daily sales or monthly users. Hover over the points on the timeline to see historical values.

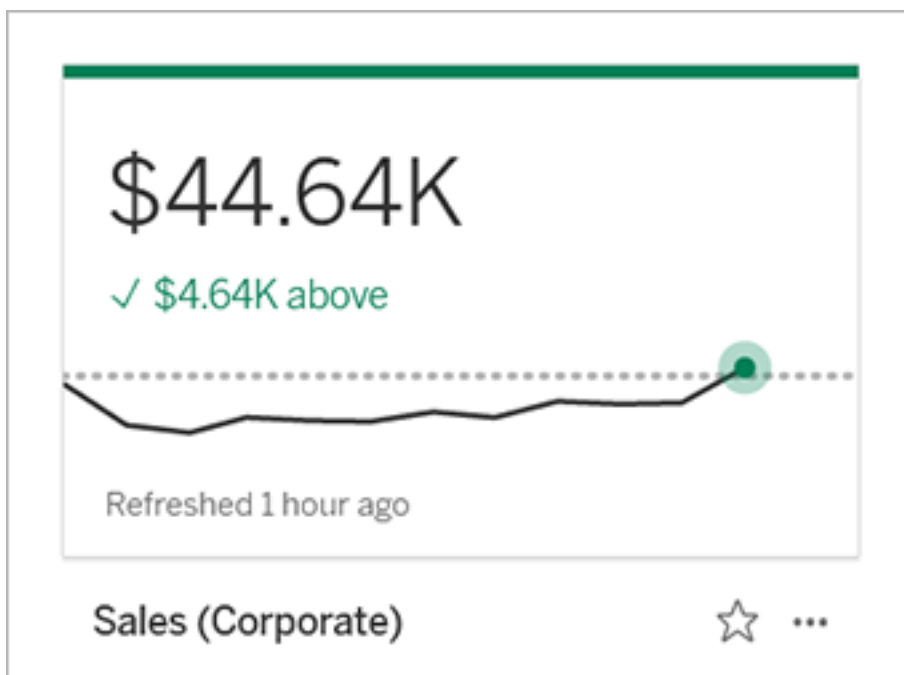

Comparison

There are two types of comparisons that you can configure for metrics: historical comparisons and constant comparisons. You can configure a historical comparison only if a metric has a date dimension associated with it, but constant comparisons can be added for any type of metric.

A historical comparison is a relative comparison between the current value and a specified number of hours, days or other unit of time previous. For example, you could set a comparison between the current value for monthly sales and the value from 12 months ago. Every time data is added to a metric, the historical comparison will adjust relative to the date or time of the new data.

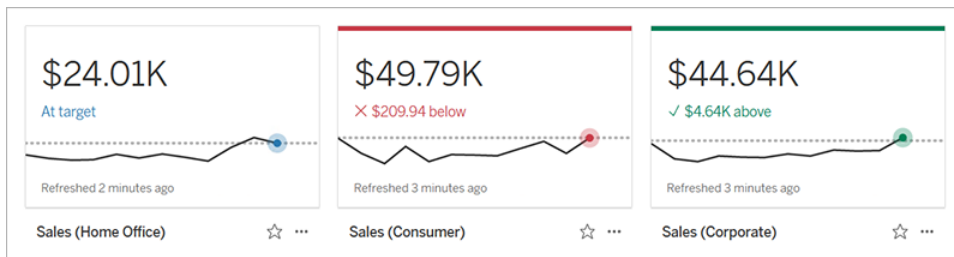

Constant comparisons are to a single value that doesn't change as new data is added. You might set a comparison to represent a threshold to stay above, for example, if you need to maintain a 90% on-time delivery rate. Or you might define a cumulative goal you are working towards, for example, a monthly sales target.

Status

For metrics with a constant comparison, you can define whether being above, below or at the comparison value is good, bad or neutral. A metric with a “good” status will display a tick next to the comparison value, and the metric card will have a green band at the top. A metric with a “bad” status will display an X next to the comparison value, and the metric card will have a red band at the top. Metrics with a “neutral” status appear the same as metrics without a status indicator; there is no icon or colour applied to the card.

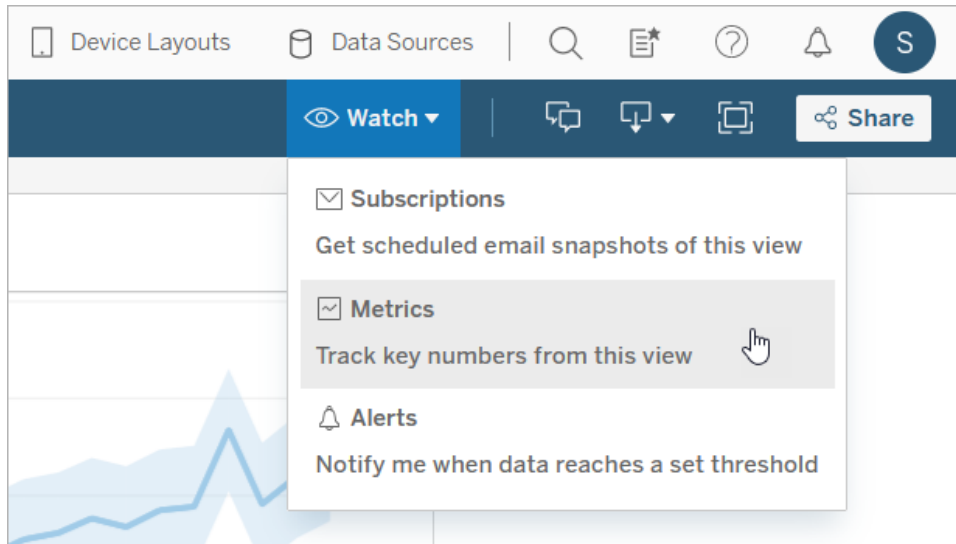

Create a metric from a view

If you have a site role of Creator or Explorer (can publish), and you have the Create/Refresh Metric capability on the relevant workbook, you can create metrics on Tableau Cloud or Tableau Server.

Before you create a metric, check the connected metrics for the view to make sure that the metric you are planning to create doesn't already exist. Instead of creating a duplicate metric, open the existing metric and add it as a favourite.

Select the mark to define your metric

1. Navigate to the view that you want to create a metric from.
2. On the view toolbar, select **Watch > Metrics**.

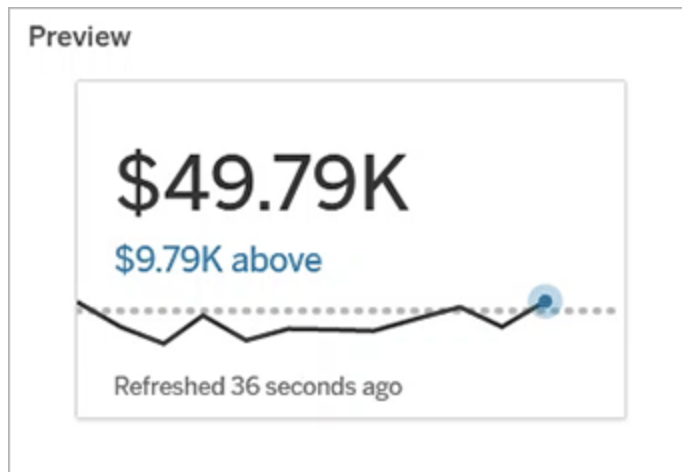

The metrics pane opens.

3. If the pane shows connected metrics, select the **Create** button to enter authoring mode.
4. Select a mark. If you encounter an error, see [When you can't create a metric on page 3249](#).

The measure associated with this mark defines your metric. Any filters you apply to the mark are applied to your metric. If this mark has a date dimension associated with it, that date dimension also defines your metric, and your metric will display a timeline.

The metrics pane shows a preview of your metric. The value in the preview is the most recent value for the metric, which may differ from the value of the mark you selected if it was not the most recent in the time series. The preview updates as you try different configurations.

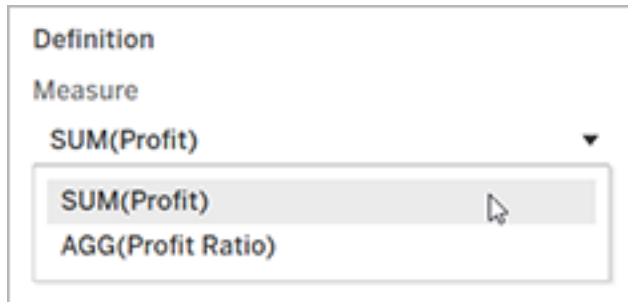

Describe and configure your metric

The options available to configure your metric depend on the mark you select and on the type of comparison you choose.

1. The **Name** field is pre-populated based on the mark you select. You can give the metric a different name. A metric must have a unique name within the project it belongs to.
2. Under **Description**, enter an optional message to help others understand your metric. For example, describe filters applied to the metric or indicate the data source used by the metric.
3. For the **Date Range** (only for metrics with a date dimension), select one of the default options, or set a custom range. If your metric has a large number of marks, limiting the date range can make it easier to read the timeline.
4. Select the **Comparison Type** for the metric: historical or constant.
5. For **Historical** comparisons:
 - Enter how far prior you want to compare against. The unit of time for the comparison is the same as the granularity of your data, such as hours or months.
 - Select **Show Comparison Line** to include a second line for the comparison period on the timeline.
6. For **Constant** comparisons:
 - Enter the value to compare against. Don't include commas or symbols in this field. To enter a percentage, simply type the number without the percent sign, for example, enter 25 instead of 0.25 for a target of 25%. When you enter a valid target value, the preview updates to show how far above or below the target the current

value is.

- Set the **Status** for the comparison to indicate whether being above, at or below the value is good, bad or neutral. By default, the status is set to neutral. Check the metric preview to see how different statuses affect your metric.
7. Under **Definition > Measure**, select the measure to use for your definition from the drop-down. This option appears only if the mark you select has more than one measure associated with it.

Finalise your metric

1. Under **Project**, select **Change Location** to choose a different project for the metric. By default, your metric will be added to the same project that the view belongs to.

Every metric in a project must have a unique name. Because a metric's name and project are initially set based on the mark you select, you might run into a conflict when you try to save your metric, if another user has already created a metric from that mark. Either choose a different project or name for your metric or, if you want to overwrite the existing metric, see [Overwrite a metric](#).

2. Click the **Create** button.

A message appears with a link to the metric in the project you added it to.

3. Verify that the permissions for your metric are correct, following the guidance in [Set permissions](#).

By default, a metric inherits the permissions of the project it is created in. Anyone with access to your metric will be able to see the metric's data, even if they don't have permission to access the connected view or data source.

Now that you've created a metric, you can manage the metric the same way you manage other independent pieces of content on your Tableau site. Though metrics are created from a view, they exist independently of that view, unlike data driven alerts or subscriptions. You can move the metric to a different project without moving the connected view. For information about managing content on your Tableau site, see [Manage Web Content](#).

Overwrite a metric

Once a metric is created, you can change the name, description and configuration of the metric, but you can't change how the metric is defined. If you want to change the data that the metric uses, you must overwrite it. In order to overwrite a metric, you need to be the metric owner or be granted the correct permission capability.

1. To overwrite a metric, create a metric with the same name in the same project as the metric you want to overwrite.

The Overwrite Metric dialog appears.

2. Click the **Overwrite** button.

When you overwrite a metric, the metric continues to appear for those who have added it to their favourites, and any changes made to permissions for the previous metric will apply to the new metric.

When you can't create a metric

If you select a mark on a chart that doesn't support metrics, you'll get an error message explaining why you can't create a metric. The table below summarises these scenarios.

| Reason | Scenarios |
|---|---|
| You don't have the correct permissions. | <ul style="list-style-type: none">• The workbook owner or an administrator has denied the Create/Refresh Metric capability. For more information, see Permissions. |
| You can't access the complete data. | <ul style="list-style-type: none">• Row level security or user filters limit the data you can see. For more information, see Restrict Access at the Data Row Level. |

| Reason | Scenarios |
|--|--|
| The password for the workbook's data source is not embedded or is no longer valid. | <ul style="list-style-type: none"> The workbook prompts for a password. For more information, see Set Credentials for Accessing Your Published Data. |
| The data isn't at the correct level of granularity. | <ul style="list-style-type: none"> The data in the chart isn't aggregated. Metrics use aggregations, such as sum or average. For more information, see Data Aggregation in Tableau. There are multiple values per cell of data – a result of data blending. For more information, see Troubleshoot Data Blending. |
| The date dimension is not supported. | <ul style="list-style-type: none"> The chart includes both date parts and date values. For more information, see Change Date Levels. The date dimension uses the ISO 8601 calendar rather than the standard Gregorian calendar. For more information, see ISO-8601 Week-Based Calendar. The date dimension is aggregated at the custom level of Month / Year or Month / Day / Year. For more information, see Custom Dates. |

Edit a metric's configuration

Starting in 2022.2, you can change the configuration for a metric. A metric's configuration includes the comparison, date range and status indicator. The configuration options available depend on the type of metric. Metrics with a timeline allow you to set a historical comparison or a constant comparison. Single-number metrics support only a constant comparison.

A metric's configuration does not include the metric definition (the measure and date dimension that generate the metric value). If you want to change the definition, overwrite the metric with a new metric.

To edit a metric's configuration, you must have the overwrite capability for the metric.

1. Open the metric details page for the metric you want to edit.
2. Mouse over the configuration section. Click anywhere on the section to enter editing mode.

Metric Details

Owner
[Jane Johnson](#)

Description
No description available.

Configuration 

| | |
|------------|----------------|
| Date Range | Last 12 months |
| Comparison | 1 month ago |

3. For a timeline metric, set the date range to be displayed on the metric card and details.
4. Select the comparison type. For a constant comparison, set a comparison value and status. For a historical comparison, set how far prior you want to compare against and choose whether to show a comparison line on the timeline.
5. Click **Save**. Your configuration changes will appear to anyone who views the metric.

How metrics refresh

When a metric refreshes, it checks the connected view (the view the metric was created from) for new data. A refresh doesn't necessarily update the value of a metric, because there may be no changes to the data.

Metrics refresh at a frequency either based on an extract's refresh schedule or, for live data, every 60 minutes. The time of the last refresh is displayed on the metric.

Fix failing refreshes

If a metric isn't able to access the connected view or its underlying data, the refresh will fail. If the refresh for your metric fails, you'll receive a notification, which notes the time of the failure and the affected metric.

Metric refreshes may fail for one of the following reasons.

- The connected view was deleted or modified.
- Permissions changed for the connected view.
- The password for the data source is no longer embedded or is no longer valid.

- The metric owner doesn't have the required site role to refresh the metric. A site role of Creator or Explorer (can publish) is required.
- There was a temporary connectivity issue, which will resolve itself.

To identify the cause of the failure, look at the metric details. Make sure that the metric owner has the required site role to refresh the metric. Then inspect the **Connected View**.

If the connected view is still listed

Open the view to investigate the cause of the failure.

If the view loads, check that the measure and (optional) date dimension that define the metric are still present in the view.

- If the view appears to be unchanged, you might no longer have permission to refresh metrics from it. The content owner or a Tableau administrator can change the Create/Refresh Metric permission capability. For more information, see [Permissions](#).
- If the measure is no longer present, the view has been modified so the metric can't connect to the data needed to refresh. The content owner or a Tableau administrator can check the revision history and restore previous versions. For more information, see [View Revision History](#).

If the view doesn't load, but instead prompts for a password or displays an error when connecting to the data source, the password for the data source is not embedded or is no longer valid. The content owner or a Tableau administrator can edit the data source connection to embed the password. For more information, see [Edit Connections](#).

If there is no connected view listed

The view was deleted or you no longer have permission to access the view. Contact your Tableau administrator for assistance.

Resume suspended refreshes

If a refresh fails enough times, the refresh is suspended. You'll receive a notification if the refresh for your metric is suspended.

When a metric refresh is suspended, Tableau no longer attempts to get new data for the metric. Metrics with suspended refreshes continue to present historical data.

If the cause of the failure is fixed, you can resume the refresh.

1. Open the affected metric.
2. On the warning message, click **Resume refresh**.

Tableau attempts to perform the refresh. If this attempt succeeds, you'll receive a notification, and the refresh will resume on schedule. If the attempt doesn't succeed, your refresh remains suspended.

Try overwriting the metric if the connected view is still available. For more information, see [Overwrite a metric](#). Otherwise, you can keep the metric to reference past data or delete the metric.

Note: If the metric refresh is suspended because you don't have the required site role for it to refresh, you won't be able to resume the refresh or delete the metric.

Metrics appear in Tableau Catalogue

Starting in 2019.3, Tableau Catalog is available with Data Management in Tableau Cloud and Tableau Server. When the Tableau Catalogue is enabled in your environment, you can see metrics in the Catalogue lineage tool, and metrics affected by data quality warnings display those warnings. For more information about Tableau Catalog, see "About Tableau Catalog" in the [Tableau Server](#) or [Tableau Cloud](#) Help.

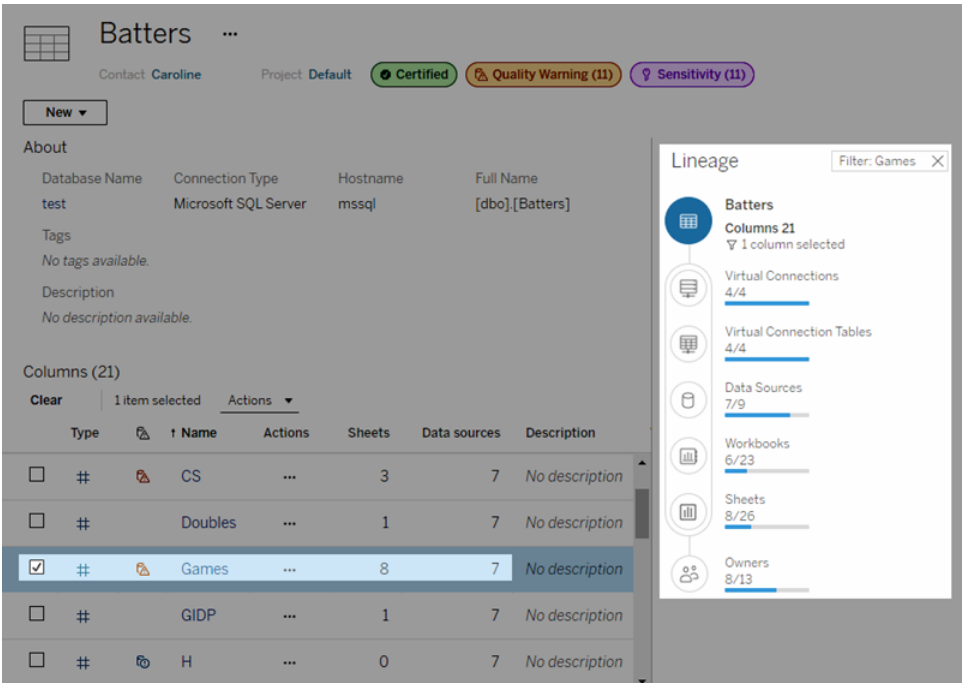

When you have metrics defined for the numbers you want to monitor, it's important to know if the data that the metrics rely on are impacted in any way. You can use Catalogue in a couple of ways to know this. First, data quality warnings set on the data your metric is based on show on the metric. These warnings appear when you open a metric in Tableau Mobile and in Tableau Server and Tableau Cloud when you hover over a metric in grid view and on the metric details page, as shown below:

For more information, see "Set a Data Quality Warning" in the [Tableau Server](#) or [Tableau Cloud](#) Help.

You can also use the lineage tool in Tableau Catalogue to see the upstream sources that your metric relies on. When doing an impact analysis, you can see which metrics are affected if a certain column or a table is changed or deprecated, or if certain workbooks are removed.

Including metrics in the lineage means that Catalogue gives a full picture of the impact changes can have on the assets in your environment.

For more information, see "Use Lineage for Impact Analysis" in the [Tableau Server](#) or [Tableau Cloud](#) Help.

Keyboard Accessibility for Tableau on the Web

Interact with views

Users sent a link to a WCAG-conformant view or workbook in Tableau Cloud or Tableau Server can interact and explore using commonly supported WAI-ARIA standards for keyboard navigation. The following keyboard navigation also applies to embedded views.

All components

| What to do | Keystrokes |
|---|------------|
| Move focus to next navigation component | Tab |

| What to do | Keystrokes |
|---|-------------------|
| Move focus to previous navigation component | Shift+Tab |
| Button activation | Spacebar or Enter |

Navigation panel and toolbar

To skip the navigation panel and toolbar, select **Skip to Content**.

| What to do | Keystrokes |
|---|------------|
| Move focus to next component in navigation panel | Tab |
| Move focus to next item in toolbar | Right |
| Move focus to previous item in toolbar | Left |
| Activate the selected toolbar button | Enter |
| Escape toolbar button window | Esc |
| In a toolbar button window, move focus between components | Tab |
| In a toolbar button window, move focus for drop-down menus | Arrow keys |
| Choose a new menu item from drop-down menus | Enter |
| Move focus between people or groups in a user selection box | Up/Down |
| Delete or remove additions in a selected toolbar window | Delete |

Custom views toolbar window

| What to do | Keystrokes |
|--------------------------------------|--------------------------------------|
| Rename custom view | Ctrl+R |
| Set default custom view | Ctrl+D |
| Make visible to others toggle on/off | Ctrl+P |
| Delete selected custom view | Windows: Delete Mac OS: Fn+Delete |

Comments pane

| What to do | Keystrokes |
|------------------------------------|-----------------------------------|
| Apply comment snapshot to the view | Enter or Spacebar |
| Delete comment | Delete or Backspace |

Sheet tabs

| What to do | Keystrokes |
|-----------------------------|------------|
| Move focus to previous | Left/Up |
| Move focus to next | Right/Down |
| Navigate to the focused tab | Enter |

Legends

| What to do | Keystrokes |
|---|------------|
| Move focus to previous | Up |
| Move focus to next | Down |
| (Single column) move focus to previous, (Multi-column) move focus to left | Left |
| (Single column) move focus to next, (Multi-column) move focus to right | Right |
| Move focus to first item | Home |
| Move focus to last item | End |
| Toggle item selection | Spacebar |
| Toggle highlighting on and off | Enter |
| Note: This is the keyboard equivalent of Highlight Selected Items . | |
| Clear all item selections | Esc |

What to do**Keystrokes**

Note: To view legend item text with more contrast, select individual legend items, and then switch highlighting on and off.

Filters**What to do****Keystrokes**

| | |
|---|------------|
| Move focus to previous item | Left/Up |
| Move focus to next item | Right/Down |
| Move focus to first item | Home |
| Move focus to last item | End |
| Toggle selection (tick/clear tick boxes, select/clear radio buttons) | Spacebar |
| Apply changes, if Cancel or Apply buttons are available | Enter |
| Revert changes to default settings | Esc |

Filter controls and search**What to do****Keystrokes**

| | |
|--|------------|
| Move focus from filter item to filter control buttons (search, Single Value (List)/Multiple Values (List), Single Value (Dropdown)/Multiple Values (Dropdown), Include/Exclude Values). Press Spacebar to select a button. | Shift+Tab |
| Move focus in the drop-down menu | Arrow keys |
| Choose a menu item | Enter |
| Press the search button and enter search term | Spacebar |
| Press to clear search input. Press Esc again to dismiss Search. | Esc |

Parameter controls

Single value (list)

| What to do | Keystrokes |
|---|------------|
| Move focus to previous item | Left/Up |
| Move focus to next item | Right/Down |
| Commit selection and update parameter value | Spacebar |

Single value (dropdown)

| What to do | Keystrokes |
|--|------------|
| Dropdown list collapsed: Move focus to previous item and commit to value, | Up |
| Dropdown list open: Move focus to previous item and commit to value; doesn't commit to value | |
| Dropdown list collapsed: Move focus to next item and commit to value, | Down |
| Dropdown list open: Move focus to next item and commit to value; doesn't commit to value | |
| Dropdown list collapsed: Open or close domain list, | Spacebar |
| Dropdown list open: Commit selection of focused item | |
| Dropdown list open: Collapse domain list without making a selection | Esc |

Slider

| What to do | Keystrokes |
|--|------------|
| See previous item in domain and commit | Left/Up |
| See next item in domain and commit | Right/Down |

View Data window

Note: The View Data keyboard shortcuts are available in Tableau Cloud, Tableau Server and Tableau Desktop.

| What to do | Keystrokes |
|---|--|
| Move focus to a visualisation (viz) | Within a dashboard or workbook, press Enter |
| With a viz in focus, open the View Data window | Shift+Enter |
| <p>Note: The screen reader you're using might require some combination of modifier keys (Shift, Ctrl, Alt, Cmd) in conjunction with Enter. See the documentation for your screen reader.</p> | |
| Move focus to any cell within the data grid | Arrow keys |
| Interact with cells in a grid | Use the arrow keys to navigate to the cell. Press Enter to focus on an element within a cell. Then interact with the element using keyboard navigation, such as Enter or Space. To return to navigation mode, press Esc. |
| Move a column | Within the data grid, use the arrow keys to move focus to a cell in the desired column. Press Enter, use the down arrow key to select Move Left or Move Right and then press Enter. |
| Sort by column | Within the data grid, use the arrow keys to move focus to a cell in the desired column. Press Enter, use the down arrow key to select Sort Ascending or Sort Descending and then press Enter. |
| Remove a column | Within the data grid, use the arrow keys to move focus to a cell in the desired column. Press Enter, use the down arrow key to select Remove , and then press Enter. |

| What to do | Keystrokes |
|---|---|
| Move focus to another data table | Press Tab to move the focus to the Summary tab. Use the down arrow key to move the focus to the desired data table within the Tabs pane. |
| Edit number of rows | Press Tab to move the focus to the row count field. Type the desired row number, and then press Enter. |
| Show or hide aliases | Press Tab to move the focus to the Settings button. Press Enter to show aliases, and press Enter again to hide aliases. |
| Add or remove fields | Press Tab to move the focus to the Show Fields button. Press Enter to display a list of fields in the data source. Use the arrow keys to move the focus to each field name. Press Enter to remove any undesired fields from the data grid. To add fields back to the data grid, press Enter on the desired field to reselect it. |
| Download the data as it displays in the View Data window | Press Tab to move the focus to the Download button, and then press Enter. A CSV file containing your customised view of the data downloads in your browser. |
| Close the View Data window | Windows: ALT+F4 Mac OS: Cmd+W |

In the **View Data** window, there are several tab stops that enable you to customise the data that displays.

- **A** - Selected cell within the data grid
- **B** - **Tabs** pane, expand/collapse
- **C** - **Tabs** pane, current selection
- **D** - **Row count** field
- **E** - **Settings** button
- **F** - **Show Fields** button
- **G** - **Download** button

Visualisation headers

What to do

Move focus to a visualisation (viz)

With a viz in focus, move to the left, top, right or bottom headers

Navigate into a header

Keystrokes

Within a dashboard or workbook, press Enter

Arrow keys

Enter

| What to do | Keystrokes |
|---|------------|
| Navigate within a header or nested header | Arrow keys |
| Toggle header highlighting on/off | Spacebar |
| Back out of a header | Esc |

Example: Navigate a View in Tableau Cloud or Tableau Server

This example shows how you can navigate and interact with a view using keyboard navigation.

1. Press Tab to move the focus to the visualisation.

Note: The **Skip to Content** button lets you skip over the navigation panel and toolbar. To go directly to the view page, press Enter to select **Skip to Content**.

Note: In a workbook that has multiple sheet tabs, press Tab to move the focus to the **Tabs** pane, and use the arrow keys to move focus between tabs. Then press Enter or Spacebar to open a specific sheet.

This image shows the visualisation area in a sheet. A blue border indicates the focus.

2. Navigate to filters and legends in the view by pressing Tab.

To change a filter setting, press Tab to move focus to the filter and then press the arrow keys to move between items.

- Press Spacebar to switch item selections.
- For drop-down filters – Press Enter to apply filter changes. Press Esc to revert changes to the default settings.

To highlight legend items, press Tab to move focus to the legend and then press the arrow keys to move between items.

- Press Spacebar to switch item selections.

Note: To view legend item text with more contrast, select individual legend items, and then switch highlighting on and off.

- Press **Enter** to highlight the selected legend items in the view. Press **Enter** again to turn off highlighting.
- Press Esc to clear all item selections.

See the table of keystrokes at the beginning of this article for the list of keystroke options for legends and filters.

3. To access underlying data that can be read by your screen reader, tab the focus to the visualisation area and then press Enter.

Note: Your screen reader may require some combination of modifier keys (Shift, Ctrl, Alt, Cmd) in conjunction with Enter. See the documentation for your screen reader for details.

The **View Data** window opens in a new browser window.

Summary 96 rows 7 fields

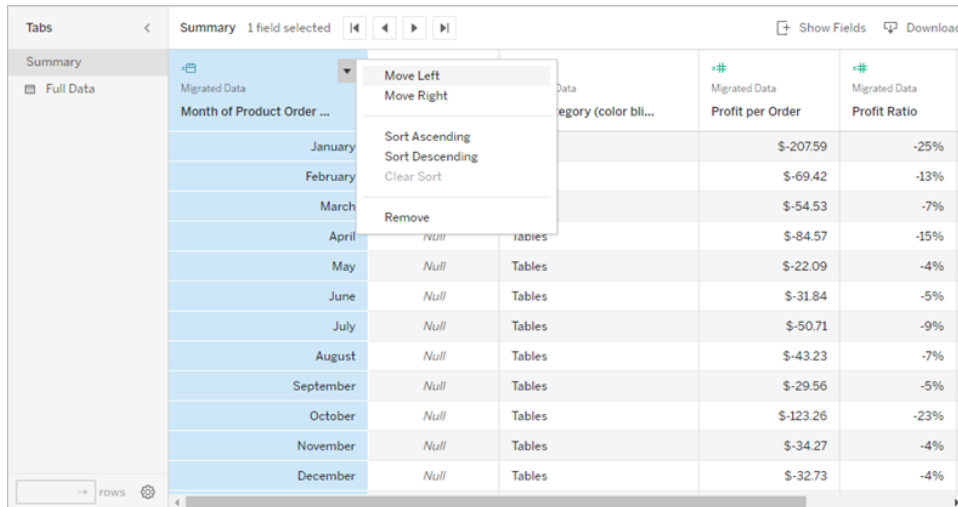

Show Fields Download

| Month of Product Order ... | Sub-Category | Sub-Category (color bli... | Profit per Order | Profit Ratio |
|----------------------------|--------------|----------------------------|------------------|--------------|
| January | Null | Tables | \$-207.59 | -25% |
| February | Null | Tables | \$-69.42 | -13% |
| March | Null | Tables | \$-54.53 | -7% |
| April | Null | Tables | \$-84.57 | -15% |
| May | Null | Tables | \$-22.09 | -4% |
| June | Null | Tables | \$-31.84 | -5% |
| July | Null | Tables | \$-50.71 | -9% |
| August | Null | Tables | \$-43.23 | -7% |
| September | Null | Tables | \$-29.56 | -5% |
| October | Null | Tables | \$-123.26 | -23% |
| November | Null | Tables | \$-34.27 | -4% |
| December | Null | Tables | \$-32.73 | -4% |

rows

In the View Data window, the first cell of the data grid is in focus. Use the arrow keys to move the focus to any cell within the data grid.

With a cell in focus, press Enter to open the context menu to move, sort or remove a column.

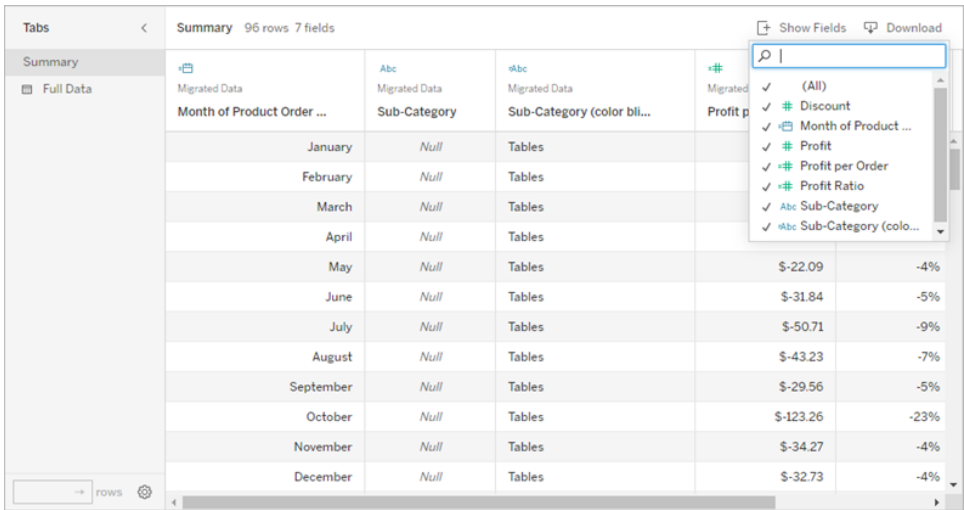

To move the focus to the **Tabs** pane, press Tab. Press Enter to expand or collapse the pane.

To change the data shown within the table, press Tab to move the focus within the **Tabs** pane. Use the arrow keys to move the focus to a specific data table, and press Enter.

Press Tab to move the focus to the **row count** field. To edit the row count, type the desired row number and press Enter.

Press Tab to move the focus to the **Settings** button. Press Enter to **Show Aliases**, and press Enter again to hide aliases.

Press Tab to move the focus to the **Show Fields** button. Press Enter to display a list of fields in the data source. Use the arrow keys to move the focus to each field name. Press Enter to switch the selection of fields in the data grid.

The screenshot shows a Tableau Desktop interface. On the left, there's a 'Tabs' pane with 'Summary' selected. The main view is a table titled 'Summary' with 96 rows and 7 fields. The table has columns for 'Month of Product Order ...', 'Sub-Category', 'Sub-Category (color bli...', and 'Profit p'. The rows list months from January to December. In the top right, there's a toolbar with a 'Download' button. A dropdown menu is open next to the 'Download' button, showing a list of fields to include in the export. The fields listed are: (All), Discount, Month of Product ..., Profit, Profit per Order, Profit Ratio, Sub-Category, and Sub-Category (colo....

| Month of Product Order ... | Sub-Category | Sub-Category (color bli... | Profit p |
|----------------------------|--------------|----------------------------|----------------|
| January | Null | Tables | |
| February | Null | Tables | |
| March | Null | Tables | |
| April | Null | Tables | |
| May | Null | Tables | \$-22.09 -4% |
| June | Null | Tables | \$-31.84 -5% |
| July | Null | Tables | \$-50.71 -9% |
| August | Null | Tables | \$-43.23 -7% |
| September | Null | Tables | \$-29.56 -5% |
| October | Null | Tables | \$-123.26 -23% |
| November | Null | Tables | \$-34.27 -4% |
| December | Null | Tables | \$-32.73 -4% |

Press Tab to move the focus to the **Download** button. Press Enter. A CSV file containing your customised data is downloaded in your browser.

Note: The web browser you're using might require a different key combination to open downloaded files. See the documentation for your web browser.

Press ALT+F4 (Windows) or Cmd+W (Mac OS) to close the **View Data** window.

4. To access buttons in the toolbar, tab the focus to the toolbar area and then use the right arrow to move to the next toolbar button.

Press **Enter** to activate the Comments button on the toolbar.

Type your comment in the **Add a comment** field. To add a snapshot to your comment, press Tab to move the focus to the snapshot button. Press Enter to add a snapshot. Press Tab to move the focus to the **Post** button. Press Enter to add the comment.

Press Tab to move through options in the button's window, including exiting the window.

Manage Content

Use the following keyboard interactions to manage content on Tableau Server or Tableau Cloud.

Organise Your Favourites or Collections

On your Favourites page or collections that you own, you can move items when content is displayed in grid view. The order you arrange items in appears as the custom order under the Sort By menu. For more information, see [Mark Favourites](#) on page 3290.

| What to do | Keystrokes |
|-----------------|---------------------------------------|
| Pick up item | Windows: Alt+Up Mac OS: Option+UP |
| Move item left | Left |
| Move item right | Right |
| Undo move | Esc or Tab |
| Drop item | Windows: Alt+Down Mac OS: Option+Down |

Interact with Tableau Pulse

Edit Tableau Pulse definitions

Navigate Visualisations with Assistive Technology

Starting in Tableau version 24.3, you can navigate Marks on all online visualisation types on Tableau Cloud using a keyboard and other assistive technologies.

Note: Viz navigation isn't currently supported for server-rendered visualisations. To learn more about server and client-side rendering, see [Configure Client-Side Rendering](#).

Navigate marks in a visualisation

1. To activate the experience, navigate to a visualisation and press **Enter**.
2. Select **Enter** again to navigate the Marks.
3. Use the **Arrow** keys to navigate between headers, columns and rows.

If your visualisation has a dual axis, or if it's a scatter plot or map, an additional navigation affordance appears. Use the Arrow keys to move the focus to a group of marks and select Enter to navigate the marks in the group.

4. To navigate out of the text table, press **Esc**.

Note: Prior to entering mark-level navigation, you can use the Arrow keys to navigate different areas of the view, such as the header and axis.

Navigate marks in the View Data pane

1. To open the View Data pane, move your focus to the viz and press **Shift + Enter**.
2. Use the **Arrow** keys to navigate between headers, columns and rows.
3. To close the View Data pane, press **ALT + F4** (Windows) or **Cmd + W** (Mac OS).

To learn more about keyboard navigation on Tableau, see [Keyboard Accessibility for Tableau Views](#).

Explore and Manage Web Content

What Can I Do with a Tableau Web View?

You've seen hundreds of presentations, emails, and documents with data charts. Those things are static and unhelpful. Firstly, the data is frozen in time. Secondly, if you have any questions about the charts, you have to ask whoever created them. . . if you can find them.

Tableau is different. When someone sends you a link to a web view, you're often seeing the freshest data available, and more importantly, you can *interact* with it. Want to dig deeper and answer questions the minute they occur to you? Simply click the view right in your web browser; it's that simple.

What can you do with a Tableau web view? A lot!

Note: We're covering the most popular ways you can interact with views. Sometimes, view creators enable only a subset of these features.

Will I hurt the data?

Not at all. When you interact with a view, you're simply changing how it *looks* for a moment. The next time you or your colleagues open the view, it will look exactly as it originally appeared. The underlying data always remains safe and sound, so feel free to explore!

Filter and sort data

Want to trim or rearrange the visible data so you can focus on stuff you're interested in? There are a couple of easy options:

Filter data

Most view creators add filters that let you limit visible data to specific date ranges, regions, and categories. When you see these, feel free to click or drag them as needed.

[Click the image above to replay the animation.](#)

Sort data

If you're looking at a table of data and want to sort it alphabetically or numerically, just hover over a column header and click the sort icon.

[Click the image above to replay the animation.](#)

See details about specific data points

As you move the mouse across a view, you'll often see tooltips that reveal details about each data point, or *mark*. Marks can take many forms; here's how they look in maps, bar charts, and tables:

Click the image above to replay the animation.

| May | Jun | Jul |
|----------|-----------------------|----------|
| \$6,913 | \$13,206 | \$10,821 |
| \$9,375 | \$7,714 | \$13,674 |
| \$15,120 | | \$13,069 |
| \$16,958 | Furniture | \$11,813 |
| \$7,136 | May 2015 | \$15,121 |
| \$9,114 | Sales: \$9,375 | \$4,720 |
| \$13,035 | Profit: \$901 | \$12,924 |
| \$13,737 | | \$10,241 |

View underlying data

If you're the inquisitive type, you might want to see summarised source data to get a better sense of the numbers behind the visuals. If the view creator has given you permission, you can click any mark in the view, and then click the **View Data** icon.

| | | | |
|-------|---------|----|----|
| \$18 | 13.7% | 6 | 4 |
| \$219 | 43.1% | 24 | 20 |
| \$9 | 48.0% | 3 | 4 |
| \$20 | 6.3% | 6 | 5 |
| \$23 | 7.5% | 6 | 4 |
| \$177 | 29.2% | 18 | 12 |
| \$123 | 15.6% | 18 | 15 |
| \$80 | 48.0% | 3 | 5 |
| (\$6) | -265.0% | 1 | 2 |
| (\$1) | -1.3% | 6 | 5 |
| \$6 | 48.0% | 3 | 3 |

[Click the image above to replay the animation.](#)

Collaborate on data

Data becomes more meaningful when you explore it with other people.

Add comments

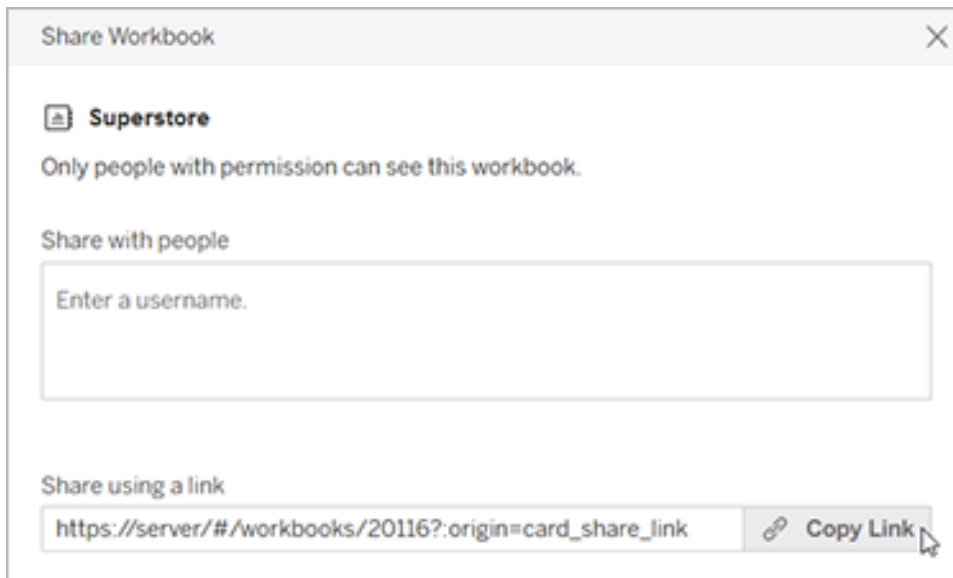

To quickly ask questions or share insights, click on the comments icon in the toolbar. You can pair your remarks with a snapshot of the view that reflects any filters or other changes you made.

