Manage Server
Tableau Server on Linux integrates with a number of components in your IT infrastructure to provide a unique self-service data analytics culture for your users. It's important that you, as a server administrator, understand how Tableau Server fits into your IT infrastructure.

The topics in this section provide information on planning, deploying, tuning, and managing Tableau Server.

If you are new to Tableau Server, and you want to deploy it in your organization, we encourage you to deploy Tableau Server as a single server in a test environment first. The easiest way to do a single-server installation and to understand the essential requirements is to follow the steps in Everybody’s Install Guide.
This topic provides a brief overview of how to think about Tableau Server and how it interacts with your existing IT infrastructure.

Architectural overview

Tableau Server is a collection of processes that work together to provide a full self-service analytic platform for your users. The following diagram shows a high-level architectural view of Tableau Server.

Multiple server processes (shown in blue above) work together to provide services at various tiers. The Gateway process is the component that redirects traffic from all Tableau clients to the available server nodes in a cluster.

Data Services is a logical grouping of services that provide data freshness, shared metadata management, governed data sources, and in-memory data. The underlying processes that power Data Services are the Backgrouter, Data Server and Data Engine processes.
Analytics Services, composed of the VizQL and Cache Server processes, provide user-facing visualization and analytics services and caching services.

Sharing and Collaboration, and Content Management Service are powered by the Application Server process. Core Tableau Server functionality such as user login, content management (projects, sites, permissioning, etc.) and administration activities are provided by the Application Server process.

All of the above services use and rely on the Repository process, which contains structured relational data like metadata, permissions, workbooks, data extracts, user info, and other data. The File Store process enables data extract file redundancy across the cluster and ensures extracts are locally available on all cluster nodes. Under heavier loads, extract files are available locally across the cluster for faster processing and rendering.

Tableau’s architecture is flexible, allowing you to run the platform just about anywhere. You can install Tableau Server on-premises, in your private cloud or data center, on Amazon EC2, on Google Cloud Platform, or on MS Azure. Tableau analytics platform can also run atop virtualization platforms. We recommend you follow the best practices for each virtualization platform to ensure the best performance from Tableau Server.

**Tableau and your data**

When you install Tableau Server into your organization, it becomes a core component of the analytics pipeline to the data your users need. It’s important to understand how Tableau Server interacts with your business data. Specifically, Tableau Server can store extracts of data in your organization. It can also connect to live data sources. How you choose to provide the data to your Tableau users is informed by a number of variables: data source type, user scenario, performance and access requirements, and infrastructure conditions.

Tableau Server has not been architected as a data warehouse server where static, native data files are housed. In fact, using Tableau Server as a traditional data warehouse is a poor use of your investment. Rather, when it comes to data storage, we recommend hosting optimized data extracts on Tableau Server. While a data extract is often a subset of a larger
data source in your organization, you can also create extracts for data sources that are overtaxed during work hours by scheduling the extract refresh for off-hours.

Extracts are also useful for modeling data or to enable highly-performant visualization authoring. For example, to improve visualization authoring and interaction performance you may optimize extracts by filtering the source data to the essential fields for a given department or project.

Tableau Server also provides direct, authorized access to live data sources, allowing users to build and run complex filtered queries against a variety of connected data sources. For this scenario, Tableau requires highly performant network access to the data sources in your organization and to those in the cloud. Tableau Server and the target data sources also need to be properly sized to handle the processing load required by high-volume, complex data operations.

User access

Tableau Server is also a web-based collaboration platform, where users connect to share, view, and interact with data visualizations and data sources from a variety of devices. This means that Tableau Server must be accessible to Tableau users within your local protected network. You can also extend access to data visualizations to desktop, mobile, and authenticated web users outside your organization.

Tableau Server integrates with the following user authentication solutions: Active Directory, SAML, OpenId, and Kerberos.

Where should I install Tableau Server in my network?

Because of the highly-sensitive nature of most data that organizations manage with Tableau Server, and because Tableau Server requires access to internal data stores, Tableau Server must be run inside a protected network. Authenticated access from the internet is configured to connect to Tableau Server through a reverse proxy or a VPN solution.
Some organizations embed Tableau views in public webpages, or, for internal users, on generic web servers on the internal network.

Tableau Server can be configured to support such scenarios with either authenticated or anonymous access. For authorized access, where users can only view underlying data to which they have permission, you can configure trusted tickets with a generic web server. In this scenario, Tableau Server authorizes access to the underlying data in an embedded view. This scheme enables you to host interactive data visualizations on a web server in a DMZ or outside the protected network.

Anonymous access to embedded Tableau views requires that you enable "guest user" for Tableau Server. Guest user also requires that you license Tableau Server according to the number of cores you are running, rather than a named-user (interactor) model.

**Sizing and scalability**

Depending on the size and data usage in your organization, you can scale Tableau Server up or out. As you scale your server, you can also selectively allocate resources to meet your data needs and user needs.

When you scale up Tableau Server, you add hardware resources to a single server. For example, you might increase the memory and processing power of the computer running Tableau Server.
When you scale out Tableau Server, you add computers (or nodes). To create a highly available deployment with failover, you need at least three nodes. For example, you might run most CPU-intensive server processes on two nodes and use the third node for the gateway and coordination controller services.

Whether you scale up or scale out, you can selectively allocate resources by configuring the number and type of server processes that run. If your organization has a lot of data and creates a lot of data extracts, you can increase the number of processes that are dedicated to refreshing and storing extracts. Alternatively, if your organization wants to optimize for heavy user loads, you can increase the number of processes dedicated to responding to user requests. Additionally, you can integrate Tableau Server into industry-standard network load balancers to further optimize your server for user requests.

**Tableau Server management model**

Tableau Server has been designed to support a management scheme with two high-level administrators: server administrator and site administrator. In small organizations, these roles may be assumed by the same person or team, but in larger organizations, the roles often diverge.

In this model, server administrators are IT professionals who maintain and deploy heterogeneous server solutions. Essential areas for server administrators may include networking, hardware tuning and maintenance, security and access, and managing users and directory services. The tools and documentation that we deliver with Tableau Server for the server administrator support these core server IT areas.

Site administrator, on the other hand, is an administrative role specific to Tableau Server or Tableau Online deployments. The Tableau site administrator is fundamentally concerned with data content. The site administrator manages users and their access to projects, workbooks, and data sources. To learn about sites and how to plan your deployment for them, see What is a site
Management tools

Tableau Server includes a number of toolsets for managing the system:

- **Tableau Server administrator page:** This is the web-based administrative site that is installed on each Tableau Server instance. Tasks performed on the administrator page are day-to-day tasks for both server and site administrators. Server-related tasks include creating sites and site administrator accounts, optionally importing users, setting up synchronization with directory services, setting up extract refresh schedules, monitoring server performance and usage, and other global settings.

  Site-related tasks include managing content and assign permissions, running extract refreshes, create groups and projects, monitoring site activity, optionally adding users, and other content-related tasks.

  Permissions required for the Tableau Server administrator page are role based. The roles are generated and managed by Tableau Server.

- **tsm Command Line Reference** - This is the primary interface for server-wide configurations. The configurations made with TSM CLI are rarely revisited after initial configuration. For example: SSL, subscriptions, data caching, service account, SMTP alerting, user authentication, and single-sign on configuration are all performed with TSM CLI.

- **tabcmd:** You can use the tabcmd command-line utility on a Windows or Linux computer to create scripts to automate administrative tasks on your Tableau Server sites. For example, use tabcmd for creating or deleting users, projects, and groups.

- **REST API:** With the Tableau Server REST API you can manage and change Tableau Server resources programmatically, via HTTP. The API gives you simple access to the functionality behind the data sources, projects, workbooks, site users, and sites on a Tableau server. You can use this access to create your own custom applications or to script interactions with Tableau Server resources.

Security

As an application server connecting to data that may be highly-sensitive, Tableau Server supports and implements a number of industry security standards. Our server admin documentation includes best practices and implementation for user authentication,
authorization, data security, and network security. While our default installation is secure by design, we also recommend following the security hardening checklist to further lock down your deployment.

For more information about security audit compliance, vulnerability reporting, and other security resources, visit http://www.tableau.com/security.

Tableau Services Manager Overview

This article provides an overview of Tableau Services Manager (TSM), which you can use to configure and administer Tableau Server. The TSM CLI was introduced with Tableau Server on Linux, version 10.5. Beginning with version 2018.2, the TSM Web UI is available.

- Functionality
- Components
- Authentication
- Connecting

Functionality

TSM gives server administrators command-line and web-based options for configuring and maintaining Tableau Server, including performing administrative task like backing up server data, restoring backups, creating log archives, and managing multi-node clusters. For example, you use TSM to perform the following tasks:

- Initial configuration of Tableau Server after installation
- Ongoing configuration management, including editing settings and changing the server topology
- Running administrative tasks such as backup, restore, and ziplogs

For administrators familiar with earlier versions of Tableau Server, TSM replaces the following tools from previous versions of Tableau Server:

- Tableau Server Configuration utility
- tabadmin command line utility
- Tableau Server Monitor
Components

TSM consists of services (called processes in this documentation) and clients. TSM processes are administrative services which manage Tableau Server processes. TSM processes run continuously after TSM is initialized, even when the rest of Tableau Server is offline.

TSM processes that run, even when Tableau Server is stopped include:

- Administration Agent
- Administration Controller
- Client File Service
- Coordination Service (based on Apache Zookeeper™)
- Service Manager
- Licensing Service

For more information about TSM processes and Tableau Server processes, see Tableau Server Processes.

Authentication

Whether you use the TSM Web UI, the command line interface, or the TSM API, you need to authenticate to Tableau Server before you can perform administrative tasks.

You authenticate to TSM with a user that exists on the Tableau Server computer. This TSM user account must use password-based authentication and must be a member of the tsmadmin group that is authorized to access TSM. This user account is distinct from Tableau Server user accounts, including Tableau Server administrators and site administrators.

Connecting

As a security measure, you can only connect to TSM using HTTPS. This is because TSM allows you to perform administrative tasks and to connect to TSM from other computers.
The HTTPS connection relies on a self-signed certificate generated by the Tableau Server installer. Although the security of this HTTPS connection is not reduced by using a self-signed certificate, it does require that the CLI is configured to trust the self-signed certificate. This is done by default as part of the installation process, so you can access TSM from the local computer without additional configuration.

Infrastructure Planning

Before you install...

**Note:** You can find additional information about technical specifications for Tableau Server on the Tableau web site, [here](#).

This topic includes requirements and recommendations that you must consider before you install Tableau Server into a production environment.

If you want to install a single server, or if you want to do a minimal installation for test purposes, refer to our single-server installation guide, [Everybody's Install Guide](#).

If you are deploying Tableau Server in a distributed cluster, review Distributed Requirements in addition to the requirements and recommendations described in this topic.

Hardware recommendations

The following list describes the hardware recommendations for a single node installation of Tableau Server:

- 8 core, 2.0 GHz or higher processor
- 64-bit processor architecture
- 32 GB memory
- 50 GB disk space available
**Important:** The disk space requirement cannot be checked until you initialize TSM. If you don’t have enough space, you won’t be told this until after you install the Tableau Server package.

To see the full list of recommendations and to see the minimum hardware requirements, see Minimum Hardware Requirements and Recommendations for Tableau Server.

For public cloud deployments on Amazon Web Services and Google Cloud Platform, their “vCPU” is actually a CPU hyper-thread, and not a full CPU core. When sizing cloud instances, you will need twice as many vCPU as the Tableau Server CPU core requirements given (4 vCPU for a minimum trial installation, 16 vCPU for a recommended installation).

**Operating system requirements**

The following distributions of Linux are supported:

- Red Hat Enterprise Linux (RHEL) 7.3 and higher, CentOS 7.3 and higher, Oracle Linux 7.3 and higher, and Amazon Linux 2.

  Version 8.x is **not supported**.

  These are collectively referred to in this documentation as RHEL-like.

- Ubuntu 16.04 LTS only.

  Version 17.04 is **not supported**.

Previous versions of CentOS and Ubuntu are not supported because Tableau Server requires systemd for process management.

Custom kernels are not supported.