Share links

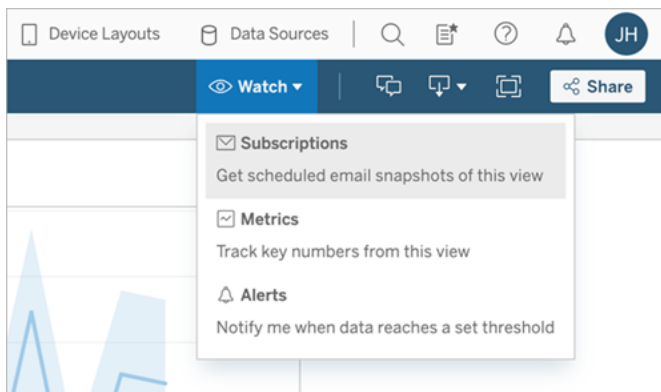

Want to share the excitement of directly engaging with data? Click **Share** in the toolbar, copy the link to the view, and then email or instant-message it to anyone with a Tableau account at your organisation.

Get views emailed to you on a schedule

To automatically receive emails of a view on a regular schedule (before weekly meetings, for example), click **Watch > Subscriptions** in the toolbar.

Note: You might also receive emails to views that other people have arranged for you, including data-driven alerts that notify users when data crosses key thresholds for your business.

Download a view

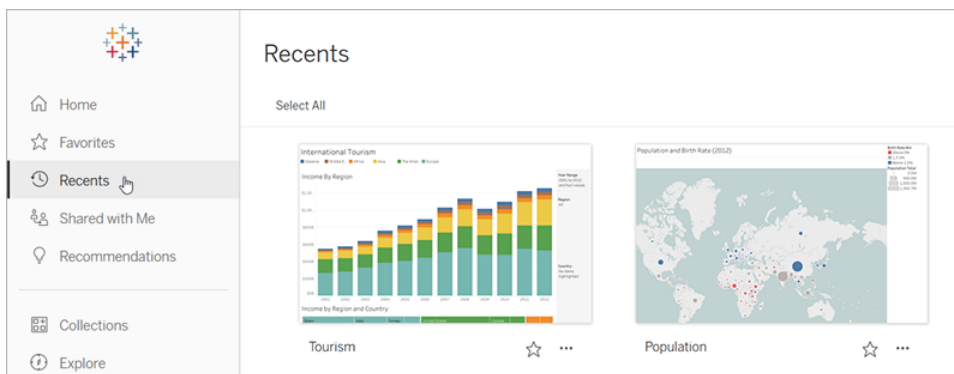

You've seen the power of interactive Tableau web views. But there are times when you may want to display that data outside the browser. If the view creator has given you permission, click

on the download icon in the toolbar to create a static .png, .pdf or .pptx file that reflects the view as it looks right now.

Find a recently accessed view

If you come across an interesting view but later forget where you found it, don't worry. Tableau keeps track for you. You can find your 12 most recently accessed views on the Recents page, which you can open from the navigation panel.

You can also find a smaller selection of your most recently accessed views on the Home page.

Add a view to favourites

As the Tableau content in your organisation grows, you'll want to easily find data important to you. To add a view to your favourites, click the star icon in the header.

To return to a favourite, open the Favourites page from the navigation panel.

Favourites you choose in Tableau Server or Tableau Cloud also appear in the Tableau Mobile app, and vice versa, giving you instant access to key data wherever you go.

Congratulations, data rockstar!

See how easy that was? Now that you're familiar with web views, start exploring all the Tableau content available at your company. Answer questions. Share insights. You've got this!

[Zoom and Pan Views and Select Marks on page 1982](#)

Use Tags

Tags are keywords that you add to items on Tableau Server and Tableau Cloud to categorise them. Tags help users find and filter Tableau content (workbooks, views, metrics, data sources and flows) and, with Tableau Catalogue, external assets (databases, files and tables). (The legacy Metrics feature was retired in February 2024 for Tableau Cloud and in Tableau Server version 2024.2. For more information, see [Create and Troubleshoot Metrics \(Retired\)](#).)

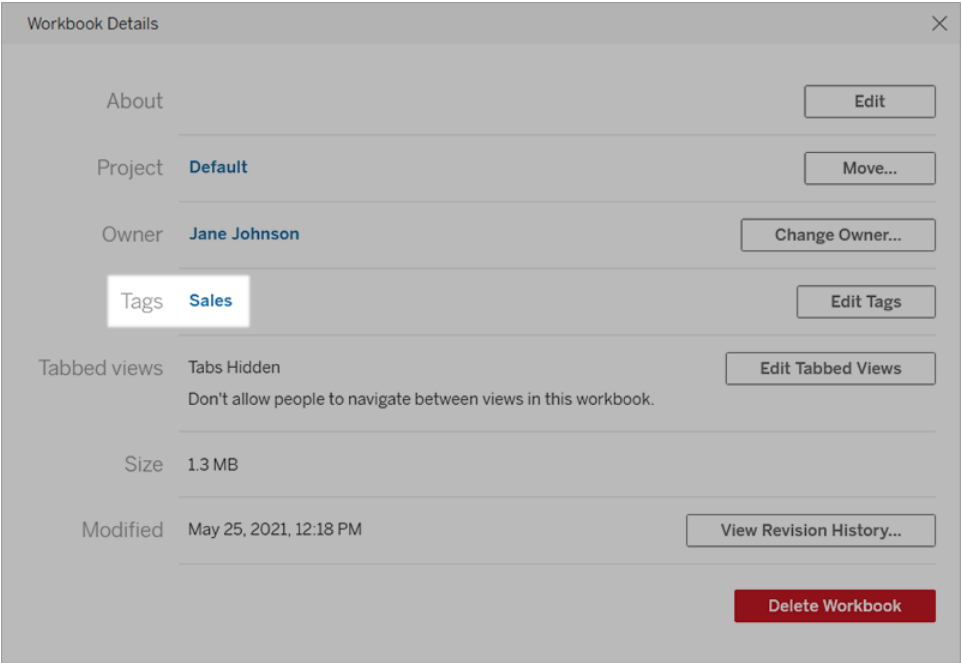

If you have a site role of Explorer or Creator, you can add tags and delete the tags you have added. Authors can also tag content when they publish from Tableau Desktop or Tableau Prep to a Tableau site.

Note: You can't tag projects, data roles or Ask Data lenses.

Tableau Catalog, part of Data Management for Tableau Server and Tableau Cloud, is required to be able to tag external assets (databases, files, tables and columns). For more information about Tableau Catalog, see "About Tableau Catalog" in the [Tableau Server](#) or [Tableau Cloud](#) Help.

See tags for an item

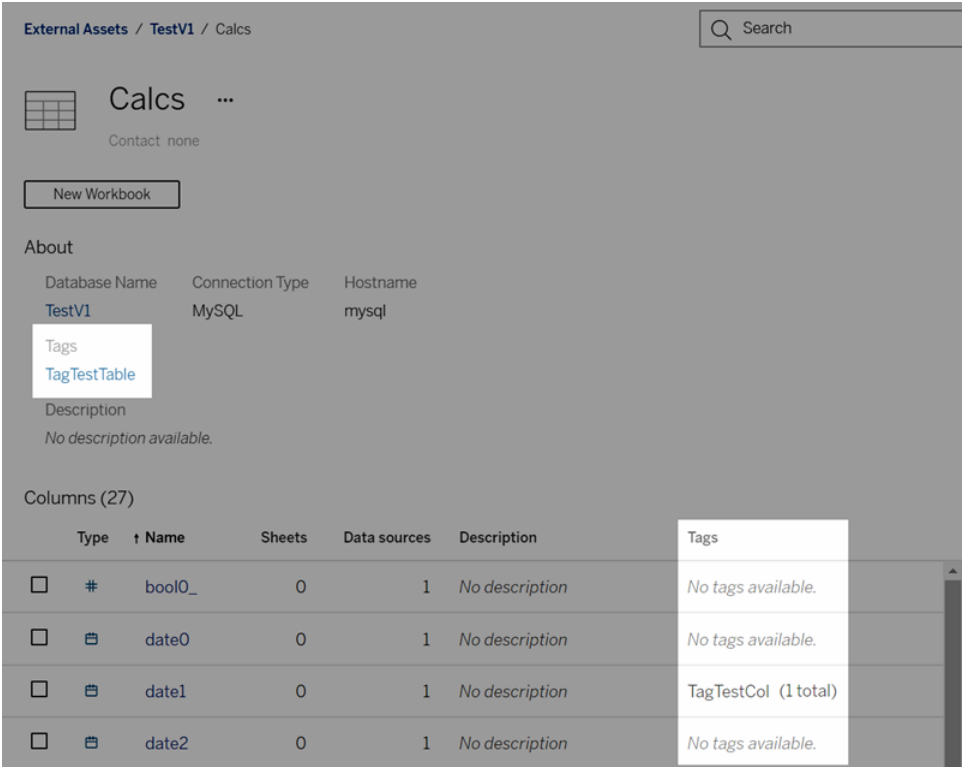

Tags appear in the details for workbooks, metrics and data sources. Click on a tag to see a list of all items of that type with that tag.

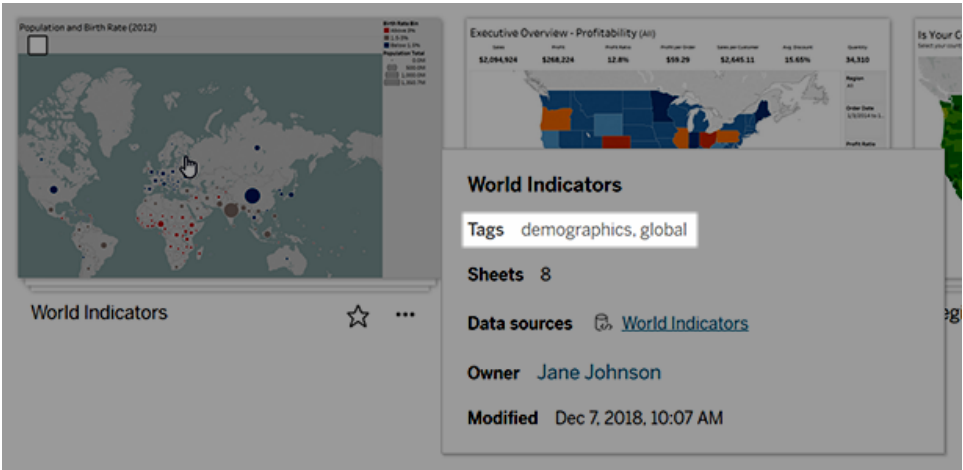

For flows, tags appear at the bottom of the Overview page.

When Tableau Catalogue is enabled, tags for external assets appear in the About section. Tables also include a Tags column that lists the tags for each column in the table.

When you browse content in grid view, tags appear in the tooltips shown when you hover over thumbnails. If an item has no tags, the tags section doesn't appear. There is no grid view for external assets.

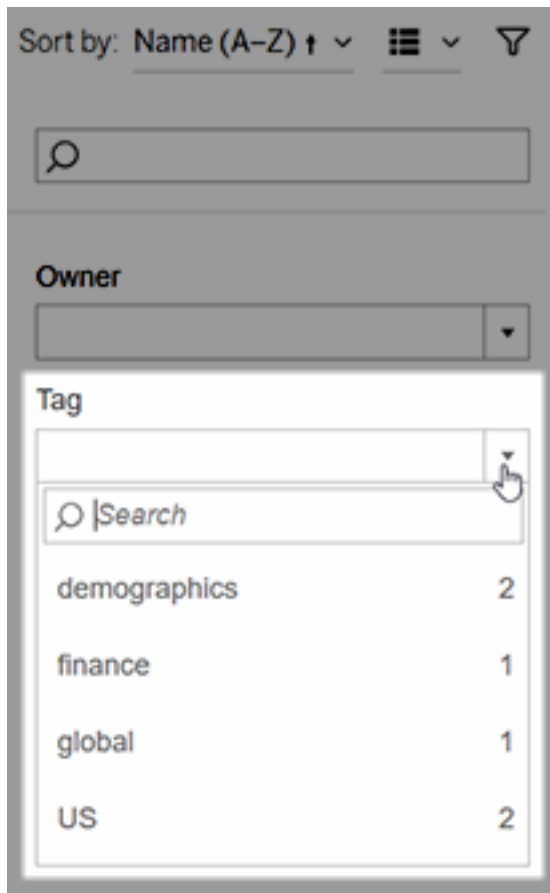

Find tagged content

Use tags to find content with quick search.

Or use filters to search the list of tags.

Note: The tag filter doesn't appear if you are looking at multiple types of content in a project. To access the tag filter from within a project, first use the content type selector to display a single type of content that can be tagged, such as workbooks.

When to use and when not to use tags

The purpose of tags is to help users filter content in order to find relevant items. Because any user can add tags, they aren't recommended for scenarios when you need tight control over the categorisation of content. For example, don't use the existence of a tag to make decisions around whether to grant access to sensitive content.

Examples of when to use tags:

- Add the tag "Sales" to content located across different projects that is relevant to salespeople, so they can easily find it.

- Add a tag to content created during a particular initiative, so it can be viewed together, regardless of which projects it lives in.

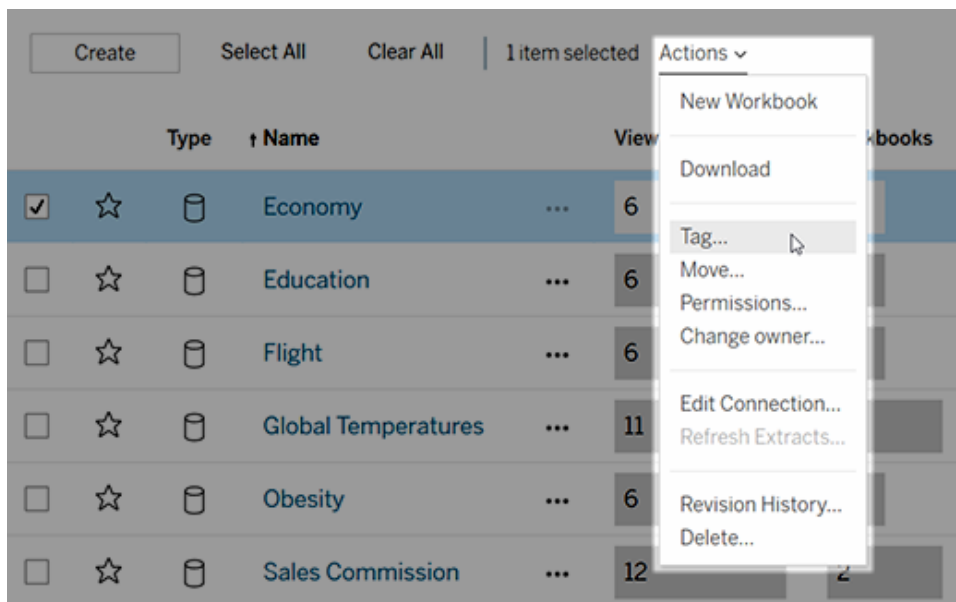

Examples of when not to use tags:

- Don't add tags with the intention of using them to decide how to set permissions for content. Anyone can add these tags to content.
- Don't add a tag about whether data is approved to share with a certain people. Another user can add this tag without approval.

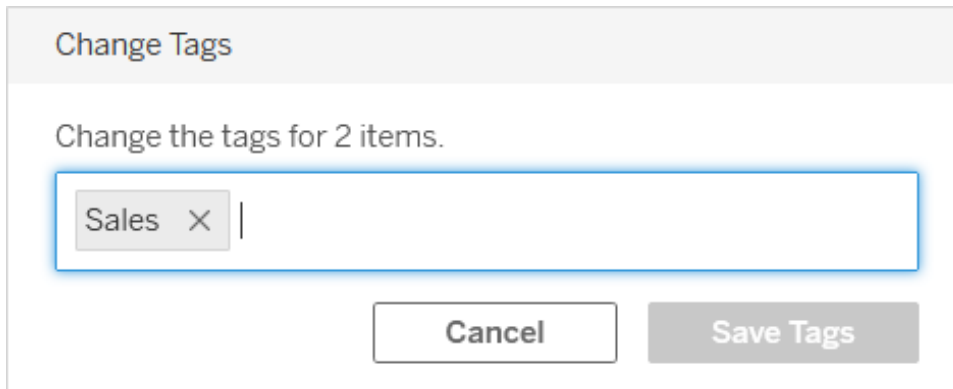

Add tags

If you have a site role of Explorer or Creator, you can add tags to any items that you have permission to access. You don't need to be the owner of an item to tag it. (To add a tag to a column, see [Use Tags on page 3278](#).)

1. Navigate to a list of items.
2. Select one or more items you want to tag, and then select **Actions > Tag**.

3. Enter one or more tags in the text box, and then click **Save Tags**.

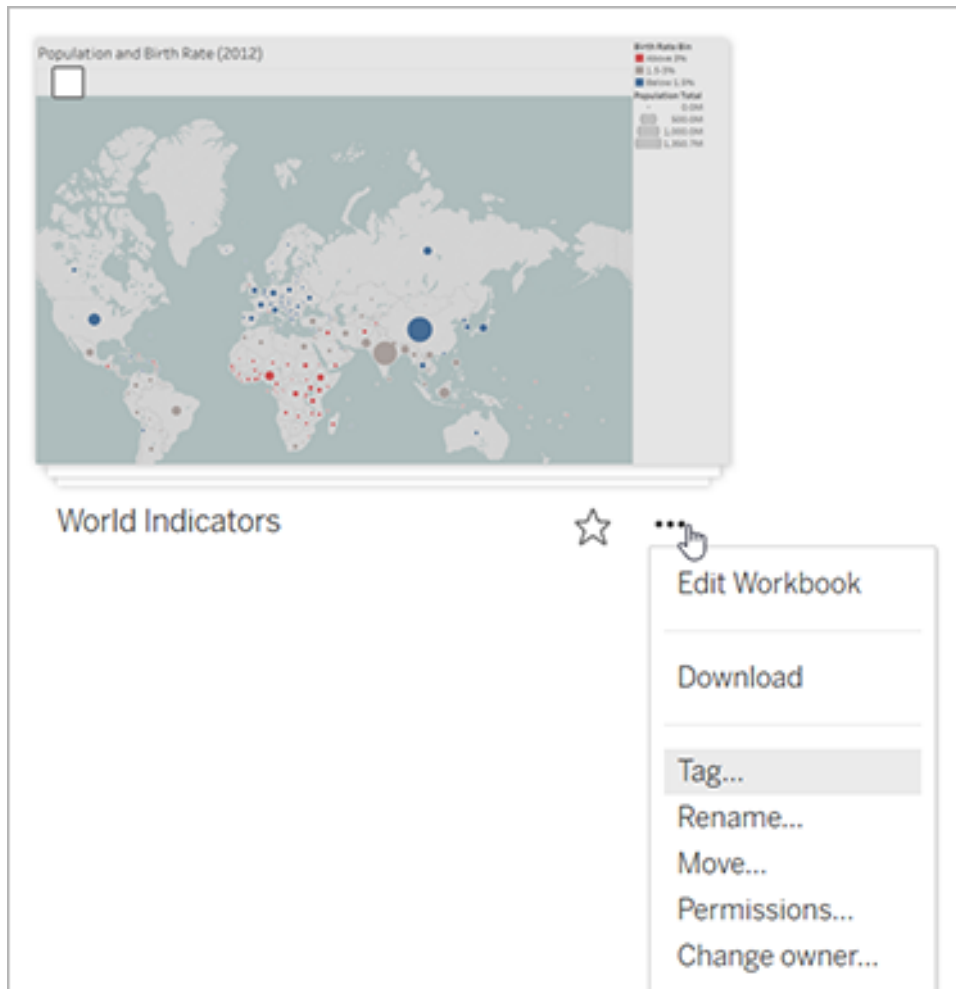

The image shows a 'Change Tags' dialog box. At the top, the title 'Change Tags' is displayed in a light gray header. Below the header, the text 'Change the tags for 2 items.' is shown. A text input field is highlighted with a blue border; it contains the tag 'Sales' followed by a small 'X' icon and a vertical cursor. At the bottom of the dialog, there are two buttons: 'Cancel' and 'Save Tags'.

Delete tags

You can delete tags that you have added.

1. Click the Actions menu (...) for an item, then select **Tag**.

2. Click the 'x' next to the tag you want to remove, and then click **Save Tags**.

Other places tag information is surfaced

Tags you add are visible to others via auto-complete when users add their own tags.

In addition to seeing tag information in the product ([See tags for an item on page 3278](#)), you can also surface tag information using the REST API or Metadata API to query lineage-related tasks. For more information about these APIs, see [Tableau Metadata API](#) and [Tableau REST API - Metadata Methods](#).

Tag item count mismatch

When you search tags, the item count shown for a tag represents the items you have permission to view. Depending on how your site is configured, when you look at lineage data, the item count shown for a tag might be the total number of items regardless of your permission to view those items. However, all sensitive information about items you don't have permission to view will be obfuscated. For information about sensitive lineage data, see "Access lineage information" in the [Tableau Server](#) or [Tableau Cloud](#) Help.

Search Your Tableau Site

Tableau Server and Tableau Cloud offer search capabilities to help you navigate to and discover the content on your site. Search can retrieve all the content that is available on your Site and in your Personal Space, but it will only show the content that you have access to view. Tableau provides two primary search experiences: quick search and full search.

Quick search

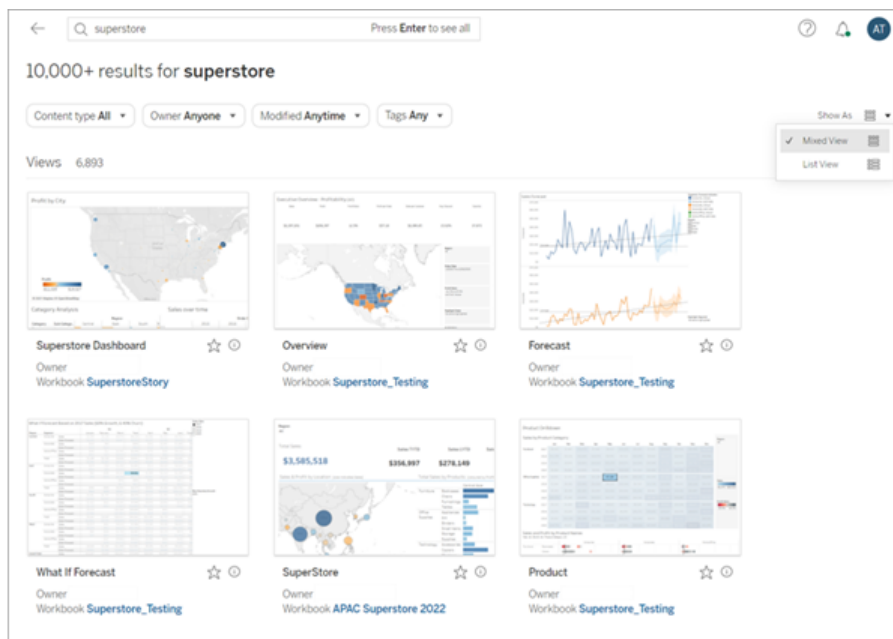

You can access Search by clicking into the search bar in the top right-hand corner of any page on your Tableau Server or Tableau Cloud site. As you type, quick search dynamically renders content suggestions corresponding to the characters you've typed. Quick search matches your query terms to the keywords in content Title or Owner fields, and it ranks results through a combination of quality, popularity and relevance signals, increasing the likelihood that the content you're looking for shows up at the top of the results page. You can click on these results to

navigate directly to the content, or you can press **Enter**, which will land you on the search results page.

When you click into the search bar, you will also see the past queries you have typed, as well as quick link buttons for a subset of content types and content owners, corresponding to the owners of the content that you've recently viewed. When you click a quick link button, you'll navigate to the search results page with the applied scope of the button you just clicked. From there, you can type a search with that applied scope.

Full search

When you navigate from the quick search experience to the search results page, you are in the full search experience. By default, the results are shown in **Mixed View**, which is a combination of grid and list view, depending on the content type.

To change the way the results are displayed, select **Show As > List View**. List View provides more field metadata per result.

You can filter your results by content type such as All, Views, Workbooks and Data Sources. You can further refine your search results with the other filters located above the results. To see more results for a given content type, click **See All** or select a particular content type from the content type menu. When you're in the single content type view, you can also change the **Sort By** options. By default, results are sorted by relevance, which ranks results by various usage, quality and personalisation attributes. Some content types can also be sorted by popularity, which uses the frequency and recency of content item views to order the results. For **Data Sources, Tables and Objects**, and **Databases and Files**, sorting by popularity orders the results by the number of connected workbooks.

Tableau Catalogue users may see search results for non-embedded databases and tables before ingestion to catalogue is finished. When this happens, if you click this entry from the quick search results, a "Showing partial results..." warning message displays. If you review the search results page, the entry is greyed out until ingestion to catalogue is complete.

To find tips on making the most of Tableau search, see [Blog: The Evolution of Tableau Search and Best Practices for](#)

Mark Favourites

To make it easy to find your most-used content, you can mark it as a favourite. You can add any type of content to your favourites, except for embedded data sources.

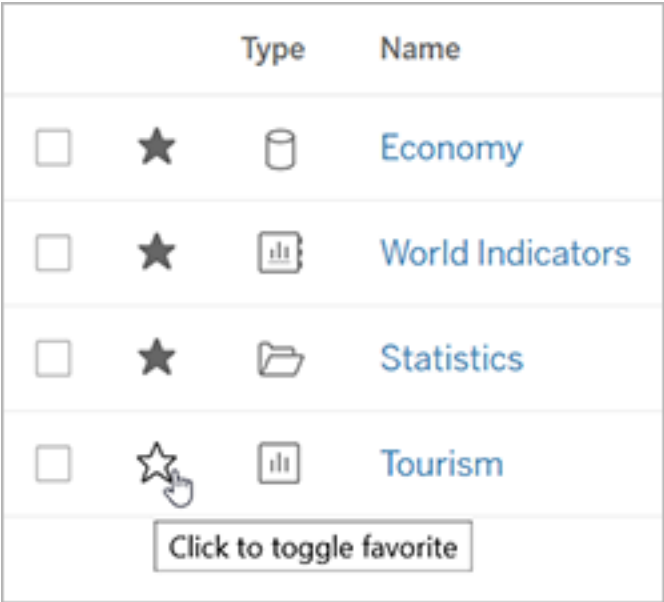

Mark content as a favourite

Click the favourites star near the content name.

In grid view:

Or in list view:

Alternatively, when you have a view open, click the star in the header.

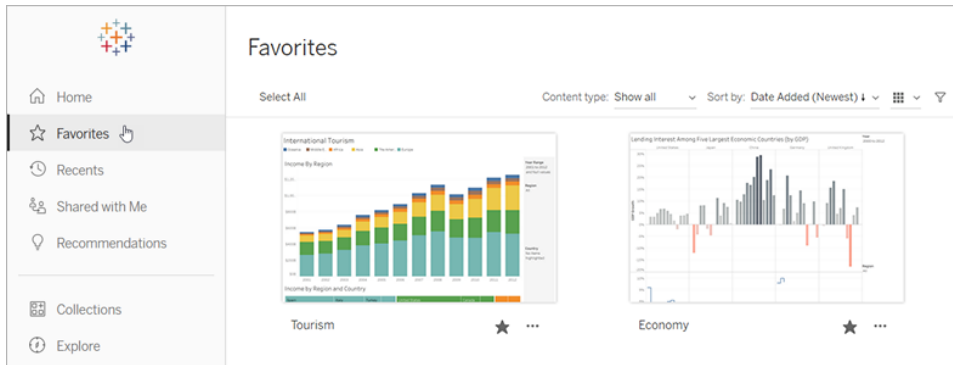

Remove an item from favourites

Click the star that you used to mark the favourite.

Find favourites

To access your Favourites page, from the navigation panel, click **Favourites**.

You can filter the content on your Favourites page to find specific items. Filters are helpful if you accumulate a large number of favourites. For more information, see [Filtered search](#).

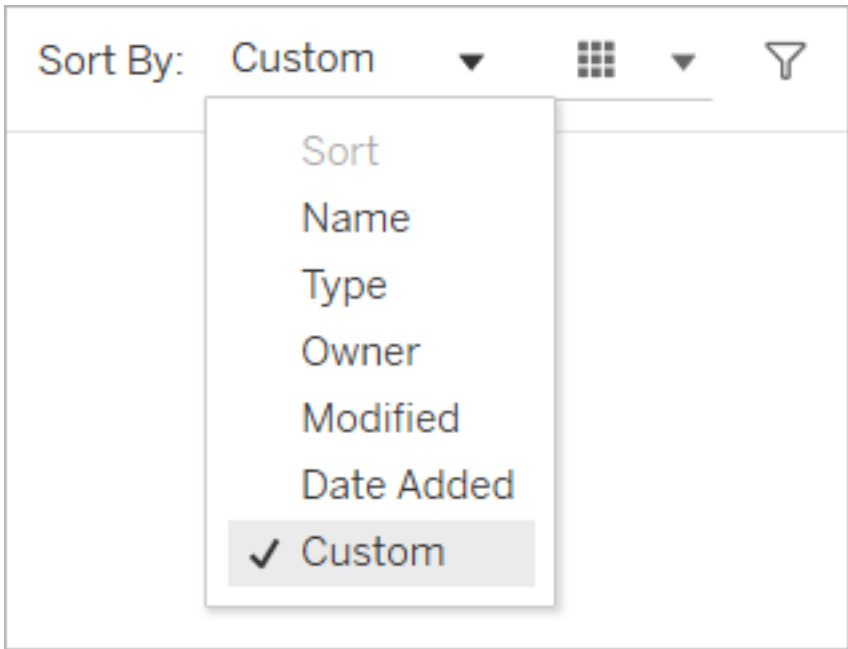

Note: Your recently added favourites also appear on the Home page.

Organise your favourites

In grid view, drag and drop cards to reorder your favourites.

Switch between the custom sorting order you create and other orders like date or name using the **Sort By** menu.

Note: For information about how to organise favourites using a keyboard, see [Keyboard Accessibility for Tableau on the Web](#) on page 3255.

Access favourites from a view

To access your favourites while looking at a view, click the list icon on the right side of the header. Enter keywords into the search box to find specific items.

Organise Items in a Collection

Collections let you gather related items into an easy-to-access list. With a collection, you can organise items in a way that is meaningful to you, without worrying about who owns an item or which project it lives in on your Tableau site.

You can keep a collection private or share it with others. When you give others access to a collection, there's no risk of exposing data because collections don't affect the permissions for the items they contain. In a collection, users see only the items that they have permission to access.

You might want to build a collection to:

- Onboard new employees with data that is appropriate for their roles
- Organise the data that you frequently use for a project in one place
- Promote certified data and approved dashboards in your organisation

Find collections

From the navigation pane, click Collections to see all the collections you have permission to view. The collections that you are the owner of appear under the My Collections tab. Collections aren't included in the Explore section of your site or when you search, but they do appear in Favourites and Shared with Me, if applicable.

When you open a collection, you'll see the items you have permission to view. If there are many items in the collection, filter and sort to find specific items (some filter and sort options are limited in collections). The number of items displayed in a collection may differ from the total number of items listed in the collection details, depending on the permissions for the individual items.

Create a collection

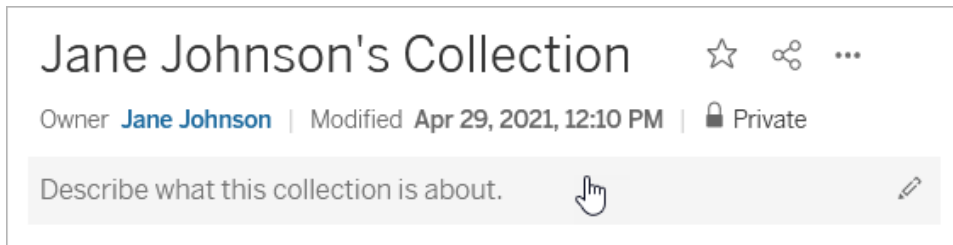

To add items to a collection, you first need to create one. Anyone can create a collection. You don't need a specific role or permission.

1. From the navigation pane, click **Collections**.
2. Click the **New Collection** button.

The collection is created with a default name.

3. To change the name from the default, mouse over the name and click on the highlighted text. Enter a new name, and then click **Save**.
4. To add a description, mouse over the description area and click on the highlighted text.

Enter a description, and then click **Save**.

Jane Johnson's Collection

Owner [Jane Johnson](#) | Modified **Apr 29, 2021, 12:10 PM** | Private

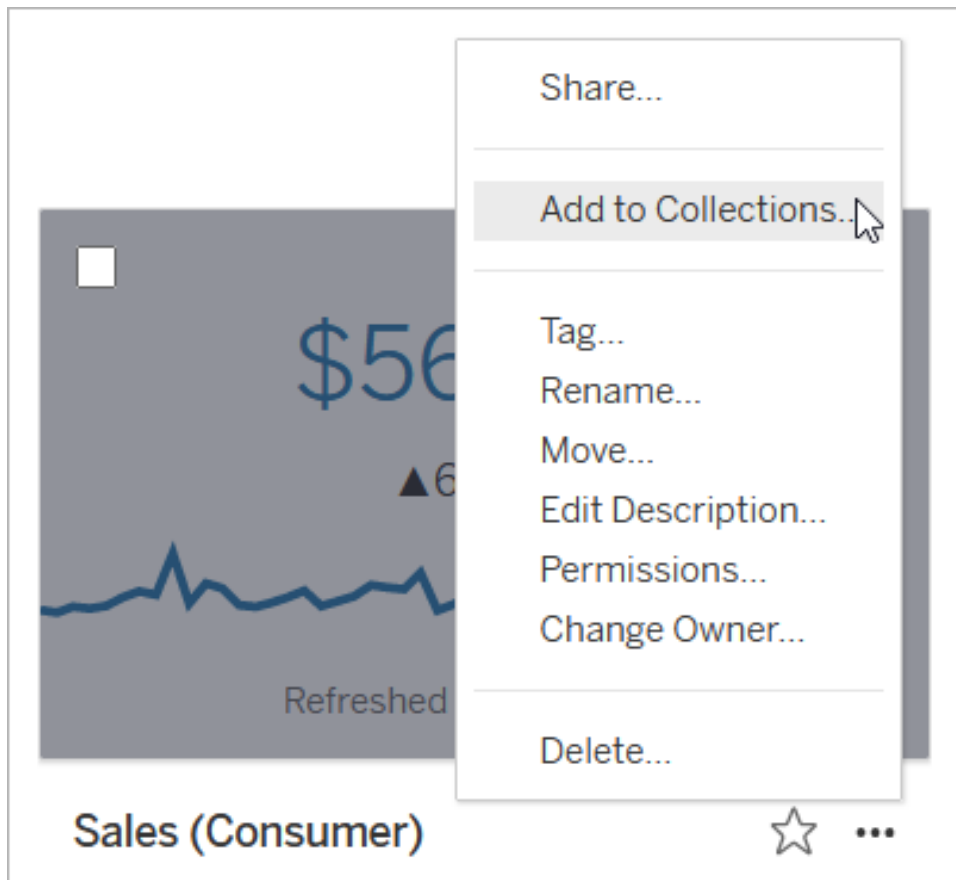

Describe what this collection is about.

You can also create a collection from the Add to Collections dialog, shown below.

Add items to a collection

If you can view an item on your site, you can add it to your collection, with the exception of external assets (databases, files and tables), lenses and other collections. You must own a collection to be able to add items to it. Although the items you collect might belong to different projects, you can add them to a collection without needing to move or copy them.

1. Navigate to the item that you want to add to a collection.
2. Click on the Actions (...) menu, and then click **Add to Collections**.

To add multiple items to a collection, select tick boxes for the items, and then click **Actions > Add to Collections**.

3. On the Add to Collections dialog, select the collection you want to add the item or items to. You can select multiple collections. If a collection name isn't selectable, that means that the collection doesn't have enough space to accommodate the items. A collection can contain a maximum of 1000 items.

(Optional) If you want to make a new collection for these items, create one by clicking the **New Collection** button. Once you create it, the new collection will be pre-selected in the dialog.

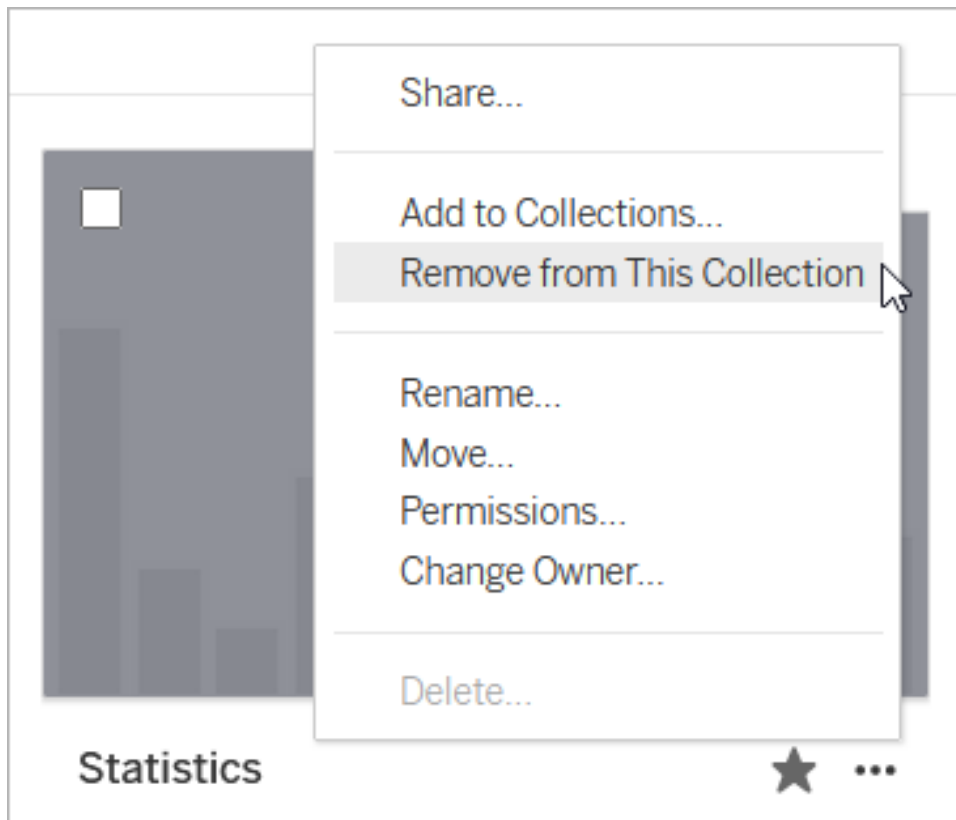

4. Click **Add**.

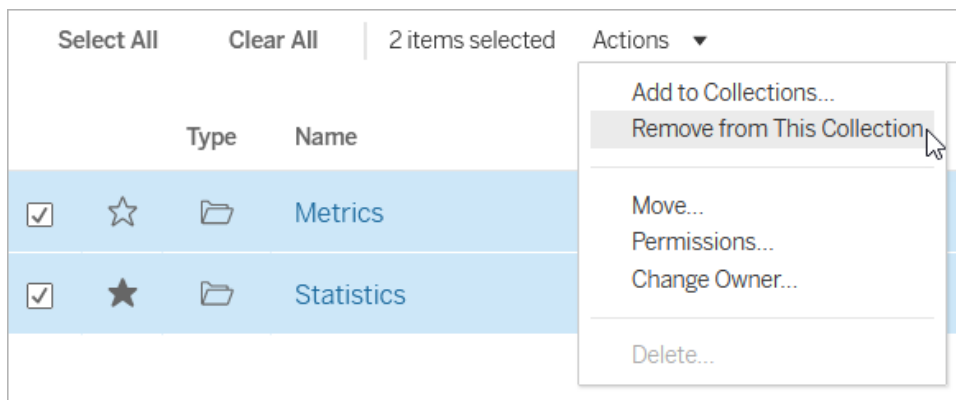

Remove items from a collection

You can remove items from collections that you own.

1. From the navigation pane, click **Collections**.
2. Click on the **My Collections** tab.
3. Open the collection you want to remove items from.
4. To remove a single item, click the Actions (...) menu for that item, and then click **Remove from This Collection**.

To remove multiple items, select tick boxes for the items, and then click **Actions > Remove from This Collection**.

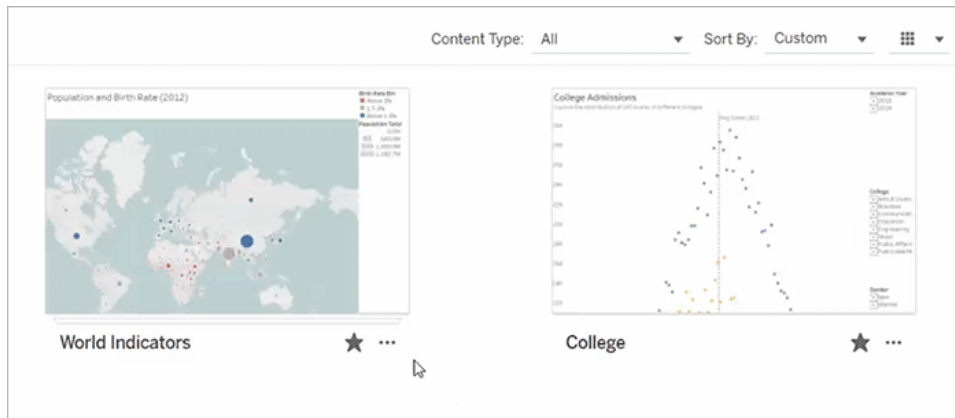

If you accidentally remove an item, don't worry. You can simply navigate back to where it lives and re-add it.

Deleting a collection or removing items from a collection won't delete the actual items because the link between the collection and the items it contains is like a shortcut. This is different to

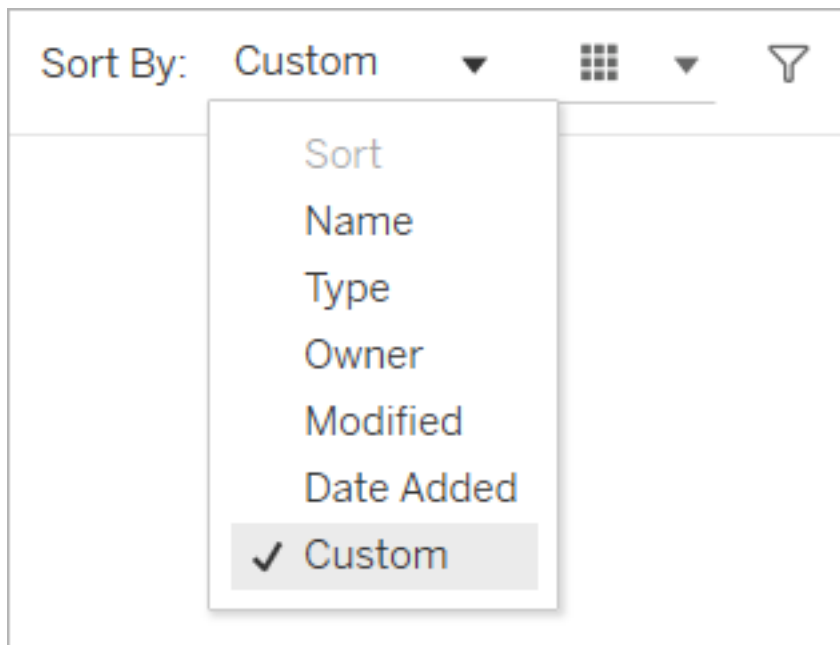

deleting a project or an item in a project, where you are managing the actual items. The Delete action is disabled from within a collection, so there is no risk of accidentally deleting an item while managing items in a collection.