In a multi-node installation of Tableau Server, all of the computer nodes where you are installing Tableau must run Linux and the same distribution of Linux.
Note: You cannot install Tableau Server on a combination of Linux and Windows computers.

Installation directory

The core Tableau Server bits are installed in the /opt directory. You cannot change the install directory. The directory where you install Tableau Server must have at least 15 GB of free disk space. If you attempt to install Tableau Server on a computer that does not have enough space, the Tableau Server package will install, but you will be unable to continue with setup.

Data directory

By default, Tableau Server will create a data directory for all content that is managed by Tableau. The directory is created at /var/opt/tableau/tableau_server.

You can specify a different directory for data (extract) storage during installation. If you plan to use a different directory, do not create the directory. Instead, let Tableau Server setup create the directory. The data directory requires specific permissions that are set by the initialize-tsm script during the installation process. See Install and Initialize TSM.

Additional requirements

Make sure that your environment also meets the following additional requirements:

Hostname

The hostname of the computer where you install Tableau Server must be unique in your environment, and once you have installed Tableau Server the hostname cannot change. Other hostname related requirements:

- Tableau Server must be able to resolve the hostname to an IP address either using the domain name server (DNS) or with a local host file on the computer running Tableau Server. By default, host files are stored at /etc/hosts.
The hostname of the server must not change after you start Tableau Services Manager during the setup process. For example, this might happen if you use the cloud-init package to initialize a virtual machine, and you install Tableau Server on that virtual machine.

Hostnames that include underscores (_) are not supported by Tableau Server on Linux.

Static IP address

The computer where you install Tableau Server must have a static IP address.

Database drivers

To connect to specific data sources, the computer where you install Tableau Server must have the correct database drivers installed. For more information, see Database Drivers.

Available ports

TSM and Tableau Server each require an available TCP port in order for you to access them. TSM defaults to port 8850, and the Tableau Server Gateway service defaults to port 80. We strongly recommend that you ensure that both port 8850 and 80 are not in use on your system before installing Tableau Server. If those ports are not available, the TSM and gateway ports may be dynamically remapped to different port numbers, and there is currently no interface for displaying which port they have been remapped to.

See Tableau Services Manager Ports.

Local firewall configuration

If you are running a firewall on the computer where you will be installing Tableau Server, then you will need to open the following default ports for Tableau Server traffic. All port numbers, except 443 and 8850, can be changed. See Tableau Services Manager Ports.
<table>
<thead>
<tr>
<th>Port</th>
<th>TCP/UDP</th>
<th>Used by ...</th>
<th>TYPE OF INSTALLATION</th>
<th>Distributed / High Availability</th>
</tr>
</thead>
<tbody>
<tr>
<td>80</td>
<td>TCP</td>

<td>All</td>
<td>X</td>
</tr>
<tr>
<td>27000-27009</td>
<td>TCP</td>
<td>Range of ports used by Tableau Server for License service. This range must be open on the node running the License service and accessible from other nodes. By default, the initial node runs the License service.</td>
<td>All</td>
<td>X</td>
</tr>
</tbody>
</table>

See Configure Local Firewall.

**Sudo and root access**

All installation tasks and administrative tasks for Tableau Server must be run as root. Often this is accomplished using the sudo command, but running the commands directly as the root user is also possible.
To install Tableau Server with the root account, you must specify a user account during installation. The account will be used for managing TSM. Specify the account by running the initialize-tsm script with the `-a` option. See Help Output for initialize-tsm Script.

**Account password**

The user account that you use to install and administer Tableau Server must be able to authenticate with a password. That is, the user must not use another means of authenticating (for example public key authentication).

If the account you are using to install and initialize Tableau Server does not have a password, you can set one using the `passwd` command:

```
sudo passwd $USER
```

**Port access requirements**

If you want to install Tableau Server remotely, for example by means of SSH, ensure that the following ports are open:

- **8850.** The port used for the Tableau Services Manager (TSM) web interface. You can use this interface to configure Tableau Server.
- **80.** The port used for the main Tableau Server web interface.

The Tableau Server installer attempts to open these ports during the installation process, but it can only open these ports for the `firewalld` firewall. If your computer runs another firewall, you must open the ports before you install.

**Virtual Container environments**

Installation of Tableau Server in virtual container environments such as Docker have not been tested and are not supported. Tableau Server on Linux will not function as expected if installed in these environments.

**Package requirements**

**Systemd**
Tableau Server requires `systemd` to manage services. This package is installed by default on CentOS 7 and Ubuntu 16. If you decide to test Tableau Server on a modified version of these distributions, you can run the following command to confirm that `systemd` is installed:

```bash
whereis systemd
```

If `systemd` is installed, the installation location is displayed. For example, you might see the following output:

```
systemd: /usr/lib/systemd /etc/systemd /usr/share/systemd /usr/share/man/man1/systemd.1.gz
```

If you have `systemd` installed but the Tableau installer is failing requirements checks for `systemd`, it's likely that `systemd` is not running. To verify that `systemd` is running, run the following command:

```bash
ls /run/systemd
```

The output will be a list of files and directories. If `systemd` is running, the output will include `system`. If `system` is not in the output, then `systemd` is not running.

*Continue to the next step: Install and Configure Tableau Server.*

**Disk Space Requirements**

In general, when estimating the amount of additional disk space to allocate for Tableau Server for day-to-day usage, you must consider whether or not extracts will be published to Tableau Server, and consider the number of workbooks that you expect to publish to Tableau Server. If you anticipate using extracts, Tableau recommends that you begin with a few hundred gigabytes (GB). If you do not anticipate using extracts, you may only need around 50 GB to fulfill your usage needs.

Looking for Tableau Server on Windows? See [Disk Space Requirements](#).
Here are the factors that affect disk space requirements:

Publishing extracts to Tableau Server

Consider the number of extracts that will be published to Tableau Server and the size of each extract. Test your needs by publishing several extracts to Tableau Server, and then checking the disk space used. You can use this amount of disk space to help you figure out how many extracts will be published to Tableau Server over time as well as how each existing extract will increase in size.

Refreshing extracts

Consider the space needed by the temp directory during an extract refresh. The temp directory, which is where an extract is stored to during a refresh, may require up to three times the final file size of the extract.

While there may be some cases where .hyper extracts become bigger after an extract upgrade, there are other cases when .hyper extracts become smaller after an extract upgrade. In general, the overall disk size requirements should be the same for .hyper extracts as it was for .tde extracts.

Creating many workbooks

If using workbooks, consider the number of workbooks that will be published to Tableau Server. Individual workbooks tend to take up a small amount of disk space. However, if you anticipate thousands of workbooks being published, you may want to allocate additional disk space to accommodate those workbooks.

Logging

To assist with daily management and troubleshooting, Tableau Server creates log files as a part of its normal operations. Depending on the level at which the logging is configured, it can significantly impact the amount of disk space necessary on the Tableau Server computer.
Backing up and Restoring Tableau Server

You must have adequate disk space for database backup and restore processes to run successfully. In addition to the amount of space needed for the backup file, you need temporary disk space roughly 10 times the size of the backup file (so if your backup is 4 GB, you should have about 40 GB of temporary disk space available). Similarly you will need adequate temporary disk space for restoring from a backup.

When calculating disk space, be aware that background tasks for cleaning up old extracts are temporarily paused. This means that, for the duration of the backup, extract refreshes will leave extra files in place, adding to disk space usage. If your backup takes a long time, or if your organization uses many extracts that are regularly updated, this can result in a significant amount of temporary disk space usage. These old files will be removed after the backup is complete.

Recommended Baseline Configurations

Determining the topology (number of nodes, number of Tableau Server processes) of your Tableau Server deployment requires you to consider these variables: your environment, sources of data and management to provide self-service data access, workload, and usage. However you may not have enough information about these variables when you deploy Tableau Server for the first time. This topic describes three baseline architectures that can be used as starting points for your Tableau Server installations.

In this article

Hardware Recommendations
Baseline Configurations
Beyond Baseline Configurations
Hardware Recommendations

The hardware recommendations seen below are based on the hardware that the Tableau team uses to test Tableau Server scalability. We suggest that you use these recommendations as starting points for your production deployments. For proof-of-concept deployments, see Minimum Hardware Requirements and Recommendations for Tableau Server.

<table>
<thead>
<tr>
<th>Install Type</th>
<th>Processor</th>
<th>CPU</th>
<th>RAM</th>
<th>Free Disk Space</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single Server</td>
<td>64-bit</td>
<td>8-core (physical), 2.0 GHz or higher</td>
<td>64 GB (8GB/physical Core)</td>
<td>500 GB - 1 TB</td>
</tr>
<tr>
<td>Multi-node and enterprise deployments</td>
<td>Nodes must meet or exceed the minimum hardware recommendations, except nodes running backgrounder, where 4 cores may be acceptable.</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Note:** For deployments using virtual machines, Tableau recommends dedicated CPU affinity. If you are running Tableau Server in a virtual environment, use your VM host’s best practices for vCPU allocation in relation to the number of physical CPU cores on the VM host. Typically 2 vCPUs = 1 physical core for Tableau Server. For example, for AWS installations, the 4 core minimum recommendation is equivalent of 8 AWS vCPUs. Similarly, follow the best practices provided by your virtual infrastructure provider to make sure Tableau Server has access to the appropriate compute, memory, and data resources. If you are installing Tableau Server in a virtual environment or a cloud-based deployment, see Virtual Machines and Public Cloud Deployments section later in this topic.

Estimating Disk Space

There are several factors that affect disk space requirements, including whether or not you will be publishing extracts and the number of workbooks to Tableau Server. For more
information see Disk Space Requirements.

Baseline Configurations

- Single Server Installations
- Two Node Installations (Specialized for extract heavy environments)
- High Availability Installations (HA)

Single Server Installations

Recommendations

We recommend using a single machine to install your Tableau Server for initial deployments with limited usage and are not mission critical. Single Server installations can also be expanded to multi-node installation as your workloads grow.

Here are some instances when a single server installation may not be right for you:

- If your system is considered mission critical and needs to be highly available. High availability is about minimizing the system downtime. It is achieved by eliminating single points of failure, and having a reliable failover mechanism. Tableau Server requires a minimum of a three-node configuration to provide redundancy and eliminate the single points of failure. This is one of the primary reasons to move to a multi-node configuration.

- If you have a lot of active users and a lot of extract refreshes, the two types of loads may be competing for the same resources on the machine. In such a scenario, a single server configuration may not be the right option as you may need additional specialized nodes to isolate the difference workloads.

**Note:** Active users represent the interactive, concurrent requests made to Tableau Server, including consuming dashboards on a laptop or mobile device, web authoring, and connecting to and querying Published Data Sources.
Server Configuration

- Stand-alone single server node with all the processes installed on one machine.

- Below are the number of processes for an 8 core machine:
  - VizQL Server: Set to 2 instances (Number of physical cores divided by 4, up to a maximum of 4).
  - Backgrounder, Cache Server, and Data Server: Set to 2 instances.
  - All other processes, only one instance of the process is installed, regardless of hardware.

Multi-Node Installations

Running Tableau Server on more than one machine is called a multi-node installation, or a cluster. There are various reasons why you might want to have a multi-node installation. For example, you may have heavy extract environments which can mean dedicating some hardware resources to Backgrounder process. For systems that have high availability requirements, you need a multi-node environment that has at least three nodes.

Two Node Installations (Specialized for extract heavy environments)

Recommendations

Start with a two node configuration when the following conditions apply to you:
• **Extract heavy environment**: Majority of your data sources are extracts. Having just a few, extremely large extracts could put your deployment in this category, as would having very many small extracts.

• **Frequent extract refreshes**: Refreshing an extract is a CPU-intensive task. Deployments where extracts are frequently refreshed (for example, several times a day during business hours) are often helped by more emphasis on the background process, which handles refresh tasks.

**Important**: Two-node configurations do not meet the minimum requirements for high availability. If you need a system that is highly available, see High Availability Installations (HA).

**Server Configuration**

- On the initial node, install all the processes except for the backgrounder. Below is the number of instances of the processes for an 8 core machine:
  - VizQL Server: Set to 2 instances. (default calculation: Number of physical cores divided by 4, up to a maximum of 4).
  - Cache Server, and Data Server: Set to 2 instances.
• Backgrounder: Minimum 2, maximum 4.

• All other processes, only one instance of the process is installed, regardless of hardware.

• Isolate backgrounder on the additional node. To calculate the minimum number of backgrounder processes to run, divide the computer’s total number of physical cores by 4. To calculate the maximum number, divide the computer’s total physical cores by 2. When you install the backgrounder, Tableau Server automatically installs one instance of the Data Engine.

As you monitor and gather data about the performance and usage, you can fine tune and configure the number of instances for these processes. For example, initially, you can set the number of backgrounders to minimum (total number of cores divided by four), and increase the number of backgrounder processes later if you find that:

• Extract refreshes are taking a long time to complete

• Subscriptions and alerts are not completing on time

For more information on performance tuning, see Performance Tuning Examples topic.

High Availability Installations (HA)

Recommendations

A highly available installation of Tableau Server is a distributed installation that is designed to maximize the availability of Tableau Server. High availability basically means that the system is available with minimal amount of downtime. To build in redundancy for HA related items such as repository, file redundancy, and failover, you need a minimum of three nodes. The tolerance for downtime will vary for each organization and depends on the SLAs you have established in your organization.

High availability is achieved by eliminating single points of failure and detecting failures and setting up a reliable failover system. HA in Tableau Server is mainly achieved by:
- File redundancy with multiple File Store/Data Engine instances.
- Active/Passive Repository across two nodes.
- Adding an external load balancer to make sure your installation is robust to Gateway failures and make sure that requests only get routed to functioning Gateway processes.

Server Configuration

Three-node configuration:

- To build in redundancy, you need to add additional nodes to host instances of the repository and File Store/Data Engine processes. You can add instances of other processes, including multiple instances of a process on a node.
- To reduce the system’s vulnerability, you can run multiple gateways and additional instances of some of the server processes. The fewest number of computers required to achieve this configuration is three.
- A second, passive instance of the repository has been added to one of the new nodes.
NOTE: In certain circumstances you may want to limit the processes running on your initial node. Reasons for doing this include wanting to run as few processes as possible on the node to limit processing requests on the node. You might also remove licensed Tableau Server processes from the node if you have a core-based license and do not want the initial node cores to count against your core use. When considering this, be aware that there can be performance implications for backup and restore when the repository and File Store are moved off the initial node. For more information on Tableau Server licensed processes, see Tableau Server Processes. For additional information about the potential benefit of locating the repository and File Store on the initial node, see tsm maintenance backup.

Virtual Machines and Public Cloud Deployments

In general, the considerations and recommendations described in this topic apply to virtual environment and cloud deployments.

If you are running Tableau Server in a virtual environment, use your VM host’s best practices for vCPU allocation in relation to the number of physical CPU cores on the VM host. Typically 2 vCPUs = 1 physical core for Tableau Server. For example, for AWS installations, the 4 core minimum recommendation is equivalent of 8 AWS vCPUs.

For more information on cloud-based deployments, see:

- Install Tableau Server in the Cloud.

For more information on installing Tableau Server on VMware, see Tableau Server on VMware VSphere.

Beyond Baseline Configurations

Disaster Recovery Considerations

While HA configurations reduce downtime, you may still encounter failures in case of a disaster or hardware failures. In addition to the above considerations, you should evaluate the
importance of disaster recovery in your organization and plan for a deployment that helps you meet your disaster recovery goals and objectives.

When planning for disaster recovery (DR) in your Tableau environment, there are two main factors to consider:

- **Recovery Time Objective (RTO)**, a measure of how much downtime your business can accept before a full recovery.
  - Influences how often you restore your backups to an alternative cluster and the amount of infrastructure investment.
- **Recovery Point Objective (RPO)**, a measure of how much data loss your business can tolerate.
  - Influences how often you will need to take backups of your system.
  - For Tableau Server the RPO cannot be shorter than the time it takes to complete a full backup of your server.

The diagram below illustrates how to plan for a range of RTO requirements:
Tableau Server Scalability

These baseline configuration may not be enough as your needs change and grow, and you might need to scale your Tableau Server beyond these configurations. Like other enterprise platforms, Tableau Server scales up by adding processor, memory, and disk to existing node, and scales out by adding more nodes to a cluster. However, scalability and performance are heavily dependent on external systems and user activity. The configuration of your Tableau Server can be different depending on your requirements and variables:

For more information on Tableau Server scalability and the variables affecting scalability, see Tableau Server 10.5 Scalability whitepaper.

Identity Store

Tableau Server requires an identity store to manage user and group information. There are two kinds of identity stores: local and external. When you install Tableau Server you must configure either a local identity store or an external identity store.

For information about configuration options for the identity store, see identityStore Entity.

Local identity store

When you configure Tableau Server with a local identity store, all user and group information is stored and managed in the Tableau Server repository. In the local identity store scenario, there is no external source for users and groups.
External identity store

When you configure Tableau Server with an external store, all user and group information is stored and managed by an external directory service. Tableau Server must synchronize with the external identity store so that local copies of the users and groups exist in the Tableau Server repository, but the external identity store is the master source for all user and group data.

If you have configured the Tableau Server identity store to communicate with an external LDAP directory, then all users (including the initial admin account) that you add to Tableau Server must have an account in the directory.

When Tableau Server is configured to use an external LDAP directory for authentication, you must first import user identities from the external directory to the identity store. When users sign in to Tableau Server, their credentials are passed to the external directory, which is responsible for authenticating the user; Tableau Server does not perform this authentication. However, the Tableau user names stored in the identity store are associated with rights and permissions for Tableau Server. Therefore, after authentication is verified, Tableau Server manages user access (authorization) for Tableau resources.

Active Directory is an example of an external user store. Tableau Server is optimized to interface with Active Directory. For example, if you are installing Tableau Server on an Active Directory domain-joined computer, then Setup will detect some Active Directory configurations. If you are installing into Active Directory, we recommend configuring the identity store with TSM web interface. If you are using TSM CLI to install Tableau Server, then you must use the LDAP - Active Directory template to configure identity store.

If you will be running Tableau Server in an Active Directory environment, review User Management in Active Directory Deployments before you deploy.

For all other external stores, Tableau Server supports LDAP as a generic way to communicate the identity store. For example, OpenLDAP is one of several LDAP server implementations with a flexible schema. Tableau Server can be configured to query the OpenLDAP server. To do so, the directory administrator must provide information about the
schema. During setup, you must use TSM CLI to configure a connection to other LDAP directories.

LDAP bind

Clients that wish to query a user store using LDAP must authenticate and establish a session. This is done by binding. There are multiple ways to bind. Simple binding is authenticating with a username and password. For organizations that connect to Tableau Server with simple bind, we recommend configuring an SSL encrypted connection, otherwise the credentials are sent over the wire in plaintext. Another type of binding Tableau Server supports is GSSAPI binding. GSSAPI uses Kerberos to authenticate. In Tableau Server’s case, Tableau Server is the client and the external user store is the LDAP server.

LDAP with GSSAPI (Kerberos) bind

We recommend binding to LDAP directory with GSSAPI. To bind with GSSAPI you will need a keytab file specifically for the Tableau Server service.

If you are installing into Active Directory, and the computer where you are installing Tableau Server is already joined to the domain, then the computer may already have a configuration file and a keytab file. In this case, the Kerberos files are for the operating system functionality and authentication. Strictly speaking, you can use these files for GSSAPI bind, but we don’t recommend using them. Instead, contact your Active Directory administrator and request a keytab specifically for the Tableau Server service. See Understanding Keytab Requirements.

Assuming your operating system has a properly configured keytab for authentication to the domain, then the Kerberos keyfile for GSSAPI bind is all you need for the base installation of Tableau Server. If you plan to use Kerberos authentication for users, then configure Kerberos for user authentication and Kerberos delegation to data sources after installation is complete.
LDAP over SSL

By default, LDAP with simple bind is not encrypted. If you are configuring LDAP with simple bind, we strongly recommend that you enable LDAP over SSL (LDAPS).

If you already have certificates installed for LDAP on the computer running Tableau Server, then LDAPS should work with minimal configuration during the installation process.

Specifically, if you have installed Tableau Server, and you have valid certificates installed in the Tableau keystore (/etc/opt/tableau/tableau_server-/tableauservicesmanagerca.jks), then you can specify SSL when you configure the identity store.

The default password for the Java keystore is changeit.

If you do not have certificates already in place on your computer that are configured for the LDAP server then you must obtain a SSL certificate for the LDAP server and import it into the Tableau system keystore.

Use the "keytool" Java tool to import certificates. In a default installation, this tool is installed with Tableau Server at /opt/tableau/tableau_server-/packages/respository.<installer version>/jre/bin/keytool.

The following command (for RHEL-like distributions) imports the certificate:

`sudo "$PROGRAMFOLDER"/packages/repository*/jre/bin/keytool - import -file "$CERTSDIR" -alias $OPENLDAPSSLSERVER -keystore /etc/opt/tableau/tableau_server/tableauservicesmanagerca.jks - storepass changeit -noprompt`

System users and groups

Tableau Server on Linux uses one user, and two groups for proper operation.
Users

The `initialize-tsm` script can automatically create the user and groups locally during installation. See Help Output for `initialize-tsm` Script. The user and groups can be local or from an LDAP directory service. If you want to use an existing user account in your LDAP directory, or if you want to create a new user account in your LDAP directory for Tableau Server then follow these recommendations.

The user account is an unprivileged user with normal login privileges. By default, the account is named `tableau`. You can specify a different user during installation. If you specify a different account, configure it with the following characteristics:

- Shell set to `/bin/bash`.
- For convenience, consider setting the home directory to the data directory path. The account must have ownership and write privileges to the home directory.

Groups

In a default installation, the `tableau` account belongs to a primary group named `tableau`. However, if you specify an alternate unprivileged user during installation, then the primary group for that alternate account will be used. As a convenience, any account can be added to this group to be able to read the Tableau Server log files (without becoming root).

The final group is used to authorize which users are allowed to use the REST API of the Tableau Services Manager (TSM), which is required to initialize and maintain Tableau Server. Any user in this group will be able to send commands to TSM, so it should be restricted to Tableau Server administrators. By default, this group is named `tsadmin`.

If there is an existing LDAP group that matches these criteria, it can be used. Otherwise, a new LDAP group could be created, and all Tableau Server administrators can be added to this new group. Note that at least one administrator must be in this group in order to successfully initialize Tableau Server.
Authenticating clients

Basic user authentication in Tableau Server is by username and password sign-in for both local and external user stores. In the local case, user passwords are stored as a hashed password in the repository. In the external case, Tableau Server passes the credentials to the external user store and awaits a response as to whether the credentials are valid. External user stores can also handle other kinds of authentication like Kerberos or SSPI (Active Directory only), but the concept is still the same, Tableau Server delegates the credentials or user to the external store and awaits a response.

You can configure Tableau Server such that username-password sign-in is disabled. In these scenarios other authentication methods, such as trusted authentication, OpenID, or SAML can be used. See Authentication.

User Management in Active Directory Deployments

This topic describes important technical details that you should be familiar with if you use Active Directory to authenticate users for Tableau Server. This topic assumes that you are familiar with Active Directory user management and basic Active Directory schema and domain concepts.

Note: If you run Tableau Server on Linux, all external directory communication is configured and managed with a LDAP identity store. In the context of user and group synchronization, Tableau Server configured with LDAP identity store is equivalent to Active Directory. Active Directory synchronization features in Tableau Server function seamlessly with properly configured LDAP directory solutions.

Active Directory user authentication and Tableau Server

Tableau Server stores all user names in the Tableau Server identity store, which is managed by the repository. If Tableau Server is configured to use Active Directory for authentication, you must first import user identities from Active Directory to the identity store. When users sign in to Tableau Server, their credentials are passed to Active Directory, which is
responsible for authenticating the user; Tableau Server does not perform this authentication. (By default, NTLM is used for authentication, but you can enable Kerberos or SAML for single sign-on functionality—however, in all these cases, authentication is left to Active Directory.) However, the Tableau user names stored in the identity store are associated with rights and permissions for Tableau Server. Therefore, after authentication is verified, Tableau Server manages user access (authorization) for Tableau resources.