Organise your collection

You can reorder items in collections that you own. In grid view, drag and drop an item to move it.

Switch between the custom sorting order you create and other orders like date or name using the **Sort By** menu. The custom order that you create will appear as the default sort order for others who can view your collection as well.

Manage collection permissions

Collections are private by default. You can give other users access to a collection either by configuring the permissions for the collection directly or by granting access after sharing the collection.

Be aware that permissions for a collection do not affect the items in the collection. This means that some users might see fewer items in your collection than you do because they don't have permission to access all of the items. Contact the content owner or your site administrator for help with permissions for restricted items.

Configure permissions

If you are the owner of a collection, you can configure permissions for the collection. There is only one capability available for collections: View. Giving users the View capability will allow them to see the collection, but they won't be able to add or remove items from the collection. The View capability for a collection doesn't give users access to items in the collection that they don't have permission to. For more information about how permissions work in Tableau, see

[Permissions](#).

1. Click on the Actions menu (...) for the collection, then click **Permissions**.
2. Under Permission Rules, click **Add Group/User Rule**.
3. Enter a user or group name.
4. Under Template, click **View**.
5. Click **Save**.

The collection will now appear on the Collections page for the users you added. These users won't be notified about the change in permissions, so if you want to make them aware of the collection, share it with them.

Grant access by sharing

The option to grant access appears after you share a collection if you are the collection owner.

1. Click on the Share () button for the collection.
2. Enter the name of the user or users you want to share with.
3. Click **Share**.
4. On the Grant Access dialog that appears, click **Grant Access**.

If the people you shared with already have access to the collection, either because you previously configured permissions or because their site role gives them access, you won't see the grant access dialog.

Manage Web Content

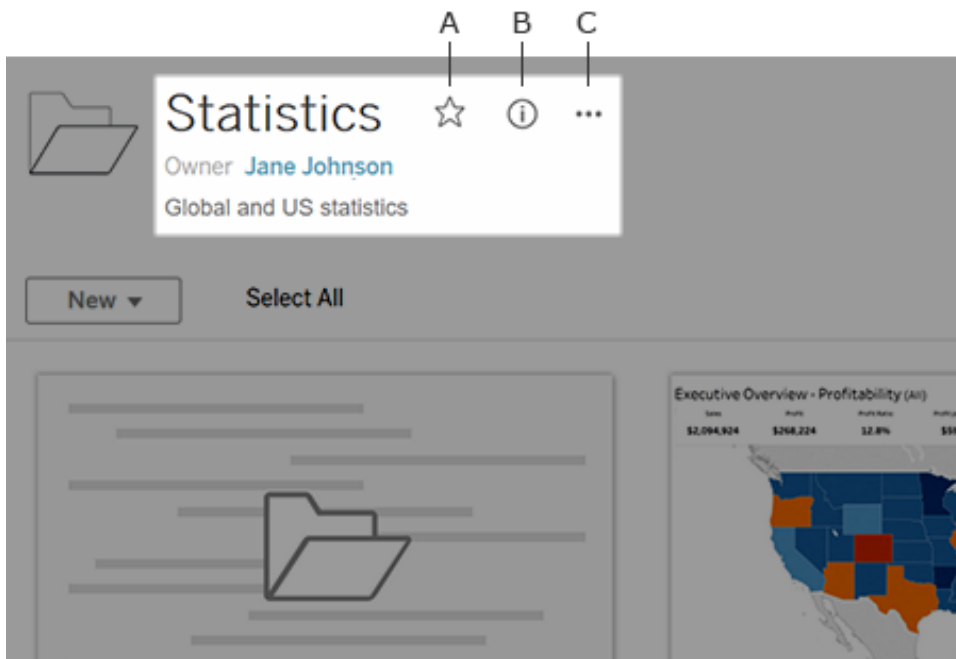

Use the options detailed in this topic to edit item descriptions or perform actions like moving or renaming items on your Tableau site. The options available to you are based on your site role and permissions.

Note: If Tableau Catalogue is enabled on your site, you can add descriptions to fields on a published data source page. You can also access external assets (databases and tables). Some of the options for external assets differ from the options for Tableau content (project, workbooks, views, data sources, data roles and flows).

Tableau Catalog is available in the Data Management for Tableau Server and Tableau Cloud. For more information, see "About Tableau Catalog" in the [Tableau Server](#) or [Tableau Cloud](#) Help.

Access options

The top of the page for each item displays the name of the item and the owner or contact. Some pages might show additional information, such as a description of the item or the date the item was last modified.

You can use the icons next to the item name to:

- **A** - Add the item to your **favourites**.
- **B** - View the item's details.
- **C** - **Perform actions** on the item.

Add or edit descriptions

Descriptions make it easier for everyone in your organisation to find the right items. If you own an item or have the appropriate permissions, you can edit the item's description.

Describe projects, workbooks and data sources

1. From the navigation pane, select **Explore**.
2. Navigate to the project, workbook or data source you want to describe.
3. Click the details icon .
4. To the right of **About**, click **Edit**.
5. Enter a description in the **About** field. You can format the text in a message with bold, underline and italics, and include a link or an image. To see text formatting tips, click **Show formatting hints** under the text box.
6. Click **Save**.

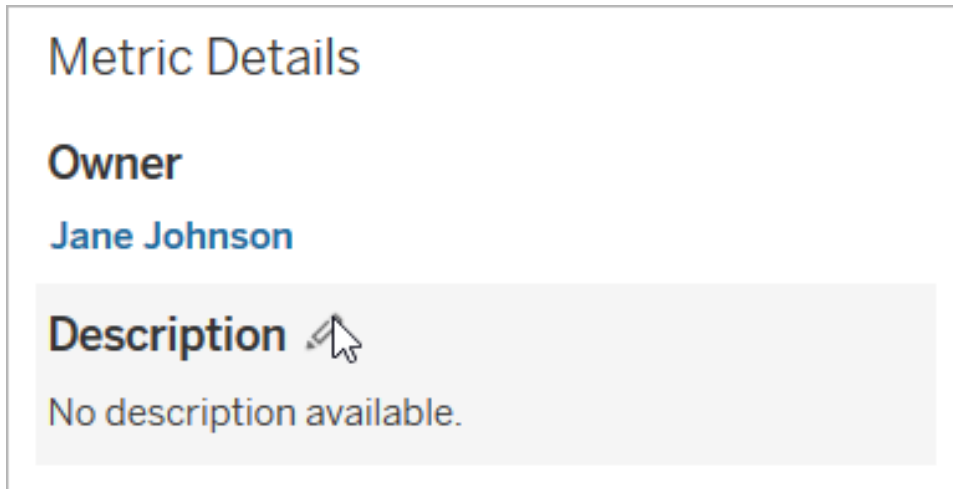

Starting in Tableau Cloud June 2024, if both Tableau Catalog and AI in Tableau are turned on, you can have generative AI draft workbook and data source descriptions for you. For more information, see [Use AI to draft workbook, data source and table descriptions](#).

Describe metrics, data roles, Ask Data lenses and collections

1. From the navigation pane, select **Explore**.
2. Navigate to the content you want to describe.

3. For metrics and data roles, mouse over the **Description** header and click anywhere on the grey background that appears. (The legacy Metrics feature was retired in February 2024 for Tableau Cloud and in Tableau Server version 2024.2. For more information, see [Create and Troubleshoot Metrics \(Retired\)](#).)

For lenses and collections, mouse over the description text and click anywhere on the grey background that appears.

4. Enter a description, then click **Save**.

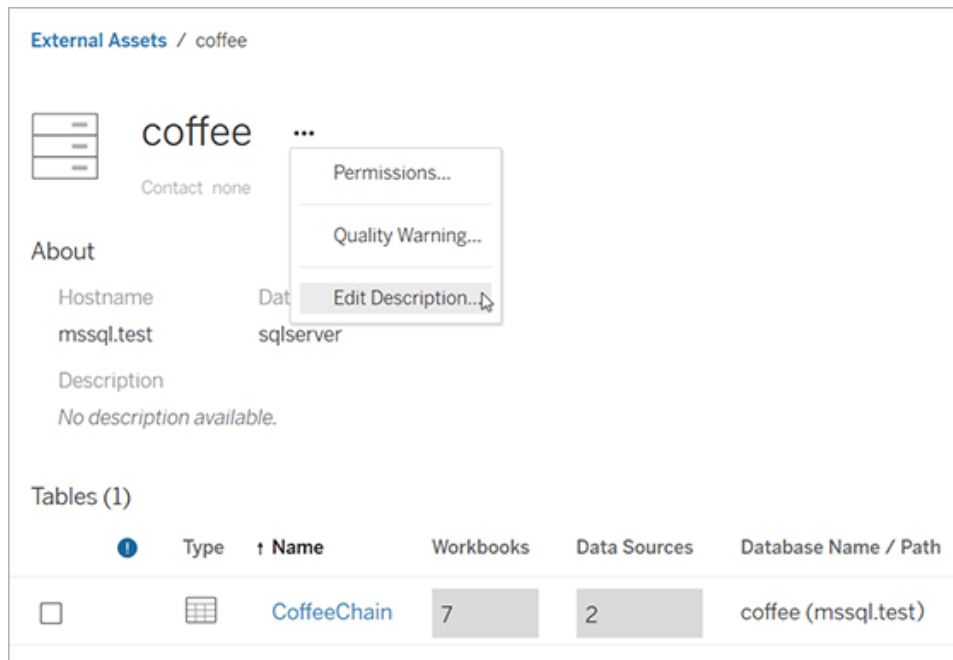

Describe flows

1. From the navigation pane, select **Explore**.
2. Select **All Flows** from the drop-down menu.
3. In the **Name** column, select the flow you want to describe.
4. On the **Overview** tab, click the edit icon next to **Description**.
5. Enter a description. You can format the text in a message with bold, underline and italics, and include a link or an image. To see text formatting tips, click **Show formatting hints** under the text box.
6. Click **Save**.

Describe databases and tables (available if Tableau Catalogue is enabled)

1. From the navigation pane, select **External Assets**.
2. Select **Databases and Files** or **Tables and Objects**.
3. In the **Name** column, select the asset you want to describe.
4. From the Actions (...) drop-down menu to the right of the asset name, select **Edit Description**.

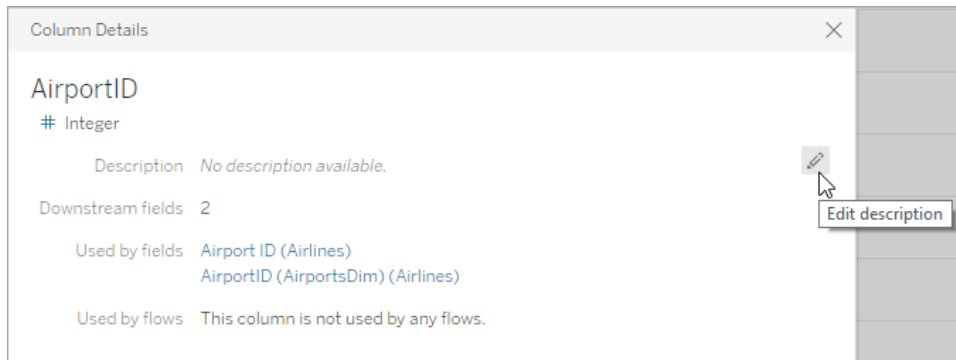

5. In the **Edit Description** dialog box, enter a description. Format the text with bold, underline and italics, and include a link or an image. To see text formatting tips, click **Formatting Guide** under the text box.
6. Click **Save**. There might be a delay before you can see your change.

Starting in Tableau Cloud June 2024, if both Tableau Catalog and AI in Tableau are turned on, you can have generative AI draft table descriptions for you. For more information, see [Use AI to draft workbook, data source and table descriptions](#).

Describe table columns (available if Tableau Catalogue is enabled)

1. From the navigation pane, select **External Assets**.
2. Select **Databases and Files** or **Tables and Objects**.
3. From the list, select the name of the asset with the column you want to describe.
4. On the table page, under **Columns**, select the name of the column.

5. In the **Column Details** dialog box, select the edit icon to the right of **Description**.

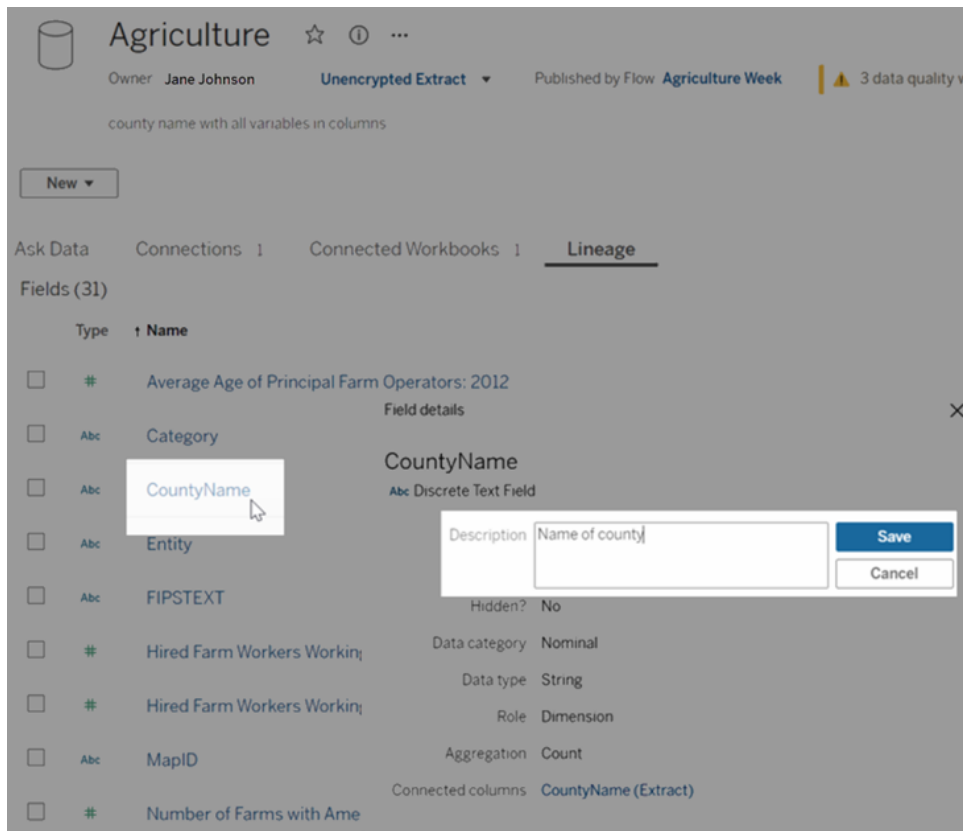

6. Enter a description in the **Description** field. You can format the text in a message with bold, underline and italics, and include a link or an image. To see text formatting tips, click **Formatting Guide** under the text box.
7. Click **Save**.

When you add the description, there might be a delay before you can see your change. After the description has been applied, you can see it in the **Description** column on the table page **Lineage** tab.

Describe fields in a published data source (available if Tableau Catalogue is enabled)

1. From the navigation pane, select **Explore**.
2. Select **All Data Sources** from the drop-down menu.
3. Click on the data source name to open the data source page.
4. On the **Lineage** tab, select the field you want to describe.
5. In the **Field Details** dialog box, select the edit icon to the right of **Description**.
6. Enter a description in the **Description** field. You can format the text in a message with bold, underline and italics, and include a link or an image. To see text formatting tips, click **Formatting Guide** under the text box.
7. Click **Save**.

When you add the description, there might be a delay before you can see your change. After the description has been applied, you can see it in the **Description** column on the data source page **Lineage** tab. When you build a visualisation, you can see the description on the **Data** tab by hovering your mouse over the field name.

How field descriptions are inherited (if Tableau Catalogue is enabled)

When a description exists upstream from a field that has no local description, that field inherits the nearest upstream description. Information about where the description is inherited from also appears.

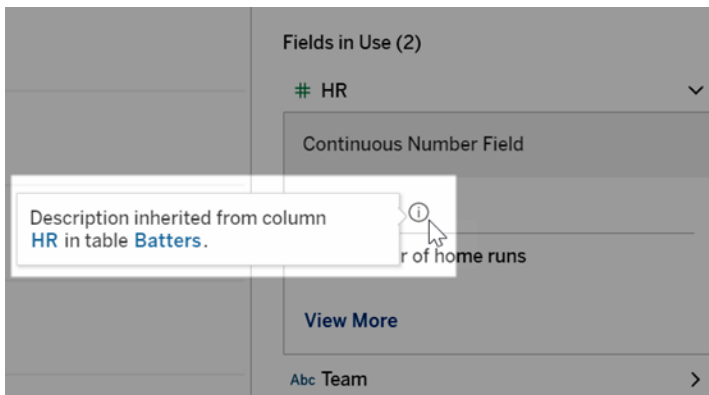

In web authoring on Tableau Server or Tableau Cloud, inherited descriptions always appear. In Tableau Desktop, inherited descriptions appear only when you're connected to Tableau Server or Tableau Cloud.

Note: Inherited descriptions do not appear when using virtual connections in Tableau Desktop or web authoring.

On Tableau Server and Tableau Cloud, inherited descriptions also appear in lineage pages and data details panes.

| Fields (59) | | | |
|--------------------------|------------------------|--------|---------------------------------------|
| Type | Name | Sheets | Description |
| <input type="checkbox"/> | City Name | 0 | The primary city the airport services |
| <input type="checkbox"/> | CityName (AirportsDim) | 0 | The primary city the airport services |

Inherited descriptions have the following caveats. They:

- Don't appear for calculated fields.
- Aren't supported if your data source or workbook has more than 500 fields.
- Aren't supported if your data source or workbook is so large that the inheritance query times out.

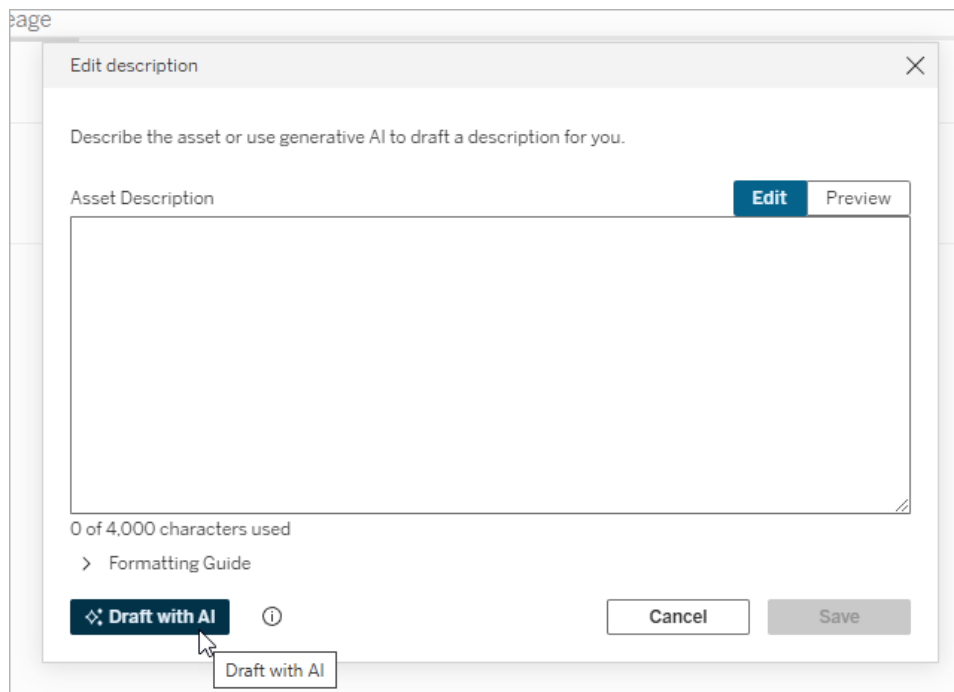

Use AI to draft workbook, data source and table descriptions

Starting in Tableau Cloud June 2024, if both Tableau Catalog and AI in Tableau are turned on, you can have generative AI draft workbook, data source and table descriptions for you. This feature is only available in Tableau Cloud. For information on enabling AI in Tableau, see [Turn On AI in Tableau for Your Site](#) in the Tableau Cloud Product Help.

Note: This feature uses generative AI, which is built on the Einstein Trust Layer. Your data stays safe and secure through data and privacy controls that are seamlessly integrated into the user experience. For more information, see [Einstein Trust Layer](#).

Draft a workbook or data source description using AI

1. Select the Actions (...) menu for the asset, then **Edit Description....**
2. In the **Edit description** dialog, use the **Draft with AI** button to generate a suggestion based on metadata, like field names. Click the **Draft with AI** button more than once to see alternative suggestions.
3. Adjust the draft if needed. You can change the text or format it with bold, underline and italics. You can also include a link or an image. To see text formatting tips, select **Formatting Guide** under the text box.
4. Select **Save**.

Draft a table description using AI

1. From the navigation pane, select **External Assets**.
2. Select **Databases and Files** or **Tables and Objects**.
3. In the **Name** column, select the table you want to describe.
4. From the Actions (...) drop-down menu to the right of the table name, select **Edit Description**.

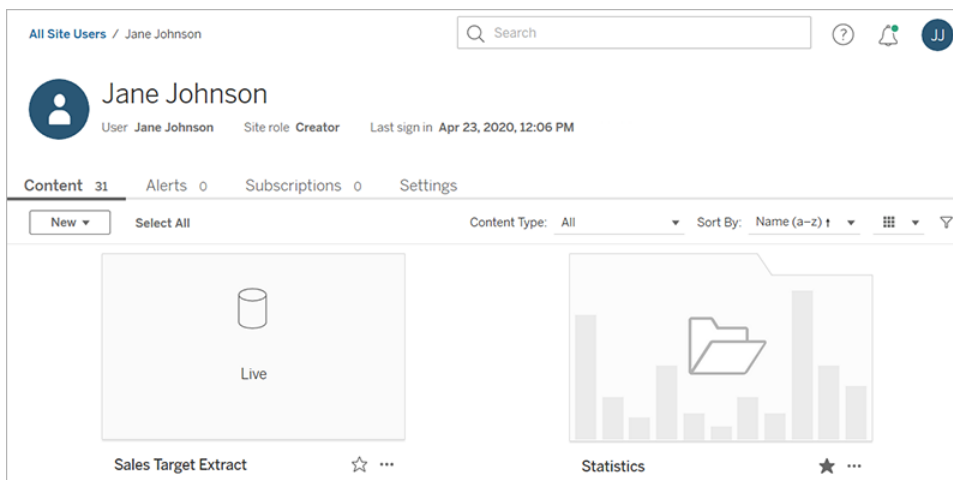

5. Select the **Draft with AI** button to generate a suggestion based on metadata, such as table and column names. Click the **Draft with AI** button more than once to see alternative suggestions.
6. Adjust the draft if needed. Format the text with bold, underline and italics, and include a link or an image. To see text formatting tips, click **Formatting Guide** under the text box.
7. Click **Save**.

Access your content

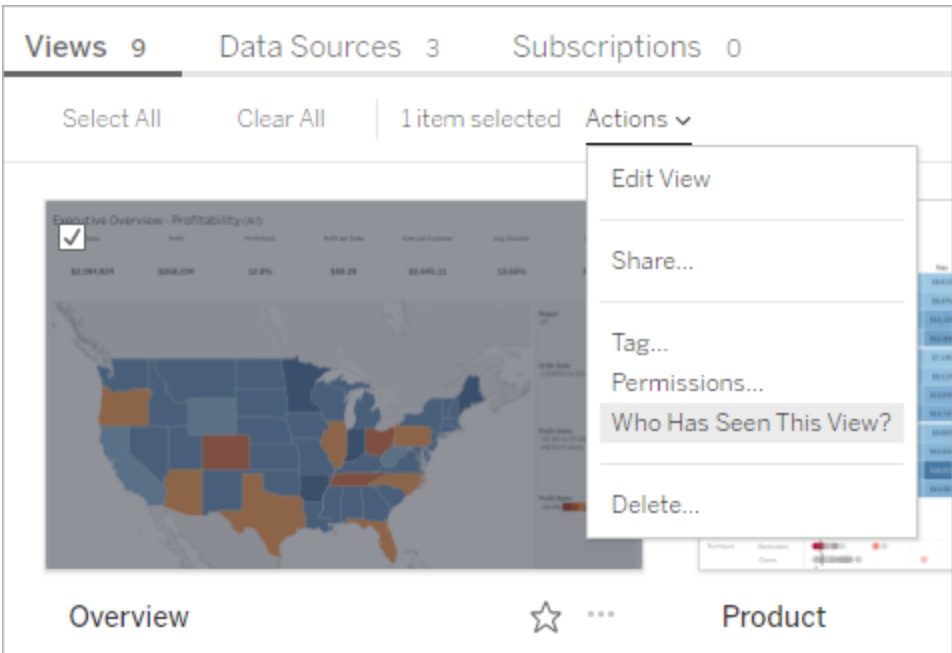

To see the content you own, click your profile image or initials at the top of the page, and then click **My Content**.

Your content page displays your user information and the content that you own. From this page, you can also access your alerts, subscriptions and account settings. To learn more, see [Manage Your Account Settings on page 3333](#).

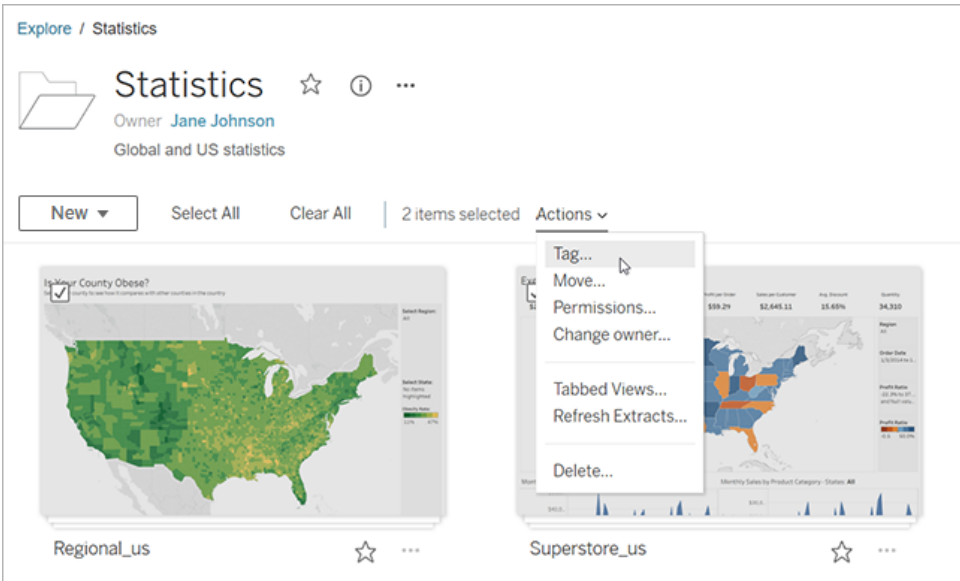

For the views you own, you can see which users have looked at a particular view by selecting **Who Has Seen This View?**.

Perform actions

Tick the boxes to select items, then click the **Actions** drop-down menu to access commands available for those items.

If you don't have permission to perform an action on the item selected, the action will be disabled. If you select multiple items, and you don't have permission to perform an action on one of the items selected, you will get an error when you try to perform the action on that item.

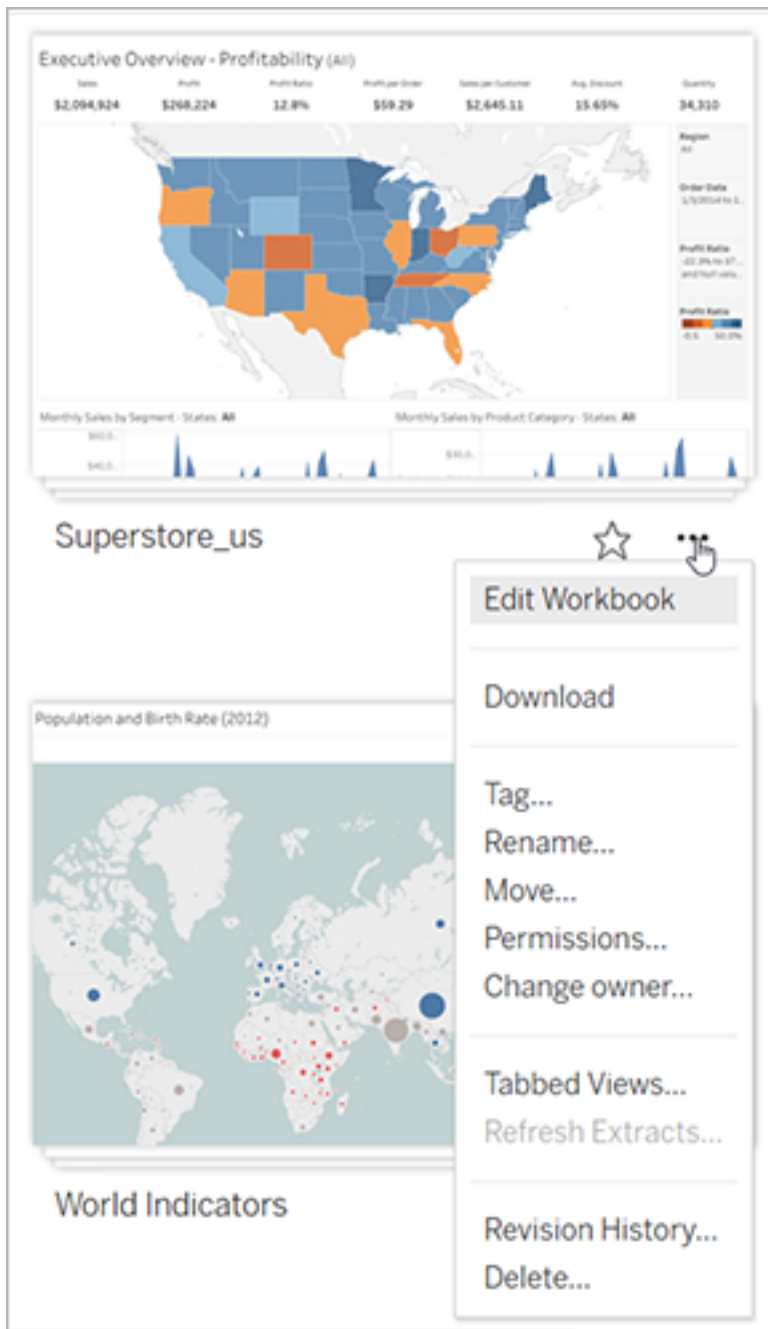

Note: Different types of items have different actions available. If you select more than one type, for example, selecting a workbook and a data source, the actions you see will be limited to those in common between the types.

Access the actions menu for the item you currently have open by clicking the ... at the top of the page. This actions menu is disabled if you have the boxes ticked for other items on the page; instead, use the actions menu shown above to modify ticked items.

In grid view, access the actions menu from the lower-right corner of a thumbnail.

In list view, access the actions menu to the right of the item's name.

Delete content

In order to delete content, you must meet one of the following criteria:

- Have a site role of Explorer (can publish) or Creator AND have the Delete capability for the content
- Be the content owner
- If the item is in a project and not in Personal Space: Be the project owner or project leader where the content is located.

For more information about how permissions and site roles interact, see [Effective Permissions](#).

Tip: Be careful when deleting content from your site. Deleting is a permanent action for all types of content except for views.

To delete content:

1. From the navigation pane, select **Explore**.
2. Navigate to the content you want to delete.
3. From the Actions (...) drop-down menu, select **Delete**.

Some areas of your site, like collections, recommendations and external assets, provide links or references to items. These links or references do not affect the items themselves. You can remove an item from a collection or hide a recommendation without worrying about deleting the original item.

Consequences of deleting content

| Type of content | Consequence |
|--|---|
| Workbooks, metrics, flows and data roles | The content is permanently deleted. You can't undo this action. |
| Views | The view is removed from the site; however, it is still accessible if you edit or download the workbook. The effect is the same as if the view had been hidden upon publishing. For more information, see Show or hide sheets on page 3121 . |
| Projects | <p>The project, and any Tableau content inside the project, is permanently deleted.</p> <p>External assets are moved to the External Assets Default Project. (In Tableau Server 2022.3 and earlier, external assets are irrelevant since they can't be in a folder to begin with.)</p> |
| Collections | The collection is permanently deleted, but the items added to the collection are not deleted. |

Work with Content Revisions

When you publish a workbook or data source, a version is saved in the revision history for Tableau Server and Tableau Cloud. You can revert to a previous version at any time.

Required permissions for revision history

To access revision history, you must have a site role of **Creator** or **Explorer (Can Publish)**, plus the following permissions, depending on the content type:

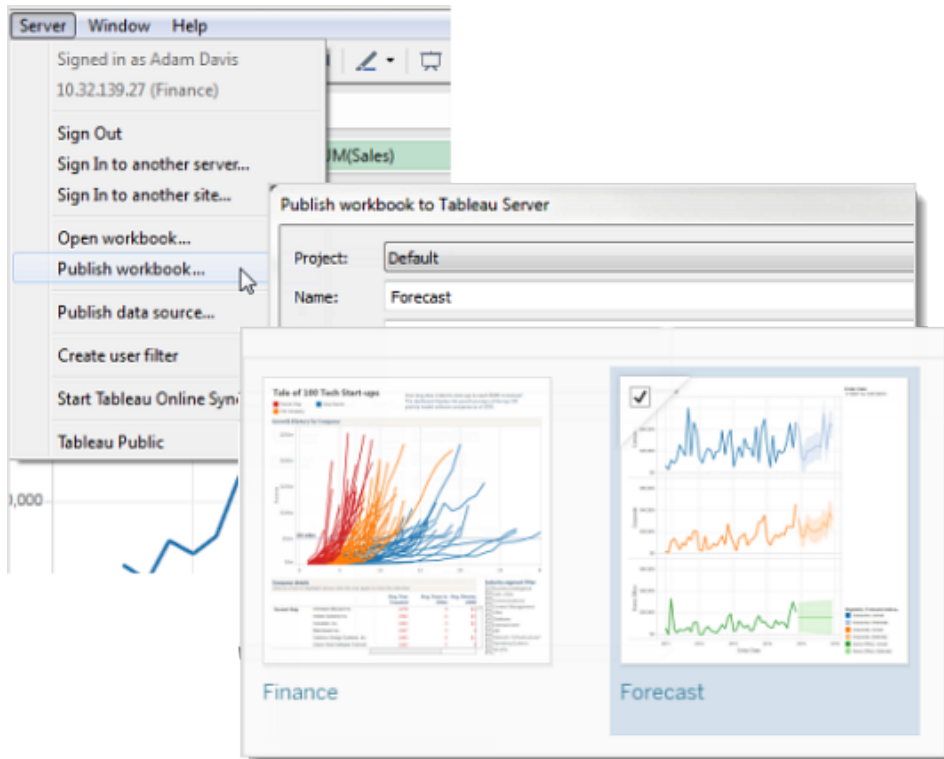

- Project: **View** and **Save**
- Workbooks in the project: **View**, **Save** and **Download Workbook/Save As**
- Data sources in the project: **View**, **Save** and **Download Data Source**

For virtual connections in the project, you must have a **Creator** site role and the **View** and **Overwrite** permissions. See "Use a Virtual Connection" in the [Tableau Cloud](#) or [Tableau Server](#) help for details. (Virtual connections require Data Management. See [About Data Management](#) for details.)

Publish your content

In Tableau Desktop, click **Server > Publish Workbook** or **Server > Publish Data Source**. Make changes to the workbook or data source, and then publish it again to the same project, with the same name. (You'll need to confirm that you want to overwrite the existing content.)

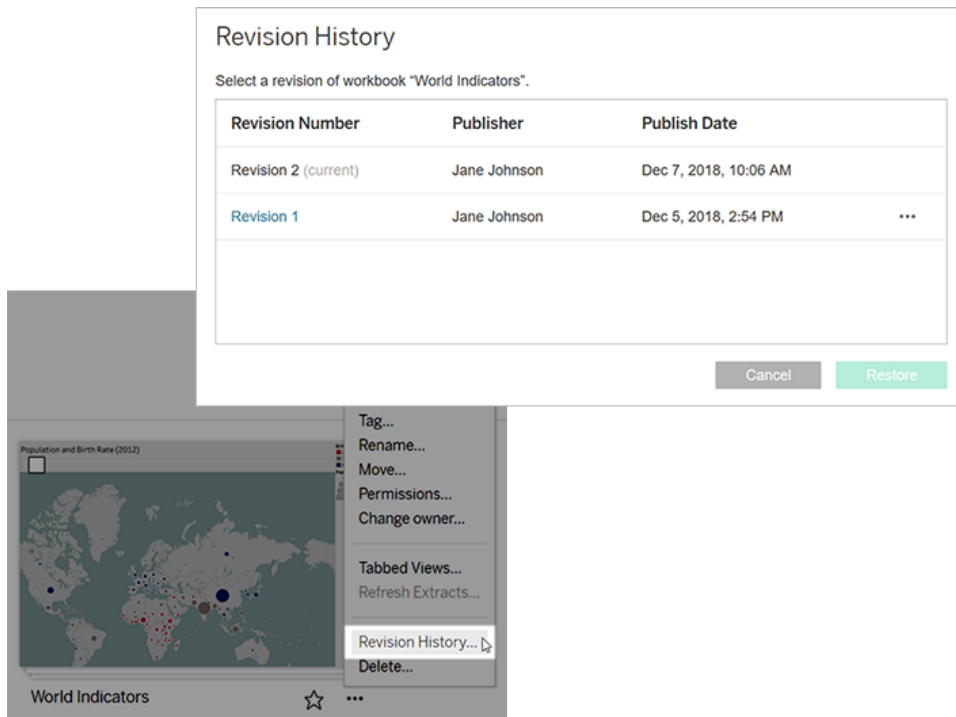

You can also save workbook revisions by editing and saving a workbook in the web-authoring interface of Tableau Server and Tableau Cloud.

View revision history

- Click the actions menu (⋮) for a workbook or data source, then click **Revision History**.

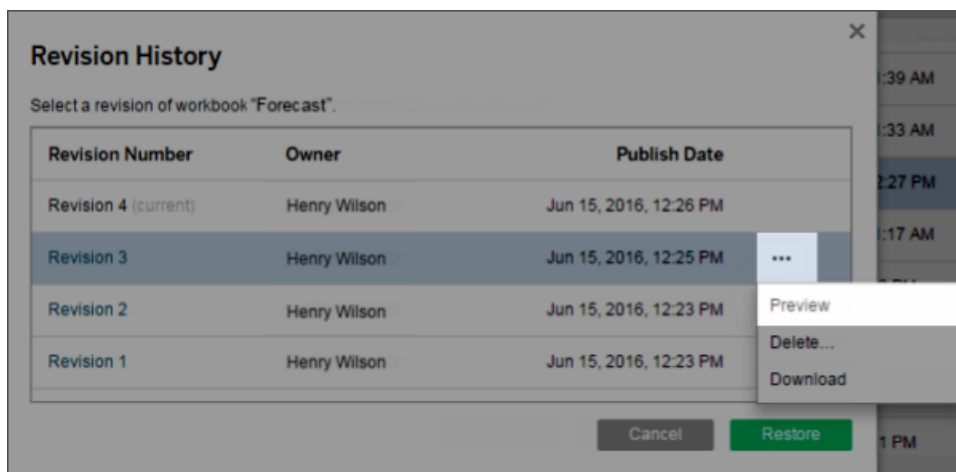

The following image shows a workbook's revision history.

Manage revisions

Preview a workbook revision

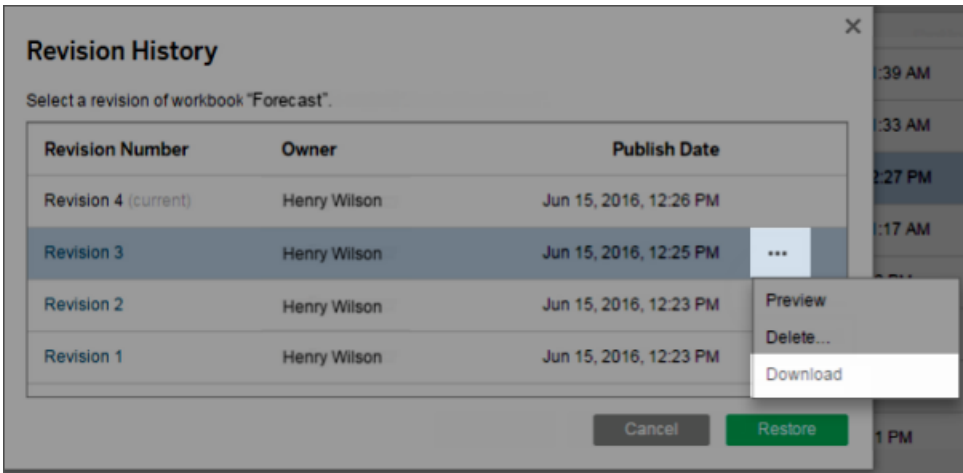

- From the actions menu of a revision (⋮), click **Preview**.

If a preview is available, it opens in a new tab in the browser. For workbooks that you can't preview on the server, such as those with OAuth data connections, you can download the revision and open it in Tableau Desktop.

Download a workbook or data source revision

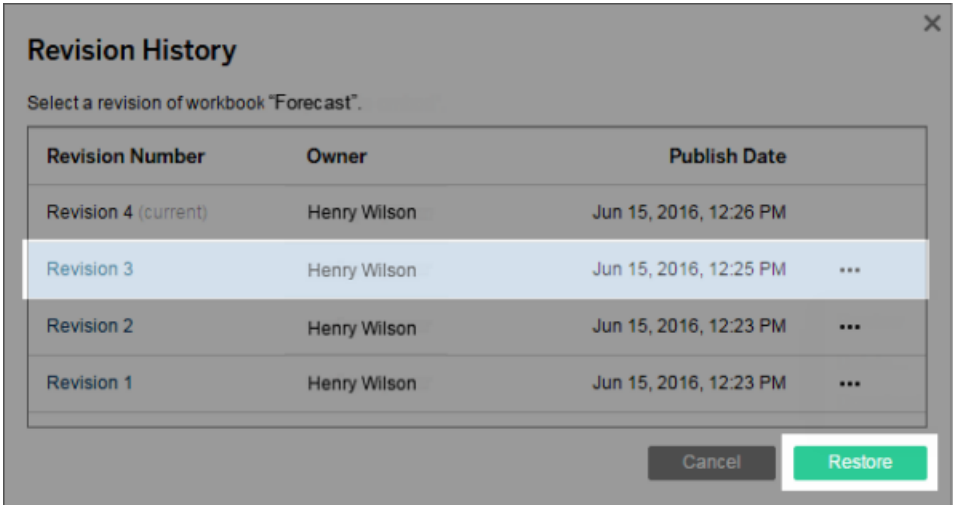

- 1. From the actions menu of a revision (. . .), click **Download**.

- 2. Open the downloaded file in Tableau Desktop.

Restore a workbook revision

- In the revision history, select a revision, and then click **Restore**.

The restored version becomes the current version.

Note: If a revision can't be restored directly on the server, download the revision, open it in Tableau Desktop, and republish it.

Restoring workbooks that require database credentials

If a workbook uses a live data connection that prompts for a user name and password, you have the option to embed credentials for the connection. If the workbook uses a data source with multiple connections, you might need to provide credentials for each one.

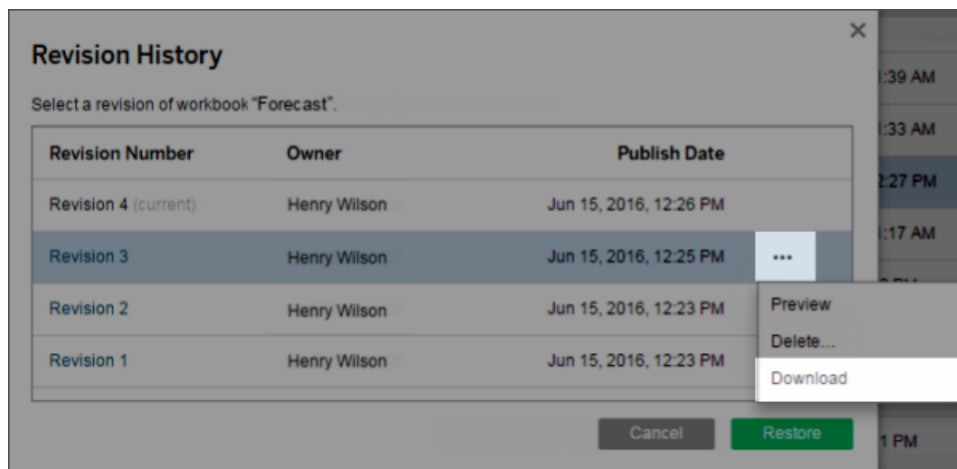

If a workbook uses data extracts with scheduled refreshes and embedded credentials, you'll need to edit the data connection to provide the credentials.

Restore a data source revision

For a variety of reasons. For example, extracts are commonly on refresh schedules, therefore a previous revision of a data source will not include the extract as it was published at the time. To restore the extract, you can download the previous revision of the data source (in .tdsx format), open it in Tableau Desktop, and re-publish the extract.

For more information, see [Data changes and deletions on the facing page](#) under **Potential revision history issues on the facing page**.

1. Sign in to the Tableau Server or Tableau Cloud web editing environment, navigate to the data source and open its revision history.
2. From the actions menu of a revision (⋮), click **Download**.

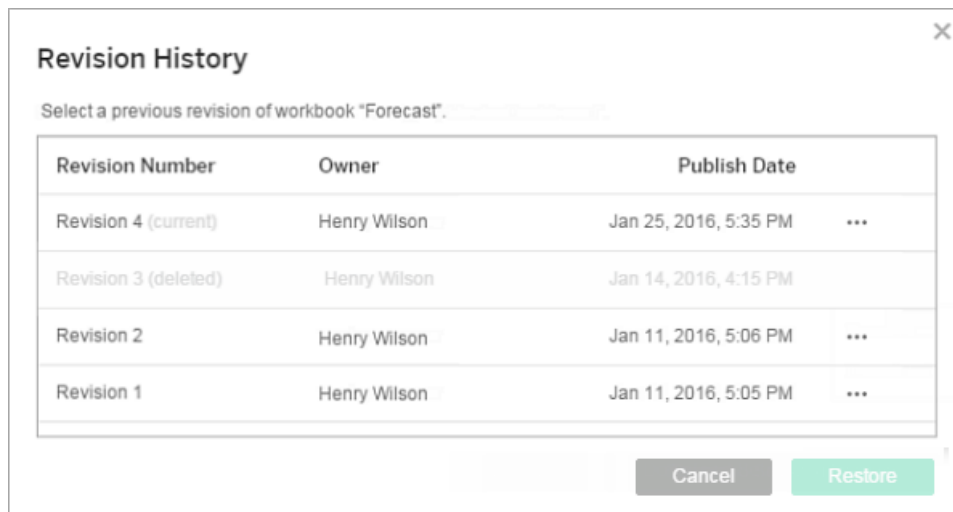

3. Open the downloaded file in Tableau Desktop and then republish it with the same name to the same location on your Tableau Server or Tableau Cloud site (confirming that you want to overwrite the existing version).

The uploaded version becomes the most current version.

Delete a workbook or data source revision from history

1. From the actions menu of a revision (. . .), click **Delete**.

The revision history list updates to indicate a revision has been deleted.

Potential revision history issues

Overwriting content with the same name

If a different author publishes over a workbook or data source with the same name, the most recent author becomes the owner of the content and can see its entire revision history.

Data changes and deletions

- Workbooks and data sources are downloaded with the latest configuration of their extract or data connection. If the data model or data connection has changed between revisions, you might need to update the downloaded workbook or data source.
- Revisions of workbooks and data sources that use .xls or .csv files are saved with an extract of that data.

- Revisions are saved for .hyper files with a direct connection. Revisions are not saved for extracts.
- If a workbook or data source is deleted from a site, all revisions are also deleted.

Turning revision history on and off

On Tableau Server, server administrators can disable revision history for specific sites.

If revision history is turned on and then off, saved revisions are retained, and new versions overwrite the latest version. If revision history is then turned on again, version numbering starts from the last saved revision.

If you're a Tableau Server administrator, see [Enable Users to Save Revision History](#) for more about revision history settings.

Refresh Data or Pause Automatic Updates

Tableau Server and Tableau Cloud let you control how views interact with data sources so you can keep data fresh and improve performance.

Refresh Data

If a data source is changed (for example, with new fields, field names or data values), the view reflects those changes the next time you load the page. To manually update data while you interact with a view, such as performing several actions at once without updating between each one, click the refresh icon on the toolbar.

When you refresh data, Tableau Server and Tableau Cloud clear any cache and retrieve the latest information from the data source. If you're working with a complex view or a large data source, refreshing data can take a long time.

Pause Automatic Updates

As you interact with a view, the server sometimes has to query the data source to update the view. To temporarily stop updates so that you can more quickly interact with a view, click on the pause icon on the toolbar.

Click on the resume icon to again automatically query the data source as needed.

Stop long-running actions

When an interaction takes a long time to load, a dialog appears that allows you to stop the action. If you stop, the viz goes into a suspended state similar to pausing automatic updates.

After stopping an action, you can choose to:

- Cancel the action and return to the previous state. To do so, use the **Undo** button in the toolbar.
- Allow the action to finish. To do so, use the **Resume Auto Updates** button in the toolbar.
- Continue working but without the viz updating. The behaviour is the same as pausing automatic updates. When you're ready for the viz to update, use the **Resume Auto Updates** button in the toolbar.

When you do resume automatic updates, be aware it can take a while to complete the action.

Use Custom Views

A custom view is a shortcut to a specific state of interaction, such as filter selections and sorting, for a published viz. Custom views don't impact the underlying content. They're a good option if you find yourself adjusting the same filters or zooming into the same data every time you look at a viz.

Custom views aren't the same as web editing, which changes the underlying published content itself. See [Edit Tableau Views on the Web](#).

If the custom views are specifically for filter settings, consider using embedding filter parameters in a shared URL. See [Filter a published dashboard by editing the URL](#) from [The Data School](#).

Notes on custom views

- A custom view doesn't modify the content it's built on.
- Deleting the original content deletes its custom views.

- If the original content is updated or republished, the custom view is also updated.

Tip: Some changes to the original content can break the custom view. See [Maintain Content with Custom Views](#) for best practices on modifying content with custom views.

- If a user is removed from the site, any shared custom views they owned are also lost.
- Subscriptions and data-driven alerts based on custom views may be more fragile than those based on the original content.

Note: As of the 2022.3 release, Tableau replaced user names in the custom view URL with IDs. Bookmarked URLs still work but are redirected to the new URL schema. This change is to add more company and user data protection.

Create a custom view

Start by navigating to the individual view. Make whatever changes you want to capture in the custom view, such as selecting marks, filtering data or changing sorts.

1. When you're ready to save the changes you've made as a custom view, select **Save Custom View** from the toolbar.

Note: The **Save Custom View** button appears in the toolbar after any changes are made to the current view.

2. In the **Save Custom View** dialogue, enter a name for the custom view.
3. (Optional) Select **Make it my default**.
4. (Optional) Select **Make visible to others**. This makes the custom view available to everyone who can see the original content. However, there are several instances when this option isn't available:
 - The user is a Viewer site role.
 - The site's [User Visibility setting](#) is set to Limited.
 - The permission capability [Share Customised](#) is denied on the workbook.
5. Click **Save**.

Find a custom view

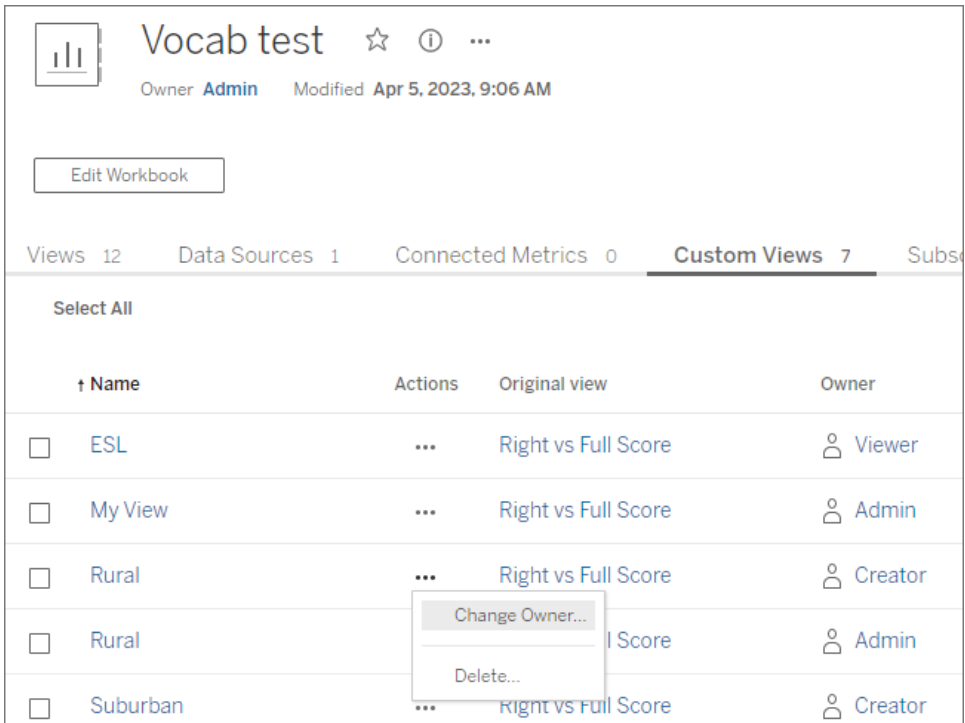

From a view

When you're looking at a viz, you can change to a different custom view by selecting the View icon in the toolbar. If there's room in the toolbar, the name of the custom view you're looking at is shown.

Any custom views you've made, and all visible custom views made by other users, appear in the list.

From the workbook

When you're looking at content at the workbook level, use the **Custom Views** tab to see all the available custom views for that workbook.

Set a default custom view

After you've found or made a custom view, you make it the default you see when you open that viz.

1. Select the **View** icon in the toolbar.
2. Check the **Set this view a your default** option.
3. Close the dialogue to save.

The next time you open that viz, you'll land on that custom view.

Share a custom view

By default, custom views are private and only appear for the user who created them.

Note: Users with a Viewer site role can't make custom views visible to others. However, they can share a custom view by copying and sharing the URL.

Users with a site role of Explorer or higher can set a custom view as visible to others. This setting allows anyone with access to the original content to see the custom view.

To change an existing private custom view to be visible to others (or to make a visible view private):

1. Select the **View** icon in the toolbar.
2. Toggle the eye icon to the view you want to share to the desired state.
3. Close the dialogue to save.

The eye with a slash  indicates the view is private to you. The eye  indicates the view is visible to others.

Delete a custom view

To delete a custom view:

1. Select the **View** icon in the toolbar.
2. Select the trash icon of the view you want to delete.
3. Confirm that you want to delete the view.

Take care when deleting

If you're the owner of a custom view that's visible to others, remember it's deleted for everyone if you delete it.

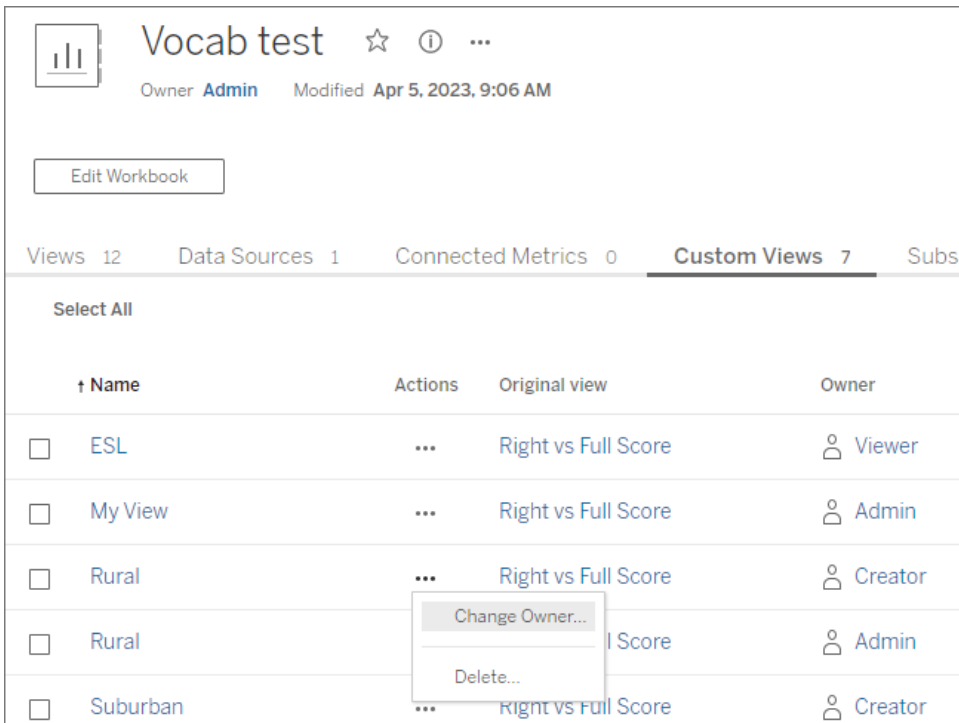

Deleting a custom view also deletes any subscriptions or data-driven alerts based on that custom view.

Manage custom views

Administrators can change ownership for custom views and delete custom views created by other users.

Custom views can be managed for a piece of content or for a specific user.

1. Go to the Custom Views tab for the workbook or user.
2. Use the action menu to change the owner or delete the custom view.

Tip: It's a best practice to change ownership of any custom views belonging to a user before removing them from the site. Deleting a user also deletes their custom views, including public views others may be using.

Safely change content with custom views

If you need to modify a view that has custom views (or the data source the view is built on), be aware that certain changes can break custom views. For more information, see [Maintain Content with Custom Views](#).

Maintain Content with Custom Views

As a content creator, it's important to understand how updates you make to workbooks and data sources can impact the end user. Custom views are a popular way to personalise how vizzes are consumed, but custom views can break if their source content changes. Avoid making changes known to impact custom views, if possible. When changes need to be made, follow the steps outlined later in this topic.

In general, there are some best practices when working with content known to use custom views.

- Advise end users to only create custom views on stable content.
 - Use projects or naming systems to identify workbooks that are being modified and recommend users don't create custom views on them.
- Test changes in a staging or development environment. Test custom views that are representative of the expected filters, user actions, parameter settings and other customisations.
- Proactively notify users before publishing changes that may break custom views.
(Retrieve a list of all custom views applied to a workbook [using the custom views methods in Tableau's REST API](#).)

Changes known to impact custom views

While it's best to test any changes to verify their impact on custom views, there are some updates that are known to impact custom views.

This list isn't comprehensive and is intended for guidance only.

Workbook changes

- **Name changes.** Changing the name of the workbook (or the sheet the custom view is associated with) breaks the custom views.
- **Parameters.** Adding or removing a parameter may cause a custom view to break or fail to update as expected.
 - If a parameter is added to the original content, the custom view may break.
 - If a parameter control is removed, calculated fields that used its input retain their last value and are no longer adjustable.
- **Filters.** Removing a filter removes the filter control but leaves the data in a filtered state.
 - In general, if a filter is deleted in the original content, a custom view that used that filter continues to work. However, the data remains filtered with no filter control present. This means users can't change the filter selection from the custom view.
 - Changing the filter control from slider to relative date doesn't adjust the filter to accurately reflect the relative date as expected.
 - If custom views are used to control filter selections, consider using embedding filter parameters in a shared URL instead.
- **Hiding sheets.** Setting a sheet to hidden, even if it's later unhidden, breaks custom views on that sheet.
- **Republishing.** Deleting and republishing a workbook breaks its custom views.

Data source changes

- **Data source changes.** Replacing a data source using the Replace data source functionality or replacing an embedded data source with a published copy of the same data source breaks the custom views.
- **Data type.** Changing the data type of a field relevant to the custom view breaks the custom view.
- **Removing fields.** Removing fields, calculations, groups or sets that custom views are based on breaks the custom view.

Update content safely

The following is a set of best practices to minimise the risk of breaking existing custom views.

- Edit the workbooks and changes to the data sources separately.
- Don't republish a workbook that has a replaced data source.
- Edit a local version of the workbook or data source and republish it with the same name.

Modify a workbook

These steps assume the workbook uses a live connection to a separately published data source and has existing custom views.

Modify a workbook with web editing

Web editing is the preferred method for modifying a workbook. Only use Tableau Desktop if necessary.

1. Edit a workbook in the browser, avoiding the items addressed earlier that are known to break custom views.
 - If changes need to be made to the data, don't make them now. See the section on modifying a data source.
2. Publish the workbook to the same location with the same name, saving over the existing version.

Modify a workbook with Tableau Desktop

When possible, modify workbooks in the browser. Only use Tableau Desktop if necessary.

1. Open a local version of the workbook (download the workbook first if necessary).
2. Edit the workbook, avoiding the items addressed earlier that are known to break custom views.

- If changes need to be made to the data, don't make them now. See the section on modifying a data source.
3. Publish the workbook to the same location with the same name, replacing the existing version.
 - *Don't* check the option to "Update the workbook to use the published data source".

Modify a data source

1. Open a local version of the data source in Tableau Desktop by downloading the workbook and creating a local copy of the data source:
 - a. Download the workbook and open it in Tableau Desktop.
 - b. Right-click the data source and select "Create Local Copy".
 - c. Right-click the new data source and select "Replace Data Source..."
 - d. Swap the existing connection to the published data source with the newly created local copy.

Note: Using a local version in a workbook is the preferred method because it allows you to verify data source changes directly in the workbook. Alternatively, you can download the data source or use a locally stored copy.

2. Edit to the data source, avoiding the items addressed earlier that are known to break custom views.
3. Publish the data source.
 - a. Use the same name and save over the existing data source.
 - b. Don't check the option to "Update the workbook to use the published data source".
 - c. Don't publish the workbook with the modified data source. If changes need to be made to the workbook contents, see the section on modifying workbooks.

Investigate broken custom views

Note: This section assumes familiarity with XML and basic command-line interactions.

In a .twb workbook file, the XML of a workbook contains identifying tags for elements of the workbook. When a custom view is created, a snapshot is taken of the interactive elements (such as filter or set values, parameters or selected marks) and their values. When a custom view is accessed, Tableau applies the attribute values stored with the custom view to the relevant element IDs. If the element IDs are changed or the attribute values can't be loaded, the custom view breaks.

It may be possible to identify what changed to break a custom view by comparing a .twb from before and after the change.

1. You need a .twb of the workbook when the custom view is functioning (save a copy of content before making any changes).
2. In another copy of the workbook, make the change thought to cause the custom view to break and save it as a different .twb.
3. In the command line, run the following command (substituting the files from step one as file1.twb and from step two as file2.twb).

```
vdmdiff file1.twb file2.twb
```

4. The results highlight changes between the files.

Some IDs or attribute values (in **[brackets]**) that are known to break custom views if changed:

```
<datasources>
  <datasource name=' [ID] '>

<worksheets>
  <worksheet name=' [ID] '>

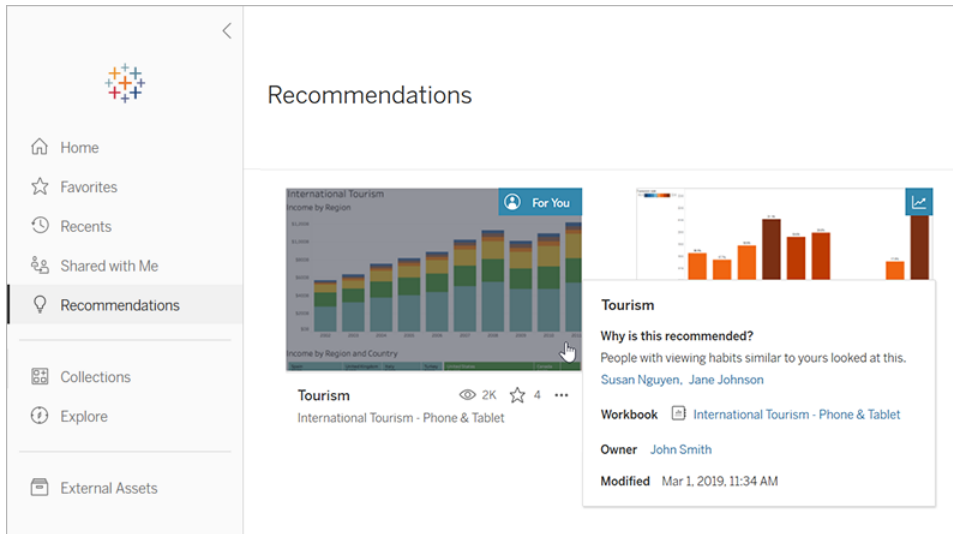

<table>
<view>
<datasource-dependencies datasource=' [ID] '>
<column datatype=' [Value] ' name=' [Value] '>

<dashboards>
  <dashboard name=' [ID] '>
```

Discover Recommended Views on Your Tableau Site

Recommendations make it easier to discover relevant content on your Tableau site.

Recommendations for views appear both on the Home page and on the Recommendations page, accessed from the left navigation pane.

Why are these views recommended?

The model used to recommend content looks at the viewing habits of users and trends in popularity of content on your site. Recommendations that are For You are personalised based on the content you have looked at. Recommendations that are Trending have been popular across your site in the past week.

Tip: If a recommendation isn't useful, you can hide it by selecting the actions menu (...), and then selecting **Hide**.

Whose names are shown?

On recommendations that are For You, you might see the names of other users who have looked at that content. These are users on your site who have viewing habits similar to yours. The names give you an additional indicator of why you might want to investigate a view, because a colleague with similar interests looked at it.

The visibility of names on recommendations is controlled by a site-wide setting. If you don't see names on a For You recommendation, the setting might have been turned off for your site.

Which views appear as recommendations?

You will see recommendations for particular views only if you have the correct permissions to see those views. You can't exclude a view from being recommended to others on your site; however, you or your site administrator can set permissions so that only users who should have access to a workbook or view are able to see it. That way, the view will not show up in recommendations for the wrong users.

Manage Your Account Settings

In Tableau Server and Tableau Cloud, your Account Settings page lets you manage your credentials, email settings and user interface options in one central place.

Go to your Account Settings page

At the top of a page, click your profile image or initials, and then select **My Account Settings**.

Profile image

To change your profile image, click the current image or initials on your account settings page.

Account

Under **Account**, you can review the username you use to sign in to Tableau Cloud or Tableau Server.

Manage multi-factor authentication verification methods

After **Tableau with MFA** has been enabled and you've registered your verification method, you use your Tableau credentials and verification method each time you sign in to Tableau Cloud.

To add or remove verification methods, you can click the **Manage My Verification Methods** link to do the following:

- Add additional verification methods for backup purposes
- Delete existing verification methods if you no longer need them

For more information, see [Manage verification methods](#) in Tableau Cloud Help.

Manage your credentials and passwords

When you access a workbook or data source that has a live connection to data and requires you to sign in, Tableau offers to save your password for you. If you accept, it stores your credentials in a cookie or an access token, depending on the data type. You can remove these credentials if you no longer use the data, or you have exceeded the maximum number of saved credentials and want to make room for a new one.

Under **Saved Credentials**, do either of the following:

- Select the **Delete** link next to an individual access token.
- Select **Clear All Saved Credentials**.

When you clear all credentials, the following items are removed from your user account:

- Passwords you used to access published data sources or workbooks that connect to them.
- Access tokens for OAuth data connections, such as to Google or Salesforce.com data.

Caution: Removing an access token is effectively like “changing the locks.” If the token is stored with workbooks or data sources you published, deleting the token also removes access to the data from those workbooks and data sources. If the token is embedded in an extract connection, and the extract is refreshed on a schedule, the refreshes will not be able to complete until you embed the new credentials or access token into the connection.

Create and manage personal access tokens

Create personal access tokens (PATs) to authenticate automated tasks with the Tableau REST API. We recommend creating a PAT for each automation task that requires authentication. By creating PATs for this purpose, managing many automated tasks is simplified if you need to remove a task. To remove a task immediately, you can just revoke the PAT associated with the task.

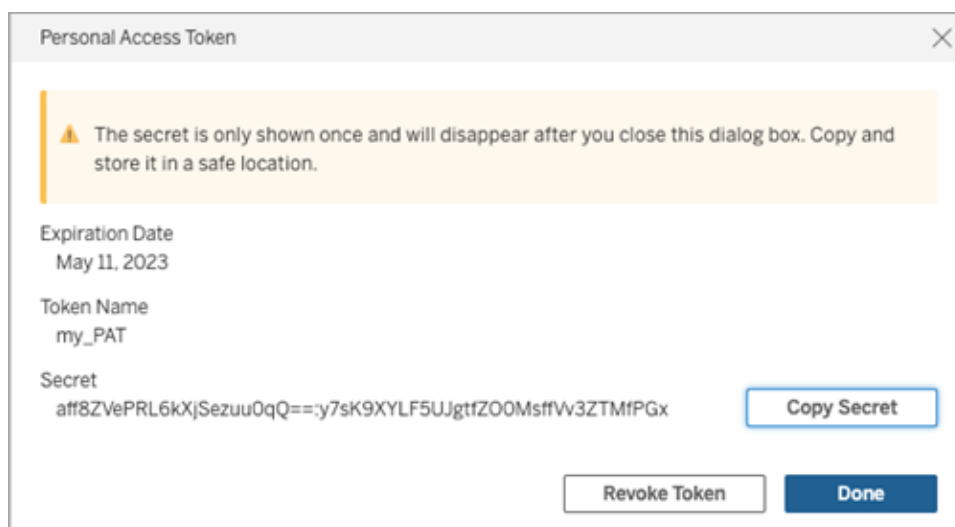

Note: If multi-factor authentication (MFA) is enabled with Tableau authentication, PATs are required. You must use a PAT, instead of user name and password, to make a Tableau REST

API sign in request to Tableau Cloud. For more information, see [Tableau with MFA](#) in the Tableau Cloud Help.

Create a personal access token

This procedure requires you to copy a secret to a file. The secret is the string that you will include in your automation scripts and will be used to authenticate to Tableau Cloud or Tableau Server. Handle the secret as you would a password: protect the secret and do not share it with others.

1. Under **Personal Access Tokens**, enter a descriptive name for your token in the **Token Name** field, and then click **Create Token**.
2. In the Personal Access Token dialog box, click the **Copy Secret** button.

3. Paste the secret to a file and store the file in a safe location.
4. When finished, click the **Close** button.

Note: If using Tableau Server, you can have up to 10 PATs by default. If using Tableau Cloud, you can have up to 104 PATs.

Check when a personal access token expires

Expiration of PATs in Tableau Cloud depends on the PAT's site setting. Default expiration of PATs created on Tableau Server is one year.

1. Under **Personal Access Tokens**, identify the PAT name.
2. Next to the PAT name, review its expiration date.

Note: When PATs expire, they are removed from your **My Account Settings** page.

Revoke a personal access token

1. Under **Personal Access Tokens**, identify the token name that you want to revoke.
2. Click the **Revoke Token** (in Tableau Cloud) or **Revoke** (in Tableau Server) button next to the token name.
3. In the Delete dialog box, click the **Delete** button to revoke the PAT.

Remove connected clients

The first time you sign in to Tableau Server or Tableau Cloud from a Tableau *connected client* like Tableau Desktop, Tableau Prep Builder or Tableau Mobile, a secure refresh token is created and stored in your account. This refresh token allows you to access the site from the connected client, without having to sign in each time.

You can delete a connected client (refresh token) if you no longer use it, or if you want to add a new client but get an error that says you're already using the maximum number of connected clients. After you remove a connected client from your account, you will need to provide your credentials the next time you access Tableau Server or Tableau Cloud from that client.

- In the **Connected clients** section, next to the client you want to remove, click **Delete**.

Change notification settings

Notifications are messages that let you know when something happens to content you own, that is shared with you or you are @mentioned on.

In the **Notifications** section, you can select the notification types that you want to receive. You can receive notifications as an email, on the Tableau site or in your Slack workspace if your administrator has connected your site to Slack. The types of notifications you receive, such as data alerts, comment mentions and shares depend on your site and server settings.

When you enable **On Tableau**, you can see notifications by clicking the bell icon in the upper right corner of your browser and can update your settings by clicking the gear icon.

Notifications

| Preferences | On Tableau | Email | Slack |
|-----------------------|-------------------------------------|-------------------------------------|-------------------------------------|
| Collaboration | | | |
| Comment mentions | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| Share | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| Data alerts | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| Predictive Model | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| Systems Status | | | |
| Flow runs | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| Extract jobs | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| Webhooks | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| View Acceleration | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |

If grayed out, the notification option is disabled for use.

Note: Recreate your notification settings when upgrading from 2020.4 or earlier to 2021.1 and later. Older notification settings are not automatically moved to the Notifications setting.

Change subscription settings

1. Under **Subscription time zone**, select the time zone for schedules you create.
2. To modify subscriptions, click **Subscriptions** at the top of the page, and then select a workbook or view.
3. From the **Actions** drop-down menu, select **Change Schedule**, **Change Subject**, **Change Empty View Mode**, or **Unsubscribe**.

(The empty-view option sends subscription emails only when data exists in a view. It's a good choice for high-priority alerts.)

Enable or disable data alerts

Choose to enable or disable emails for alerts on your site due to repeated failures.

Enable or disable the Data Management features message

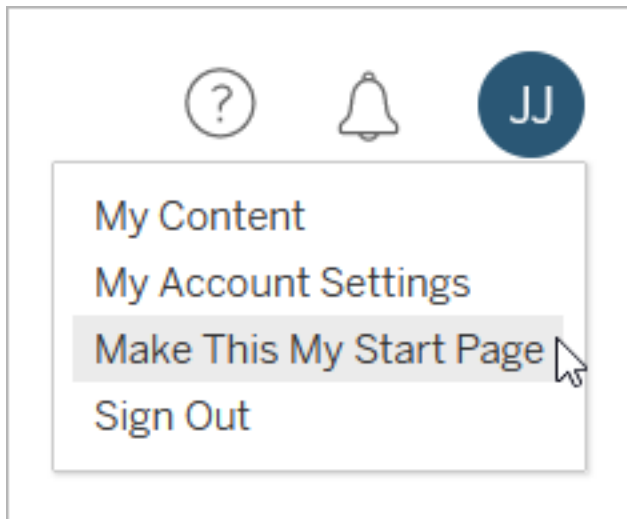

(Tableau Cloud only) Choose to hide or show the Data Management features message. If you haven't purchased the Data Management licence, information about the available features will be

displayed when you are signed into Tableau Cloud.

| | |
|-------------------------------------|--|
| Data Management Features | Show messaging about Data Management features. |
| <input checked="" type="checkbox"/> | Show Tableau Catalog feature overview |
| <input checked="" type="checkbox"/> | Show Tableau Prep Conductor feature overview |

Change your start page

To change the start page that appears when you sign in, navigate to the page you want, click your name in the upper right area of the page, and then click **Make This My Start Page**. Updates to your start page take effect the next time the page loads completely, or after you sign out, and then sign in again.

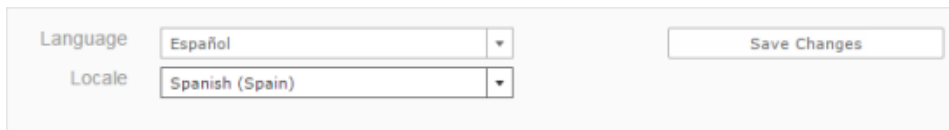

To return to the default start page, click your user name, and then click **My Account Settings**. In the start page section, click **Reset to Default**. (The URL for your current start page is displayed here too; click the link to go to the page.)

| | | |
|---|-----------|---------------------|
| Start page | /projects | Reset to Default... |
| To change your start page, navigate to a page and select "Make This My Start Page" from the drop-down menu in the upper-right corner of the page. | | |

Change language and locale

The **Language** setting determines the language you see for user interface options. **Locale** affects views, such as how numbers are formatted, or which currency is used.

Change the **Language** and **Locale**, and then click **Save Changes**. The language and locale update immediately.

A screenshot of a settings panel with a light gray background. It contains two dropdown menus. The first is labeled 'Language' and has 'Español' selected. The second is labeled 'Locale' and has 'Spanish (Spain)' selected. To the right of these menus is a button labeled 'Save Changes'.

If you use Tableau Server and want to select a language that isn't currently supported, contact your administrator.

Change your display name, password or email address in Tableau Server

Change your display name

If Tableau Server is configured to use the internal user management system (Local Authentication) instead of Active Directory, you can change your display name. Select the display name text and enter the new display name, and then click **Save Changes**.

A screenshot of a user profile settings form. It has a gray background. At the top, 'Username' is 'jjohnson'. Below it, 'Display name' is 'Jane Johnson (Lead)' and is highlighted with a white selection box. Below that, 'Email' is 'jjohnson@myco.com'. At the bottom left is a link 'Change Password'. At the bottom right is a button 'Save Changes'.

Change your password

If Tableau Server is configured to use the internal user management system (Local Authentication) instead of Active Directory, you can change your password by clicking **Change Password**. Click **Save Password** to save your changes.

A screenshot of the same user profile settings form as above. The 'Display name' field is no longer highlighted. The 'Change Password' link at the bottom left is now a button with a white background and gray text. The 'Save Changes' button remains at the bottom right.

Change your email address

If you subscribe to views or receive data-driven alerts on Tableau Server, the related email account appears on the My Account Settings page. Enter the new email address in the **Email** text box, and then click **Save Changes**.

The screenshot shows a user interface for account settings. It includes a 'Username' field with the value 'jjohnson', a 'Display name' field with the value 'Jane Johnson (Lead)', and an 'Email' field with the value 'jjohnson@myco.com'. There is a 'Save Changes' button and a 'Change Password' link.

Note: Starting with Tableau Server 2022.3.7, you can update your email address if site-specific SAML is configured for your site. In Tableau Server 2022.3.6 and earlier, only admins have the ability to change a user's email address. If you are unable to change your email address, contact your admin to request a change.

Change your display name or password in Tableau Cloud

If your site is not set up for single sign-on (SSO), your Tableau Cloud display name and password are based on your Tableau credentials. Your Tableau credentials are managed through your Tableau account and allow access to Tableau Cloud, the Tableau website, the Customer Portal and other resources.

If you're not signed in to Tableau Cloud and forgot your password

To reset your password, go to <https://online.tableau.com>, enter your site URI (if prompted), enter the email address you use to sign in to Tableau Cloud and then click the **Forgot password** link. Then follow the instructions in the email you receive.

If you're signed in to Tableau Cloud and want to update your password or display name

1. Open your **My Account Settings** page, and click **Change Password**.
This redirects you to the Tableau website.
2. If prompted, sign in using your Tableau Cloud credentials, and then select the **Change Password** link at the top of the page.
 - In the fields provided, type your current and new passwords, confirm the new password, and click **Change Password**.

Change Password

Passwords are case sensitive, 8-100 characters long. Requires at least one number (0-9), one uppercase letter, one lowercase letter, and one of the following characters: ! " # \$ % & ' () * + , - . / : ; < = > ? @ [] ^ _ ` { | } ~. You cannot use previously used passwords.

CHANGE PASSWORD

- To change your display name, click **Manage Account**.

On the User Profile page, change your first or last name, update any other information that might be out of date, and click **Update**.

Note: When you change your display name or password, you're directed outside of Tableau Cloud to your Tableau ID account profile. You can also access your Tableau ID profile by navigating to the [Tableau](#) website and clicking **Sign In**.

Manage Saved Credentials for Data Connections

Saved credentials enable you to connect to a data source without being prompted for your credentials. The credentials saved for your connection can be OAuth access tokens, or other credentials, such as user name and password. You can manage saved credentials on your account settings page.

Note: When editing Tableau Prep flows on the web, you may still be prompted to re-authenticate.

Test connections using saved credentials

If the connector supports test functionality, you can test the connection using saved credentials.

1. While you're signed in to Tableau Server or Tableau Cloud, display your Account Settings page.
2. In the Saved Credentials section, select the **Test** link next to the stored connection that you want to test.

This test confirms that Tableau Cloud or Tableau Server can access your account using this corresponding saved credential. If the test succeeds, but you can't access your data through this managed connection, confirm that the credentials you provided for this connection can access your data.

For example, if you accidentally created the connection using your personal Gmail account, but you use a different account to access a Google Analytics database, you'll need to delete the saved credentials and sign in to the data using the appropriate Gmail account.

Update saved credentials

To help ensure uninterrupted data access from existing Tableau content after a custom OAuth client has been configured for your site, we encourage you to update your saved credentials. To update saved credentials, you can delete the previous saved credentials for a particular connector and then add them again.

When you add saved credentials again, both new and existing Tableau content will access the data using the custom OAuth client configured by your .

1. Sign in to Tableau Server and navigate to your **My Account Settings** page.
2. Under **Saved Credentials for Data Sources**, do the following:
 1. Click **Delete** next to the saved credentials for a connector.
 2. Next to the same connector, click **Add** and follow the prompts to 1) connect to the custom OAuth client that your site admin notified you about and 2) save the latest credentials.

Clear all saved credentials

When you select **Clear All Saved Credentials**, the following items are removed from your user account:

- All saved credentials for connections that are stored in your account.

Caution: If any of these saved credentials are stored with published workbooks or data sources, deleting them also removes access to the data source from those locations. Effectively, this is like "changing the locks" anywhere the affected saved credentials are used.

- Passwords you've used to access published data extracts or workbooks that connect to them.

Remove saved credentials

To remove Tableau access to data, delete the associated saved credentials for that data from your account. After you delete the credentials, you'll need to sign in to the data the next time you access it. This creates new saved credentials.

Your administrator might choose for all users to use the same shared credentials for connecting to a data source. If this is the case, the saved credential is associated with the data connection for all users, and it doesn't appear under Saved Credentials on your Account Settings page.

Note: If you're a Tableau Server user and can't delete saved credentials, ask your administrator if they've cleared the Allow users to save data source access tokens option in the server settings.

Share and Collaborate on the Web

Use the topics below to learn more about sharing and collaborating on the web with Tableau.

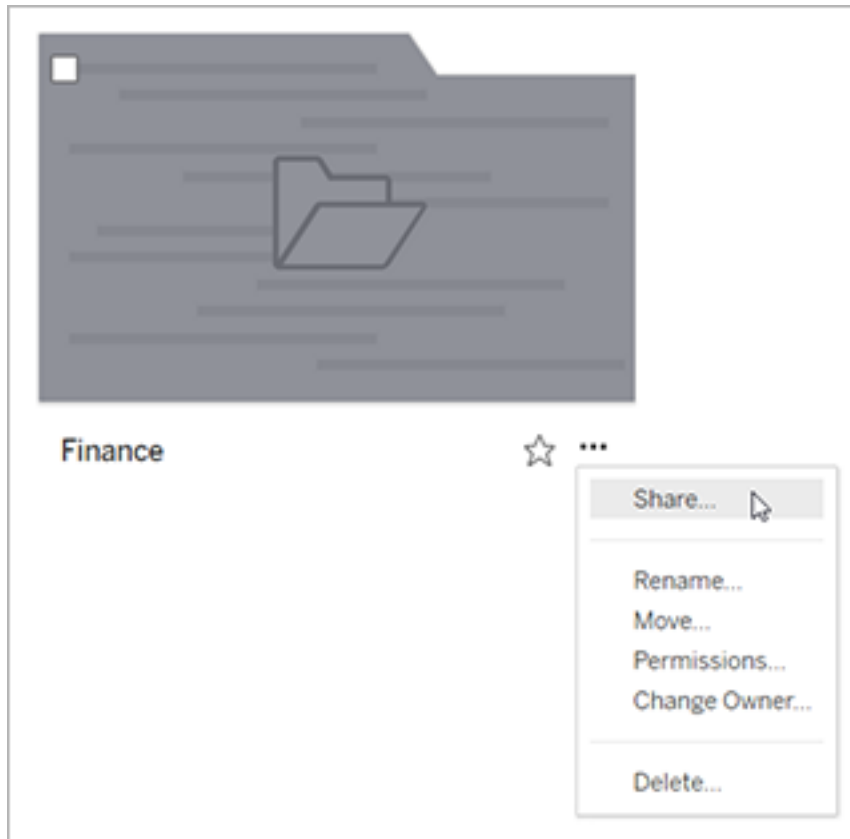

Share Web Content

Share projects, collections, workbooks, views, metrics, data sources and flows either directly with other users or by copying a link to the content. For views and metrics, you can also copy code to embed them in a webpage. (The legacy Metrics feature was retired in February 2024 for Tableau Cloud and in Tableau Server version 2024.2. For more information, see [Create and Troubleshoot Metrics \(Retired\)](#).)