Active Directory user name attributes and Tableau Server

Active Directory uniquely identifies user objects using several attributes. (For details, see User Naming Attributes on the MSDN website.) Tableau Server relies on two Active Directory user naming attributes:

- **sAMAccountName.** This attribute specifies the logon name that was originally designed for use with older versions of Windows. In many organizations, this name is combined with the NetBIOS name for authentication, using a format like `example\jsmith`, where `example` is the NetBIOS name and `jsmith` is the sAMAccountName value. Due to the original design in Windows, the sAMAccountName value must be less than 20 characters.

  In the Windows Active Directory Users and Computers administrative console, this value is in the field labeled User logon name (pre-Windows 2000) on the Account tab of the user object.

- **userPrincipalName (UPN).** This attribute specifies a user name in the format `jsmith@example.com`, where `jsmith` is the UPN prefix and `@example.com` is the UPN suffix.

  In the Windows Active Directory Users and Computers administrative console, the UPN is a concatenation of two fields on the Account tab of the user object: the User logon name field, and the domain drop-down list next to it.
Adding users from Active Directory

You can add users individually from Active Directory, either by typing them in the server environment or by creating a CSV file and importing the users. You can also add Active Directory users by creating a group via Active Directory and importing all of the group's users. The result can be different depending on which approach you're using.

Adding users individually

In most case, Tableau Server uses the sAMAccountName value for the user name. When you import users individually from Active Directory (either by typing in their names or by using a CSV file), Tableau queries Active Directory with the user name that you provide. If a match is found, then that name is imported into Tableau Server and it becomes the name that the user enters in order to sign in to Tableau Server.

The user name that Tableau Server will import into the identity store will be the sAMAccountName value unless one of the following is true:

- If the user name that you specify is longer than 20 characters.
- If the user name that you specify contains an @ character.

If the user name you enter meets either of these conditions, then Tableau will import the UPN prefix of the userPrincipalName attribute, which will become the user's Tableau logon user name.

If user names were inadvertently imported using UPN names, you can delete the accounts in Tableau Server and then reimport those accounts using the sAMAccountName value for the user name, as shown in User logon name (pre-Windows 2000) in the Windows Active Directory Users and Computers administrative console.

Adding user groups

If you import an Active Directory user group, Tableau will import all users from the group using the sAMAccountName.
Sync behavior when removing users from Active Directory

Users cannot be automatically removed from Tableau Server through an Active Directory sync operation. Users that are disabled, deleted, or removed from groups in Active Directory remain on Tableau Server so that you can audit and reassign the user's content before removing the user's account completely.

However, Tableau Server will act upon user objects differently based how the status of that user object changes in Active Directory. There are two scenarios: deleting/disabling users in Active Directory or removing users from synchronized groups in Active Directory.

When you delete or disable a user in Active Directory and then synchronize that user's group on Tableau Server, the following occurs:

- The user is removed from the Tableau Server group you synchronized.
- The user's role is set to "unlicensed."
- The user will still belong to the All Users group.
- The user is unable to sign in to Tableau Server.

When you remove a user from a group in Active Directory and then synchronize that group on Tableau Server, the following occurs:

- The user is removed from the Tableau Server group you synchronized.
- The users role is retained: it is not set to "unlicensed."
- The user will still belong to the All Users group.
- The user will still have permission to the Tableau Server with access to everything that the All Users group is granted permission to use.

In both instances, to remove a user from Tableau Server, the server administrator must delete the user from the Server Users page in Tableau Server.

Domain nicknames

In Tableau Server, domain nickname is equivalent to the Windows NetBIOS domain name. In a Windows Active Directory forest, a fully qualified domain name (FQDN) can have an arbitrary NetBIOS name. The NetBIOS name is used as the domain identifier when a user logs in to Active Directory.
For example, the FQDN west.na.corp.lan might be configured with a NetBIOS name (nickname) of SEATTLE. The user jsmith in that domain could log on to Windows using either of the following user names:

- west.na.corp.example.com\jsmith
- SEATTLE\jsmith

If you want your users to sign in to Tableau Server with a NetBIOS name instead of the FQDN, then you'll need to verify that the nickname value for each domain where users log in is set. See edidomain for information on how to view and set the nickname value for each domain.

Support for multiple domains

You can add users from a domain that's different from the domain of the Tableau Server computer in these cases:

- Two-way trust has been established between the server’s domain and the users’ domain.

- The server’s domain trusts the users’ domain (one-way trust). See Domain Trust Requirements.

The first time you add a user from the non-server domain, use the fully-qualified domain name with the user name. Any additional users you add from that domain can be added using the domain’s nickname, provided the nickname matches the NetBIOS name.

Duplicate display names

If user display names are not unique across multiple domains, then managing users with the same display name in Tableau can be confusing. Tableau Server will display the same name for two users. For example, consider an organization with two domains, example.lan and example2.lan. If user John Smith exists in both domains, then adding that user to groups and other administrative tasks will be confusing in Tableau Server. In this scenario, consider updating the display name in Active Directory for one of the users to differentiate the accounts.
Sign in to Tableau Server with NetBIOS name

Users can sign in to Tableau Server using the domain nickname (NetBIOS name), for example, SEATTLE\jsmith.

Tableau Server cannot query for NetBIOS name for a given FQDN. As a result, Tableau sets the nickname of a given FQDN according to the first entry in the namespace. For example, given the FQDN west.na.corp.lan, Tableau sets the nickname to west.

Therefore, you might need to update the domain nickname on Tableau Server before users can sign in using the nickname. If you do not update the nickname, users will have to sign in using a fully qualified domain name. For more information, see Users From New Domain Unable to Log In and Do Not Appear in User List in the Tableau Knowledge Base.

Domain Trust Requirements

When you run Tableau Server in an Active Directory environment across multiple domains (either in the same Active Directory forest or in different forests), some Tableau functionality is dependent on the trust relationship between the domains. For example, some administrators manage users in domains that are separate from where they deploy server applications, such as Tableau Server. In other organizations, a Tableau Server deployment might be shared with external partners or with different partners in the organization. Finally, Windows-authenticated data sources, such as SQL Server, MSAS, or Oracle, that Tableau Server connects to may also be in other domains.

If it's feasible, we recommend configuring two-way trust between all domains that interact with Tableau Server. If this is not possible, Tableau Server can be configured to support user authentication where a one-way trust has been configured. In this case, a one-way trust between domains is supported when the domain in which Tableau Server is installed is configured to trust the domain where user accounts reside.

The following illustration shows one-way trust between the domain where Tableau Server is installed and the domain where user accounts reside:
In this scenario, Tableau Server is in the dev.local domain, and users from the users.lan Active Directory domain are imported into Tableau Server. A one-way trust is required for this scenario; specifically, the dev.local domain is configured to trust the users.lan domain. Users in the users.lan domain can access Tableau Server in the dev.local with their normal Active Directory credentials. However, you may need to update the domain nickname on Tableau Server before users log on with the nickname. Refer to the Tableau Knowledge Base for more information.

When you configure Tableau Server for this scenario, specify the user domain during installation. See Configure Initial Node Settings.

Kerberos single sign-on is supported in this one-way trust scenario.

Review User Management in Active Directory Deployments to understand how multiple domains, domain naming, NetBIOS, and Active Directory user name format influence Tableau user management.

Connecting to live data in one-way trust scenarios

In the one-way trust scenario, users connecting to Tableau Server can connect to live data that’s hosted in the cloud or on any other data source on premises that does not rely on Windows authentication.
Data sources that require Windows-authentication might have additional authentication requirements that complicate the scenario, or that can even prevent Tableau Server users from connecting. This is because Tableau Server uses a service account for authentication with such data sources. If you are running Tableau Server in a different domain than data sources that use Windows authentication, verify that the service account that is used for Tableau Server can access the data source.

Communicating with the Internet

In most enterprises, Tableau Server needs to communicate with the internet. Tableau Server was designed to operate inside a protected internal network. Do not set up Tableau Server directly on the internet or in a DMZ. Instead, communications between your network and the internet should be mediated using proxy servers. If the computer running Tableau Server cannot access the internet directly, then you may need to deploy forward proxy servers to mediate traffic from inside the network to targets on the internet.

For inbound traffic, we recommend running Tableau Server behind reverse proxy servers.

How Tableau communicates with the internet

Tableau Server requires outbound access to the internet for these scenarios:

- Working with maps. Tableau uses map data that is hosted externally.

  Tableau Server needs to connect to maps.tableausoftware.com using port 443. If it cannot make this connection, maps may fail to load. You can test connectivity by accessing the Miami and Havana (blue water) map.

  This is the URL:

  https://maps.tableausoftware.com/tile/d/mode=named|from=tableau1_2_base/-mode=named|from=tableau1_2_admin0_borders(mode=named|from=tableau1_2_place_
Licensing. Tableau products connect to the internet to activate license keys. Unless you activate Tableau software with the **Offline Activation Tool**, all Tableau products must have continuous access to the internet to validate their licenses.

Tableau Server needs to connection to the following internet locations for licensing purposes:

- licensing.tableau.com:443
- atr.licensing.tableau.com:443
- o.ss2.us
- ocsp.rootg2.amazontrust.com
- ocsp.rootca1.amazontrust.com
- ocsp.sca1b.amazontrust.com
- crt.sca1b.amazontrust.com
- crt.rootca1.amazontrust.com
- ocsp.sca0a.amazontrust.com
- crt.sca0a.amazontrust.com
- ocsp.sca1a.amazontrust.com
- crt.sca1a.amazontrust.com
- ocsp.sca2a.amazontrust.com
- crt.sca2a.amazontrust.com
- ocsp.sca3a.amazontrust.com
- crt.sca3a.amazontrust.com
- ocsp.sca4a.amazontrust.com
- crt.sca4a.amazontrust.com

Requests to the above domains may be on port 80 or 443.

If Tableau Server cannot make a connection while attempting to activate its license, you will be prompted to do an offline activation.

- Working with external or cloud-based data.

Tableau Server can run without internet access. For more information about deploying Tableau Server in organizations without access to the internet, see Install Tableau Server in a Disconnected (Air-Gapped) Environment.

In many enterprises, users also need to access Tableau Server from outside the network (that is, from the internet). For example, in many enterprises, users want to be able to reach Tableau Server from their mobile devices in order to interact with views that are stored on the server. To configure access to Tableau Server from the internet or from mobile devices, you should use a reverse proxy. See Configuring Proxies for Tableau Server.

**Configuring Proxies for Tableau Server**

In most enterprises, Tableau Server needs to communicate with the internet. Tableau Server was designed to operate inside a protected internal network. Do not set up Tableau Server directly on the internet or in a DMZ. Instead, communications between your network and the internet should be mediated using proxy servers. Forward proxy servers mediate traffic from inside the network to targets on the internet. Reverse proxy servers mediate traffic from the internet to targets inside the network.
Who should read this article?

This article is for IT professionals who are experienced with general networking and gateway proxy solutions. The article describes how and when Tableau requires internet access, and describes how to configure your network and Tableau to use forward and reverse proxy servers for access to and from the internet. There are many third-party proxy solutions available, so some of the content in the article is necessarily generic.

Before you configure a proxy server, see Communicating with the Internet.

Configure a forward proxy server

To enable communication from Tableau Server to the internet, deploy Tableau Server behind a forward proxy server. When Tableau Server needs access to the internet, it doesn’t send the request directly to the internet. Instead, it sends the request to the forward proxy, which in turn forwards the request. Forward proxies help administrators manage traffic out to the internet for tasks such as load balancing, blocking access to sites, etc.

If you use a forward proxy, you must configure the computers that run Tableau Server inside the network to send traffic to the forward proxy.

Configuring Tableau Server on Linux to work with a forward proxy

This procedure describes how to create a forward proxy configuration file for Tableau Server on Linux.

The configuration file is stored in the following directory:

~<unprivileged_user>/.config/systemd/tableau_server.conf.d

By default, Tableau Server creates the unprivileged user, tableau. Therefore, the default path to the configuration directory is:

~tableau/.config/systemd/tableau_server.conf.d

The proxy configuration file name in this topic and in the configuration file below is referred to as 20-proxy.conf. You can name this file according to your own convention, but it must
use the .conf extension. systemd will process files stored in the tableau_server.conf.d directory in lexical order according to file name.