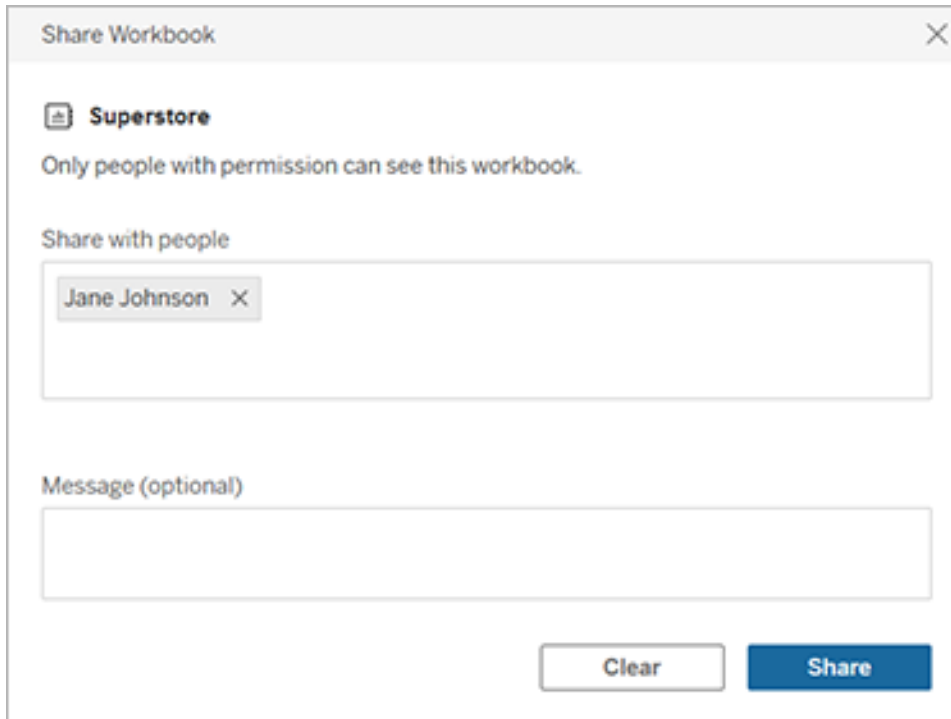

Share directly with other users

When you share content directly with other users on your site, they receive a notification with a link to that content. The content is also added to their Shared with Me page, so they can easily find it later. Notifications can come by email, in Tableau's in-app notifications centre or in the Tableau for Slack app if the site is connected to a Slack workspace. For more information, see [Manage Your Account Settings](#) on page 3333 and [Receive Notifications, Search and Share Using the Tableau App for Slack](#) on page 3419.

1. Open the Actions (...) menu for the content you want to share.
2. Select **Share** from the menu.

3. Under **Share with people**, enter at least one user name. When you type, names that match your text appear.

A screenshot of the 'Share Workbook' dialog box in Tableau. The dialog has a title bar with 'Share Workbook' and a close button. Inside, it shows the workbook name 'Superstore' with a small icon. Below that is the text 'Only people with permission can see this workbook.' followed by a section 'Share with people' containing a list box with 'Jane Johnson' and a close button. Below the list box is a text area labeled 'Message (optional)'. At the bottom right are two buttons: 'Clear' and 'Share'.

4. Under **Message**, enter an optional note to your recipients.
5. Click the **Share** button.

Grant access to shared content

To access the content you share with them, users must have permission to view that content on Tableau Server or Tableau Cloud.

If you control permissions for the content, you can grant access when you share it. If any of the users you shared with don't have the ability to view the content, the option to grant access will appear automatically after you share. You can only grant the capabilities for the view template via the grant-access dialog. To grant users other permission capabilities, follow the instructions on [Set permissions](#).

If you don't have the ability to set permissions for the content, the users you share with will be able to request access upon opening the link to the shared content. Their request for access is sent to the user who controls permissions for the content.

Copy a link to share

Copy the link generated for a piece of content to share without sending an email to specific users.

1. Open the Actions (...) menu for the content you want to share.
2. Select **Share** from the menu.
3. Click the **Copy Link** button, then paste the link into an application to share it with others.

Tip: If you don't see the **Sharing using a link** option, clear any names from under **Share with people**.

Share and embed views and metrics

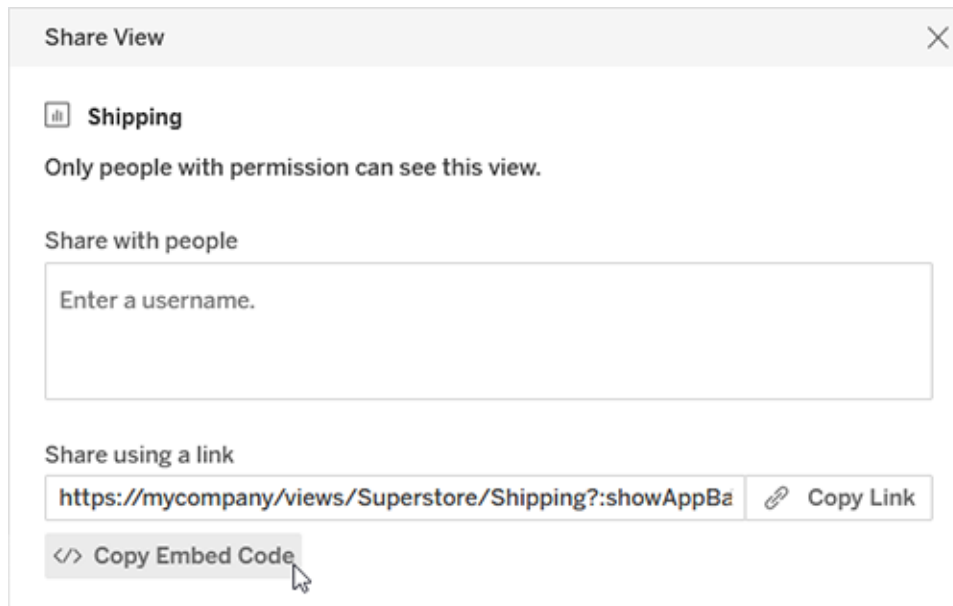

In addition to the sharing options listed above, views have unique options available when you click the **Share** button on the toolbar for a view. You can share a view that you have modified, and you can get the embed code for a view.

You can also embed metrics by copying the embed code from the share dialog.

Embed views and metrics

1. Click **Share** in the toolbar for the view you want to embed or on the metric you want to embed.
2. Click **Copy Embed Code**, then paste the embed code into the source code for the webpage where you want to embed the view.

For more information, see [Embed Views into Webpages](#) on page 3362 or [Embed Metrics into Webpages \(Retired\)](#) on page 3364.

Retirement of the legacy metrics feature

Tableau's legacy metrics feature was retired in Tableau Cloud in February 2024 and in Tableau Server version 2024.2. In October 2023, Tableau retired the ability to embed legacy metrics in Tableau Cloud and in Tableau Server version 2023.3. With Tableau Pulse, we've developed an improved experience to track metrics and ask questions of your data. For more information, see [Create Metrics with Tableau Pulse](#) to learn about the new experience and [Create and Troubleshoot Metrics \(Retired\)](#) for the retired feature.

Share modified or custom views

If you modify a view, by selecting marks or filters, Tableau captures these modifications by generating a unique link when you click the Share button. This unique link replaces the link to the original view for all sharing and embedding options. That way, the people you share with will see exactly what you were seeing when you shared.

The link generated for a modified view expires two years after it was last accessed, or two years after it was created if never accessed.

To share a custom view that you have saved, simply open the custom view and use any sharing option.

Find content shared with you

You receive a notification message when someone shares content with you directly, either as an email, on your Tableau site by selecting the bell icon in the upper right corner or in a connected Slack workspace with the Tableau for Slack app.

The Shared with Me page, accessed from the navigation pane, stores items that have been shared with you. The most recently shared items also appear in the Shared with Me channel on the Home page. Each item shows who it was shared by, the date it was shared, and any message added by the sharer.

| Type | Name | Shared Versions | Actions | Shared By | Date Shared | Owner |
|----------------------------|------------------|-----------------|---------|--------------|----------------|-----------------|
| <input type="checkbox"/> ★ | World Indicators | | ... | Jane Johnson | 3 seconds ago | Fred Suzuki |
| <input type="checkbox"/> ★ | Statistics | | ... | Jane Johnson | 15 seconds ago | Laura Rodriguez |
| <input type="checkbox"/> ☆ | Customers | | ... | Jane Johnson | 10 minutes ago | Susan Nguyen |

If an item has been shared with you multiple times, the information shown is for the most recent share. Views include additional information if multiple versions of the view have been shared with you. Custom views, modified views and the original view all appear with unique details and links under **Shared Versions**.

Create a Subscription to a View or Workbook

Subscriptions email you an image or PDF snapshot of a view or workbook at regular intervals – without requiring you to sign in to .

Set up a subscription for yourself or others

When you open a view in , if you see a subscription icon (📧+) in the toolbar, you can subscribe to that view or to the entire workbook. You can subscribe other users who have permission to view the content if you own a workbook, if you are a project leader with an appropriate site role, or if you are an administrator.

1. From the Explore section of your site, select **All Workbooks** or **All Views**, or open the project that contains the view you want to subscribe to.

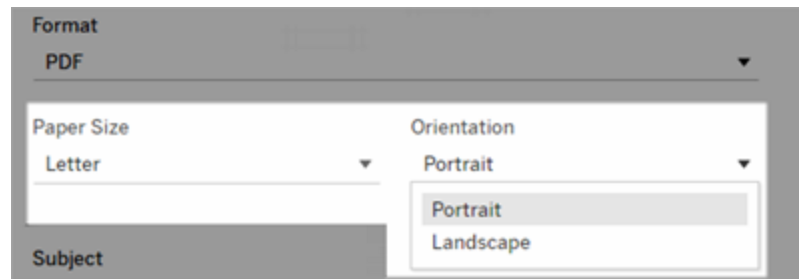

2. Open a view either directly, or after opening the containing workbook.
3. On the view toolbar, select **Watch > Subscriptions**.

4. If you own the workbook, select **Subscribe me**.

Notes:

- When you subscribe a group, each user is added individually at the time the subscription is created. If more users are added to the group later, you must re-subscribe the group for those new users to receive the subscription. Likewise, users later removed from the group will not have their subscriptions removed automatically unless their permissions to the subscribed view are removed.
 - You can't subscribe a group set.
5. Choose whether subscription emails include the current view or the entire workbook. If the view contains data only when high-priority information exists, select **Don't send if view is empty**.
 6. Choose the format for your snapshot: as a PNG image, a PDF attachment or both.
 - If PDFs, choose the paper size and orientation you'd like to receive.

7. To clarify subscription emails, customise the subject line and add a message.

Note: To update the subscription message, you must unsubscribe from the existing subscription and create a new subscription with a different message. For more information, see [Update or unsubscribe from a subscription](#).

8. When the workbook uses one data extract on a published connection, you can pick a frequency:
 - **When Data Refreshes:** Sends only when data in the view or workbook is refreshed by running refresh schedules.
 - **On Selected Schedule:** Pick a schedule for the subscription.
9. Click **Subscribe**.

When you receive a subscription email, you can select the image (or the link in the message body for PDF subscriptions) to be taken to the view or workbook in .

Update or unsubscribe from a subscription

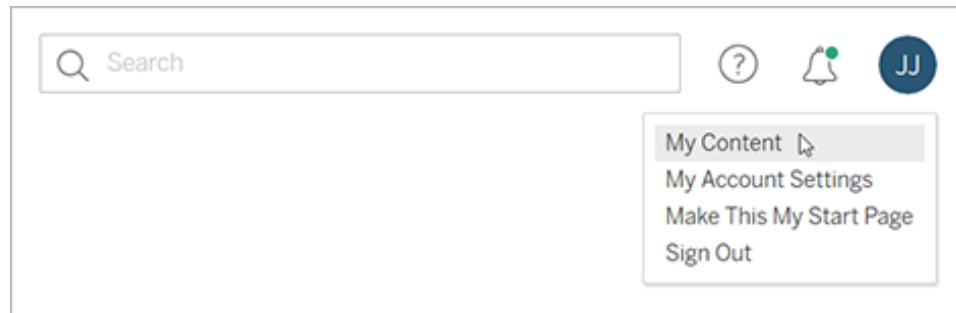

You can unsubscribe from an existing subscription, or make changes to a subscription's format, schedule, subject or empty view mode.

1. Access your account settings by doing one of the following:
 - Click **Manage my subscriptions** at the bottom of a subscription email.

- Sign in to . At the top of the page, select your user icon, and then select **My**

Content.

2. Click **Subscriptions**.
3. Tick the box next to the view you want to unsubscribe from, click **Actions**, and then click **Unsubscribe**, or select the subscription option you'd like to change.

Resume or delete suspended subscriptions

Sometimes, subscriptions fail because of an issue with the workbook or a problem loading the view. If a subscription fails more than five times, you'll receive a notification email that your subscription has been suspended. There are a few ways to resume a suspended subscription if you're a subscription owner or administrator:

- From the My Content area of Tableau web pages, an icon appears in the Last update column to indicate that the subscription is suspended. Select ... > **Resume Subscription** to resume.
- From the Subscriptions tab of the affected workbook, an icon appears in the last update column to indicate that the subscription is suspended. Select ... > **Resume Subscription** to resume.

You'll receive an email notification when the subscription is working again.

See also

[Change subscription settings](#) in the Tableau Desktop and Web Authoring Help.

[Project-level administration](#) in the Tableau Cloud Help, to learn which site roles allow full Project Leader capabilities.

Send Data-Driven Alerts from Tableau Cloud or Tableau Server

When data reaches important thresholds for your business, data-driven alerts automatically send notifications to key people you specify. Data alerts can be sent as an email or as a notification either in your Tableau site or in a connected Slack workspace through the Tableau for Slack application. You can set data-driven alerts on dashboards and views, but not story points.

For time-based charts, use [relative date filters](#) so people automatically receive alerts as new data appears. If you don't own the content, ask the author to make this change.

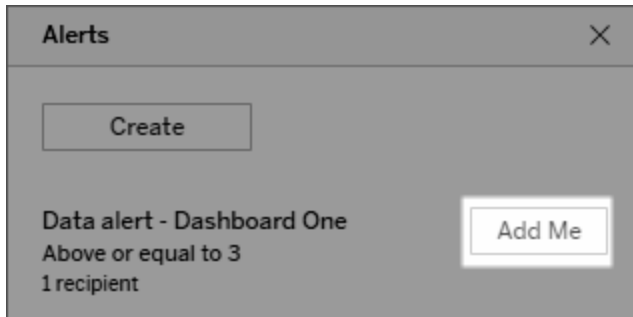

Create a data-driven alert

1. Select a continuous numeric axis of any chart other than a Gantt chart or map. (Numeric bins and discrete numeric axes aren't supported.)
2. Select **Create** from the Alerts side panel.
3. In the view, a red line shows where the threshold falls relative to your current data.

4. Specify the email subject line, schedule and recipients. Select **Make visible to others** if you'd like others users to see your alert and add themselves to it For more information, see [Add yourself to an existing data-driven alert](#) below.
5. Click **Create Alert**.

Add yourself to an existing data-driven alert

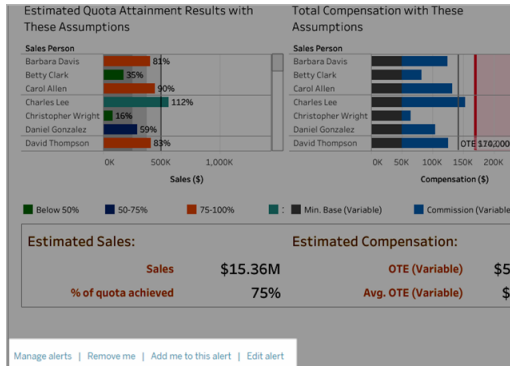

Anyone with access to a view can see alerts created by others. Select the alert to see its details, including its threshold, schedule and notification frequency. Add yourself to the alert by selecting **Add Me**.

Manage your data-driven alerts

You can manage alerts from the [My Content](#) area of Tableau web pages, but doing so directly from alert emails can be quicker. Click the links below the image to manage all your alerts, or add or remove yourself from the emailed alert. If you're the alert owner, click **Edit this alert** to change alert settings such as threshold, schedule and recipients.

Tip: To add recipients to an alert you don't own, you can forward an alert email and ask people to click **Add me to this alert**, or ask them to select **Add Me** from the Alert side panel.

If you are an owner of an alert, you also can manage that alert through the **Actions** menu from the Alerts side panel of the dashboard or view.

Manage your alert notifications

You can receive data-driven notifications as emails in your Tableau site and in a connected Slack workspace through the Tableau for Slack app. For more information, see [Change Notification Settings](#) and [See Tableau notifications in Slack](#).

Fix failing data-driven alerts

Alerts can sometimes fail, usually for these reasons:

- Temporary connectivity issues. In this case, the alert will fix itself.
- A data source has been removed
- Credentials to data have expired
- The workbook or sheet that the alert was created on has been removed.

If an alert fails, you'll receive a notification email that tells you which alert failed and when, with a link to your site to fix the problem.

To fix a failing alert if you're the alert owner, click **Edit this alert** to change alert settings such as threshold, schedule and recipients. A warning will appear to tell you if the workbook or sheet that your alert was created on has been removed.

You'll receive an email notification when the alert is working again.

Resume or delete suspended data-driven alerts

If an alert fails enough times, you'll receive a notification email that your alert has been suspended. There are a few ways to resume a suspended alert if you're an alert owner or administrator:

- From the My Content area of Tableau web pages, an icon appears in the Last checked column to indicate that the alert is suspended. Select ... > **Resume Alert** to resume the alert.
- Click **Resume Alert** in the notification email to resume the alert. A notification will either allow you to resume the alert, or indicate that the view has changed and the alert should be deleted.

You'll receive an email notification when the alert is working again.

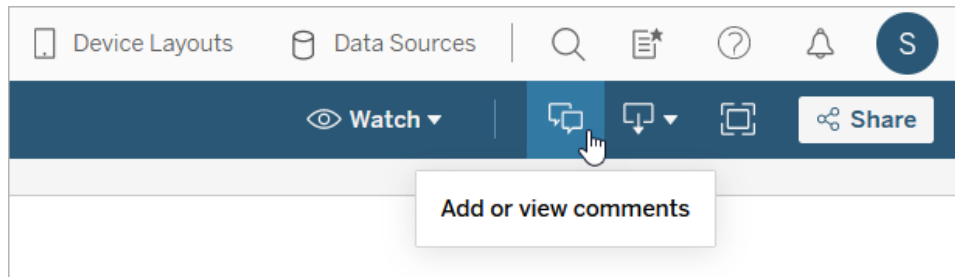

Comment on Views

Comments let you share a conversation about data discoveries with other Tableau Server or Tableau Cloud users.

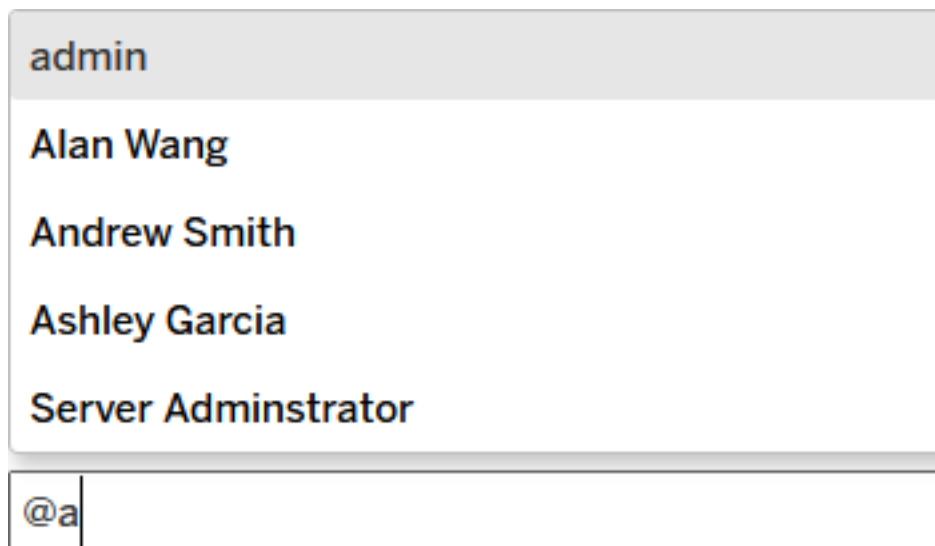

Tip: To keep comments when you republish a workbook, be sure to use the same workbook and view names.

Add comments

1. In the toolbar above a view, click the comments button.

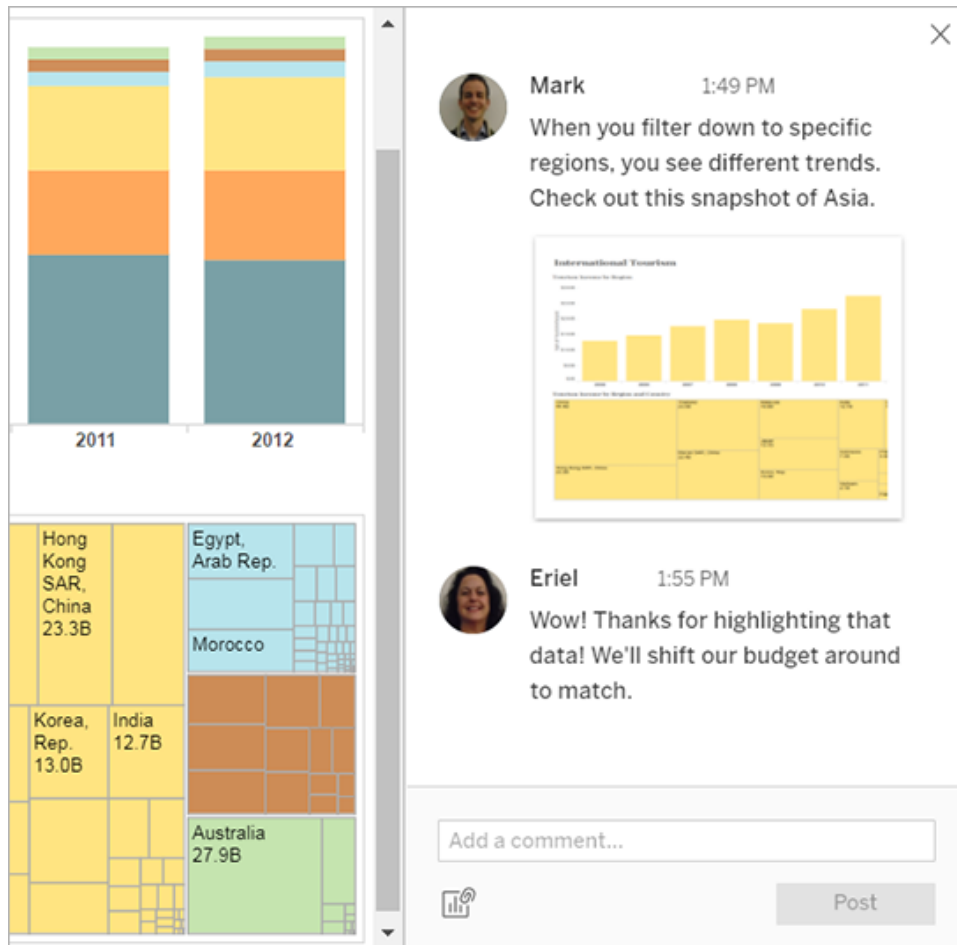

2. In the Comments pane at right, enter your remarks.
3. If you'd like to notify others about the comment, include an @mention. The @mention search shows a maximum of ten users, in alphabetical order. If you have trouble locating someone, try searching for a username instead of a display name, such as, jjohnson instead of Jane Johnson.

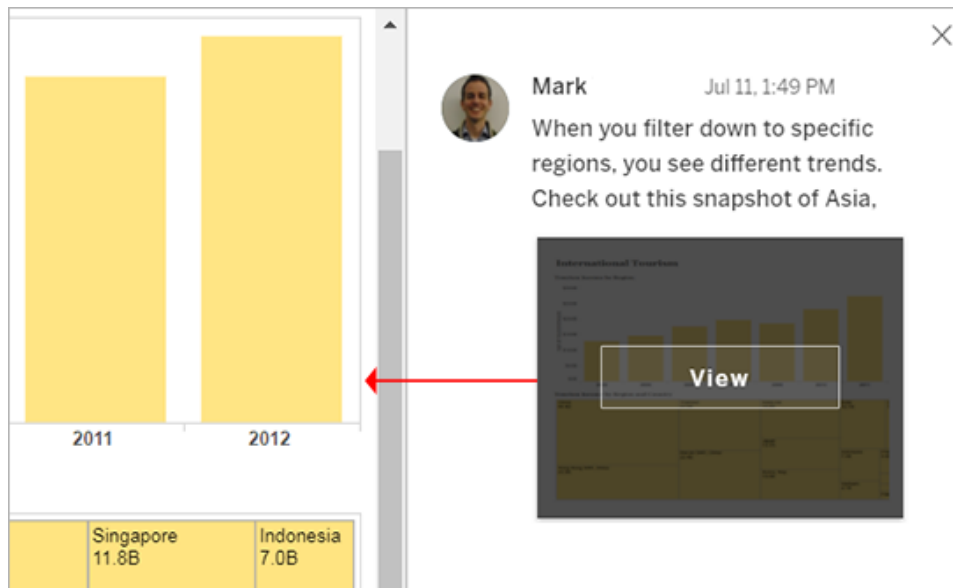

4. If you've filtered the view, click the snapshot icon  to share an interactive image that highlights the data you're describing.

Note: The snapshot icon doesn't appear if a view is **user-filtered**, protecting secure data.

5. Click **Post**.

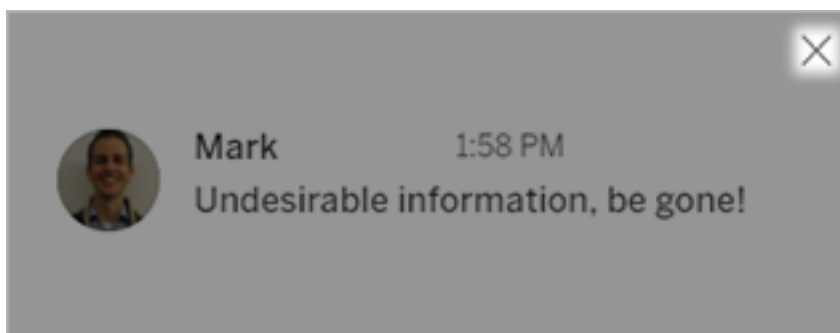

6. To filter a view and see a data snapshot in detail, hover over the thumbnail image, and click **View**.

The person you've mentioned will receive a notification about your comment. Notifications can come by email, in Tableau's in-app notifications centre or in the Tableau for Slack app if the site is connected to a Slack workspace. For more information, see [Manage Your Account Settings](#) on page 3333 and [Receive Notifications, Search and Share Using the Tableau App for Slack](#) on page 3419.

Delete comments

If a comment is unnecessary or inaccurate, you can quickly delete it. Just click the **X** in the upper-right corner.

You can delete a comment if you created it, are the content owner, are a project leader with an appropriate site role, or are an administrator. To learn which site roles are required for full project leader access, see [Project-level administration](#) in the Tableau Cloud Help.

Embed Views and Metrics

Retirement of the legacy metrics feature

Tableau's legacy metrics feature was retired in Tableau Cloud in February 2024 and in Tableau Server version 2024.2. In October 2023, Tableau retired the ability to embed legacy metrics in Tableau Cloud and in Tableau Server version 2023.3. With Tableau Pulse, we've developed an improved experience to track metrics and ask questions of your data. For more information, see [Create Metrics with Tableau Pulse](#) to learn about the new experience and [Create and Troubleshoot Metrics \(Retired\)](#) for the retired feature.

Embed Views into Webpages

The embed code for Tableau Server 2022.3 and later and Tableau Cloud has changed to use the Embedding API v3. This topic contains basic information about getting started with embedding. For comprehensive guidance on embedding Tableau views, see the [Tableau Embedding API help](#). For information about switching from an older version of the Embedding API, see [Migrating from Embedding JSAPI v1 or v2 to Embedding API v3](#).

You can embed interactive Tableau views into web pages, blogs, wiki pages, web applications and intranet portals. Embedded views update as the underlying data changes, or as their workbooks are updated on Tableau Server or Tableau Cloud.

Embedded views follow the same licensing and permission restrictions used on Tableau Server and Tableau Cloud. To see a Tableau view that's embedded in a web page, the person accessing the view must also have an account on the Tableau site it is embedded from. For more information, see [Authentication and Embedded Views](#).

An exception to the account restriction is if your organisation uses a core-based licence on Tableau Server with a Guest account. This allows people to view and interact with Tableau views embedded in web pages without having to sign in to the server. Contact your Tableau administrator to find out if the Guest user is enabled for your Tableau site.

Note: Your Tableau administrator can limit the sites where embedding is allowed or disable embedding entirely. If your embedded view doesn't load, check with your administrator to make sure that the site where you have embedded it is on the embedding allow list. For more information, see [Tableau Site Settings for Embedding](#).

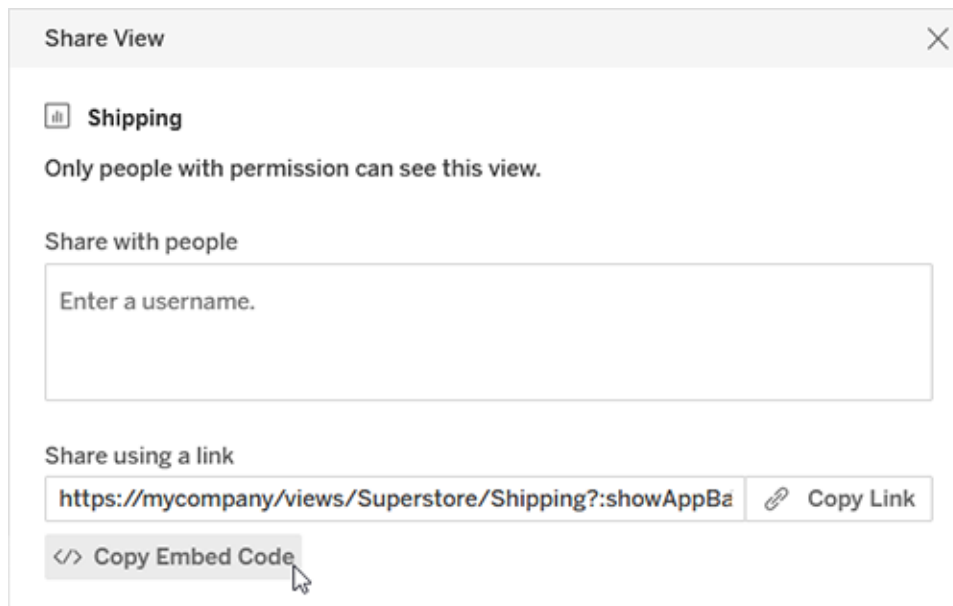

Copy the embed code

The easiest way to embed a view is to copy the embed code provided by Tableau Server or Tableau Cloud. You can access this code from the share dialog on a view.

1. With a view open, click the Share button in the toolbar.

2. Click **Copy Embed Code**, then paste the code into your webpage. To customise your embedded view, use the options documented in the [Tableau Embedding API](#).

Use the Embedding API

To modify the basic embed code that you copied from the share dialog, or to create custom embedded applications, use the [Tableau Embedding API](#). You can use the API to enable single sign-on (SSO) for embedded content and customize and control user access to data with Tableau connected apps, control toolbar options, apply filters, trigger actions for events, enable embedded web authoring and more.

Embed Metrics into Webpages (Retired)

Retirement of the legacy metrics feature

Tableau's legacy metrics feature was retired in Tableau Cloud in February 2024 and in Tableau Server version 2024.2. In October 2023, Tableau retired the ability to embed legacy metrics in Tableau Cloud and in Tableau Server version 2023.3. With Tableau Pulse, we've developed an improved experience to track metrics and ask questions of your data. For more information, see [Create Metrics with Tableau Pulse](#) to learn about the new experience and [Create and Troubleshoot Metrics \(Retired\)](#) for the retired feature.

You can embed metrics to display them alongside other web content, in the context where they are most relevant to your viewers. When you load an embedded metric, you get the freshest data available because you're connecting directly to your data on Tableau Server or Tableau Cloud.

To embed metrics into a webpage, copy the HTML embed code provided on Tableau Server or Tableau Cloud or use the JavaScript example shown below. You can embed multiple metrics on a single page, as long as the metrics come from the same Tableau site.

Embedded metrics work with the same web browsers that are supported by Tableau Cloud and Tableau Server. For a list of supported browsers, see the [Technical Specifications](#). Though embedding is supported by Safari, viewers must turn off "Prevent cross-site tracking" to see embedded content.

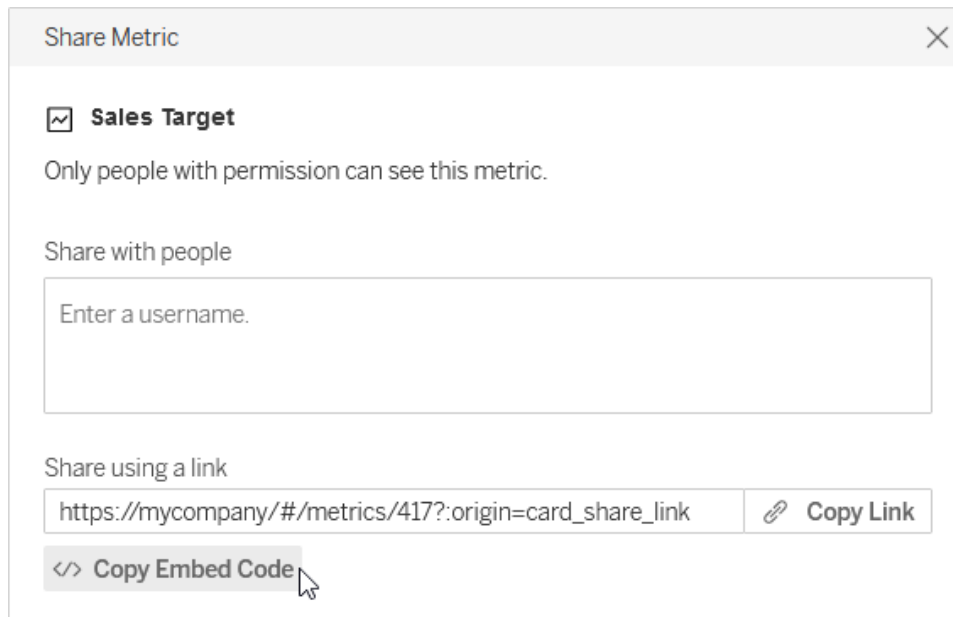

The embed code and parameters for embedded metrics differ from those used for embedded views. For information about embedded views, see [Embed Views into Webpages on page 3362](#).

Note: Your Tableau administrator can limit the sites where embedding is allowed or disable embedding entirely. If your embedded metric doesn't load, check with your administrator to make sure that the site where you have embedded it is on the embedding allow list. For more information, see [Tableau Site Settings for Embedding](#).

Copy the embed code

The fastest way to embed a metric is by copying the embed code provided by Tableau.

1. On Tableau Cloud or Tableau Server, navigate to the details page for the metric that you want to embed.
2. Click the **Share Metric** button.

3. Click **Copy Embed Code**.

4. Paste the embed code into the webpage where you want to embed the metric.

Write your own embed code

When you copy the embed code from Tableau Server or Tableau Cloud, you are copying the HTML embed code, without any optional parameters. If you want more control over the embedded metric, you can either customise the HTML or use the JavaScript example to write your own script.

HTML example

```
<tableau-metric
  src='https://mycompany/#/metrics/1'
  link-target='https://example.com'>
</tableau-metric>
<script type='module' src-
='https://mycompany/javascripts/api/tableau.metric.1.latest.min.js'></-
script>
```

JavaScript example

```
<div id='metricDiv'>
<script type='module'>
```

```
import { TableauMetric } from 'https://-
mycompany/javascripts/api/tableau.metric.1.latest.min.js';

let metric = new TableauMetric();

metric.src = 'https://mycompany/#/metrics/1';
metric.linkTarget = 'https://example.com';document.getElementById
('metricDiv').appendChild(metric);
</script>
```

Parameters for embed code

The parameters for the embed code can be used to customise both the HTML and JavaScript embedding options.

| Parameter | Values | Description | Example |
|--|--------|---|-------------------------------|
| src (required) | string | The URL of the metric on Tableau Server or Tableau Cloud. | https://mycompany/#/metrics/1 |
| link-target (HTML) | string | The URL that viewers will be directed to if they click on the metric. If no target is specified, the embedded metric will link to the source URL. | http://example.com |
| linkTarget (JavaScript) (optional) | | | |

Authentication for embedded metrics

Embedded metrics follow the same licensing and permission restrictions used on Tableau Server and Tableau Cloud. To see an embedded metric, the viewer must sign in to an account on the Tableau site that the metric is embedded from. Unlike embedded views, embedded metrics don't allow for the use of a Guest account to display metrics to viewers who are not signed in.

Viewers who haven't signed in to Tableau Server or Tableau Cloud in another tab will be prompted to sign in from the embedded metric itself. To successfully sign in from an embedded metric, the viewer's browser must be configured to allow third-party cookies.

Embedded metrics support all authentication methods for Tableau Server and Tableau Cloud, with the exception of trusted authentication. For metrics embedded from Tableau Server, the server must use HTTPS to secure communication.

To enable a single sign-on experience for embedded metrics, your Tableau administrator must configure a trust relationship between Tableau Server and an external authorisation server (Tableau Server only) or a Tableau connected app and a webpage. For more information, see [Register EAS to Enable SSO for Embedded Content](#) in the Tableau Server help or [Configure Tableau Connected Apps to Enable SSO for Embedded Content](#) in the Tableau Cloud help.

How metric URLs are structured

To embed a metric, you specify the metric URL and the URL of the JavaScript used to render the metric. Metric URLs follow slightly different patterns on Tableau Cloud, Tableau Server environments with a single site and multi-site Tableau Server environments. If you're not sure how to format the URL, copy the embed code, as it includes both the metric URL and the JavaScript URL.

Metrics must be hosted on Tableau Server or Tableau Cloud. You can't embed a metric from a local file.

Metric URL structure

- **Tableau Cloud site:** `https://<pod>.online.tableau.com/#/site/<sitename>/metrics/<metric>`
- **Tableau Server single site (or the Default site):** `https://<server-name>/#/metrics/<metric>`
- **Tableau Server multi-site:** `https://<server-name>/#/site/<sitename>/metrics/<metric>`

JavaScript URL structure

The metric URL changes based on the site you are embedding from, but the URL for the JavaScript that renders the metric doesn't change because it doesn't include the site.

- **Tableau Cloud site:** `https://<pod>.online.tableau.com/javascripts/api/tableau.metric.1.latest.min.js`
- **Tableau Server:** `https://<server-name>/javascripts/api/tableau.metric.1.latest.min.js`

Writing Embed Code for Views

The embed code for Tableau Server 2022.3 and later and Tableau Cloud has changed to use the Embedding API v3. For current information on how to embed a view with the Embedding API v3, see [Basic Embedding](#) in the [Embedding API help](#). The information in this topic is for prior versions of embedding (using the Tableau JavaScript API v1 and v2).

Writing embed code for prior versions of embedding

If you're writing your own embed code, you can take one of two approaches:

- **Use Tableau JavaScript:** This is the preferred approach. Use the embed code that Tableau generates as the starting point for your own code, adding or editing object parameters that control the toolbar, tabs, and more. The default embed code, which relies on a Tableau JavaScript file, is also the only way to control the load order of multiple embedded views.
- **Specify the View URL:** Embed a view using an iframe or image tag, where the source is the URL you get when you click **Share** on a view and then click **Copy Link**. You may want to do this if you can't use JavaScript on your website. There may also be situations when all you can specify is a URL.

When you embed a view, you should define a width and height that the view will be displayed in. Otherwise, the client browser will arbitrarily pick a width and height.

Note: When you need to specify the server name for Tableau Cloud in embed code (for example, to point to the location of the JavaScript API), use the URL <https://online.tableau.com>.

Use Tableau JavaScript

The following code shows an example of embed code that is generated when you click **Share** on a published view. Special characters in the `host_url` parameter are URL encoded, and those in the `site_root` and `name` parameters are notated as HTML numeric character references.

Tableau Server example:

```
<script type='text/javascript' src-  
='http://myserver/javascripts/api/viz_v1.js'></script>
```

```
= 'display:none; '>
```

Tableau Cloud example:

```
<script type='text/javascript' src-
='https://online.tableau.com/javascripts/api/viz_v1.js'></script>

= 'display:none; '>

value='https%3A%2F%2Fonline.tableau.com%2F' />
```

```
<div class='tableauPlaceholder' id='viz_v1' >
<object class='tableauViz' width=100% height=100%
  <param name='host_url' value='https%3A%2F%2Fonline.tableau.com%2F' />
  <param name='site_root' value='https%3A%2F%2Fonline.tableau.com%2F' />
  <param name='name' value='MyCompany Sales Score Card' />
  <param name='tabs' value='yes' />
  <param name='toolbar' value='yes' />
  <param name='embed' value='yes' />
</object>
</div>
```

The source for the `<script>` tag is the URL for the Tableau Server and Tableau Cloud JavaScript file, **viz_v1.js**. The JavaScript file handles assembling the full URL of the view that's displayed for your users. The `name` and `site_root` object parameters are the only required parameters; all other parameters are optional.

Specify the View URL

Here's an example of embedding the same view using an `iframe`, where the source is the URL you get when you click **Share** on a view and then click **Copy Link**.

Tableau Server example:

```
<iframe src="http://myserver/t/Sales/views/MyCoSales/SalesScoreCard
?embed=yes&tabs=yes&toolbar=yes" width=100% height=100%
t="600"></iframe>
```

Tableau Cloud example:

```
<iframe src=
c="https://online.tableau.com/t/Sales/views/MyCoSales/SalesScoreCard
?embed=yes&:tabs=yes&:toolbar=yes" w
height="600"></iframe>
```

The `embed` URL parameter is required, and you can optionally include parameters that control the toolbar and revert options, among others. You can also add filters to the URL that control the specific data that shows when a view is loaded.

Tip: When using this method, add the HTML attribute `allowfullscreen="true"` to the `iframe` element to enable the Full Screen button on the view.

Embed Code Parameters for Views

The embed code for Tableau Server 2022.3 and later and Tableau Cloud has changed to use the Embedding API v3. For a current list of classes and methods in the Embedding API v3, see the [Embedding API Reference](#) in the [Embedding API help](#). The information in this topic is for prior versions of embedding (using the Tableau JavaScript API v1 and v2).