We recommend configuring Tableau Server to work with your forward proxy solution as part of the installation process. Specifically, follow the procedure below after you run ./initialize-tsm and log out, as described in Install and Initialize TSM.

1. If you are configuring forward proxy after you have deployed Tableau Server, then run the tsm stop command.

If you are configuring forward proxy as part of the installation process, as described in Install and Initialize TSM, then start at Step 2.

2. Start a session as the unprivileged user. By default, tableau, is the unprivileged user created by Tableau Server during installation. Run the following command:

```bash
sudo su -l tableau
```

3. Create the 20-proxy.conf file in the tableau_server.conf.d directory. Run the following command:

```bash
touch .config/systemd/tableau_server.conf.d/20-proxy.conf
```

4. Open the 20-proxy.conf file in a text editor. Copy the Proxy configuration file contents into the file.

The Proxy configuration file contents include instructions on how to set forward proxy configurations. After you have edited and saved the file go to Step 5.

**Proxy configuration file contents**

```
# Always edit this file on Tableau Server as the unprivileged user. By default, tableau, is the unprivileged user created by Tableau Server during installation.
```
Set environment variables http_proxy and https_proxy to point to your proxy host.
For example, to set the proxy to example-host for ports 80 and 443, run the following commands:

```
http_proxy=http://example-host:80/
https_proxy=http://example-host:443/
```

Take care to use 'http' when you specify the URL for the https_proxy environmental variable.
Do not specify the 'https' protocol for the value of the https_proxy environmental variable.

To bypass the proxy server, specify exceptions in the no_proxy variable. Use this variable if your proxy server does not route internal addresses.
You should also add exceptions to this proxy configuration to guarantee that all communications within a local Tableau Server cluster (if you have one now or will have one later) do not route to the proxy server.
For example, to specify exceptions for internal traffic and to another node in the cluster:

```
no_proxy="localhost,127.0.0.1,other.node"
```

Where other.node is the host name of another node in the Tableau Server cluster.

5. Restart the TSM services. Run the following commands:

```
systemctl --user restart tabadmincontroller_0
systemctl --user restart appzookeeper_0
systemctl --user restart clientfileservice_0
```
systemctl --user restart fnplicenceservice_0

systemctl --user restart licenseservice_0

systemctl --user restart tabadminagent_0

6. Perform one of the following actions:

   • If you are configuring Tableau Server as part of the installation process, then continue with installation. See Activate and Register Tableau Server.

   • If you are configuring a forward proxy after completing the full Tableau Server installation process, then run the following commands to finish the configuration:

     systemctl --user restart tabsvc_0

     tsm restart

How a reverse proxy works with Tableau Server

A reverse proxy is a server that receives requests from external (internet) clients and forwards them to Tableau Server. Why use a reverse proxy? The basic answer is security. A reverse proxy makes Tableau Server available to the internet without having to expose the individual IP address of that particular Tableau Server to the internet. A reverse proxy also acts as an authentication and pass-through device, so that no data is stored where people outside the company can get to it. This requirement can be important for organizations that are subject to various privacy regulations such as PCI, HIPAA, or SOX.

The following diagram illustrates the communication path when a client makes a request to Tableau Server that is configured to work with a reverse proxy server.
1. An external client initiates a connection to Tableau Server. The client uses the public URL that's been configured for the reverse proxy server, such as https://tableau.example.com. (The client doesn't know that it's accessing a reverse proxy.)

2. The reverse proxy maps that request in turn to a request to Tableau Server. The reverse proxy can be configured to authenticate the client (using SSL/TLS) as a pre-condition to passing the request to Tableau Server.

3. Tableau Server gets the request and sends its response to the reverse proxy.

4. The reverse proxy sends the content back to the client. As far as the client is concerned, it just had an interaction with Tableau Server, and has no way to know that the communication was mediated by the reverse proxy.

Proxy servers and SSL

For better security, you should configure reverse proxy servers to use SSL for any traffic that's external to your network. This helps to ensure privacy, content integrity, and authentication. Unless you've deployed other security measures to protect traffic between your internet gateway and Tableau Server, we also recommend configuring SSL between the gateway proxy and Tableau Server. You can use internal or self-signed certificates to encrypt traffic between Tableau Servers and other internal computers.

Mobile access

Tableau Server adds an X-header to all HTTP responses for Tableau Mobile sessions. By default, most proxy solutions will preserve X-headers. If your proxy solution does not
preserve X-headers, then you will need to configure your proxy server to preserve the following header to all HTTP responses for Mobile client sessions: X-Tableau: Tableau Server.

If you have configured authentication at the proxy server gateway, then your proxy server must respond to Tableau Mobile HTTP requests with a HTTP 302 response. The 302 must include a redirect to the identity provider login page. To view a diagram that describes the 302 authentication sequence, see Tableau Mobile Authentication Sequence in the Tableau Community.

Reverse proxy and user authentication

Tableau Server will always authenticate users. This means that even if you are authenticating inbound connections at the gateway for your organization, Tableau Server will still authenticate the user.

However, not all clients will support user authentication with a reverse proxy:

- For supported web browsers, you can use SAML, OpenID Connect, Kerberos, Trusted Tickets or manual authentication with a reverse proxy. However, we recommend a transparent scenario where user requests are not prompted for authentication at the gateway. This recommendation doesn’t prohibit using SSL for client/server system-level authentication at the gateway proxy, in fact, we strongly recommend SSL system-level authentication.

- Tableau Mobile supports SAML or manual authentication with a reverse proxy. The iOS version of Tableau Mobile additionally supports Kerberos with a reverse proxy. The same recommendation above applies.

- Tableau Desktop does not support authentication with a reverse proxy. To support remote access with Tableau Desktop, use a VPN solution or configure your reverse proxy to route traffic from Tableau Desktop directly to Tableau Server for authentication.

If your organization is authenticating with Active Directory:
- Active Directory with Enable automatic logon (SSPI) is not supported with a reverse proxy.
- Tableau Server must be configured for reverse proxy before configuring Tableau Server for Kerberos. For more information, see Configure Kerberos.

Configure Tableau Server to work with a reverse proxy server

Before you configure Tableau Server, you'll need to collect the following information about the proxy server configuration. To configure Tableau Server, you use the `tsm configuration set` command. The information you need to collect corresponds to options you'll need when you run `tsm`.

Most of the following `tsm` options are also used to configure Tableau Server deployments that operate behind a load balancer. For more information, see Add a Load Balancer.

<table>

</tbody>
</table>

If you are using a distributed installation of Tableau Server, then run the following `tsm` commands on the initial node in your cluster.

1. Enter the following command to set the FQDN that clients will use to reach Tableau Server through the proxy server, where `name` is the FQDN:

   ```
   tsm configuration set -k gateway.public.host -v 'name'
   ```
For example, if Tableau Server is reached by entering https://tableau.example.com in the browser, enter this command:

```bash
tsm configuration set -k gateway.public.host -v 'tableau.example.com'
```

2. Enter the following command to set the address or the CNAME of the proxy server, where `server_address` is the IPv4 address or CNAME value:

```bash
tsm configuration set -k gateway.trusted -v 'server_ip_address'
```

If your organization uses multiple proxy servers, enter multiple IPv4 addresses, separating them with commas. IP ranges are not supported. To improve startup and initialization of Tableau Server, minimize the number of entries for `gateway.trusted`.

3. Enter the following command to specify alternate names for the proxy server, such as its fully qualified domain name, any not fully qualified domain names, and any aliases. If there's more than one name, separate the names with a comma.

```bash
tsm configuration set -k gateway.trusted_hosts -v 'name1, name2, name3'
```

For example:

```bash
tsm configuration set -k gateway.trusted_hosts -v 'proxy1.example.com, proxy1, ftp.example.com, www.example.com'
```

4. If the proxy server is using SSL to communicate with the internet, run the following command, which tells Tableau that the reverse proxy server is using port 443 instead of port 80:

```bash
tsm configuration set -k gateway.public.port -v 443
```
Note: If the proxy server is using SSL to communicate with Tableau Server, SSL must be configured and enabled on Tableau Server.

5. Enter the following command to commit the configuration change:

```
tsm pending-changes apply
```

The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

Configure the reverse proxy server to work with Tableau Server

When a client accesses Tableau Server through a reverse proxy, specific message headers have to be preserved (or added). Specifically, all proxy servers in the message chain must be represented in the `gateway.trusted` and `gateway.trusted_hosts` settings.

The following graphic shows example headers for a single-hop message chain, where the proxy server is communicating directly with Tableau Server:

The following graphic shows example headers for a multiple-hop message chain, where the message traverses two proxy servers before connecting to Tableau Server:
The following table describes what these headers are and how they relate to the configuration settings on Tableau Server:

<table>
<thead>
<tr>
<th>Headers</th>
<th>Description</th>
<th>Related Tableau Server settings</th>
</tr>
</thead>
<tbody>
<tr>
<td>REMOTE_ADDR and X-FORWARDED-FOR (XFF)</td>
<td>Tableau Server needs these headers to determine the IP address of origin for requests. X-FORWARDED-FOR header must present IP address chain to Tableau Server in the order the connections have occurred.</td>
<td>The IP address that you set in gateway.trusted must match the IP presented in REMOTE_ADDR. If you sent multiple addresses in gateway.trusted, one of them must match the IP presented in REMOTE_ADDR.</td>
</tr>
<tr>
<td>HOST and X-FORWARDED HOST (XFH)</td>
<td>These headers are used to generate absolute links to Tableau Server when it replies to the client. X-FORWARDED-HOST header must present host names to Tableau Server in the order the connections have occurred.</td>
<td>The host names that are presented in X-FORWARDED-HOST header must be included in the host names that you specify in gateway.trusted_hosts.</td>
</tr>
<tr>
<td>X-FORWARDED-PROTO (XFP)</td>
<td>This header is required if SSL is enabled for traffic from the client to the proxy, but not for traffic from the</td>
<td>Port configuration on reverse proxy (inbound con-</td>
</tr>
</tbody>
</table>
proxy to Tableau Server.

The X-FORWARDED-PROTO headers are important for scenarios where HTTP or HTTPS is not maintained along each hop of the message route. For example, if the reverse proxy requires SSL for outside requests, but traffic between the reverse proxy and Tableau Server is not configured to use SSL, X-FORWARDED-PROTO headers are required. Some proxy solutions add the X-FORWARDED-PROTO headers automatically, while others do not. Finally, depending on your proxy solution, you might have to configure port forwarding to translate the request from port 443 to port 80.

Connections from client and out-bound connections to Tableau Server) must be specified in the corresponding parameter: gateway.public.port, which is the port clients use to connect to the proxy.

If the proxy server is using SSL to communicate with Tableau Server, SSL must be configured and enabled on Tableau Server.

Validate reverse proxy setup

To validate your reverse proxy setup, publish workbooks and datasources using Tableau Server web authoring or Tableau Desktop. If you are connecting with a web browser to Tableau Server from the internet, verify that you are using a recommended browser. Publish and view workbooks that use existing datasources as well as a datasource that you’ve published. Use the links below to familiarize yourself with connecting with Tableau Server as an end-user.

<table>

Install and Configure Tableau Server

The topics referenced at the bottom of this page describe the steps to install and configure Tableau Server. If you are installing a distributed deployment (cluster), use the steps in this topic to install the initial node, then, to install additional nodes, see Distributed and High Availability Tableau Server Installations.

After you run the installation, you must then continue setup by activating a license, registering Tableau Server, and configuring various settings including authentication.
Other installation methods

There are a few alternative methods that you can use to install Tableau Server.

- If you want a quick start procedure to install Tableau Server in a non-production environment, see Jump-start Installation.
- Automated Installation of Tableau Server.
- If you are installing Tableau Server in an environment without a connection to the internet, see Install Tableau Server in a Disconnected (Air-Gapped) Environment.
- You can also install Tableau Server onto various cloud platforms. See Install Tableau Server in the Cloud.
- For single-server installations in departments or small businesses, see Everybody's Install Guide.

Before you begin

To install Tableau Server you must have a computer that satisfies the hardware requirements. You will get an informational message if your computer meets the minimum requirements but does not satisfy the recommended minimum requirements. In this case, your computer hardware can handle a trial installation of Tableau but is not adequate for a production environment. For more information, see Before you install....

Installation steps

The following steps describe how to install Tableau Server on a single computer. Use the steps to install Tableau Server in a single server deployment. Use the steps to install the initial node in a multi-node Tableau Server deployment. Run the steps sequentially.

1. Install and Initialize TSM
2. Activate and Register Tableau Server
3. Configure Initial Node Settings

4. Add an Administrator Account

5. Validate Installation

Before you install...

**Note:** You can find additional information about technical specifications for Tableau Server on the Tableau web site, [here](#).

This topic includes requirements and recommendations that you must consider before you install Tableau Server into a production environment.

If you want to install a single server, or if you want to do a minimal installation for test purposes, refer to our single-server installation guide, [Everybody's Install Guide](#).

If you are deploying Tableau Server in a distributed cluster, review Distributed Requirements in addition to the requirements and recommendations described in this topic.

**Hardware recommendations**

The following list describes the hardware recommendations for a single node installation of Tableau Server:

- 8 core, 2.0 GHz or higher processor
- 64-bit processor architecture
- 32 GB memory
- 50 GB disk space available
**Important:** The disk space requirement cannot be checked until you initialize TSM. If you don’t have enough space, you won’t be told this until after you install the Tableau Server package.

To see the full list of recommendations and to see the minimum hardware requirements, see Minimum Hardware Requirements and Recommendations for Tableau Server.

For public cloud deployments on Amazon Web Services and Google Cloud Platform, their “vCPU” is actually a CPU hyper-thread, and not a full CPU core. When sizing cloud instances, you will need twice as many vCPU as the Tableau Server CPU core requirements given (4 vCPU for a minimum trial installation, 16 vCPU for a recommended installation).

**Operating system requirements**

The following distributions of Linux are supported:

- Red Hat Enterprise Linux (RHEL) 7.3 and higher, CentOS 7.3 and higher, Oracle Linux 7.3 and higher, and Amazon Linux 2.
  
  **Version 8.x is not supported.**

  These are collectively referred to in this documentation as RHEL-like.

- Ubuntu 16.04 LTS only.
  
  **Version 17.04 is not supported.**

Previous versions of CentOS and Ubuntu are not supported because Tableau Server requires systemd for process management.

Custom kernels are not supported.

In a multi-node installation of Tableau Server, all of the computer nodes where you are installing Tableau must run Linux and the same distribution of Linux.
Note: You cannot install Tableau Server on a combination of Linux and Windows computers.

Installation directory

The core Tableau Server bits are installed in the /opt directory. You cannot change the install directory. The directory where you install Tableau Server must have at least 15 GB of free disk space. If you attempt to install Tableau Server on a computer that does not have enough space, the Tableau Server package will install, but you will be unable to continue with setup.

Data directory

By default, Tableau Server will create a data directory for all content that is managed by Tableau. The directory is created at /var/opt/tableau/tableau_server.

You can specify a different directory for data (extract) storage during installation. If you plan to use a different directory, do not create the directory. Instead, let Tableau Server setup create the directory. The data directory requires specific permissions that are set by the initialize-tsm script during the installation process. See Install and Initialize TSM.

Additional requirements

Make sure that your environment also meets the following additional requirements:

Hostname

The hostname of the computer where you install Tableau Server must be unique in your environment, and once you have installed Tableau Server the hostname cannot change.

Other hostname related requirements:

- Tableau Server must be able to resolve the hostname to an IP address either using the domain name server (DNS) or with a local host file on the computer running Tableau Server. By default, host files are stored at /etc/hosts.
• The hostname of the server must not change after you start Tableau Services Manager during the setup process. For example, this might happen if you use the cloud-init package to initialize a virtual machine, and you install Tableau Server on that virtual machine.
• Hostnames that include underscores (_) are not supported by Tableau Server on Linux.

Static IP address

The computer where you install Tableau Server must have a static IP address.

Database drivers

To connect to specific data sources, the computer where you install Tableau Server must have the correct database drivers installed. For more information, see Database Drivers.

Available ports

TSM and Tableau Server each require an available TCP port in order for you to access them. TSM defaults to port 8850, and the Tableau Server Gateway service defaults to port 80. We strongly recommend that you ensure that both port 8850 and 80 are not in use on your system before installing Tableau Server. If those ports are not available, the TSM and gateway ports may be dynamically remapped to different port numbers, and there is currently no interface for displaying which port they have been remapped to.

See Tableau Services Manager Ports.

Local firewall configuration

If you are running a firewall on the computer where you will be installing Tableau Server, then you will need to open the following default ports for Tableau Server traffic. All port numbers, except 443 and 8850, can be changed. See Tableau Services Manager Ports.
<table>
<thead>
<tr>
<th>Port</th>
<th>TCP/UDP</th>
<th>Used by ...</th>
<th>TYPE OF INSTALLATION</th>
<th>Distributed / High Availability</th>
</tr>
</thead>
<tbody>
<tr>
<td>80</td>
<td>TCP</td>
<td>Gateway</td>
<td>All</td>
<td>X</td>
</tr>
<tr>
<td>443</td>
<td>TCP</td>
<td>SSL. When Tableau Server is configured for SSL, the application server redirects requests to this port. Do not change this port.</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>8850</td>
<td>TCP</td>
<td>Tableau Services Manager. Do not change this port.</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>8060</td>
<td>TCP</td>
<td>PostgreSQL database.</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>8061</td>
<td>TCP</td>
<td>PostgreSQL backup verification port</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>8000-9000</td>
<td>TCP</td>
<td>Range of ports reserved by default for dynamic mapping of Tableau processes</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>27000-27009</td>
<td>TCP</td>
<td>Range of ports used by Tableau Server for License service. This range must be open on the node running the License service and accessible from other nodes. By default, the initial node runs the License service.</td>
<td>X</td>
<td></td>
</tr>
</tbody>
</table>

See Configure Local Firewall.

**Sudo and root access**

All installation tasks and administrative tasks for Tableau Server must be run as root. Often this is accomplished using the sudo command, but running the commands directly as the root user is also possible.
To install Tableau Server with the root account, you must specify a user account during installation. The account will be used for managing TSM. Specify the account by running the initialize-tsm script with the -a option. See Help Output for initialize-tsm Script.

**Account password**

The user account that you use to install and administer Tableau Server must be able to authenticate with a password. That is, the user must not use another means of authenticating (for example public key authentication).

If the account you are using to install and initialize Tableau Server does not have a password, you can set one using the `passwd` command:

```bash
sudo passwd $USER
```

**Port access requirements**

If you want to install Tableau Server remotely, for example by means of SSH, ensure that the following ports are open:

- **8850.** The port used for the Tableau Services Manager (TSM) web interface. You can use this interface to configure Tableau Server.
- **80.** The port used for the main Tableau Server web interface.

The Tableau Server installer attempts to open these ports during the installation process, but it can only open these ports for the `firewalld` firewall. If your computer runs another firewall, you must open the ports before you install.

**Virtual Container environments**

Installation of Tableau Server in virtual container environments such as Docker have not been tested and are not supported. Tableau Server on Linux will not function as expected if installed in these environments.

**Package requirements**

**Systemd**
Tableau Server requires `systemd` to manage services. This package is installed by default on CentOS 7 and Ubuntu 16. If you decide to test Tableau Server on a modified version of these distributions, you can run the following command to confirm that `systemd` is installed:

```
whereis systemd
```

If `systemd` is installed, the installation location is displayed. For example, you might see the following output:

```
systemd: /usr/lib/systemd /etc/systemd /usr/share/systemd /usr/share/man/man1/systemd.1.gz
```

If you have `systemd` installed but the Tableau installer is failing requirements checks for `systemd`, it’s likely that `systemd` is not running. To verify that `systemd` is running, run the following command:

```
lsof /run/systemd
```

The output will be a list of files and directories. If `systemd` is running, the output will include `system`. If `system` is not in the output, then `systemd` is not running.

*Continue to the next step: Install and Configure Tableau Server.*

**Minimum Hardware Requirements and Recommendations for Tableau Server**

The following minimum hardware requirements and recommendations apply to all computers running Tableau Server, including physical hardware and virtual machines (VMs):

- **Minimum requirements for testing and prototyping** are the minimum hardware your computer must have in order to install Tableau Server. If your computer does not meet these requirements, the Setup program will not install Tableau Server. These requirements are appropriate for testing and prototyping, but are not appropriate for most production environments.
• **Minimum recommendations for production** go beyond the minimum requirements, and represent the minimum hardware configuration you should use for a production installation of Tableau Server. If your computer meets the minimum requirements but does not meet these recommendations, the Setup program will display a warning, but you can continue the installation.

In addition, Tableau Server should not be installed on a physical computer or on a VM instance that is also running resource-intensive applications such as databases or application servers.

**Note**: If you install Tableau Server on a computer that meets the minimum requirements but does not have at least 8 cores and 16 GB of system memory, the default number of all processes installed is reduced to one of each process by design. For more information about processes, see Server Process Limits.

Looking for Tableau Server on Windows? See [Minimum Hardware Requirements and Recommendations for Tableau Server](https://www.tableau.com/).

### Minimum Hardware Requirements for Testing and Prototyping

The computer on which you are installing or upgrading Tableau Server must meet the minimum hardware requirements. If the Setup program determines that your computer does not meet the following requirements, you will not be able to install Tableau Server.

These minimum requirements are appropriate for a computer that you use for prototyping and testing of Tableau Server. They apply to single-node installations and to each computer in a distributed installation.

<table>
<thead>
<tr>
<th>Minimum Hardware Requirements</th>
<th>CPU</th>
<th>RAM</th>
<th>Free Disk Space</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>2-core</td>
<td>8 GB</td>
<td>15 GB</td>
</tr>
<tr>
<td>Minimums</td>
<td>CPU</td>
<td>RAM</td>
<td>Free Disk Space</td>
</tr>
<tr>
<td>----------</td>
<td>-----</td>
<td>-----</td>
<td>-----------------</td>
</tr>
</tbody>
</table>

**Note**: These minimum requirements are not recommended for use in production environments. For production minimum recommendations, see Minimum Hardware Recommendations for Production.

For the requirements:

- Free disk space is calculated after the Tableau Server Setup program is unzipped. The Setup program uses about 1 GB of space. You may need to allocate additional disk space depending on various factors like whether you will be using extracts. For more information, see Disk Space Requirements.

  The core Tableau Server bits must be installed in the `/opt` directory where there is at least 15 GB of free disk space. You cannot change the installation path for Tableau Server. If you attempt to install Tableau Server on a computer that does not have enough space, the Tableau Server package will install, but you will be unable to continue with setup.

  If you plan to make heavy use of extracts then you may need to allocate additional disk space. You can specify a different directory for data (extract) storage during installation. See Install and Initialize TSM.

- Core count is based on "physical" cores. Physical cores can represent actual server hardware or cores on a virtual machine (VM). Hyper-threading is ignored for the purposes of counting cores.
Minimum Hardware Recommendations for Production

For production use, the computer on which you install or upgrade Tableau Server should meet or exceed the minimum hardware recommendations. These recommendations are general. Actual system needs for Tableau Server installations can vary based on many factors, including number of users and the number and size of extracts. If the Setup program determines that your computer does not meet the following recommendations, you will get a warning, but you can continue with the setup process.

<table>
<thead>
<tr>
<th>Install Type</th>
<th>Processor</th>
<th>CPU</th>
<th>RAM</th>
<th>Free Disk Space</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single node</td>
<td>64-bit</td>
<td>8-core, 2.0 GHz or higher</td>
<td>32 GB</td>
<td>50 GB</td>
</tr>
<tr>
<td>Multi-node and enterprise deployments</td>
<td>Contact Tableau for technical guidance.</td>
<td>Nodes must meet or exceed the minimum hardware recommendations, except nodes running backgrounder, where 4 cores may be acceptable.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

For hardware recommendations for Tableau Server in the cloud, see the following:

- Selecting an AWS Instance Type and Size in the Tableau Server on Linux in the AWS Cloud Administrator Guide
- Selecting a Google Compute Engine Virtual Machine Type and Size in the Tableau Server on Linux in the Google Cloud Platform Administrator Guide
- Selecting a Microsoft Azure Virtual Machine Type and Size in the Tableau Server on Linux in Microsoft Azure Administrator Guide

Install and Initialize TSM

This topic guides you through the process of installing Tableau Server and initializing Tableau Services Manager (TSM).
Important: Do not install a beta version of Tableau Server in your production environment. You should also never restore a production Tableau Server installation using a backup of a beta version.