Parameters for prior versions of embedding

You can configure an embedded view using either of these methods:

- [Object parameters for JavaScript tags below](#)
- [URL parameters for iframe tags on page 3385](#)

Object parameters for JavaScript tags

| Object Para- meter | Val- ues | Descrip- tion | Examples |
|--------------------------|-------------|---|--|
| dataD- etails | no | Hides the Data Details button | <code><param name='dataDetails' value='no' /></code> |

| Object | Parameter | Values | Description | Examples |
|--------|-----------------|--------|---|---|
| | | | in the toolbar, which lets users see details about the data used in that view. | |
| | showDataDetails | yes | If Tableau Catalogue is enabled, it shows the view with the Data Details pane open. | <code><param name='showDataDetails' value='yes' /></code> |
| | alerts | no | Hides the Alerts button in the | <code><param name='alerts' value='no' /></code> |

| Object Para- meter | Val- ues | Descrip- tion | Examples |
|--------------------------|--|--|--|
| | | toolbar, which lets users create data- driven alerts. | |
| cus- tomVi- ews | no | Hides the View button in the toolbar, which lets users save custom views. | <code><param name='customViews' value='no' /></code> |
| device | de- sk- to- p; ta- bl- e- t; ph- on- e | If a dash- board has lay- outs for mobile device- s, dis- plays a specific layout, | <code><param name='device' value='phone' /></code> |

| Object Para- meter | Val- ues | Descrip- tion | Examples |
|--------------------------|-------------|--|----------|
| | | regard- less of screen size. If this para- meter isn't set, Tablea- u Server or Tablea- u Cloud detects screen size and loads a cor- respon- ding layout. See Embed Dash- boards on page 3- 405 for exampl- es. | |

| Object Para- meter | Val- ues | Descrip- tion | Examples |
|--------------------------|-------------|---|---|
| filter | stri- ng | Filters the data displayed when the view opens. You can also filter using URL parameters. | <code><param name='filter' value='Team=Blue' /></code> |
| host_ url | stri- ng | Required. The server name as it appears in the URL. | <code><param name='host_url' value='http://myserver.exampleco.com/'></code> <code><param name="host_url" value="http://localhost/"></code> |
| link- target | stri- ng | The target window name for external hyper- | <code><param name="linktarget" value="_blank"/></code> |

| Object Para- meter | Val- ues | Descrip- tion | Examples |
|--------------------------|------------------|---|--------------------------------------|
| | | links. | |
| load- order | nu- mb- er | When mul- tiple views are embed- ded, determ- ines the order in which they load on the page. Neg- ative num- bers are allowe- d. | <param name="load-order" value="2"/> |
| mobile | ye- s | Dis- plays touch- optim- ised quick fil- ters for mobile | <param name='mobile' value='yes'/> |

| Object Para- meter | Val- ues | Descrip- tion | Examples |
|--------------------------|-------------|--|---|
| | | device- s. | |
| name | stri- ng | Requir- ed object para- meter, with this struc- ture: [work- book name]/ [sheet name]/ [option- al cus- tom view name] Format optiona l custom view names like this: userna me@d | <param name='name' value= ='ExampleCoSales/Sales' /> <param name='name' value='ExampleCoSales/Sales/jsmith@example.com/E astRegionSales' /> |

| Object Para- meter | Val- ues | Descrip- tion | Examples |
|--------------------------|-------------|---|--|
| | | omain/ [custo m view name] | |
| | | If you refer to the Tablea u Server or Tablea u Cloud URL to confirm the value of name, exclud e the session ID (:iid= <n>) at the end of the URL. | |
| :ori- ginal_ view | ye- s | If the name | <param name='filter' value=':original_view- w=yes' /> |

| Object Para- meter | Val- ues | Descrip- tion | Examples |
|--------------------------------|-------------|--|---|
| | | para- meter refers to a work- book or sheet URL (and does not expli- citly refer to a cus- tom view) includ- ing this para- meter dis- plays the view as the ori- ginal view. | |
| path (Tablea u Server | stri- ng | For trusted authen- | <pre><param name='path' value='trusted/Etdpsm_Ew6rJY-9kRrALjauU/views/workbookQ4/SalesQ4' /></pre> <pre>http://tableauserver/trusted/Etdpsm_Ew6rJY-9kRrALjauU/views/workbookQ4/SalesQ4?:embed=yes&:tabs=yes</pre> |

| Object Para- meter | Val- ues | Descrip- tion | Examples |
|--|-------------|---|----------|
| only. Not applica- ble to Tableau Cloud.) | | ticalion only, cannot be used with the ticke- t para- meter. Over- rides value of the name para- meter and is used as the URL. For more inform- ation, see Dis- play the View with the Ticket in the Tablea- u | |

| Object Parameter | Val- ues | Descrip- tion | Examples |
|---------------------|-------------|--|--|
| | | Server Admin- istrator help. | |
| showShareOptions | true; false | Controls whether the Share options are displayed in an embedded view. | <code><param name='showShareOptions' value='true' /></code> |

URL parameters for iframe tags

Note: Before you add URL parameters, remove `:iid=[#]` at the end of the URL. This is a temporary view counter for your current browser session.

| URL Para- meter | Values | Description | Examples |
|--------------------|--------|---|---|
| :dataDe- tails | no | Hides the Data Details button in the toolbar, which lets users see details about the data used in that view. | <code>http://tabserver/views/Date- Time/DateCalc- s?:embed=yes&:dataDetails=no</code> |

| URL Parameter | Values | Description | Examples |
|------------------|------------------------|--|---|
| :showDataDetails | yes | If Tableau Catalogue is enabled, it shows the view with the Data Details pane open. | <code>http://tabserver/views/Date-Time/DateCalcs?s?:embed=yes&:showDataDetails=yes</code> |
| :alerts | no | Hides the Alerts button in an embedded view. | <code>http://tabserver/views/Date-Time/DateCalcs?s?:embed=yes&:alerts=no</code> |
| :customViews | no | Remember my changes option. | <code>http://tabserver/views/Date-Time/DateCalcs?s?:embed=yes&:customViews=no</code> |
| :device | desktop; tablet; phone | If a dashboard has layouts for mobile devices, displays a specific layout, regardless of screen size. If this parameter isn't set, Tableau Server or Tableau Cloud detects screen size and loads a corresponding layout. See Embed Dashboards on page 3405 for | <code>http://tabserver/views/sales/sales_dashboard?s?:device=tablet</code> |

| URL Parameter | Values | Description | Examples |
|---|-------------|--|---|
| | | examples. | |
| :display_count (Tableau Public only) | yes | Shows the total number of pageviews when you click the Tableau logo at the lower left. | https://public.tableau.com/en-us/s/gallery/what-emoji-say-about-music?:display_count=yes |
| :embed | yes | Required URL parameter. Hides the top navigation area, better blending of the view into your web page. | http://tabserver/views/Date-Time/DateCalcs?:embed=yes |
| :format | pdf; png | Displays a view as a PDF or .png file. | http://tabserver/views/Sales/Q2?:format=pdf |
| :highdpi | false | Renders a view using standard DPI (dots per inch) for high-resolution displays and devices. | http://tabserver/views/Sales/Q2?:highdpi=false |
| :link-target | string | The target window name for external hyperlinks. | http://tabserver/views/Date-Time/DateCalcs?:embed=yes&:linktarget=_blank |

| URL Parameter | Values | Description | Examples |
|--------------------|--------|--|--|
| :openid_hd | string | Used when authenticating with OpenID Connect. Specifies the hosted domain to which a user belongs. For example, you might use this option if you do not want to render the domain selection pane. Used in conjunction with :openid_login_hint to specify the full user identifier. | http://t- abserver/views/Sales/Q2?:openid_ hd=example.com |
| :openid_login_hint | string | Used when authenticating with OpenID Connect. Specifies the full user identifier (email address). Used in conjunction with :openid_hd to specify the hosted domain to | http://t- abserver/views/Sales/Q2?:openid_ login_hint=tara@example.com |

| URL Parameter | Values | Description | Examples |
|--|--------|---|--|
| | | which the user belongs. | |
| :record_performance (Tableau Server only. Not applicable to Tableau Cloud.) | yes | Starts a performance recording for a view. Add this at the end of the URL, immediately before the session ID (:iid=<n>). For more information, see Create a Performance Recording in Tableau Server help. | http://tabserver- abserver- /views/Sales2013/Re- gions?:recordperformance=yes |
| :refresh | yes | Renders the view using the latest data from Tableau Server or Tableau Cloud. | http://tabserver/views/Date- Time/DateCalc- s?:embed=yes&:refresh=yes |

Tip: To continually refresh a view, in the <head> section

| URL Parameter | Values | Description | Examples |
|---------------|---------------------|--|--|
| | | <div>of the web page, add <meta http-equiv="refresh" content="#">, where # is the number of seconds between refreshes.</div> | |
| :render | true; false; number | <div>If client-side rendering is enabled (the default), setting this to <code>false</code> forces server-side rendering for the session. Setting this to <code>true</code> forces client-side rendering for the session.</div> | <div>http://tabserver/views/DateTime/DateCalcs?:render=false</div> |

| URL Parameter | Values | Description | Examples |
|----------------|---|---|---|
| | | A number from 1 to 100 can be entered to set the complexity threshold above which views are rendered by the server. For more information, see About Client-Side Rendering in Tableau Server help. | |
| :revert | all; fil- ter- s; sort- s; axe- s; shel- ves | Returns the item to its original state. | <code>http://tabserver/views/Date-Time/DateCalcs?:embed=yes&:revert=all</code> |
| :showAppBanner | fals- e | Hides the “Open in Tableau Mobile” banner in mobile web browsers. | <code>http://tabserver/views/Date-Time/DateCalcs?:embed=yes&:showAppBanner=false</code> |

| URL Parameter | Values | Description | Examples |
|---------------------------------------|--------------|--|---|
| :showAskData | false | Hides the Ask Data button in the toolbar in an embedded view. By default the Ask Data button displays. | http://tabserver/views/Date-Time/DateCalcs?s?:embed=yes&:showAskData=false |
| :showShareOptions | true; false | Controls whether the Share options are displayed in an embedded view. | http://tabserver/views/Date-Time/DateCalcs?s?:embed=yes&:showShareOptions=true |
| :showVizHome (Tableau Public only) | yes; no | Shows or hides the content navigation interface of Tableau Public. Set to no when embedding vizzes in other web pages. | https://public.tableau.com/en-us/s/gallery/what-emoji-say-about-music?s?:showVizHome=no |
| :subscriptions | no | Hides the Subscribe button in an embedded view. | http://tabserver/views/Date-Time/DateCalcs?s?:embed=yes&:subscriptions=no |
| :tabs | yes; no | Displays or hides tabs. | http://tabserver/views/Date-Time/DateCalcs?s?:embed=yes&:tabs=no |
| :toolbar | yes; no; top | The toolbar is displayed by default on the | http://tabserver/views/Date-Time/DateCalcs?s?:embed=yes&:toolbar=no |

| URL Parameter | Values | Description | Examples |
|-----------------------|---------------------------------------|---|---|
| | | bottom when this parameter is not set. When <code>no</code> the toolbar is excluded from the embedded view. When <code>top</code> , the toolbar is placed above the view. | |
| <code>:tooltip</code> | <code>yes</code> ; <code>no</code> | Tooltips are displayed by default in a view when this parameter is not set. If set to <code>no</code> , tooltips are excluded from the embedded view. | <code>http://tabserver- /views/- work- bookQ4/SalesQ4?:embed=yes&:tooltip=no</code> |

Add Filters to Embed Code for Views

The embed code for Tableau Server 2022.3 and later and Tableau Cloud has changed to use the Embedding API v3. For current information about filtering, see [Filter the View](#) in the [Embedding API help](#). The information in this topic is for prior versions of embedding (using the Tableau JavaScript API v1 and v2).

Filter using prior versions of embedding

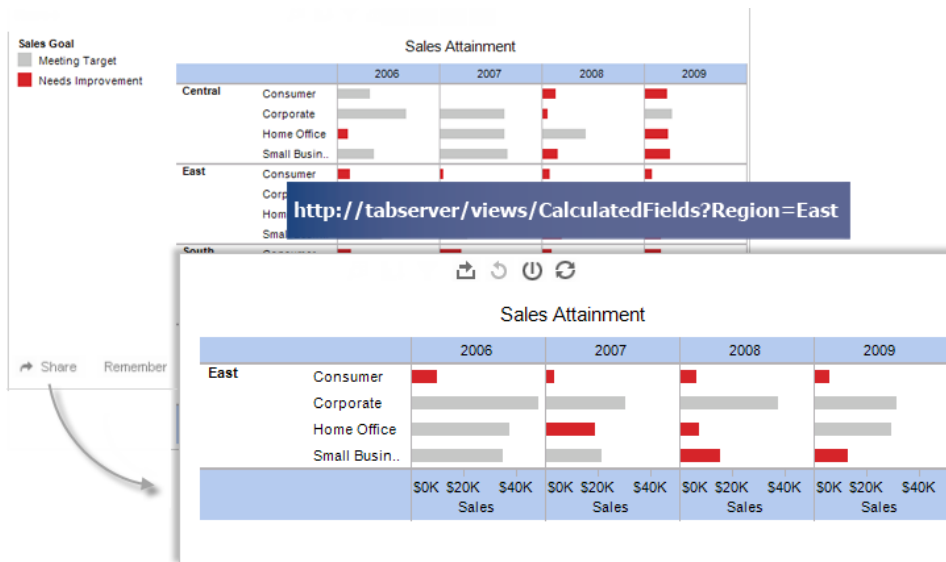

You can include filter values in embedded views so they highlight just the data you want. For example, you may want to include a hyperlink from another part of your web application to an

embedded sales performance view that shows only a specific region.

Note: Stories don't support embedded filters.

Filter on one field

Passing a filter on one field is a quick way to focus an embedded view on specific data.

Script tag example:

```
<script type='text/javascript' src-
='http://myserver/javascripts/api/viz_v1.js'>
</script>
<object class='tableauViz' width='800' height='600' style-
='display:none;'>
  <param name='host_url' value='http://myserver/' />
  <param name='site_root' value='' />
  <param name='name' value='Superstore/Product' />
  <param name='filter' value='Region=East' />
</object>
```

To pass through multiple filter values, just separate each with a comma. For example:

```
<param name='filter' value='Region=East,West' />
```

Iframe tag examples:

```
<iframe src-
c="http://myserver/views/Superstore/Product?:embed=y&Region=East,West"
width="800" height="600"></iframe>
```

Filter on multiple fields

You can pass filters on as many fields as you want, including fields that are not in visible the original view.

Script tag example:

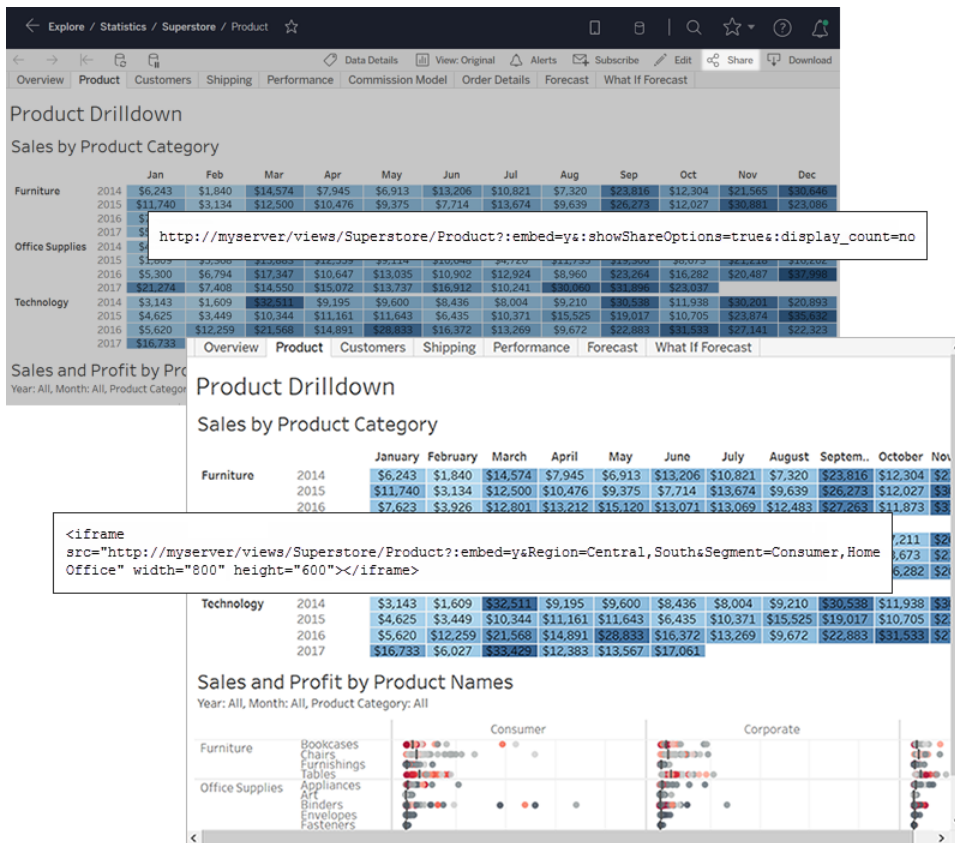

```
<script type='text/javascript' src-
='http://myserver/javascripts/api/viz_v1.js'>
</script>
<object class='tableauViz' width='800' height='600' style-
='display:none;'>
  <param name='host_url' value='http://myserver/' />
  <param name='site_root' value='' />
  <param name='name' value='Superstore/Product' />
  <param name='filter' value='Region=Central,South&Customer Seg-
ment=Consumer,Home Office' />
</object>
```

Iframe tag example:

```
<iframe src-
="h-
ttp://myserver-
/views/Su-
perstore/Product?:embed=y&Region=Central,South&Segment=Consumer,Home
Office"
width="800" height="600"></iframe>
```

The first image below shows an example of the URL you get when you click **Share** on a view and then click **Copy Link**.

The second image shows how you might modify the URL and add it to an iframe by deleting the `showShareOptions` and `display_count` parameters, adding filter parameters for Region and Segment, and adding width and height parameters, to create an embed link that displays only Consumer and Home Office products from the Central and South regions.

Note: If a filter value contains a special character, such as a comma, replace the character with the URL encoding sequence for \ (backslash, %5c) followed by the URL encoding sequence for the special character. The backslash is needed to escape the special character. For example, the URL encoding sequence for \, (backslash, comma) is %5c%2c.

Filter dates and times

If you want to filter on a Date/Time field, include the value using the default Tableau format shown below:

yyyy-mm-dd hh:mm:ss

The time part uses a 24-hour clock. Many databases store all date values as Datetime fields, so you may need to pass a time value along with your date.

Script tag example:

```
<script type='text/javascript' src-  
='http://myserver/javascrpts/api/viz_v1.js'></script>  
<object class='tableauViz' width='800' height='600' style-  
='display:none;'>  
  <param name='host_url' value='http://myserver/' />  
  <param name='site_root' value='' />  
  <param name='name' value='Sales/Sales-Performance' />  
  <param name='filter' value='Date=2012-12-01' />  
</object>
```

This example filters on both a date field and a datetime field:

```
<param name='filter' value='2012-12-01%2022:18:00' />
```

Iframe tag example:

```
<iframe src="http://myserver/Sales/SalesPer-  
formance?:embed=yes&Date=2008-12-01%2022:18:00" width="800" height-  
t="600"></iframe>
```

To filter multiple dates, separate each date with a comma.

Filter measures

You can filter measures by including one or more values. There is no support for greater than, less than or ranges. The example below filters to show only \$100 and \$200 sales.

Script tag example:

```
<script type='text/javascript' src-  
='http://myserver/javascrpts/api/viz_v1.js'>  
</script>  
<object class='tableauViz' width='800' height='600' style-  
='display:none;'>  
  <param name='host_url' value='http://myserver/' />  
  <param name='site_root' value='' />  
  <param name='name' value='Sales/Sales-Performance' />  
  <param name='filter' value='Profit=100, 200' />  
</object>
```

Iframe tag example:

```
<iframe src="http://myserver/views/Sales/Sales-Per-
formance?:embed=yes&Profit=100,200"
width="800" height="600"></iframe>
```

How View URLs Are Structured

The embed code for Tableau Server 2022.3 and later and Tableau Cloud has changed to use the Embedding API v3. With the Embedding API v3, you no longer add parameters to view URLs to filter when embedding. Instead you filter by adding attributes to a filter web component. For more information, see [Filter the View](#) in the [Embedding API help](#). The information in this topic is for prior versions of embedding (using the Tableau JavaScript API v1 and v2).

To understand how Tableau structures view URLs, let's take a close look at an example in the browser address bar.

The structure of the base URL

- In Tableau Server or Tableau Cloud, the basic URL pattern for a Tableau view is:
`http://<servername>/#/views/<workbook>/<sheet>`
- In a multi-site environment, for views saved to sites other than Default, the site ID is also included in the URL:
`http://<servername>/#/site/<sitename>/views/<workbook>/<sheet>`

Filter with URL parameters using prior versions of embedding

Adding parameters to the base URL

Appending a query string

To create a filtering URL, you append a *query string* to the base URL. In a query string, the view filters are the parameters. To construct a query string:

- Begin the query string with a question mark (?).
- Separate the parameters using ampersands (&).
- Separate multiple values per parameter using commas (,).

For example:

```
http://<servername>/#/views/<workbook>/sheet
?param1=value1,value2&param2=value
```

In addition, any characters in your field or sheet names that cannot appear in URLs are URL-encoded. For example, a space is converted to %20.

Note: Before you add URL parameters, remove `:iid=[#]` at the end of the URL. This is a temporary view counter for your current browser session.

Reflecting the capitalisation of field names

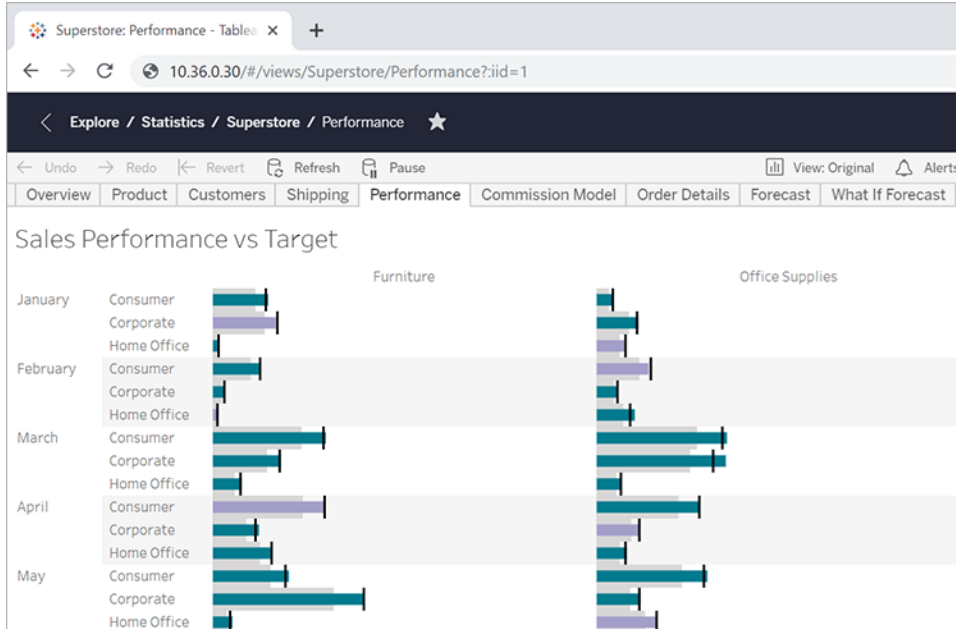

URL parameters are case-sensitive. When you append query strings, be sure to precisely reflect the capitalisation of field names in your source data.

How query strings affect dashboards

Unlike visible filters in a dashboard, which sometimes affect only one sheet, URL parameters apply to all sheets. Before appending URL parameters, become familiar with the fields shown in each sheet to avoid accidentally filtering out data you'd like to retain.

Select an example view to work with

The examples in this article use the Performance view, in the Superstore sample data that comes with Tableau Server.

The example URL reflects the following attributes:

- The sheet name is **Performance**
- The workbook name is **Superstore**
- The server name is indicated using a placeholder IP address, where your on-premise server name or `online.tableau.com` would appear.

To follow along with the examples, you can look at a similar view from Superstore, or you can adjust the example URLs to use the field, sheet, and other names from your own environment. If you are using your own view, make sure you first publish it to the server.

Filter the view

For the example view used in this article, the base URL is:

`http:<servername>/#/views/Superstore/Performance`

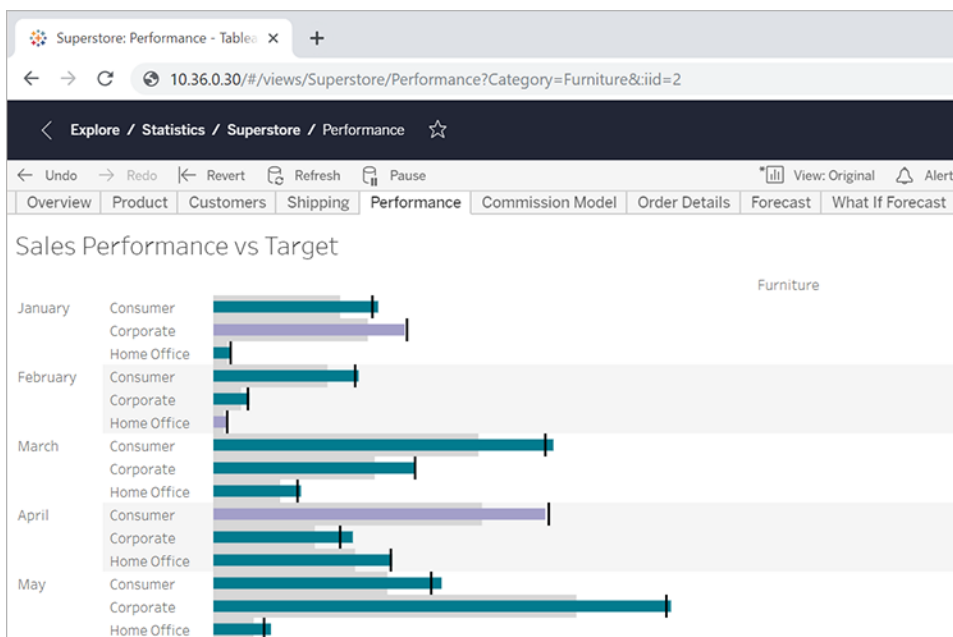

Furniture only

To display only sales of furniture, at the end of the URL, add the following query string:

`?Category=Furniture`

For example:

`http:<servername>/#/views/Superstore/Performance?Category=Furniture`

Consumer only

To limit the view to Consumer sales, change the URL to:

`http:<servername>/#/views/Superstore/Performance?Segment=Consumer`

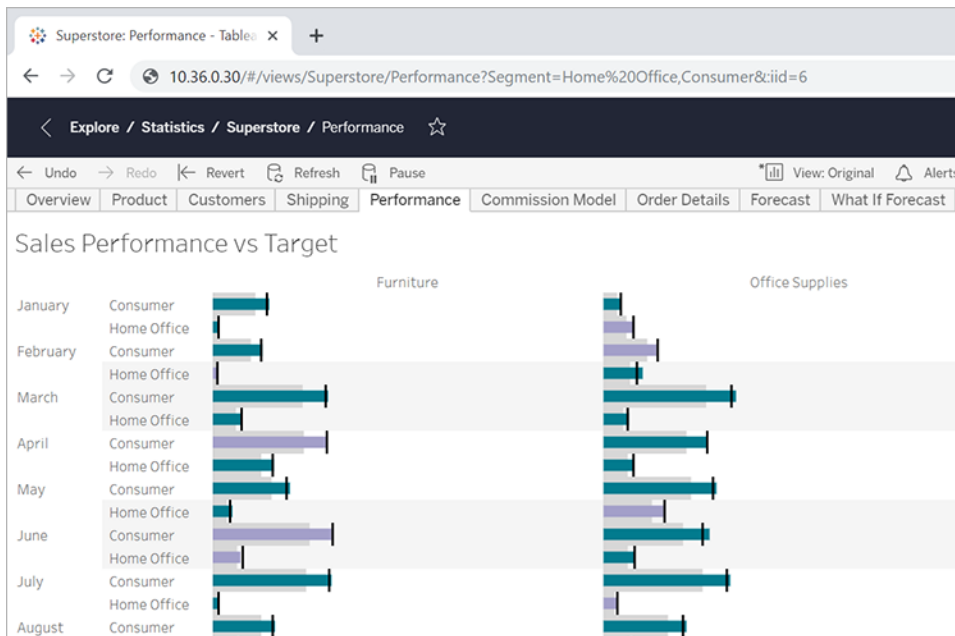

Home Office and Consumer

To show both home office and consumer sales, change the URL to:

`http:<servername>/#/views/Superstore/Performance
?Segment=Home%20Office,Consumer`

Notice that in the field name "Home Office," %20 represents the URL-encoded space character, as described in [Adding parameters to the base URL on page 3398](#).

Here multiple values per parameter are separated with a comma, but not a space.

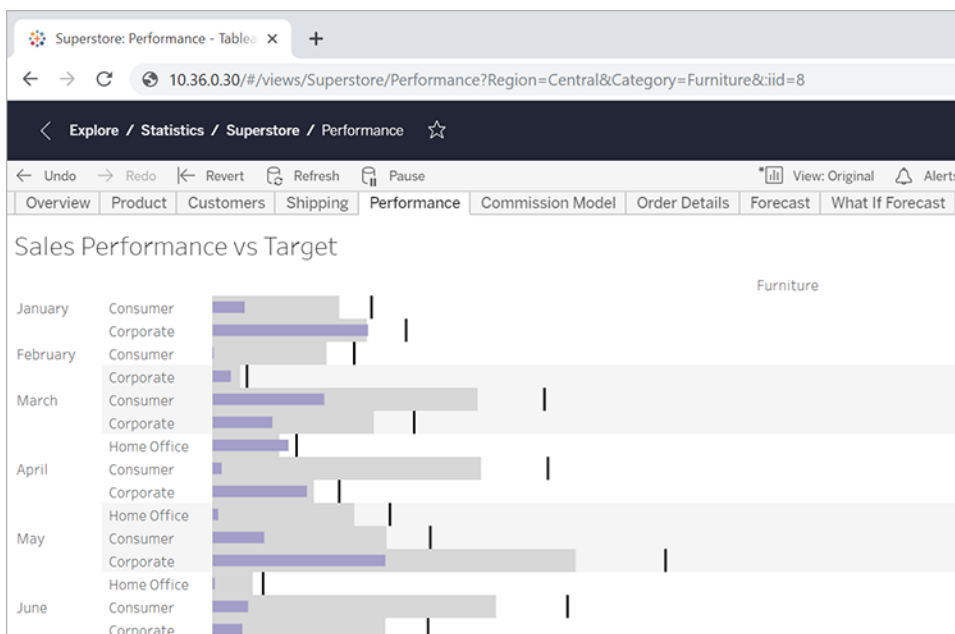

Furniture in the Central

To show multiple field/value pairs, separate them with an ampersand:

`http:<servername>/#/views/Superstore/Performance`

?Region=Central&Category=Furniture

Exclusive filtering

So far, the examples shown in this article display all values for the fields in the resulting views. For more flexibility, you can specify multiple values for a specific filter, and include an additional parameter that displays only particular intersections of those values.

The following URL describes the base, unfiltered view used in this example, showing department sales by region:

```
http://<servername>/#/views/Superstore/Performance
```

Next, to show sales for only the Furniture and Technology departments in the Central and West regions, you would add the following query string to the base URL:

```
?Region=Central,West&Category=Furniture,Technology
```

To show only Furniture sales in the Central region and Technology sales in the West region, add the `~s0` parameter to the query string:

```
?Region~s0=Central,West&Category~s0=Furniture,Technology
```

The final URL looks like this:

```
http://<servername>/#/views/Superstore/Performance?Region~s0=Central,West&Category~s0=Furniture,Technology
```

Special considerations for date filtering

When you want to filter date fields, take into account how dates are formatted and behave in a database environment.

- Date (and time) values passed via URL parameter need to match the following Tableau default format:
`yyyy-mm-dd hh:mm:ss`
- Many databases store dates as datetime values, so you may need to include a time part in the value you provide in the parameter. The time part is based on a 24 hour clock, so 10:18 pm is specified as 22:18:00.

Example date parameters

The following example query strings use a date field called **Order Date**. As in the previous examples in this article, you would add these to the base URL of your view.

- If the Order Date field type includes only the date (with no time of day), and you want to show data only for July 8, 2018, the query string would look something like this:
`?Order%20Date=2018-07-08`

- If Order Date includes the time part, to filter on July 8, 2018 at 10:18 pm, the query string might look like this:

```
?Order%20Date=2018-07-08%2022:18:00
```

- If Order Date is only the date, and you want to filter on multiple dates, you would use commas, as described earlier in this article. For example:

```
?Order%20Date=2018-07-08,2018-07-09,2018-07-10,2018-07-11
```

Parameters as DATEPART filters

To filter by date part, use the same nomenclature as in the default Tableau Desktop date hierarchy. For more information, see [Date Functions](#) in the Tableau Help.

| | |
|------------------------------------|-------------------------------|
| <code>year(Order%20Date)</code> | Integer |
| <code>quarter(Order%20Date)</code> | Integer between 1 and 4 |
| <code>month(Order%20Date)</code> | Integer between 1 and 12 |
| <code>day(Order%20Date)</code> | Integer between 1 and 31 |
| <code>hour(Order%20Date)</code> | Integer 0–23 |
| <code>minute(Order%20Date)</code> | Integer 0-59 |
| <code>second(Order%20Date)</code> | Integer 0-59 |
| <code>week(Order%20Date)</code> | Integer 1-53 |
| <code>my(Order%20Date)</code> | Six-digit integer: YYYYMM |
| <code>mdy(Order%20Date)</code> | Eight-digit integer: YYYYMMDD |

Control Load Order for Multiple Embedded Views

The embed code for Tableau Server 2022.3 and later and Tableau Cloud has changed to use the Embedding API v3. For current information about embedding, see the [Embedding API help](#). The information in this topic is for prior versions of embedding (using the Tableau JavaScript API v1 and v2).

Control load order using prior versions of embedding

You can control the order in which multiple views load for the people working with your views. This feature can be accessed only using embed code that relies on the Tableau JavaScript file.

In the following example, two views are embedded. The second view loads first, followed by the top view. If you embed multiple views and give them all the same load order value, or if you don't specify load order parameters, they are loaded in the order in which they appear on the page.

Script Tag Example

```
<script type='text/javascript' src-  
='http://myserver/javascripts/api/viz_v1.js'>  
</script>  
<object class='tableauViz' width='600' height='400' style=  
='display:none;'>  
  <param name='host_url' value='http://myserver/' />  
  <param name='site_root' value='' />  
  <param name='name' value='MyCoSales/TopPerformers' />  
  <param name='tabs' value='yes' />  
  <param name='toolbar' value='yes' />  
  <param name='filter' value='Salesperson=Top 5' />  
  <param name='load-order' value='0' />  
</object>  
<script type='text/javascript' src-  
='http://myserver/javascripts/api/viz_v1.js'>  
</script>  
<object class='tableauViz' width='600' height='400' style=  
='display:none;'>  
  <param name='host_url' value='http://myserver/' />  
  <param name='site_root' value='' />  
  <param name='name' value='MyCoSales/SalesScoreCard' />  
  <param name='tabs' value='yes' />  
  <param name='toolbar' value='yes' />  
  <param name='load-order' value='-1' />  
</object>
```

Embed Dashboards

The embed code for Tableau Server 2022.3 and later and Tableau Cloud has changed to use the Embedding API v3. For current information about device specific layouts and dashboard sizing,

see [Configure Embedding Objects and Components](#) in the [Embedding API help](#). The information in this topic is for prior versions of embedding (using the Tableau JavaScript API v1 and v2).

Embed dashboards using prior versions of embedding

You can embed a Tableau dashboard in your own web site or wiki page and you can have it display in different layouts based on the size of the iframe.

- To automatically make the right layout appear for your users, regardless of which device they are using, create device-specific layouts for your dashboard in Tableau Desktop. When you do, Tableau Server and Tableau Cloud automatically display the correct layout based on iframe size, provided you use 100% for the iframe's width and height instead of exact pixel values (see below).
- To always make a certain layout appear, regardless of iframe size, use the `device` parameter in your embed code.

In the following example, the embed code displays a dashboard that's 800 pixels wide by 600 pixels high. Exact width and height values are part of the default embed code you get when you click the **Share** button at the top of a view or dashboard:

```
<script type='text/javascript' src-
='http://mysite.myserver.com/javascripts/api/viz_v1.js'></script>
  <div class='tableauPlaceholder' style='width: 800px; height:
600px;' >
    <object class='tableauViz' width='800' height='600' style-
='display:none;'>
      <param name='host_url' value='http://mysite.myserver.com' />
      <param name='site_root' value='' />
      <param name='name' value='ProfitAnalysis/Sales_Dashboard' />
      <param name='tabs' value='yes' />
      <param name='toolbar' value='yes' />
      <param name='filter' value=':original_view=yes' /></object></div>
```

In this example, where the dashboard uses device-specific layouts, the style attributes for the div class have been removed and the object class values for width and height have been replaced with 100%. In most cases, the correct layout displays; that is, if width and height aren't also being controlled elsewhere in your CSS.

```

<script type='text/javascript' src-
='http://mysite.myserver.com/javascrpts/api/viz_v1.js'></script>
  <div class='tableauPlaceholder' >
    <object class='tableauViz' width='100%' height='100%' style-
='display:none;'>
      <param name='host_url' value='http://mysite.myserver.com' />
      <param name='site_root' value='' />
      <param name='name' value='ProfitAnalysis/Sales_Dashboard' />
      <param name='tabs' value='yes' />
      <param name='toolbar' value='yes' />
      <param name='filter' value=':original_view=yes' /></object></div>

```

If the correct layout doesn't display, it may be because the HTML page you're using for embedding has a `<!DOCTYPE html>` tag, and that tag is preventing items in the body of the page from resizing to 100% (see [details on Stack Overflow](#)). A workaround is to add the following lines to the body of your HTML page:

```

<style>
  html, body { height: 100% }
</style>

```

The following example assumes that the embedded dashboard has device-specific layouts. The `device` parameter is set to `phone`. This means that, no matter which device displays the dashboard, the layout created for phones will be the one that's displayed.

```

<script type='text/javascript' src-
='http://mysite.myserver.com/javascrpts/api/viz_v1.js'></script>
  <div class='tableauPlaceholder'>
    <object class='tableauViz' width='100%' height='100%' style-
='display:none;'>
      <param name='host_url' value='http://mysite.myserver.com' />
      <param name='site_root' value='' />
      <param name='name' value='ProfitAnalysis/Sales_Dashboard' />
      <param name='device' value='phone' />
      <param name='tabs' value='yes' />
      <param name='toolbar' value='yes' />
      <param name='filter' value=':original_view=yes' /></object></div>

```

Iframe dimensions and device layouts

The dashboard layout a device displays is based on the smallest dimension (height or width) of the iframe in which the Tableau view appears. Sometimes Desktop, Tablet or Phone layouts may appear on other types of devices. For example, a Tablet layout may appear on a desktop computer if the display or browser window is small.

| If the smallest iframe dimension is... | This device layout appears... |
|--|-------------------------------|
| 500 pixels or less | Phone |
| Between 501 and 800 pixels | Tablet |
| Greater than 800 pixels | Desktop |

For details on how to create a dashboard that uses device-specific layouts, see [Create Dashboard Layouts for Different Device Types](#) on page 2778.

Embed Code for Custom Views

The embed code for Tableau Server 2022.3 and later and Tableau Cloud has changed to use the Embedding API v3. For current information on embedding custom views, see [Embed Custom Views](#) in the [Embedding API help](#). The information in this topic is for prior versions of embedding (using the Tableau JavaScript API v1 and v2).

Embed custom views using prior versions of embedding

When you embed a custom view of a workbook or sheet, the default view is determined by these factors:

- If the embed code URL specifically refers to a custom view, that view is displayed by default.
- If the embed code URL does not refer to a custom view, the Default custom view is displayed by default.
- If no Default custom view has been defined, the original view is displayed by default.

Note: To ensure the original view will be displayed by default in an embedded view, make sure the embed code URL for the name parameter does not explicitly refer to a custom

view, and include the following `filter` parameter in the embed code: `<param name='filter' value=':original_view=yes' />`.

In the following example, the embed code will always display the original view of the Profit Analysis sheet in the Profit Analysis workbook, because the `filter` parameter is set to `:original_yes`, and the `name` parameter does not refer to a specific custom view in the URL for the sheet.

```
<script type='text/javascript' src-
='http://mysite.myserver.com/javascripts/api/viz_v1.js'></script>
  <div class='tableauPlaceholder' style='width: 1496px; height:
749px;'>
    <object class='tableauViz' width='1496' height='749' style-
='display:none;'>
      <param name='host_url' value='http://mysite.myserver.com' />
      <param name='site_root' value='' />
      <param name='name' value='ProfitAnalysis/ProfitAnalysis' />
      <param name='tabs' value='yes' />
      <param name='toolbar' value='yes' />
      <param name='filter' value=':original_view=yes' /></object></div>
```

In this example, the setting for the `name` parameter in this example specifically refers to the URL for a custom view named Furniture (in the Profit Analysis sheet in the Profit Analysis workbook).

```
<script type='text/javascript' src-
='http://mysite.myserver.com/javascripts/api/viz_v1.js'></script>
  <div class='tableauPlaceholder' style='width: 1496px; height:
749px;'>
    <object class='tableauViz' width='1496' height='749' style-
='display:none;'>
      <param name='host_url' value='http://mysite.myserver.com' />
      <param name='site_root' value='' />
      <param name='name' value='ProfitAnalysis/ProfitAnalysis/Furniture'
/>
      <param name='tabs' value='yes' />
      <param name='toolbar' value='yes' /></object></div>
```

In this example, the `name` parameter does not refer to a specific custom view in the URL for the sheet, and the `original_view` parameter has not been specified. The embed code here will display the custom view that has been set to Default in the Profit Analysis sheet in the Profit Analysis workbook. However, if the original view is still the Default (no other custom view has been set to Default), then the original view will be displayed as the default view.

```
<script type='text/javascript' src-
='http://mysite.myserver.com/javascripts/api/viz_v1.js'></script>
  <div class='tableauPlaceholder' style='width: 1496px; height:
749px;'>
    <object class='tableauViz' width='1496' height='749' style-
='display:none;'>
      <param name='host_url' value='http://mysite.myserver.com' />
      <param name='site_root' value='' />
      <param name='name' value='ProfitAnalysis/ProfitAnalysis' />
      <param name='tabs' value='yes' />
      <param name='toolbar' value='yes' /></object></div>
```

Embed Views into Wikis

You can easily embed a view into a wiki or other web page simply by putting the view inside an `<iframe>` tag.