Prerequisites

Before proceeding, review the topic, Before you install....

Install Tableau Server

Install Tableau Server with your distribution’s package manager, then run a script to start TSM. The script is included with the installed package.

Important: The hostname of the server must not change after you start TSM. For example, this might happen if you use the cloud-init package to initialize a virtual machine, and you install Tableau Server on that virtual machine.

Install the Tableau Server package

Tableau Server must be installed in the /opt directory. However, you can specify a different directory for data (extracts and extract metadata) storage. The next section, Start TSM, describes how to specify a non-default data directory.

1. Log on as a user with sudo access to the computer where you want to install Tableau Server.

2. Download the .rpm or .deb installer package from the Tableau Server Downloads and Release Notes page.

3. Navigate to the directory where you copied the .rpm or .deb package.

4. Use the package manager to install the Tableau Server package.
On RHEL-like distributions, including CentOS, run the following commands:

```bash
sudo yum update

sudo yum install tableau-server-<version>.x86_64.rpm
```

**Note:** When you use `yum` to install Tableau Server, all dependent packages are automatically downloaded and installed. This is the preferred method for installing Tableau. If your organization does not allow you to use `yum` and you must install using `rpm -i`, you must also install all dependent packages separately.

On Ubuntu, run the following command:

```bash
sudo apt-get update
sudo apt-get -y install gdebi-core
sudo gdebi -n tableau-server-<version>_amd64.deb
```

**Initialize TSM**

1. **Navigate to the scripts directory:**
   ```bash
   cd /opt/tableau/tableau_server/packages/scripts.<version_code>/
   ```

2. **Run the following script to start TSM:**
   ```bash
   sudo ./initialize-tsm --accepteula
   ```

   The `--accepteula` flag accepts the Tableau Server End User License Agreement (EULA). The EULA is available in the following location:

   ```bash
   /opt/tableau/tableau_server/packages/docs.<version_code>/Commercial_EULA.txt
   ```
There are a number of flags you can set when you run `initialize-tsm`. Common options are listed here. For a complete list, run the command, `sudo ./initialize-tsm -h`, or see Help Output for `initialize-tsm` Script.

- The `-a` flag to specify a user to be added to the tsmadmin and tableau groups instead of the user running this script. If you are installing with the root account, you must specify the `-a` flag.

- The `--unprivileged-user` flag to set a different service account. By default a new user called `tableau` will be created. This account is an unprivileged service account under which most Tableau process run. We recommend creating a different user only in the case where a `tableau` user account already exists on the computer.

- The `-d` flag to specify a non-default location of the "data directory" where Tableau Server stores extracts, information about extracts, and more.

By default, Tableau Server uses the following location for the directory:

/var/opt/tableau/tableau_server

When you set this flag, the `initialize-tsm` script will create and apply permissions to the directory that you specify.

**Notes:**
- Do not specify a symbolic link or a data directory location on a Network File System (NFS) volume.
- Do not specify a data directory location with a path that includes a period ("."). If there is a period in the path, initialization will fail.
- To avoid permission and setup errors, do not specify an existing directory. Instead, specify the directory path with the name of the directory. The `initialize-tsm` script will create the directory and apply permissions.
- The **--debug** flag for troubleshooting. This option displays each command in the script as it is run and can make it easier to troubleshoot issues. Use of this option results in extensive output to the screen.

**Note:** If you want to manually manage port assignment for TSM and Tableau Server processes, you may need to use one or more port-related switches with initialize-tsm. For more information, see Controlling port remapping with initialize-tsm.

3. Log off and log on again to the terminal before you configure Tableau Server.

   When you log on again, you create a new session in which group membership changes have taken effect. The new session also has access to the environment variables added by the initialize-tsm script.

   Alternatively, you can run the following command to update your path for the current session (but not to update your group membership):

   ```bash
   source /etc/profile.d/tableau_server.sh
   ```

   Tableau Server must access the internet for map data and for default licensing functionality.

   If your organization uses a forward proxy solution to access the internet, then you need to configure Tableau Server to use the proxy server. Since the next portion of the Setup process requires access to the internet for licensing activation, we recommend configuring Tableau Server to use a forward proxy at this stage of installation. See Configuring Tableau Server on Linux to work with a forward proxy.

**Next step**

- Activate and Register Tableau Server
Activate and Register Tableau Server

This topic describes how to activate and register Tableau Server.

Tableau Server requires at least one product key that both activates the server and specifies the number of license levels you can assign to users. You can access your product keys from the Customer Portal.

If you need to activate Tableau Server on a computer that is offline, see Activate Tableau Server Offline. If you need to activate additional product keys to add capacity to an existing Tableau Server installation, see Add Capacity to Tableau Server.

Prerequisites

Before proceeding with the procedures in this topic, complete the following prerequisites as outlined in Install and Configure Tableau Server:

- Install and Initialize TSM

In this article
Use the TSM web interface
Use the TSM CLI

Use the TSM web interface

1. Sign in to Tableau Services Manager Web UI.

2. On the Activate page, Enter or paste your product key and click Activate License.
3. On the Register page, enter your information into the fields and click **Register**.
Register with Tableau. All fields are required.

**Contact Information**
- First Name
- Last Name
- Phone Number
- Email

**Company Information**
- Organization
- Industry
- Department
- Job Role

**Region Information**
- City
- Postal Code
- Country/Region
- State/Province

Register
Use the TSM CLI

Log in to Tableau Services Manager

Before you can proceed you must log in to Tableau Services Manager (TSM).

To log in to TSM, run the following command:

tsm login -u <username>

What if I can't log in?

The account that you use to configure the rest of the installation must be a member of the tsmadmin group that was created during initialization. To view the user accounts in the tsmadmin group, run the following command:

grep tsmadmin /etc/group

If the user account is not in the group, run the following command to add the user to the tsmadmin group:

sudo usermod -G tsmadmin -a <username>

After you have added the user to the tsmadmin group, run the tsm login command.

Activate Tableau Server

To activate Tableau Server for production use, you must have a license key.

To activate a license key, run the following command:

tsm licenses activate -k <KEY>

To activate a two-week trial, run the following command:

tsm licenses activate -t

If you are unable to activate Tableau, for example, if you get an error like this:
License Server not available

see Activate Tableau Server Offline.

Register Tableau Server

After activation, you need to register Tableau Server. To do this, create a registration file and then pass it as an option with the `tsm register` command.

1. Generate a template that you can edit by running the following command:

   `tsm register --template > /path/to/<registration_file>.json`

2. Edit the template file to create your completed registration file.

   Here is an example of a registration file in the required format:

   ```json
   {
   "zip" : "97403",
   "country" : "USA",
   "city" : "Springfield",
   "last_name" : "Simpson",
   "industry" : "Energy",
   "eula" : "yes",
   "title" : "Safety Inspection Engineer",
   "phone" : "5558675309",
   "company" : "Example",
   "state" : "OR",
   "department" : "Engineering",
   "first_name" : "Homer",
   "email" : "homer@example.com"
   }
   ```

3. After saving changes to the file, pass it with the `--file` option to register Tableau Server:

   `tsm register --file /path/to/<registration_file>.json`
For example:

```
tsm register --file /usr/share/tableau-reg-file.json
```  

Next step

- Configure Initial Node Settings

Activate Tableau Server Offline

Tableau Server requires at least one product key that both activates the server and specifies the number of license levels you can assign to users. You can access your product keys from the Tableau Customer Account Center.

If you are not able to activate Tableau Server directly, for example, if your computer is not connected to the internet, or has a firewall that restricts access outside your intranet, you can follow the steps below to activate Tableau offline.

Offline activation overview and prerequisites

Offline activation of Tableau Server involves several steps. If you have never activated a product key before on your computer, you need to run through the steps twice, once to initialize licensing on the computer, and a second time to activate the key. If you have had a license on the computer in the past, you run through the steps only once.

Overview of steps

Step 1 - Generate an offline activation request file

Step 2 - Upload the offline activation request to Tableau

Step 3 - Initialize or activate your license

If this is the first time a Tableau product key has been activated on the computer, you repeat these steps a second time.
Step 1 - Generate an offline activation request file

1. On the server computer, run the following command:

   tsm licenses get-offline-activation-file -k <product-key> -o <target-directory>

   You can get your product key from the Tableau Customer Portal. The target directory must already exist.

2. Copy the offline activation file (offline.tlq) from the target directory to a computer that has internet access.

Step 2 - Upload the offline activation request to Tableau

1. On the computer that has internet access, go to the Tableau Product Activations page.

2. Complete the instructions to upload your offline.tlq file.

   This creates an activation file, activation.tlf.

3. Download the resulting activation file from Tableau.

Step 3 - Initialize or activate your license

1. Copy the activation file (activation.tlf) to a location accessible from your Tableau Server computer.

2. Run the following command:

   tsm licenses activate -f <path-and-activation-file>

First time license activation

If this is the first Tableau license activated on the computer, you will see this message:

Your license has been initialized. To complete the activation, we need one more exchange. Generate and send to Tableau a second activation request file.
Repeat the steps above to activate your license, which includes making a new off-line.tlq file.

If you are not sure whether you need to repeat the steps, you can run this command:

```bash
tsm licenses list
```

If you see a message like this one you need to repeat the steps above:

```
No licenses are currently activated.
```

Subsequent license activation

If this is not the first Tableau license activated on the computer, or if you have completed the steps above two times, you should see a success message:

```
Activation successful.
```

Tableau Server is activated. If you need additional assistance, contact Tableau Technical Support.

Deactivate Tableau Server Offline

If Tableau Server does not have Internet access, you can use the instructions in this topic to deactivate Tableau Server. You will need to use a second computer that is able to access the Internet to complete this activation process.

**Note:** These instructions require you to save a file that you will use for deactivation. You must complete these steps using a browser other than Microsoft Edge, such as Google Chrome. If you use Edge, the license key return file used for deactivation is not created.

1. On the Tableau Server initial node, create a directory to store the offline deactivation file that is created in the next step.

2. Log in to TSM using a Tableau Administrator account, and then run the following command:
3. Move the `deactivate.tlq` file from the deactivation file directory that you specified in the previous command to a trusted computer that has Internet access.

4. On the trusted computer that has Internet access, open a web browser and visit the Tableau Product Activations page. Follow the instructions on that page to submit your `deactivate.tlq` file.

5. When prompted, save the license key return file (`return.tlr`) from the Product Activations page.

6. Move the license key return file (`return.tlr`) from the trusted computer that has Internet access to the Tableau Server initial node that runs the Licensing Server service.

7. Log in to TSM using a Tableau Administrator account, and then run the following command:

   ```
   tsm licenses deactivate -f <path-to-license-key-return-file>
   ```

Configure Initial Node Settings

This topic describes how to configure essential server settings as part of the initial Tableau Server installation process.

Prerequisite

Before proceeding with the procedures in this topic, complete the following prerequisites as outlined in Install and Configure Tableau Server:

- Install and Initialize TSM
- Activate and Register Tableau Server
You may also need to configure your local firewall for Tableau Server traffic. See Configure Local Firewall.

TSM web interface

After you have activated and registered Tableau Server, the installation program will display the Setup page.

If you need to configure Tableau Server to connect to an LDAP directory that is not Active Directory, then you must use the TSM CLI.
Identity store settings

You must configure the identity store settings for the Tableau Server computer. The identity store manages Tableau Server accounts. You can configure the identity store to synchronize with an external directory (for example, OpenLDAP or Active Directory) or you can configure the identity store to manage and store accounts on Tableau Server. If you will be
using a single sign on solution (OpenID, SAML, Kerberos, etc) then review the following topics before configuring the identity store:

- Identity Store
- Authentication

**Important:** After you have configured and applied settings for the identity store, it cannot be changed.

If you select **Active Directory**, Tableau Server will populate the **Domain** and **NetBIOS** fields from the computer on which you are running Setup. In some cases, Setup may not display these attributes. For more information about how Tableau Server connects and communicates with Active Directory, see User Management in Active Directory Deployments.