1. Navigate to the wiki page you want to embed a view into.
2. Edit the page and add an `<iframe>` where the source is the URL you get when you click **Share** on a view and then click **Copy Link**. For example:

```
<iframe src="http://myserver/views/Date-Time/DateCalc-
s?:embed=yes&:toolbar=no"
width="800" height="600"></iframe>
```

3. Save your changes.

If you use Tableau Server and both it and the wiki are configured to use Active Directory to automatically authenticate users, they will immediately see the view. Otherwise, users

will be asked to sign in before they can see the view.

Embed Images of Tableau Server Views

In addition to embedding a view into a `<script>` or `<iframe>` tag you can also embed the view as an image. When you embed an image the view is not interactive; however, it is updated every time the page fully reloads, showing the latest data.

Note: This approach works only if users accessing the embedded image have an active web browser session with Tableau Server and are automatically signed in using Active Directory.

1. Navigate to the page where you want to embed the image.
2. Edit the page and add an `` tag where the source is the URL you get when you click **Share** on a view and then click **Copy Link**. For example:

```

```

Embed Tableau Views into Salesforce

The Tableau Viz Lightning web component was retired from Salesforce AppExchange in May 2024 and replaced by the Tableau View native component. For more information, see [Configure Tableau Lightning Web Components and Single Sign-On \(SSO\) with Token Authentication](#).

You can easily embed Tableau views into Salesforce Lightning pages using the native Tableau View Lightning web component. When you edit a Lightning page, you simply drag and drop the Tableau View Lightning web component onto the page and then provide the URL for the Tableau view. You can embed Tableau views from Tableau Server, Tableau Cloud or Tableau Public. The Tableau View Lightning web component supports all versions of Tableau. Using the Tableau View Lightning web component, Salesforce administrators and developers can quickly integrate Tableau dashboard into Salesforce pages.

You can [set up Tableau Server and Tableau Cloud for single sign-on \(SSO\)](#) so that users of the Tableau Lightning web component won't have to sign in to Tableau every time they visit the Salesforce page.

The Tableau Lightning web component includes built-in support for filtering the view based on the Lightning record page you are embedding the view in. The component lets you configure how the view is displayed in Salesforce and provides additional filtering capabilities based on Tableau and Salesforce fields you select.

Requirements and Permissions

- The Tableau View Lightning web component is designed to run on the Salesforce Lightning Experience. Lightning web components are supported in many Salesforce experiences and tools such as Lightning Communities and Salesforce App. Salesforce Classic and Marketing Cloud do not support the Tableau View Lightning web component.
- To configure the Tableau View Lightning component, you need to have administrator privileges for the Salesforce org.
- Context and advanced filtering of the Tableau view is only available on Lightning Experience record pages.

The Tableau View Lightning web component only supports the Salesforce Lightning Experience. If you want to embed a Tableau view into Salesforce Classic, you have other options. You could use the Salesforce Canvas Adapter for Tableau, or create a customised solution using Apex code and Visualforce pages.

Configure single sign-on (SSO)

If you are embedding a Tableau view from Tableau Server or Tableau Cloud, you might want to configure SSO with Salesforce. That way, when users sign into Salesforce and open a page that contains an embedded Tableau view, they won't need to re-authenticate with Tableau. The Tableau View Lightning web component only supports SAML as the SSO method. The SAML IdP used for Tableau authentication must be either the Salesforce IdP or the same IdP that is

used for your Salesforce instance. Configuring Tableau Server or Tableau Cloud requires Tableau administrator permissions.

Note: Users in Tableau Cloud who are configured with [Salesforce Authentication](#) will need to reauthenticate to view embedded visualisations in Tableau Cloud.

- For information about setting up SSO with Tableau Cloud, see [Configure SAML with Salesforce](#) and [Configure SAML for Tableau Viz Lightning Web Component](#).
- For information about setting up SSO with Tableau Server, see [Configure SAML for Tableau Viz Lightning Web Component](#).

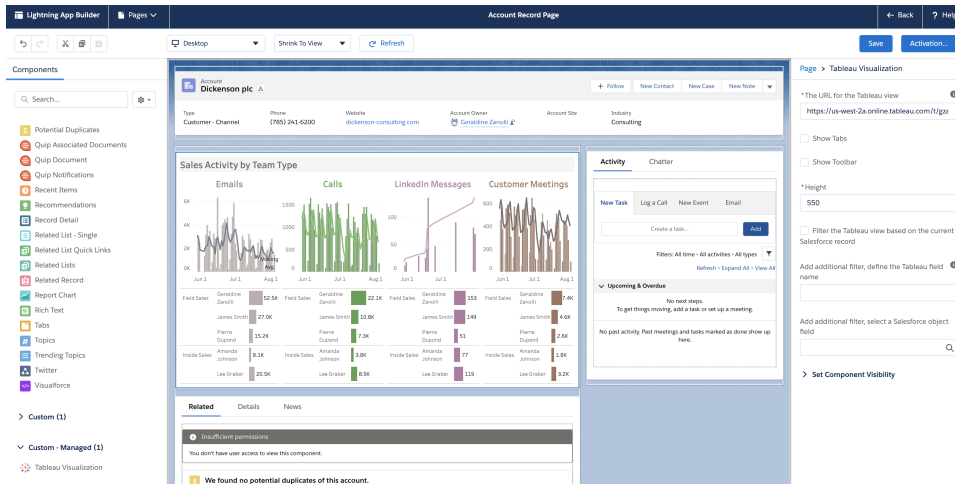

Add the Tableau view to the Lightning page

Use the native component to add a Tableau view to Lightning Experience pages.

1. From the App Launcher (), find and select a page to embed the Tableau visualisation. (For example, select **Sales** or any other App that provides a home or record page where you can embed the Tableau Lightning web component).
2. Click on the Setup gear () and then select **Edit Page**.
3. Drag the **Tableau View** component from the Lightning Components list to the top of the Page Canvas.
4. Select a Tableau view to display by providing the URL for the view in the **Enter the Viz URL** text box.
5. To find the URL for a view on Tableau Server or Tableau Cloud, click **Share** on the toolbar and select **Copy Link** from the Share View dialog box. For Tableau Public, copy the URL for the view from the address bar in your browser.
6. In Salesforce, use the options for the **Tableau View** component to control the height of the view and whether you want to show the Tableau toolbar or any tabs for the view.

You can also control when the Tableau View Lightning web component appears by selecting component visibility filters. For more information about the **Set Component Visibility** options, see [Dynamic Lightning Pages](#) in the Salesforce Help.

For the best experience, you might want to configure Tableau and Salesforce to use SSO. See [Configure single sign-on \(SSO\) on the previous page](#).

Filter the view based on the page context

The Tableau Lightning component supports two ways of filtering the Tableau visualisation. These methods of filtering only work on Lightning record pages. Filtering is not available for Home pages or App pages. For record pages, you can automatically filter the Tableau visualisation based on the page it is embedded in (*context filtering*), or you can specify the fields to use for filtering in Tableau and in Salesforce to create more sophisticated views.

To have the view filtered based on the page it is embedded in, the Tableau view needs to have a field that corresponds to the record page ID. For example, if you want to embed a view for sales on a user's page that shows just the sales for that user, the Tableau view should include a field or parameter that holds the record IDs for users.

1. In your Salesforce org, select a record page where you want to embed the viz (for example, Users or Opportunities).
2. Edit the record page and configure the component by entering the URL of the Tableau view that contains the data that you want to display. The Tableau visualisation must include a field that holds the record IDs (for example, user or account IDs).
3. Select **Filter visualisation based on the page** and save your changes to the page.

When the record ID of the page matches the corresponding value in a field in the Tableau view, the Tableau Lightning component applies that filter. For example, if you want to embed a Tableau view on the Account page and filter for the specific account, the

Tableau view needs to have a field named **Account ID**. The Tableau Viz Lightning web component uses the default field name when a user connects to Salesforce using Tableau.

Apply filters based on Tableau and Salesforce fields

If you want more control over filtering the Tableau visualisation on a records page, you can map a field or parameter in Tableau to a specific field in Salesforce. The Tableau field or parameter needs to be on the view that you are embedding. The Salesforce field must be a qualified field on the page where you are embedding the view. When the values of these two fields match, the Tableau Visualisation component will automatically filter the Tableau view.

To apply the advanced filtering, add the **Tableau View** component to a record page. For example, if you have a Tableau view that contains Salesforce data that is related to sales information, you can add that view to your opportunity record pages.

1. In your Salesforce org, click on the App Launcher (), find and select **Sales** (or any other App that provides a record page where you can embed the Tableau Lightning component). For example, the Accounts tab. Select an account, for example, Burlington Textiles from the All Accounts list.
2. Click on the Setup gear () and then select **Edit Page**.
3. Drag the **Tableau View** component from the Custom area of the Lightning Components list to the top of the Page Canvas.
4. Configure the component.
 - Enter the URL of the Tableau view that contains the sales data you want to display.
 - Provide the name of the Tableau field to use for filtering. The Tableau field needs to be the name of a field in the view that you are embedding. For example, the view might contain a field for the **User ID**.
 - Provide the name of the Salesforce field to use in filtering. You can select the qualified field names for the page from the drop-down list. For example, on the account record page, you could select **Owner ID**.

When the values from these two fields match, the Tableau View component automatically filters the view.

Important: You must enter field names as they are defined in the data source. For example, if the data source is in English, but the data source fields are translated to Japanese for a user, the user must enter the original English field name.

5. Save your changes to the page.

Link to a PNG, PDF or CSV of a View

Note: To download to these formats rather than link to them, instead see [Download Views and Workbooks on the facing page](#) Or, if you're using Tableau Desktop, see [Export Views](#) and [Export Data](#).

If you work with a website or application that doesn't support [embedded, interactive Tableau views](#), you can link to PNG or PDF versions of them.

If you're familiar with scripting, you can also use links to automatically convert multiple views into PNGs, PDFs or even CSVs. The resulting files can be shared with people who lack Tableau Cloud or Tableau Server accounts, incorporated into presentations or archived for future reference.

When you link to any of these formats, they always load the latest data available on the server. But be aware that CSVs of dashboards link to only one sheet – the one whose title is first in alphabetical order.

1. With the help of a Tableau content owner or site administrator, ensure that your audience has [permission to access the content](#). (If you're using a script to process multiple files, only you need access.)
 - For links to PNG and PDF files, users need the Download Image/PDF permission.
 - For links to CSVs, users need the Download Summary Data permission.
2. Replace the end of a view's browser URL with the appropriate file extension.

For example, change

`http://<servername>/#/views/<workbook>/sheet?iid=7` to

`http://<servername>/#/views/<workbook>/sheet.png`

3. If you want to filter a view, add a question mark after the file extension, followed by [URL parameters](#) that reflect the view's data structure.

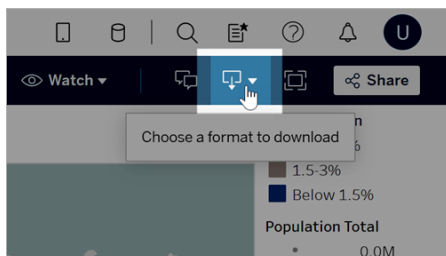

For example, change `http://<servername>/#/views/<workbook>/sheet.png` to

```
http://<servername>/#/views/<workbook>/sheet.png  
?Region=South&Department=Sales
```

Download Views and Workbooks

Note: To link to views in other formats rather than download them, instead see [Link to a PNG, PDF or CSV of a View on the previous page](#). Or, if you're using Tableau Desktop, see [Export Views](#) and [Export Data](#).

1. At the top of a view in Tableau Cloud or Tableau Server, click **Download**. Or, click the download button  wherever it appears on the page.

2. Select a download format:

Note: The download formats available to you depend on permissions granted by Tableau content owners and site administrators.

- **Image:** Downloads an image of the view in .png format. Any filters, parameters or selections currently applied in Tableau are reflected in the downloaded image.

- **Data:** Opens a new tab in the browser window and displays the view's data in summary and detail. You can then download the data as a comma-separated value (.csv) file.

When downloading from a dashboard, first click the specific sheet with data you want.

- **Crosstab:** Opens a dialog window to select download options. If viewing a dashboard, select a sheet from the dashboard to download. Under Select Format, select .csv or Microsoft Excel .xlsx.

For dashboards, all sheets will be listed, including hidden sheets.

Any filters, parameters or selections currently applied in Tableau are reflected in the downloaded crosstab.

- **PDF:** Opens a dialog window to select download options. Under **Include**, select the the part of the workbook you want to download. Select this view, specific sheets from a workbook or dashboard, or select all. Select Scaling to control the image's appearance on the PDF. Select Paper Size and Orientation.

If you're downloading a dashboard to PDF format, web page objects aren't included.

- **PowerPoint:** Downloads selected sheets as images on individual slides in a PowerPoint presentation. For untabbed views, you can select only currently visible content. However, hidden sheets visible in a dashboard can be selected if you choose **Specific sheets from this workbook**. If you select a story sheet, all story points export as separate slides.

Any filters, parameters or selections currently applied in Tableau are reflected in the exported presentation. The generated PowerPoint file includes a title slide with the name of your workbook and the date the file was generated. The title is a hyperlink that opens the workbook in Tableau Cloud or Tableau Server.

- **Tableau Workbook:** Downloads a workbook you can open with Tableau Desktop. (As an alternative, you can select **Server > Open Workbook** in Tableau Desktop.)

You have the option of downloading the workbook to different versions of Tableau or keeping the workbook in its current version. For example, if the workbook needs to be opened in Tableau Desktop 2022.2, select Tableau 2022.2. For information about version compatibility, see [Make Workbooks Compatible with Older Versions on page 3134](#).

When downloading workbooks and views, the content of the .twb or .twbx file is stored in plain text. All data, including filter values that may give semantic clues to the data, will be readable by anyone who opens the file.

Note: Downloading extremely large amounts of data can affect server performance and might not complete successfully. If you encounter these issues, try exporting the data directly from the underlying data source.

Receive Notifications, Search and Share Using the Tableau App for Slack

The Tableau App for Slack lets you work and collaborate right where you work in Slack. In Tableau 2023.1 or later, you can search for views and workbooks, and easily access your favourite and recently viewed Tableau content from the Tableau App for Slack. With the Tableau App for Slack, you can also see snapshots of visualisations, with links back to your Tableau site for further exploration. Some features (such as sharing and searching Tableau content from Slack) aren't yet available in Tableau Server. Currently, Tableau Server users can receive notifications.

In Tableau 2021.3 and later, you can get Tableau notifications in Slack for data-driven alerts, sharing activity and comment mentions. If the notification contains a view or workbook you have access to, the notification will also contain a visual snapshot.

Administrators can connect their Tableau site to a Slack workspace to enable the Tableau App for Slack for their entire organisation. For more information, see "Integrate Tableau with a Slack Workspace" in the [Tableau Cloud](#) or [Tableau Server](#) help.

After your Tableau admin connects your Tableau site to a Slack workspace:

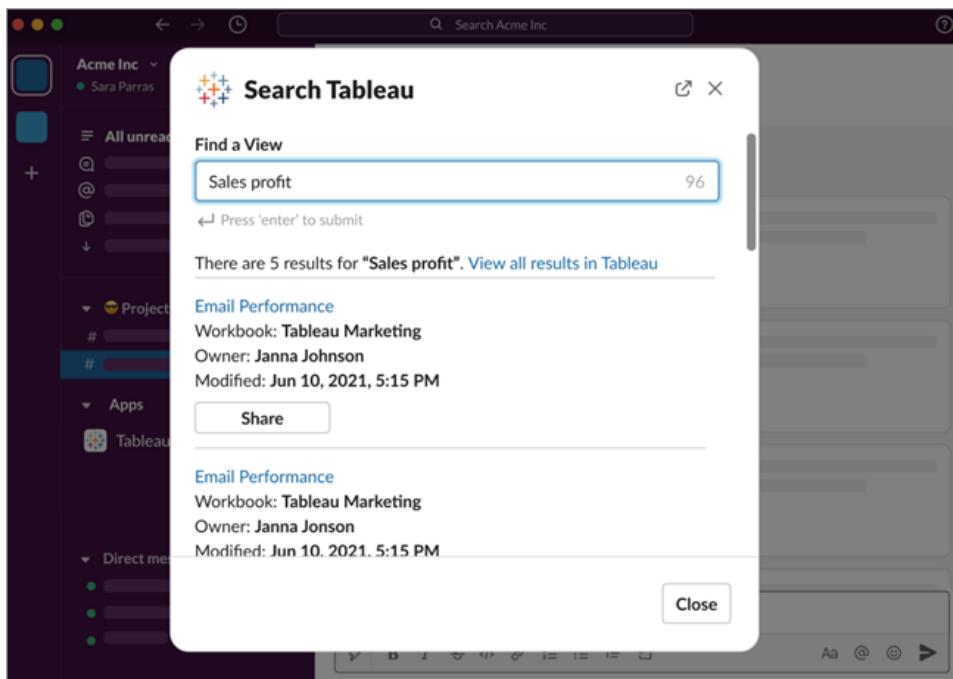

1. Add the Tableau App for Slack.
2. Select **Connect to Tableau**.
3. Log in to your Tableau site.
4. Authorise the app by choosing **Allow**.

Note: For information about privacy, see the [Privacy Policy](#).

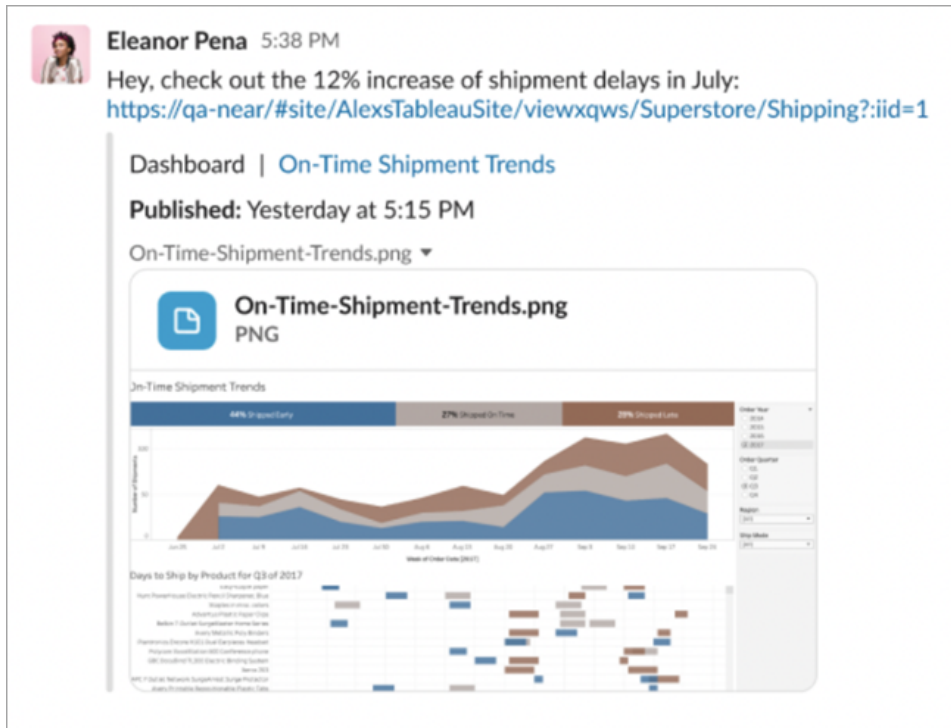

Search, share and access recents and favourites from Slack

From the Tableau App for Slack **Home** tab, you can search for views and workbooks on your Tableau Cloudsite.

After you've found the Tableau content you're looking for, select the name of the Tableau content to open it directly in Tableau or select Share to send the content to an individual or Slack channel. You can also write a custom message to provide context about the Tableau content you're sharing.

Choose **Share with Snapshot** to include a preview (Slack link unfurling) of the Tableau content in your message. You can share a snapshot if the Tableau content doesn't contain filters that restrict data access (for example, row-level security). The snapshot is visible to all people you share it with, regardless of their access level.

And without leaving Slack, you can access recently viewed Tableau content and your Tableau favourites. From the Tableau App for Slack **Home** tab, you see the five Tableau views or workbooks you visited most recently. You can also access five of your favourite Tableau views or workbooks.

Select the name of the Tableau view or workbook to open it directly in Tableau, or select the more actions menu (...) to share favourite or recently viewed Tableau content.

Receive Tableau notifications in Slack

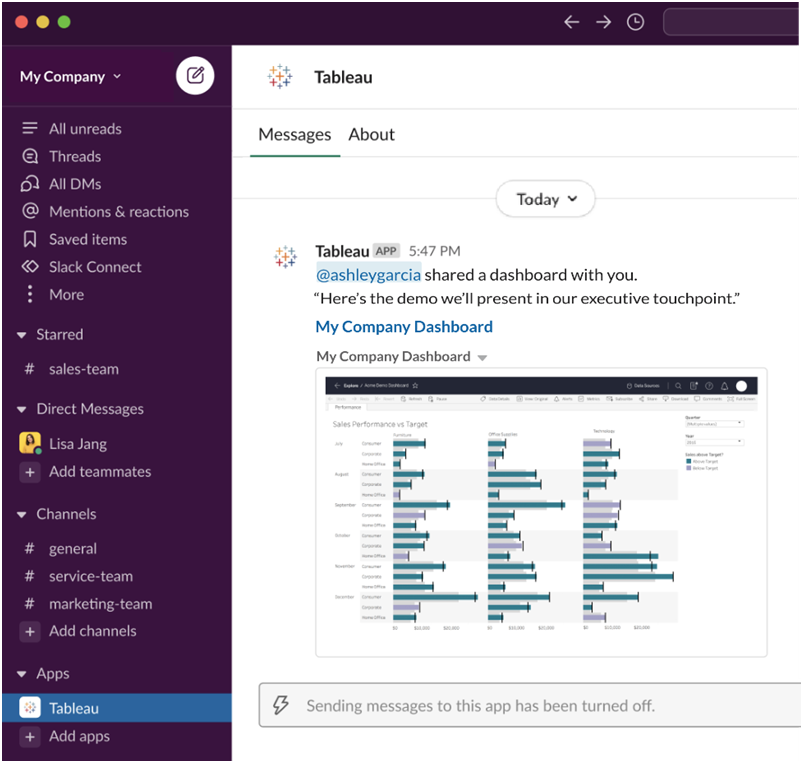

Comments

Get notified when you're @mentioned in a comment to keep the conversation going. For more information, see [Comment on Views](#).

The screenshot shows the Tableau mobile app interface. On the left is a dark purple sidebar with navigation options: 'My Company', 'All unread', 'Threads', 'All DMs', 'Mentions & reactions', 'Saved items', 'Slack Connect', 'More', 'Starred', 'sales-team', 'Direct Messages', 'Lisa Jang', 'Add teammates', 'Channels', 'general', 'service-team', 'marketing-team', 'Add channels', 'Apps', 'Tableau', and 'Add apps'. The main content area shows a message from 'Tableau APP' at 5:15 PM. The message text is: '@fredsuzuki mentioned you in a comment. "/>

Share

See when a teammate sends a Tableau asset your way, including views, workbooks and more. For more information about sharing, see [Share Web Content](#).

Data-driven Alerts

You can specify a threshold for your data and be alerted when it's met. For more information, see [Send Data-Driven Alerts from Tableau Cloud or Tableau Server](#).

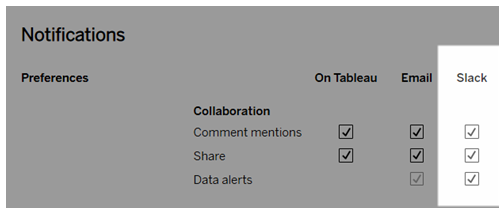

Manage Tableau notifications for Slack

Your Tableau site admin can turn on or off all notifications across the site. Tableau admins and Slack workspace admins integrate your Tableau site with Slack, and control whether site users can receive notifications. If it's enabled and your Tableau site administrator allows notifications, all site users can receive notifications in Slack through the Tableau App for Slack. Sometimes notification preferences aren't available because the site has other settings configured that affect notifications.

To control which notifications appear in your Slack workspace, or to turn off Slack notifications, at the top of a page, click your profile image or initials and then select **My Account Settings**.

Under Notifications, select or clear the tick boxes under **Slack** for comment mentions, shares and data alerts.

| Preferences | On Tableau | Email | Slack |
|----------------------|-------------------------------------|-------------------------------------|-------------------------------------|
| Collaboration | | | |
| Comment mentions | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| Share | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| Data alerts | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |

Select **Save Changes**.

For more information, see **Change notification settings** in [Manage Your Account Settings](#).

Web Authoring and Tableau Desktop Feature Comparison

For anyone familiar with Tableau Desktop and new to the web authoring environment in Tableau Server and Tableau Cloud, this topic provides a summary of the web features that you use similarly to the way you do in Tableau Desktop. It also lists some fundamental differences between the two environments.

Note: This topic summarises core authoring functionality and does not cover every difference between the desktop and web environments.

Features listed by version

For a list of the latest web editing features to be added to each release, see the web authoring sections in [Tableau Desktop and Web Authoring Release Notes](#) and [Tableau Cloud Release Notes](#), or check out the [Release Navigator](#) viz to filter and compare changes by release.

General differences in web authoring

- Your authoring capabilities are determined by your licence level. For an overview of what you can do with each licence level, see [What can I do with a Tableau site?](#)

- You can access right-click menu actions on fields in the view, but not on every item in the workspace.
- Keyboard shortcuts for web authoring and Tableau Desktop are not the same. For a list of web authoring keyboard shortcuts, see [Shortcuts for web authoring](#).

Web authoring capabilities

In the web environment, you can connect to data and create workbooks from those data sources, or data published through Tableau Desktop. You can edit views created on the web or published from Tableau Desktop.

Administrators can set at the site level what web authoring abilities users can have. Explorers can edit workbooks, create new workbooks from published data sources, connect to published data sources and create and edit views, dashboards and stories. Creators have those same capabilities, but can also create new workbooks, connect to data on the web and use Ask Data and (in Tableau Cloud) Dashboard Starters to quickly dive into analysis.

Data management

- **Creators:** Connect to data sources, upload files (text, excel, and Tableau workbooks), or use pre-built Dashboard Starter templates for certain data sources. For more information, see [Creators: Connect to Data on the Web](#).
- **Creators:** Prepare data on the web in the Data Source page. For more information, see [Creators: Prepare Data on the Web](#).

Note: There is a limitation on the number of rows that can be viewed in the Data Source page when authoring data on the web, determined by browser:

- Internet Explorer: 10,000 rows
- Other browsers: 100,000 rows

Independent of browser, the total number of records (rows by columns) that can be viewed in the Data Source page on the web is **3 million**.

- Run Initial SQL when connecting with some data sources
- Relate your data to combine data from multiple tables

- Join data from different tables in the same data source or from different databases using a multi-connection data source
- Add a join calculation
- Union data
- Pivot data
- Copy values in a grid (Ctrl+C, or Command-C on a Mac)
- **Edit Data Sources**
- Clean data using the Data Interpreter
- Create a Custom SQL query
- **Explorers:** Connect to published data sources.
 - Blend published data sources.
 - Save a data source (embedded in a published workbook) as a separate, published data source.
 - Change aggregation of measures in the view. Change the default aggregation of measures in the Data pane.
 - Search for fields in the schema.
 - Duplicate, hide or rename fields.
 - Change the data type of fields.
 - Convert measures to dimensions or vice versa.
 - Convert a discrete field to continuous and vice versa. This option is available for measures and date dimensions.
 - Assign a geographic role for a field.
 - Create aliases for members of dimensions.
 - Create and edit groups.
 - Create and edit sets (conditioned sets are not available)
 - Create, edit and remove parameters. Formatting numbers and dates, and adding comments for the parameter are not supported on the web.

Analytics

- Create, edit, rename, duplicate and clear sheets (views, dashboards and stories) in a workbook.
- Use [Ask Data](#) to automatically create views.
- Use [Explain Data](#) to automatically create views.
- Search for fields in the Data pane with schema search
- Drag fields to the view, Rows, Columns and different mark types in the **Marks** card.
- Use **Show Me** to create views. Also, from the Data pane, select and drag a field of interest to the view area to automatically create a 'Show Me' view.
- View underlying data (via tooltips).
- Viz in Tooltip works in web views, but must be configured in Tableau Desktop. [Viz in Tooltip worksheets can be hidden](#), the same way you would hide worksheets used in stories or dashboards.
- [Actions](#) work in web views, but must be configured in Tableau Desktop.
- Create and edit calculated fields.
- Create bins from continuous measures, and edit bins.
- Create and edit table calculations, and use quick table calculations.
- Create sets and show set controls. (Note that you cannot create sets from cube data sources in web authoring.)
- Use the **Analytics** pane to drag reference lines, trend lines and other objects into the view. Edit reference lines, trend lines and bands. Create and configure reference distributions on a continuous axis. Adding a cluster, and adding and modifying a forecast, are not supported for the web.
- Create groups by selecting marks in the view and then clicking Group Members (paperclip) in the tooltip for that selection. You can also edit existing groups in the Data pane.
- Create hierarchies by dragging one dimension onto another in the Data pane. **Note:** You can't create hierarchies when fields are already grouped within a folder.

- Change options for interacting with maps, including enabling or disabling pan and zoom, or showing map search, the view toolbar or map scale. Users can also map units.
- Drill up and down a continuous hierarchy in the view. In a view with a continuous hierarchy, hover near the headers on a continuous axis to display the + and - controls. Click to drill down or up.
- Show labels, totals and subtotals.
- Show, hide and format mark labels
- Show and hide titles and captions.
- Show and hide cards for filters and highlighters.
- Show, hide and resize headers in the view.
- Swap X and Y axes. Resize axes in the view.
- Change the view size.
- Show and hide the View Toolbar for any view or dashboard.
- Duplicate a sheet as a crosstab view.

Filtering and sorting

- Use data highlighting.
- Add, edit, and remove filters, and edit filter control layouts.

Note: There is a limitation on the number of results that can be filtered when authoring data on Tableau Cloud or Tableau Server. Only the first 100 results are returned to limit the performance impact one user has when loading a large domain on the server.

- Filter across published data sources.
- Apply filters to multiple sheets
- Create context filters (**Add to Context** option in the Filters shelf) and dependent filters (**Only Relevant Values** option in a filter control shown in a view).
- Apply table calculation filters to totals in the view.
- Show hidden fields, and exclude or remove fields from the view.

- Sort fields in the view in ascending or descending order. Access the **Sort** dialog box by right-clicking a dimension on the Rows or Columns shelf. Nested sorting on dimension values within the context of each pane.
- Drag and drop headers to create a custom sort order within a view.

Formatting

- Resize the width of row headers and the height of column headers.
- Edit workbook formatting, including formatting lines.
- Edit worksheet and dashboard titles.
- Edit axes (double-click an axis in the view). Other options available: **Synchronise dual axes**, clearing the axis range (**Reset**), and tick mark settings. Enable or disable **Dual axis** in a field context menu (right-click a measure field on Rows or Columns shelf). Logarithmic scales can be positive or symmetric (includes 0 and negative values).
- Edit number formatting (decimal places, percentage, thousands separator, units and currency).
- Create, edit, move and resize point, mark, and area annotations.
- Add and edit dashboards objects, including: horizontal and vertical layout containers, text, images, navigation buttons, web page links and dashboard extensions.
- Create transparent worksheet backgrounds (set background colour to **None**). Combine transparent worksheets with transparent filters, highlighters and parameters.
- Change the colour palette. For categorical fields you can assign specific colours and custom colours (using a hex code) to data items. For continuous fields, you can set custom colours for start and end colours (using a hex code).
- Create, rearrange, and preview device-specific dashboard layouts
- Set a dashboard item's exact size, position and spacing.
- Add padding, borders and background colours around items in dashboards.
- Select a background map in map views.
- Legends per measure. If you create separate colour legends for the measures in your view, Tableau assigns the default colour palette to each new colour legend. To change the colour legend for each measure, click the drop-down arrow on the colour legend to

open the **Edit Colours** dialog box and select the palette that you want to use. For more details, see [Legends per measure](#).

Install or Upgrade Tableau Desktop

For comprehensive installation information, see the [Tableau Desktop and Tableau Prep Deployment Guide](#).

When you install or upgrade you have the option to share usage data with us to help us continually improve our product to better meet your needs. For more information about the data we collect, see [Tableau Product Usage Data](#). For information about how to opt out of sharing usage data see [Turn off usage reporting](#) in the Tableau Desktop and Tableau Prep Deployment Guide.

Accessing the repository from a previous version

When you upgrade to Tableau 2022.4 from previous versions, your repository is upgraded. Any bookmarks, workbooks, and data sources that you had in your old repository will still be accessible by the application. In addition, the new sample data sources and workbooks will replace the old samples unless you have modified them and saved them as your own.

Note: Your recent workbooks are automatically imported and restored to your Start page along with your recent connections list and any organization-specific settings on the Discover pane.

Accessing the repository from a beta version

If you have participated in the Tableau Software Beta program, you also have a beta repository. While this folder will still exist after you install Tableau 2022.4, the application will no longer access it. To make your beta workbooks accessible in Tableau 2022.4, copy the workbooks from the beta repository to your new 2022.4 repository.

Turn Product Updates Off or On

To ensure that you always have the most up-to-date features, security resolutions and corrected issues, Tableau Desktop includes a product update feature. When you start Tableau Desktop,

product updates prompts you to download an updated maintenance version of Tableau Desktop, if one exists. The update downloads immediately and then installs when you exit Tableau.

You can also choose to postpone or skip the update. If you do this, you can always check for product updates at any time by selecting **Help > Check for Product Updates**.

For more information about how to turn product updates off or on, see the [Control Product Updates](#) article in the Tableau Desktop and Tableau Prep Deployment Guide.

Note the following:

- The product update installers are downloaded to the Downloads/TableauAutoUpdate folder. If the Downloads folder doesn't exist, the installers are downloaded to the TEMP/TableauAutoUpdate folder.
- Updates are not downloaded and installed on your computer if your Product Maintenance has expired. For more information, see the [Renewing your Licences with Tableau](#).
- You may not be prompted for product updates. There are a number of reasons why this may be so. For details, see the **Troubleshoot maintenance updates** section in the [Troubleshoot Tableau Desktop Installation](#) article in the Tableau Desktop and Tableau Prep Deployment Guide.

Turn off product updates

Product updates is on by default. You can turn off product updates from the Help menu, or on Windows, by running the installer.

Use the Help menu

Select **Help > Settings and Performance > Enable Automatic Product Updates** and clear the tick box.

Run the installer (Windows only)

To turn off product updates on Windows, run the Tableau Desktop installer, and then click **Customise**. In the Custom setup dialog box,

1. Clear the **Check for Tableau product updates** tick box.
2. Click **Install**.

To turn product updates on again, run the installer, click **Customise**, and tick the box.

Administrators control product updates

As an administrator, you can turn product updates off or on for your users. You can also determine the Tableau Desktop version that your users will update to. Rather than having users update to the version of their choice (or choose not to update), you can make sure that your users update to the version you choose. For more information, see the [Control Product Updates](#) article in the Tableau Desktop and Tableau Prep Deployment Guide.

Maintain Licences for Tableau Desktop and Tableau Prep

Tableau Desktop and Tableau Prep Builder can be licensed under a term licence model. When you purchase a new Tableau Server or a new Tableau Cloud subscription, however, product keys are no longer issued for Tableau Desktop or Tableau Prep Builder. Instead, you use login-based licence management to activate and sign in to Tableau Server or Tableau Cloud. For more information, see [Activate Tableau using Login-based Licence Management](#).

Term licences must be renewed and the product key refreshed to continue providing uninterrupted service. You can continuously renew the term licence as each specified period expires. If you don't renew your term licence and the term expires, Tableau will stop working and you will no longer have access to the software. For more information about renewing your licence, see [How to Renew your Tableau Licences](#).

Note: Trial licences for Tableau Desktop or Tableau Prep expire after a set period of time, usually 14 days. After the trial period expires, you'll need to [purchase a licence](#) to continue using the product.

View data about your licence

After you install Tableau Desktop or Tableau Prep open the application and then navigate to **Help** > **Manage Product Keys** from the top menu to see information about the type of licence you have and when it expires.

You can also activate or deactivate a product key or refresh a maintenance product key from this dialog if you are not using the Virtual Desktop (ATR) option.

Note: Tableau offers term licences that provide a range of capabilities. The type of licence that you have is displayed in the **Product** field. For more information about the different type of user-based licences that are available, see [User-based licences](#) in the Tableau Server help.

Existing Tableau Desktop users may have a perpetual (permanent) licence. Perpetual licences don't expire and their **Licence Expires** field in the **Manage Product Keys** dialog box displays "Permanent". However, to get access to product updates and technical support you must purchase Support and Maintenance services. These services must be renewed to continue receiving the service. Perpetual (permanent) licences are no longer available for Tableau Desktop.

Use the following buttons to take action on your product key:

- **Refresh** (Non-login-based licence management and non-Virtual Desktop only): Click the **Refresh** button to refresh a maintenance licence that is expiring, then close and restart Tableau Desktop. If the **Maintenance Expires** date doesn't update, check with your licence administrator as the key or maintenance agreement may have changed.

A product key whose Licence Expires value is listed as "Permanent", as shown in the Manage Product Keys dialog box above, is a legacy product key. You can refresh a Permanent product key at any time as long as the maintenance end date listed in the Tableau Customer Portal is higher than the date reflected in the Desktop Manage Product Keys dialog box.

If the product key has reached its expiry date (non-permanent product keys), you cannot refresh the product key. Visit the Tableau Customer Portal to obtain an updated subscription product key and perform a new activation. If the product key has not reached its expiration date, you can refresh the product key. When you refresh a product key that has not yet expired, only the "Licence Expires" value will change and not the product key. The product key will change when it reaches its expiration date.

To refresh a maintenance key from the command line see [Refresh the product key](#) in the Tableau Desktop and Tableau Prep Deployment guide.

Note: You cannot refresh the product key if Tableau Desktop is offline. If you are activating Tableau Desktop in offline mode, you must obtain and activate a new key from the Tableau Customer Portal.

- **Deactivate** (Non-login-based licence management and non-Virtual Desktop only): Select a product key in the list then click **Deactivate** to deactivate the product key. Deactivate a product key if you need to move the product key to another computer or when you no longer need the product key on this computer.

For more information about deactivating a product key, see [Move or Deactivate Product Keys](#) in the Tableau Desktop and Tableau Prep Deployment guide.

- **Activate:** After Tableau Desktop or Tableau Prep is installed, click **Activate** to open the activation dialog and enter your product key. If you get an error and can't activate Tableau Desktop or Tableau Prep using your product key, contact [Tableau Support](#).

For more information about activating a product key, see [Activate and Register your Product](#) in the Tableau Desktop and Tableau Prep Deployment guide.

Automatically refresh product keys using zero downtime licensing

Beginning in Tableau version 2021.1, internet-connected Tableau Desktop and Tableau Prep Builder users may not have to manually refresh product keys. Term licences are automatically refreshed without requiring any action starting 14 days before subscription expiration if the user is signed onto Tableau Desktop or Tableau Prep Builder. Permanent product keys are not automatically refreshed and must be refreshed manually using the **Manage Product Keys** menu option.

Tableau Desktop and Tableau Prep Builder will attempt to silently refresh an active product key and will warn users 14 days before their licence is set to expire if the silent refresh was unsuccessful. Tableau will attempt to refresh a product key three times (at 14 days, 2 days and 1 day before licence expiry) to reflect licence end date extensions as a result of your subscription renewal. The product key is not refreshed unless a Tableau Desktop user signs onto Tableau Desktop during those times. For users who do not sign onto Tableau Desktop every day, you must refresh their product keys using the **Manage Product Keys** menu option.

Track Tableau Desktop licence usage and expiration data

If you want to track and view licence usage and expiration data for Tableau Desktop in Tableau Server you must configure Tableau Desktop to send licence data to Tableau Server on a set interval, and then enable reporting on Tableau Server.

This enables server administrators to access two reports:

- **Desktop Licence Usage:** This report lets server administrators see usage data for Tableau Desktop licences in your organisation.
- **Desktop Licence Expiration:** This report gives server administrators information about which Tableau Desktop licences in your organisation have expired or need maintenance renewal.

If Tableau Desktop and Tableau Server are configured for licence reporting, when signed in to Tableau Server as an Administrator, you will see these two reports listed on the **Server Status** page in the **Analysis** section.

If you don't see these reports listed, then Tableau Desktop and Tableau Server may not be configured for Tableau Desktop usage reporting.

For information about how to configure Tableau Desktop and Tableau Server for usage reporting, see [Manage Tableau Desktop Licence Usage](#) in the Tableau Desktop and Tableau Prep Deployment guide.

Additional resources

For more information about managing your licence refer to the following topics:

- To find your product key and activate Tableau Desktop or Tableau Prep Builder, see [Where's my product key](#).
- To deactivate a product key or move it to another computer, see [Move or Deactivate Tableau Desktop](#).
- To learn more about product keys for non-persistent virtual desktops or for computers that are regularly re-imaged, see [Configure Virtual Desktop Support](#).
- To learn more about product key management for Tableau Server or Tableau Cloud, see [Licensing Overview \(Linux | Windows\)](#)
- To learn more about the licence renewal process or to renew a licence, see [How to Renew your Tableau Licences](#).

OAuth Overview

OAuth (Open Authorisation) is an authentication protocol that allows users to grant limited access to their resources on one website or application to another website or application, without sharing their actual login credentials.

OAuth acts like a trusted middleman that enables you to give permission for one service to access your data from another service without revealing your username and password. This document includes a technical explanation of the OAuth workflow and a practical OAuth analogy.

OAuth workflow

OAuth provides a secure and standardized way for users to grant access to their data across different websites and applications without sharing their login credentials. It ensures that you have control over which services can access your data and allows you to revoke access at any time.

The following list is a step-by-step explanation of how OAuth works.

You (the user) want to use a website or application (called the "client") that requires access to your data on another website or application (called the "resource server").

The client requests permission to access your data from the resource server. It typically does this by redirecting you to the resource server's login page.

You enter your login credentials on the resource server's login page directly. This step is crucial because your username and password are never shared with the client.

The resource server verifies your credentials and authenticates you. Once authenticated, it generates a unique access token for the client.

The resource server redirects you back to the client application, providing the access token along with the redirection.

The client receives the access token and sends it to the resource server whenever it needs to access your data.

The resource server checks the validity of the access token. If the token is valid, it grants the client access to the requested resources for a limited period.

The client can use the granted access to retrieve or modify your data on the resource server, but only within the scope defined by the access token. The scope determines what actions and data the client can access.

If the access token expires or if the client needs additional permissions, the client can request a new access token by going through the authentication process again.

Practical OAuth analogy

The following is an analogy of how OAuth works using a practical scenario.

Imagine you are throwing a party, and you want to hire a caterer (the client) to handle the food. However, you don't want to give the caterer the keys to your house (your login credentials) because that would give them access to all your personal belongings. So, you use a trusted party organiser (OAuth) to manage the access.

You tell the party organiser that you want to hire a caterer. The party organiser knows how to handle access to your house and the caterer's services.

The party organiser contacts the caterer and sends them to your house for a meeting. You're not home at this point.

The caterer arrives at your house but realizes they can't enter without your permission (access token). They call you to ask for access.

You, as the home owner, want to verify the caterer's credibility before granting access. So, you ask the caterer some questions to confirm their identity (authentication).

Once you're satisfied with the caterer's credentials, you give them a temporary access code (access token) through the phone. This code allows them to enter your house and prepare the food but only within the scope of their catering duties.

The caterer enters your house using the access code and starts setting up the food. They can access the kitchen and dining area but are restricted from entering other rooms.

After a specified period or when the party ends, the access code expires, ensuring that the caterer can't re-enter your house without your permission.

In this scenario, you (the homeowner) are the user, the caterer is the client application, your house represents your personal data on the resource server and the party organiser is OAuth.

The access code serves as the access token, allowing the client (caterer) limited access to your resources (house) without compromising your login credentials (house keys).

OAuth acts as a trusted intermediary, facilitating the secure sharing of your data between services while maintaining control over access permissions.

Configure a forward proxy for OAuth authentication

You can configure a forward proxy in Tableau Server and Tableau Desktop to enable OAuth authentication. Forward proxies can help you manage traffic out to the internet for tasks such as load balancing.

Use Windows to connect to Tableau Desktop through a forward proxy

Complete the following steps to configure the proxy server in Windows LAN Settings.

1. Open the Local Area Network (LAN) Settings dialog box.

Tip: A quick way to get to this dialog box is to search for Internet Options in the Windows Start menu.

2. In the Internet Properties dialog box, select the Connections tab.

3. Select LAN settings.

4. Under Proxy server, select Use a proxy server for your LAN.

5. Enter the proxy server address.
6. Enter the server port.
7. Select Bypass proxy server for local addresses.

Note: If you've already followed the steps in [Configuring Proxies for Tableau Server](#) and OAuth requests through your proxy aren't working, then follow option 2.

Windows configuration option 1: Use system environment variables

You can edit the system-wide environment variables and set `http_proxy` and `https_proxy` to your proxy to enable OAuth authentication.

1. In your Windows computer search box, enter **Advanced system settings**.
2. Tap **Enter** to open the **System Properties** box.
3. On the **Advanced** tab, select **Environment Variables**.
4. Scroll through the **System variables** field.
 - If the field has `http_proxy` or `https_proxy`, verify that the values don't conflict with the proxy server address that you configured in the previous step.
 - If they're not set, set them to the values that match the proxy server address configured in the previous step.
5. Restart Tableau Desktop.
6. Attempt to connect to an OAuth connector and validate that it works as expected.

Note: If you see an **OAuth-Client can't be empty** or **SSLHandshake Exception** or **Connection Refused** exception, continue to option 2.

Windows configuration option 2: Configure Java net.properties proxy settings

1. In your file directory, locate the version of Java you're using to run Tableau Desktop.

```
C:/Program Files/Tableau/Tableau <Version>/bin/jre
```
2. In the Java locations directory, select the `conf` folder. If this directory doesn't exist, create one.
3. In the `conf` folder, locate the `net.properties` file and open it in an editor. If this file doesn't exist, create one by the same name.

Note: If you don't have write permissions on this file, use the system file settings to enable them.

4. Modify or create the following values:

- `http.proxyPort=<your proxy port>`
- `http.proxyHost=<your proxy host address>`
- `https.proxyPort=<your proxy port>`
- `https.proxyHost=<your proxy host address>`

Warning: Make sure you only include the host. If your proxy address is `http://myproxy:8888`, then set it to: `http.proxyHost=myproxy`

5. Restart Tableau Desktop, and try to connect through OAuth.

Use Mac to connect to Tableau Desktop through a forward proxy

To use Mac to connect Tableau Desktop through a forward proxy, you must configure Java `net.properties` proxy settings.

1. In your file directory, locate the version of Java you're using to run Tableau Desktop.

```
/Applications/Tableau <Version>/Plugins/jre
```

2. In the Java locations directory, select the `conf` folder. If this directory doesn't exist, create one.

3. In the `conf` folder, locate the `net.properties` file and open it in an editor. If this file doesn't exist, create one by the same name.

Note: If you don't have write permissions on this file, use the system file settings to enable them.

4. Modify or create the following values:

- `http.proxyPort=<your proxy port>`
- `http.proxyHost=<your proxy host address>`
- `https.proxyPort=<your proxy port>`
- `https.proxyHost=<your proxy host address>`

Warning: Make sure you only include the host. If your proxy address is `http://myproxy:8888`, then set it to: `http.proxyHost=myproxy`

5. Restart Tableau Desktop, and try to connect through OAuth.

Use Windows to connect through a proxy that requires OAuth authorisation

If your proxy requires you to sign in with a username and password, then complete the following steps so OAuth requests connect through the proxy.

1. In your file directory, locate the version of Java that you're using to run Tableau Desktop.

```
C:/Program Files/Tableau/Tableau <Version>/bin/jre
```

2. In the Java locations directory, select the `conf` folder. If this directory doesn't exist, create one.

3. In the `conf` folder, locate the `net.properties` file and open it in an editor. If this file doesn't exist, create one by the same name.

Note: If you don't have write permissions on this file, use the system file settings to enable them.

4. Modify or create the following values:

- `http.proxyUser=<your proxy username>`
- `http.proxyPassword=<your proxy password>`

5. Restart Tableau Desktop, and try to connect through OAuth.

Use Mac to connect through a proxy that requires OAuth authorisation

If your proxy requires you to sign in with a username and password, then complete the following steps so OAuth requests connect through the proxy.

1. In your file directory, locate the version of Java that you're using to run Tableau Desktop.

```
/Applications/Tableau <Version>/Plugins/jre
```

2. In the Java locations directory, select the `conf` folder. If this directory doesn't exist, create one.

3. In the `conf` folder, locate the `net.properties` file and open it in an editor. If this file doesn't exist, create one by the same name.

Note: If you don't have write permissions on this file, use the system file settings to enable them.

4. Modify or create the following values:

- `http.proxyUser=<your proxy username>`
- `http.proxyPassword=<your proxy password>`

5. Restart Tableau Desktop, and try to connect through OAuth.

Use Windows to connect to Tableau Server through a forward proxy

You can launch Tableau Server from behind a forward proxy to allow internet access. You can configure the proxy server in Windows LAN Settings to connect to Tableau Server through a forward proxy.

Configure the proxy

Complete the following steps to configure the proxy server.

1. Open the **Local Area Network (LAN) Settings** dialog box.

Tip: A quick way to get to this dialog box is to search for Internet Options in the Windows Start menu.

2. In the **Internet Properties** dialog box, select the **Connections** tab.

3. Select **LAN settings**.

4. Under **Proxy server**, select **Use a proxy server for your LAN**.

5. Enter the proxy server address.

6. Enter the proxy server port.

7. Select **Bypass proxy server for local addresses**.

Add exceptions

You can add exceptions to guarantee that all communications within a local Tableau Server cluster don't route to the proxy server. Complete the following steps to add exceptions.

1. In the **LAN settings** dialog box, select **Advanced**.

Note: This button is available only if you've selected the option to use a proxy server for your LAN.

2. In the **Proxy Settings** dialog box, in the **Exceptions** field, enter the following values.

- localhost
- Server host names

- IP addresses of other Tableau Server computers in the same cluster.

Note: Use semicolons to separate items.

3. Close the **Proxy settings** dialog box.
4. Close the **Local Area Network (LAN) Settings** dialog box.
5. In the **Internet Properties** dialog box, select **OK** to apply the settings.

Note: If you've completed the steps in [Configuring Proxies for Tableau Server](#) and OAuth requests through your proxy aren't working then follow option 2.

Windows configuration option 1: Use system environment variables

You can edit system-wide environment variables and set `http_proxy` and `https_proxy` to your proxy.

1. In the Windows computer search box, enter **Advanced system settings**
2. Tap **Enter** to open the **System Properties** box.
3. On the **Advanced** tab, select **Environment Variables**.
4. Scroll through the **System variables** field.
 - If the field has `http_proxy` or `https_proxy`, verify that the values don't conflict with the proxy server address that you configured in the previous step.
 - If they're not set, set them to the values that match the proxy server address configured in the previous step.
5. Restart Tableau Server.
6. Attempt to connect to an OAuth connector and validate that it works as expected.

Note: If you see an **OAuth-Client can't be empty**, **SSLHandshake** or **Connection Refused** exception continue on to option 2.

Windows configuration option 2: Configure Java net.properties proxy settings

1. In your file directory, locate the version of Java you're using to run Tableau Server.

```
C:\Program Files\Tableau\Tableau Server\packages\repository*\jre
```

2. In the Java locations directory, select the `conf` folder. If this directory doesn't exist, create one.
3. In the `conf` folder, locate the `net.properties` file and open it in an editor. If this file doesn't exist, create one by the same name.

Note: If you don't have write permissions on this file, use the system file settings to enable them.

4. Modify or create the following values:

- `http.proxyPort=<your proxy port>`
- `http.proxyHost=<your proxy host address>`
- `https.proxyPort=<your proxy port>`
- `https.proxyHost=<your proxy host address>`

Warning: Make sure you only include the host. If your proxy address is `http://myproxy:8888`, then set it to: `http.proxyHost=myproxy`

5. The proxy host default value is `http.nonProxyHosts =localhost|127.*|[: :1]`. If the default value matches the list of exceptions, bypass the proxy server, then continue to step 6. If they don't match, make sure that it has the following values.

- `localhost`
- Server host names and IP addresses of other Tableau Server computers in the same cluster.
- Each item is separated by “|”

6. Restart Tableau Server and try to connect through OAuth.

Use Linux to connect to Tableau Server through a forward proxy

You can configure Java `net.properties` proxy settings to use Linux to connect Tableau Server through a forward proxy.

1. In your file directory, locate the version of Java you're using to run Tableau Server.

```
opt/tableau/tableau_server/packages/repository*/jre
```

2. In the Java locations directory, select the `conf` folder. If this directory doesn't exist, create one.
3. In the `conf` folder, locate the `net.properties` file and open it in an editor. If this file doesn't exist, create one by the same name.

Note: If you don't have write permissions on this file, use the system file settings to enable them.

4. Modify or create the following values:

- `http.proxyPort=<your proxy port>`
- `http.proxyHost=<your proxy host address>`
- `https.proxyPort=<your proxy port>`
- `https.proxyHost=<your proxy host address>`

Warning: Make sure you only include the host. If your proxy address is `http://myproxy:8888`, then set it to: `http.proxyHost=myproxy`

5. The proxy host default value is `http.nonProxyHosts =localhost|127.*|[::1]`. If the default value matches the list of exceptions, bypass the proxy server, then continue to step 6. If they don't match, make sure that it has the following values.

- `localhost`
- Server host names and IP addresses of other Tableau Server computers in the same cluster.
- Each item is separated by “|”

6. Restart Tableau Server and try to connect through OAuth.

Use Windows to connect to Tableau Server through a proxy that requires OAuth authorisation.

If your proxy requires that you sign in with a username and password, then complete the following steps to allow OAuth requests to connect through the proxy.

1. In your file directory, locate the version of Java you're using to run Tableau Server.

```
C:\Program Files\Tableau\Tableau Server\packages\repository*\jre
```

2. In the Java locations directory, select the `conf` folder. If this directory doesn't exist, create one.

3. In the `conf` folder, locate the `net.properties` file and open it in an editor. If this file doesn't exist, create one by the same name.

Note: If you don't have write permissions on this file, use the system file settings to enable them.

4. Modify or create the following values:

- `http.proxyUser=<your proxy username>`
- `http.proxyPassword=<your proxy password>`

5. Restart Tableau Server, and try to connect through OAuth.

Use Linux to connect to Tableau Server through a proxy that requires OAuth authorisation.

If your proxy requires that you sign in with a username and password, then complete the following steps to allow OAuth requests to connect through the proxy.

1. In your file directory, locate the version of Java you're using to run Tableau Server.

```
opt/tableau/tableau_server/packages/repository*/jre
```

2. In the Java locations directory, select the `conf` folder. If this directory doesn't exist, create one.

3. In the `conf` folder, locate the `net.properties` file and open it in an editor. If this file doesn't exist, create one by the same name.

Note: If you don't have write permissions on this file, use the system file settings to enable them.

4. Modify or create the following values:

- `http.proxyUser=<your proxy username>`
- `http.proxyPassword=<your proxy password>`

5. Restart Tableau Server, and try to connect through OAuth.

SSL handshake errors

If you're getting errors, then check to ensure you have put your SSL cert into the correct keystore. On Windows, the keystore is under the system Trusted Certs store. If the keystore is correct, and you're still getting errors, then import your cert directly into the Java keystore. Complete the following steps to import your certificate into the Java keystore.

Export the SSL certificate for your proxy to a file.

Tip: You can find your certificate under Applications, Utilities, Keychain Access, System, Category, Certificates.

1. Locate the version of Java you're using to run Tableau.
2. Open the terminal command prompt.
3. Run the following command from the directory that contains the version of Java you're using to run Tableau.

```
Keytool -import -trustcacerts -file /Users/tableau_  
user/Desktop/SSL.cer -keystore Tableau  
<version>/Plugins/jre/lib/security/cacerts -storepass changeit
```

4. Restart Tableau Server or Tableau Desktop.

Note: If you get a **FileNotFoundException** (Access denied) when running the keytool command, try running the command with elevated permissions.

```
sudo keytool -import -trustcacerts -file /Users/tableau_  
user/Desktop/SSL.cer -keystore Tableau  
2021.3.1/Plugins/jre/lib/security/cacerts -storepass changeit
```

Keyboard Shortcuts

This is a list of keyboard shortcuts for working in Tableau. For information on navigating a view using a keyboard, see [Keyboard Accessibility for Tableau on the Web on page 3255](#).

Shortcuts for managing workbooks, sheets, and files (Tableau Desktop)

| Description | Windows shortcut | Mac shortcut |
|---|-------------------------------|-----------------------------|
| New workbook | Ctrl+N | Command+N |
| New worksheet | Ctrl+M | Command+T |
| Describe sheet | Ctrl+E | Command+E |
| Cycle forward through open work-sheets | Ctrl+Tab, Ctrl+F6 | Shift+Command+Right bracket |
| Cycle backward through open work-sheets | Ctrl+Shift+Tab, Ctrl+Shift+F6 | Shift+Command+Left bracket |
| Switch in and out of Presentation Mode | F7 , Ctrl+H | Option+Return |
| Switch in and out of Full Screen mode | | Control+Command+F |
| Open file | Ctrl+O | Command+O |
| Save file | Ctrl+S | Command+S |
| Save to Tableau Public | Ctrl+Shift+S | Shift+Command+S |
| Revert workbook to last saved state | F12 | Option+Command+E |
| Close the current workbook | Alt+F4 | Command+W |

| | | |
|-----------|--------|-------------------|
| Print | Ctrl+P | Command+P |
| Open Help | F1 | Control+Command+? |

Shortcuts for managing workbooks, sheets and files (Tableau Server, Tableau Cloud)

| Description | Windows shortcut | Mac shortcut |
|---------------------------------------|------------------|--------------------|
| New worksheet | Ctrl+Alt+T | Option+Command+T |
| Switch in and out of Full Screen mode | F11 | Control+Command+F |
| Save file | Ctrl+S | Command+S |
| Save workbook as | Ctrl+Shift+S | Shift+Command+S |
| Close the current workbook | Alt+F4 | Option+Q |
| Print (or export as PDF) | Ctrl+P | Command+P |
| Open Help | F1 | Control+Command+/? |

Shortcuts for data (Tableau Desktop)

| Description | Windows shortcut | Mac shortcut |
|--|------------------|------------------|
| Connect to data source | Ctrl+D | Command+D |
| Activate the find command in the Data pane | Ctrl+F | Command+F |
| Refresh data source | F5 | Command+R |
| Run data updates on a view | F9 | Shift+Command+0 |
| Toggle automatic data updates on and off | F10 | Option+Command+0 |

Shortcuts for data (Tableau Server, Tableau Cloud)

| Description | Windows shortcut | Mac shortcut |
|------------------------|------------------|-----------------|
| Connect to data source | Ctrl+D | Command+D |
| Refresh data source | Alt+F5 | Option+F5 |
| Rename data source | Alt+F2 | Option+F2 |
| New data source | Ctrl+Alt+D | Control+D |
| Edit data source | Ctrl+Alt+Shift+D | Control+Shift+D |

Shortcuts for authoring views (Tableau Desktop)

| Description | Windows shortcut | Mac shortcut |
|--|-----------------------|------------------------|
| Show Me! | Ctrl+1 , Ctrl+Shift+1 | Command+1 |
| Add the selected field to the sheet. (Only works with a single field.) | Enter or double-click | Return or double-click |
| Place selected field on Columns shelf | Alt+Shift+C | Option+Shift+C |
| Place selected field on Filters shelf | Alt+Shift+F | Option+Shift+F |
| Place selected field on Size | Alt+Shift+I | Option+Shift+I |
| Place selected field on | Alt+Shift+L | Option+Shift+L |

Detail

| | | |
|--|---------------------------|----------------------|
| Place selected field on Colour | Alt+Shift+O | Option+Shift+O |
| Place selected field on Pages shelf | Alt+Shift+P | Option+Shift+P |
| Place selected field on Rows shelf | Alt+Shift+R | Option+Shift+R |
| Place selected field on Shape | Alt+Shift+S | Option+Shift+S |
| Place selected field on Text/Label | Alt+Shift+T | Option+Shift+T |
| Place selected field on Rows shelf | Alt+Shift+X | Option+Shift+X |
| Place selected field on Columns shelf | Alt+Shift+Y | Option+Shift+Y |

Tableau Public FAQ

What is Tableau Public?

Tableau Public is a free platform to explore, create and share data visualisations using publicly available data online. Visualisations (vizzes) that are published to Tableau Public can be embedded into web pages and blogs, shared via social media or email, and can be made available for download and exploration by other users. You can create vizzes using our free in-platform web authoring, the free Tableau Desktop Public Edition or by using Tableau Desktop Professional Edition. Click Create on Tableau Public to get started – no programming skills are required. To see some of the inspiring visualisations users create using Tableau Public, visit our [homepage](#).

Who is Tableau Public for?

Tableau Public is for anyone interested in understanding data and sharing those findings as data visualisations with the world. Journalists, writers, bloggers, state and local governments, non-profits, companies and more use Tableau Public to share data stories. Students, professors, analysts and hobbyists use Tableau Public for learning and inspiration. As soon as a workbook is published to Tableau Public, the viz is accessible by anyone on the internet (with some restrictions – see details below), so be sure to only use data that is suitable for a public audience. If you or your organisation wants to analyse non-public data, check out other available [Tableau products](#).

Tableau Public Account Issues

I didn't activate my account in the 48 hours following receipt of the email. Can I still activate it now?

Yes, you can still activate your account. Follow these steps:

1. Select **Forgot your password** and then enter your email address to get a reset password email.
2. Go to your email, open the "Tableau Software Account Activation" email and then select the **Activate Account** link. You'll be redirected to your profile page.
3. Enter a new password and then re-enter it to confirm.
4. Select **Activate**.

I forgot my password. How do I reset it?

1. From the Sign In screen, select **Forgot Password**. Or go directly to the [Reset Password](#) page.
2. Enter your email address to get a reset password email.
3. Go to your email, open the "Password reset" email and select the link to reset your password. You'll be redirected to your profile page.
4. Enter your new password, re-enter it to confirm and select **Reset Password**.

How do I change the email address associated with my account?

1. Sign in to your Tableau account. From your profile icon, select **Edit My Tableau Account** and then click **Edit Email**.
2. Enter a new email address.
3. Select **Change Email**.

Help! I didn't receive my activation email and/or password reset email.

For security reasons, we use an automatic service to send activation and password reset emails. If you don't receive your email (and it's not in your spam folder), it's possible that it has been removed by a firewall filter. Try requesting your activation or password reset email again from a different device (for example, on your mobile phone instead of your laptop), and on a different network (for example, on your home Wi-Fi, instead of your work Wi-Fi). If you're still having trouble accessing your account, contact public@tableau.com.

I've received notification that my Tableau.com and Tableau Public accounts have been integrated. What does this mean for my Tableau Public account?

All Tableau Public users will now be able to access both Tableau.com and Tableau Public using a single user account. Check for a verification email sent to the email address you use to sign in to your Tableau Public account. If you already have a verified account, [sign in](#).

What if I didn't receive a verification email after the Tableau.com and Tableau Public account integration?

If you didn't receive a verification email and don't have an existing Tableau account associated with the same email address, you can follow these steps to confirm your account:

1. [Reset your password](#).
2. Enter the email address you were previously using to log in to your Tableau Public account.
3. Look for the password reset email in your inbox.
4. Select the reset password URL.
5. Enter your new password.

Still have questions about your account? Contact public@tableau.com.

What if I no longer have access to the email address that was linked to my Tableau or Tableau Public account?

To change the email address associated with your Tableau Public account, follow these steps:

1. Navigate to <https://public.tableau.com/app/discover>
2. Sign in to Tableau Public.
3. Select your profile icon.

4. Select **Settings**.
5. Select **Change Email**.
6. Enter the new email address you'd like to use.
7. Select **Change Email**.

If you've followed the steps above and are not given the option to change your Tableau Public email address, your email may be connected to a Tableau Cloud account. Submit the [Having a problem with your account?](#) form and indicate that you are unable to change the email address you use to sign in to your Tableau Public account. Once a customer representative contacts you, they will do the following:

- Send an email to your old email address to see if someone responds or if it bounces.
- Request that you verify your identity by sending a scan of your ID or a utility bill from the new email address you'd like to use.

If you're requesting a change to a corporate or institutional account, we will require you to send an email from the business domain and an image of your corporate credentials (e.g. work badge).

What if I want to delete my Tableau Public account?

You can delete your Tableau Public profile including your visualisations, favourites, follows and profile data directly from your account settings page.

1. Sign in to Tableau Public.
2. From your profile icon, select **Settings**.
3. Go to the **Delete Tableau Public Profile** section, and then select **Delete My Tableau Public Profile**.
4. Enter the email address associated with your Tableau Public profile, and then select **Delete**.

If you navigate back to Tableau Public in future after deleting your profile, a new blank account will be created that will be connected to your Tableau account. For more information about our privacy practices, see [Privacy Information](#).

Will subscription offerings impact my Tableau Public profile?

Subscription offerings will not affect your Tableau Public profile. If you currently pay for other Tableau products, contact your sales rep to learn how this impacts you. If you are curious about the new offerings, you can learn more on our [pricing page](#).

How much storage space do I get?

We provide ten gigabytes (10 GB) of storage space for your content.

Why does my session on Tableau Public keep expiring?

Tableau Public requires you to sign in frequently if you have not given consent for functional cookies. These are required to preserve your sign-in session. To configure your cookies on the Tableau Public site:

1. Scroll down to the bottom of the [homepage](#) and select **Cookie Preferences**.
2. Select **Functional Cookies**.
3. Select the toggle to turn on functional cookies.
4. Select **Save Settings**.

[Back to Top](#)

Using Tableau Public

How do I customise or edit my profile details, image or banner?

When you sign up for Tableau Public, an account profile is generated for you that includes the name you entered when creating the account. Once you've verified your email address, you can edit your profile to add details about yourself including a bio, your title, location and social media links. You can also upload a profile picture and customise your profile banner.

For all profile customisations, start by selecting your profile icon and then select **My Profile**.

- To edit your profile details, select **Edit Profile**. Make any applicable changes, and then select **Save**.
- To add or change a profile picture, hover over the existing picture (this will be a placeholder image if you haven't added one yet), and then select **Update profile picture**. Select a picture, adjust the cropping and then select **Save**.
- To customise the colour and style of your profile banner, select **Customise Banner** in the top-right corner of the banner. Choose a colour from the colour picker, select a pattern and then select **Save**.

How do I customise how my vizzes are organised and displayed on my profile?

Tableau Public users with 10 or more published visible vizzes can organise the vizzes on their profile page to be displayed in categories. You can let Tableau AI suggest category names, or you can manually add your own custom category names.

The first time you select **Organise Your Vizzes** from your profile page, any vizzes published within the last two weeks appear in the **Recent** category. All other vizzes appear in the **Other** category.

From the Organise Vizzes page, you can choose to organise your vizzes into **Categories** or to list all of your vizzes together by **Date Published**. Select **Save Organisation** when you've finished making changes.

The **Auto-Categorise** button uses Tableau AI to sort your vizzes into the available categories. When you select **Auto-Categorise**,

- if you haven't manually added any category names yet, Tableau AI automatically generates category name suggestions and organises your vizzes into those categories.
- if you've manually added your own category names before selecting Auto-Categorise, your vizzes are sorted into your custom categories or the Other category.

Note: If you've already manually or automatically categorised your vizzes and you want Tableau AI to suggest new category names, you must first delete all existing category names (except Recent and Other, which can't be deleted) and then select **Auto-Categorise**.

Warning: Every time you select **Auto-Categorise**, any previous organisation (whether automated or manual) is reset, and Tableau AI re-sorts all of your vizzes into the available categories.

Manually add a new category name

1. From the Organise Vizzes page, ensure that Organise By is set to **Categories**.
2. In the Categories text field, enter a category name and then select the enter key or the **+** icon.

Note: Category names can't exceed six words.

Rename a category

Select the **Actions** drop-down menu for the category that you want to update and then select **Rename**. Enter a new name and then select **Update**. The Recent and Other categories can't be renamed.

Delete a category name

Select the **x** icon on the category name. Or select the **Actions** drop-down menu for the category that you want to delete, and then select **Delete**. The Recent and Other categories can't be deleted.

Reorder categories

Click and hold the dotted icon on the category name, and then drag and drop the category in the order you prefer. The Other category can't be reordered.

Add or remove vizzes for a specific category

1. Select the **Actions** drop-down menu for the category that you want to update, and then select **Add Vizzes**. Or select the **Add Vizzes** button in the description of an empty category.
2. Tick the box for each viz that you want to add to the category.
3. Select **Save**.

Important: Select **Save Organisation** on the Organise Vizzes page to save any changes you make to category names or how your vizzes are organised.

You can also manually change the categories that a viz appears in from an individual viz card. Select the **More Actions (...)** menu on a viz card, and then use the **Viz Category** drop-down to select and clear tick boxes for the available category names. Select **Apply** to save the changes.

Notes:

- You can add a viz to multiple categories, but each viz must exist in at least one category. You can't remove a viz from a category if that's the only category the viz is assigned to.
- If you delete a category name, any vizzes in that category that aren't also assigned to another category are automatically moved to the Other category.
- If you organise by category, any new vizzes that you publish are automatically added to the Recent category.

How do I share the visualisations I've saved to Tableau Public with others?

Once you [save your work to Tableau Public](#), you can share it by sending people the link to the visualisation's homepage via email, Twitter, Facebook, etc. To embed the viz in your own website, select the viz homepage, select Share and then copy the Embed Code.

What are the different ways that I can sort or filter my search results on Tableau Public?

When you search for vizzes or authors on Tableau Public, you can use sorting and filtering to surface results that matter to you.

For vizzes, you can sort by relevance, view count or published date.

- **Relevant** (Default): See vizzes that most closely match your search terms, that have been published recently and that have high view and favourite counts.
- **View count**: See results sorted by highest view count.
- **Recently published**: See results sorted by the initial published date.

You can also filter results to only see vizzes that can be downloaded or copied.

For authors, you can sort by relevance, number of followers or by recent activity.

- **Relevant** (Default): See authors that most closely match your search terms and that have a high follower count.
- **Follower count**: See results sorted by highest number of followers.
- **Recently active**: See results sorted by authors who have recently published a workbook or updated the metadata for an existing workbook.

You can also filter results to only see authors that are available for hire.

Can I prevent people from finding the visualisations I've saved to my Tableau Public profile?

Tableau Public is meant as a platform for sharing data visualisations on the web. However, you can hide vizzes on your profile. This feature can be handy when, for example, you want to save a draft of your work in progress. You can find all of your hidden vizzes on your profile page under the Hidden tab. Visitors to your profile page can't see your hidden vizzes.

Note: Anyone who knows (or stumbles across) the URL for the viz can see it, so be sure not to use this service for data that isn't meant for sharing.

Can my viz or the data behind my viz be downloaded by others? What's the Download link on the viz?

By default, any Tableau Public viz as well as the underlying data can be downloaded by clicking the **Download** link in the lower-right corner of the viz. The workbook (TWBX file) can be opened by anyone with Tableau Desktop (Professional or Public Edition). You can toggle off the ability to download the workbook and the underlying data set in the viz settings. You can also set the default behaviour for new vizzes in your profile settings.

I've made a viz that I'm really proud of. How can I advertise it?

First of all, congratulations on building this viz! Start by checking out a guest blog post written by Ryan Sleeper on [Making Your Tableau Public Viz Go Viral](#).

We also welcome Viz of the Day submissions. To nominate a viz, select the viz that you want to nominate, and then select the **Nominate for Viz of the Day** button.

What is the Hire Me button?

The Hire Me button allows Tableau Public authors to indicate to the community they are available for hire and allows customers to see which authors are available. Customers can fill in a form to contact the author. The author will receive an email enquiry from the customer that they can choose to respond to.

How do I activate the Hire Me button on my profile?

1. Sign in to your Tableau Public account.
2. From your profile icon, Select **My Profile**.
3. Select **Edit Profile**.
4. Check the **Available for Hire** box.
5. Confirm your preferred contact email address.
6. Select **Save**.

What email address will my Hire Me enquiries go to?

All Hire Me email inquiries and responses will be delivered to the email address that you specified in your profile details.

How do I contact an author?

Authors who are available for hire can be identified by a Hire Me button on their profile. To contact an author:

1. From the author's profile page, select **Hire Me**.
2. Enter your message in the text field.
3. Select **Send**.

How can hiring managers find talent with Tableau skills?

You can share your listing on the [Job Listings Community Forum](#).

How do I report spam or phishing emails on Tableau Public?

If you receive an email you believe to be spam or a phishing attempt, forward the email to public@tableau.com.

Where can I see stats about my vizzes and profile?

Sign in to Tableau Public, go to your profile page by clicking your profile icon and then select My Profile. Select the Stats tab to see how many times your visualisations were viewed or favourited, how often your vizzes or your profile were credited as inspiration for another author and how many authors followed you. All stats show activity over the last 30 days, and you can see a chart displaying the progression of each stat over time. You can also see a list of top vizzes contributing to the Viewed, Favourited and Inspired stats.

Why don't I see any stats on my profile?

The stats tab provides insights when others view or favourite vizzes that you create, credit your vizzes as inspiration or follow you. If you don't see any stats on your profile, create and publish more visualisations for others to explore. You can create and publish vizzes for free using in-platform Web Authoring or by downloading Tableau Desktop Public Edition.

Why did the view count for my viz decrease or reset to zero?

A view count on Tableau Public represents the number of times your workbook is viewed, including views on the Tableau Public platform and on other websites where the viz is embedded. **Workbooks are composed of sheets**, which can be in the form of worksheets (also referred to as views), dashboards or stories. The view count for a viz on Tableau Public is counted at the sheet level (a worksheet, dashboard or story), and aggregated per workbook. So deleting or adding a sheet in a workbook will impact your total view count.

Events that decrease view count include:

- A worksheet, dashboard or story that has been viewed on Tableau Public or embedded in another site is removed from the workbook.
- A worksheet, dashboard or story that has been viewed on Tableau Public or embedded in another site is renamed.
- From Tableau Desktop, you save a workbook to your profile with the same name as an existing workbook and click Yes to overwrite an existing workbook when saving. This overwrites the existing workbook on your profile, which Tableau Public treats as a brand-new workbook with a view count of zero.

Events where view count will not decrease:

- From your browser, you edit an existing workbook on your profile without deleting or renaming any worksheets, dashboards or stories that have been viewed on Tableau Public or embedded in another site.
- From Tableau Desktop, you edit an existing workbook on your profile without deleting or renaming any worksheets, dashboards or stories that have been viewed on Tableau Public or embedded in another site.

Do I need to use Tableau Desktop Public Edition if I already have access to Professional Edition?

No, Tableau Desktop is available as part of a Creator licence. With Tableau Desktop Professional or Public Edition, you can save your workbook to the Tableau Public platform or save locally. Instructions on how to publish a workbook to Tableau Public or save locally can be found on the **Save Workbooks with Tableau Public** page.

Are Tableau Public vizzes responsive?

When embedding vizzes in your website, you can optimise them for use across different devices and screen sizes:

1. Set the dashboard size to automatic or range.
2. Build different dashboards of different sizes (e.g. a large one for desktop computers and a small one for mobile devices). Then, save the dashboards under different names and have your content management system (CMS) swap out the embed code according to the size of your browser or screen. You can also define different dashboard sizes and the respective content within the app before publishing the viz. You can then save your viz as normal and use a single embed code in your CMS. The Tableau Public server will serve up the dashboard that is most suitable for the size of the browser window.

Are any plug-ins required to view a Tableau viz?

No plug-ins are required. All you need is a web browser with JavaScript activated.

How can I delete a viz from Tableau Public?

To delete a viz from Tableau Public, go to your profile page, select the **More Actions** icon for the viz you want to delete and then select **Delete This Viz**.

What happens if I delete a workbook from Tableau Public and there are links to it in blogs or other web locations?

Once a workbook is deleted from Tableau Public, it can't be retrieved from Tableau Public by anyone. All links or other references to it that may have been shared will not be able to load the viz and will display an error message on the page. This also applies to vizzes embedded in other websites.

How can I make my viz load faster?

To maximise the probability of fast load times and interactivity, take these steps and make any necessary modifications:

1. Simplify your data
 - Use only data relevant to analysis. Cut useless rows and columns, and use data source filters.
 - Aggregate data to the highest level of detail possible for the desired visualisation. For example, if a viz only shows data by year but your data source has records by day, then aggregate data in the source file to year.
 - Pre-build complex calculations into the data source as much as possible.
 - Normalise tables with relationships. If you have data with different levels of detail resulting in repeated values, split the data into separate tables and define a

relationship between tables in the Tableau Desktop data source pane. More info on normalisation and relationships.

2. Limit the number of filters

- Excessive filters on a view will create a more complex query, which takes longer to return results. Double-check your filters and remove any that aren't necessary.
- Use include filters. Exclude filters load the entire domain of a dimension, while include filters do not. An include filter runs much faster than an exclude filter, especially for dimensions with many members. Use continuous date filters. Continuous date filters (relative and range-of-date filters) can take advantage of the indexing properties in your database and are faster than discrete date filters.
- Use Boolean or numeric filters. Computers process integers and Booleans (t/f) much faster than strings.
- Use parameters and action filters. These reduce the query load (and work across data sources).

3. Minimise the number of marks (data points)

- Similar to data aggregation, can the marks in the visualisation be grouped together in any way? For example, instead of showing the dollar amount of every single customer order in a bar chart, can they be grouped together into just product category or region?

4. Delete unused sheets, stories and dashboards

Here are additional resources to optimise your workbook for performance:

- [Optimise Workbook Performance](#)
- [Make Visualisations Faster](#)
- [Streamline Your Workbook](#)
- [Tableau Performance Optimisation](#) (on the Medium website)
- [Six tips to make your dashboards more performant](#)
- [Designing Efficient Workbooks](#)

How can I see what's new since I last visited Tableau Public?

The Recent Activity channel helps you keep up with the latest updates from your network. See vizs that have been published or favoured by authors that you follow since you last visited the site so you don't miss anything. Sign in to [Tableau Public](#) to see your personalised Recent Activity channel on the homepage.

I'm not able to view the thumbnails for certain vizzes. Is this a bug on Tableau Public?

We've had reports from a few users that thumbnails for some vizzes are either blocked or don't show up on Tableau Public. This is likely due to the use of an ad blocker on your browser. If you're experiencing this issue, we recommend turning off the ad blocker and reloading the web page. To remedy this issue, you can allowlist public.tableau.com.

How can I make my Tableau Public viz more accessible?

To make your digital content accessible, it should follow the four Web Content Accessibility Guidelines (WCAG): perceivable, operable, understandable and robust.

Here are three ways to make your viz more accessible to users using assistive technologies:

Allow Access

Enable the ability to **Let others download or make a copy of this viz** on Tableau Public. This is one of the most important things you can do for user accessibility. This step lets users access the View Data page, which has a table of data that assistive technologies, like screen readers, can read.

Select the **Settings** icon in the toolbar. Under **Allow Access**, switch the option to **Let others download or make a copy of this viz** to on.

Add more text

Provide descriptive text in titles, captions, headings, legends and filters to provide context to users who are using assistive technology. Think about your views as a supplement to the text you use to describe it.

Use these guidelines to adapt the visual nature of Tableau to meet the needs of all of your users.

- Use text in titles and captions to describe your visualisations and what you are showing.
- Use text in headings on legends or filters to describe the control and what it does.
- Add alternative text (alt text) to visualisations.
- Use simple, easy-to-understand language. Avoid jargon, acronyms or abbreviations.

Use accessible colour and contrast

Using colour on your viz helps distinguish marks in your view. However, for users with visual impairments, using colour alone doesn't provide enough of a distinction.

Use these guidelines when using colour in your views:

- Use a colour palette with enough contrast and assign colours that differ from each other on the light-dark spectrum. Tableau provides a colour-blind palette that you can use to help you select suitable colours for your view.
- Use additional differentiators such as shapes, size and labels to distinguish line marks.
- Make sure that the colour contrast for text is strong and meets the contrast ratio standards of 4.5:1 (3:1 for large text). Use [contrast analyser](#) tools to select the best text colours and backgrounds with sufficient contrast ratios.

What resources are available to help me create or enhance visualisations?

- [Tableau Exchange](#) offers extensions that add new dashboard functionalities and viz types to your visual analysis for free. Use the filters to find dashboard and viz extensions that work with Tableau Public.
- Access [sample data sets](#) and data sources.
- Explore Tableau Public [community resources](#) to share your work, learn from others and participate in skill-based challenges.

How can I add viz extensions to my Tableau Public visualisations?

1. From your worksheet, expand the Mark type dropdown on the Marks card. Under Viz Extensions, select **Add Extension**.
 - To add a new extension, select **Works with Tableau Public**. Search for and select an extension and then select **Open**.
 - To add a .trex file you previously downloaded, select **Access Local Viz Extensions**.
2. Open the extension you want to use. For more information, see [Add Viz Extensions to your worksheet](#).

How can I add dashboard extensions to my Tableau Public visualisations?

From your dashboard sheet, drag **Extension** from the Objects section to the dashboard.

- To add a new extension, search for and select an extension, and then select **Add to Dashboard**. Verify that **Works with Tableau Public** is selected.
- To add a .trex file you previously downloaded, select **Access Local Extensions**. For more information, see [Use Dashboard Extensions](#).

Data and Tableau Public

What kind of data can I use?

Tableau Public supports data in a variety of formats including Microsoft Excel, multiple text file formats, statistical files, Google Sheets and web data connectors. For more information, see [Creators: Connect to Data on the Web](#).

Can I save to Tableau Public a workbook with a live connection to a data source?

Tableau Public only supports extracted data sources and does not support live connections to data. However, authors have the option to allow Tableau Public to automatically refresh data sources connecting to Google Sheets every 24 hours. For all other data sources (for example, Excel or a CSV), automatic refresh on Tableau Public is not supported. For more information, see [How is data from Google Sheets refreshed on Tableau Public?](#)

How is data from Google Sheets refreshed on Tableau Public?

When you publish a workbook to Public, an extract of the data sources is created, including any data sources that connect to Google Sheets. Every 24 hours, Tableau Public will automatically refresh Google Sheets data sources, meaning any changes in the Google Sheet will be reflected in the data source of the connected workbook on Tableau Public. If your data source uses [relationships](#), all logical tables must be a Google Sheets connection for the data source to automatically refresh. To help balance the load of refreshing the many workbooks and data sources connecting to Google Sheets, Tableau Public will automatically assign a workbook to one of three time frames when the refresh will occur daily. Although you can't customise the refresh schedule to a different frequency or time-of-day, the author can initiate a refresh by clicking Request Update. Tableau Public will refresh the data source connecting to Google Sheets, and any changes will automatically be reflected in the workbook.

Does Tableau Public support .tde files?

2024.2 is the last version of Tableau Desktop that supports any .tde-based workbooks, data sources or bookmarks. Versions 2024.3 and beyond only support .hyper format. For more information, see [Extract Upgrade to .hyper Format](#).

Embedding Tableau Public

I have my own blog or website. Can I embed my Tableau Public viz there?

Yes. Once you have saved your data visualisation on Tableau Public, you can look up the [embed code](#) and use it in your own webpage or blog. Be sure you use the generated embed code and not just the URL of the visualisation's homepage, so as to only embed the viz without the borders around it.

What blog services is Tableau Public compatible with?

- Blogger by Google (blogger.com)
- Typepad (typepad.com) – Make sure to edit your posts in HTML mode rather than Rich Text. Otherwise, the Tableau Public embed codes aren't preserved.
- WordPress (wordpress.org) – WordPress is completely customisable and can be used for almost anything. Web host required.
- Squarespace (squarespace.com) – Make sure you use a code block.

Where do I get the embed code for a viz from?

You can get the embed code for any viz by clicking the **Share** icon in the viz footer.

About Tableau Public

What kind of technology is a Tableau viz?

A Tableau viz is essentially an AJAX-based JavaScript application.

What are the system requirements for Tableau Public?

For a complete list of specs and system requirements, see the [Tableau Public Technical Specifications](#) page.

What is the difference between Tableau Desktop Public Edition and Tableau Desktop Professional Edition?

When using Tableau Desktop Public Edition, note the following:

- Tableau Desktop Public Edition gives you the option to either share workbooks publicly to your Tableau Public profile or save workbooks locally. Workbooks and data published to your Tableau Public profile are not private and are freely accessible to anyone.
- Tableau Desktop Public Edition automatically saves your work for you every few minutes. This feature is turned on by default, but you can turn it off from the toolbar under Help > Settings and Performance > Enable Autosave.
- Tableau Public is limited to 15M rows of data per workbook. For more information about logic tables and data sources, see [The Tableau Data Model](#).
- You can't connect to other servers such as Tableau Online or an Internal Tableau Server. You can only connect to Tableau Public.
- Data connectors are [limited](#).

Is Tableau Desktop (Public Edition) available for Mac?

Yes! Check out our [download page](#) for more details. Download the latest version and give it a try.

Where do I check to see if Tableau Public is down?

You can check the status of Tableau Public on the [Tableau Trust](#) site.