Tableau Server requires read access to Active Directory. You can use simple bind or GSSAPI bind to authenticate Tableau Server with Active Directory.

**LDAP simple bind**
If you are using simple bind to authenticate with Active Directory, enter a domain account and password. We recommend using LDAPS to connect. See LDAP over SSL.

**LDAP GSSAPI bind**
Identity Store

You cannot change the identity store after initializing.

- Local
- Active Directory

Domain: example.lan
NetBIOS (Nickname): example

Hostname (Optional)  Port (Optional)

Tableau Server requires read access to Active Directory. Specify how Tableau Server will authenticate with Active Directory.

- LDAP simple bind
- LDAP GSSAPI bind

Specify a user principal name (UPN) and upload the Kerberos configuration file Tableau Server will use to authenticate to the Identity Store.

UPN: tabserv@example.lan

Configuration file: Select File

Specify and configure the method Tableau Server will use to authenticate to Active Directory.

- Keytab file
- Username and password

Keytab file: Select File

Username  Password
We recommend binding to LDAP directory with GSSAPI. To bind with GSSAPI you will need a keytab file specifically for the Tableau Server service. See Understanding Keytab Requirements.

Gateway port

The default port for web access to Tableau Server (via HTTP) is port 80. If the installation program determines that port 80 is in use when you first install Tableau Server, an alternate port (for example 8000) is used and shown in the Port number box.

You may need to change the port for other networking needs, for example, if you have a hardware firewall or proxy in front of the Tableau Server host, this might make running a back-end system on port 80 undesirable.

Sample workbook installation

By default, Tableau Server will install sample workbooks in the Default site when you initialize the server.

Alternatively, you can publish samples after installation by using the publishesamples tabcmd command.
After you have configured the options on this page, click **Initialize**.

The initialization process can take a while. When initialization is complete the following page is displayed:

---

**Initialization Complete**

*You will need to create a Tableau Server Administrator account.*

Continue

---

**TSM CLI**

First, configure identity store, gateway settings, and sample workbook installation. Then apply the changes, optionally verify your LDAP connection, and then initialize Tableau Server.

Configure identity store settings

You must configure the identity store settings for the Tableau Server computer.

**Important:** After you have configured and applied settings for the identity store, it cannot be changed.
Use the json template in the identityStore Entity to create a json file. After you have filled in the options with the appropriate values, you can then pass the json file with this command:

```
tsm settings import -f path-to-file.json.
```

Configure gateway settings (optional)

Depending on your network requirements, you may need to configure the gateway settings for the Tableau Server computer. For example, if you are enabling SSL or configuring access to Tableau Server with a reverse proxy, you may need to configure gateway settings. See gatewaySettings Entity for more information.

Use the json template in the gatewaySettings Entity to create a json file. After you have filled in the options with the appropriate values, you can then pass the json file with this command:

```
tsm settings import -f path-to-json-file.json.
```

Configure sample workbook installation (optional)

By default, Tableau Server will install sample workbooks in the Default site when you initialize the server.

If you do not want to install sample workbooks during installation, run the following command:

```
tsm configuration set -k install.component.samples -v false
```

You can publish samples after installation by using the publishsamples tabcmd command.

Apply pending configuration changes

Now that you’ve created and set initial configuration, you must apply them. When you apply configuration changes, tsm will verify the settings you’ve set before committing them.

To apply configuration changes to Tableau Server, run this command:

```
tsm pending-changes apply
```
The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

Once this command has completed, TSM processes are running, and Tableau Server is configured but is not running.

Verify LDAP configuration (Optional)

If your identity store uses Active Directory or OpenLDAP, then we recommend verifying LDAP connectivity before proceeding.

To do so, run the following commands before you initialize the server:

```
 tsm user-identity-store verify-user-mappings -v <user name>
 tsm user-identity-store verify-group-mappings -v <group name>
```

User and group names must be valid names that exist in the LDAP server that you are connecting to. If your LDAP connection is set up correctly, then the user or group attributes will be returned to the shell. If your connection is not set up correctly, then an error will be returned.

Initialize and start Tableau Server

- To initialize and start Tableau Server, use the `--start-server` option:

  ```
  tsm initialize --start-server --request-timeout 1800
  ```

  This saves time by starting the server running after initialization.

- If you are going to reconfigure Tableau Server after initialization, leave the `--start-server` option off:
tsm initialize --request-timeout 1800

This stops the server after initialization.

Start Tableau Server. If you did not use the --start-server option during initialization and are finished configuring Tableau Server, use this command to start the server:

```bash
tsm start --request-timeout 900
```

**Note:** If you experience timeouts when installing or configuring Tableau Server, you may need to specify a longer timeout. For more information, see Install fails due to timeouts.

### Next Step

After initialization is complete, create the Tableau Server administrator user account. See Add an Administrator Account.

### Configuration File Example

This article provides an example of a complete JSON configuration file, with gatewaySettings and identityStore entities specified. In addition, a configuration key sets the gateway timeout to 900 seconds.

Your configuration file will look different depending on the options you need to set.

You might set multiple .json configuration files during installation. To set the values for each file in Tableau Server, you run the following command, once for each configuration file:

```bash
tsm settings import -f path-to-file.json
```

After you set the configuration files, run tsm pending-changes apply to apply the changes from all of the .json files you’ve set.

```json
{
  "configEntities": {
```
"gatewaySettings": {
    "_type": "gatewaySettingsType",
    "port": 80,
    "firewallOpeningEnabled": true,
    "sslRedirectEnabled": true,
    "publicHost": "localhost",
    "publicPort": 80
},

"identityStore": {
    "_type": "identityStoreType",
    "type": "local",
    "domain": "example.lan",
    "nickname": "EXAMPLE"
}
},

"configKeys": {
    "gateway.timeout": "900"
}
}

Entities vs keys

As shown in the example above, there are two classes of configuration parameters: configEntities and configKeys.

configEntities

Certain types of configuration are done through entity sets that map to specific scenarios, such as the identity store and gateway configurations. When you pass a set of configEntities with the `tsm settings import -f path-to-file.json` command, TSM validates the configuration. If values passed are invalid, TSM will provide an error. This enables you to make changes during the configuration process, rather than experience a configuration failure at initialization or run time.

Entities can be set only by including a configEntities block in a .json file.
Important: All files that are referenced in configEntities must be located on the local computer. Do not specify UNC paths.

configKeys

Entities cover only a small portion of the configuration values that can be set. Hundreds of keys correspond to parameters stored in .yml files. Tableau Server uses these parameters to store all of the configuration information for all services.

You can set individual keys with the tsm configuration command. But during deployment, setting them along with other configuration scenarios in JSON files, as shown above, is more convenient.

Unlike configEntities, configKeys are not validated.

Note: We do not recommend setting parameters that are not documented in tsm configuration set Options.

Add an Administrator Account

The final step in activating Tableau Server is to add the initial administrator account. The administrator will have all access to the server including the ability to manage users, groups, and projects.

The server must be running when you create the initial admin user.

If you have configured the Tableau Server identity store to use LDAP or Active Directory, then the initial administrative user that you specify must be an account in the directory. The initial administrative user is generally distinct from the user account on the Tableau Server computer that you use to run t.sm.
However, these accounts can be the same if you have configured the Tableau Server identity store to use LDAP or Active Directory and the initial admin user is a member of the tsmadmin group on the Tableau Server computer.

**Prerequisites**

Before proceeding with the procedures in this topic, complete the following prerequisites as outlined in Install and Configure Tableau Server:

- Install and Initialize TSM
- Activate and Register Tableau Server
- Configure Initial Node Settings

**In this article**

Use the TSM web interface
Use the TSM CLI

**Use the TSM web interface**

After Tableau Server is finished initializing, the installation program will display a page to create the Tableau Server administrator.

- If you configured a local identity store during setup, then specify a name and password that you want to use.

- If you configured a LDAP or Active Directory identity store during setup, then you must specify a user account that is a member of the directory.

If you are installing remotely, then you must sign in to TSM on the physical computer where Tableau Server is installing, or you can access the computer remotely and run the tabcmd initialuser command from a shell.
Use the TSM CLI

You must create the initial administrative account for Tableau Server.

- If you configured a local identity store during setup, then specify a name and password that you want to use.
- If you configured a LDAP or Active Directory identity store during setup, then you must specify a user account that is a member of the directory.

To create the initial user, run the following `tabcmd` command:

```
tabcmd initialuser --server localhost:80 --username '<new-admin-username>'
```

After you run the command, the shell will prompt for an administrative password.

Next steps

After you have created the Tableau Server administrator account, continue your deployment by working through the configuration topics at Post Installation Tasks.

**Important:** You must install the PostgreSQL driver if you want to use the built-in administrative views. You can find driver links and installation instructions for all the supported connectors on the [Driver Download page](#).

Validate Installation

To validate that Tableau Server is installed and running properly and to review the built-in administrative views, you must install the PostgreSQL driver.

Prerequisites

Before proceeding with the procedure in this topic, complete the following prerequisites as outlined in Install and Configure Tableau Server:
• Install and Initialize TSM

• Activate and Register Tableau Server

• Configure Initial Node Settings

• Add an Administrator Account

Install PostgreSQL driver and validate installation

To validate installation:

1. Download PostgreSQL drivers from the Driver Download page.

2. Install the drivers on your Tableau Server computer:
   • On CentOS and RHEL, download the .rpm file and then run the following command:
     
     ```
     sudo yum install tableau-postgresql-odbc-9.5.3-1.x86_64.rpm
     ```
   • On Ubuntu, download the .deb file and then run the following command:
     
     ```
     sudo dpkg -i tableau-postgresql-odbc_9.5.3_amd64.deb
     ```

3. To validate that the drivers installed, navigate to the Administrative Views in Tableau Server.

Initial Node Installation Defaults

By default, the Tableau Server installer configures the number of process instances that Tableau Server runs based on the hardware detected by the installer. The default configuration applies to single-server installations and to the initial server of a multi-node installation.

You can calculate the default configuration based on the following rules for each process, where the number of cores refers to the number of logical CPU cores:
<table>
<thead>
<tr>
<th>Process Name</th>
<th>Number of Processes</th>
</tr>
</thead>
<tbody>
<tr>
<td>VizQL Server</td>
<td>Equal to the number of cores divided by four, up to a maximum of four process instances.</td>
</tr>
<tr>
<td>Backgrounder</td>
<td>Set to two unless the number of cores is fewer than eight.</td>
</tr>
<tr>
<td>Cache Server</td>
<td>Set to two unless the number of cores is fewer than eight.</td>
</tr>
<tr>
<td>Data Server</td>
<td>Set to two unless the number of cores is fewer than eight.</td>
</tr>
</tbody>
</table>

For all other process types, the number of process instances is set to one, regardless of the hardware.

Here's an example default configuration for a computer with 16-cores:

<table>
<thead>
<tr>
<th>Process Name</th>
<th>Number of Processes</th>
</tr>
</thead>
<tbody>
<tr>
<td>VizQL Server</td>
<td>4</td>
</tr>
<tr>
<td>Application Server</td>
<td>1</td>
</tr>
<tr>
<td>Backgrounder</td>
<td>2</td>
</tr>
<tr>
<td>Cache Server</td>
<td>2</td>
</tr>
<tr>
<td>Data Server</td>
<td>2</td>
</tr>
<tr>
<td>File Store</td>
<td>1</td>
</tr>
<tr>
<td>Data Engine</td>
<td>1</td>
</tr>
</tbody>
</table>

**Jump-start Installation**

This topic provides all of the steps required to perform a basic, quick-start installation of Tableau Server using the command line. The purpose of the configuration described here is to provide the quickest, simplest path to a Tableau Server installation on a computer running the CentOS 7.3 (or greater) or Ubuntu distribution of Linux. Use this procedure as practice,
to try out the Tableau Server installation, management, and user experience before your actual server deployment.

**Important:** Do not use this procedure as a stand-alone resource for deploying Tableau Server into a production environment.

The organization of this topic maps to the broad steps presented in Install and Configure Tableau Server.

The procedures in this topic will install an instance of Tableau Server for Linux with the following characteristics:

- Operating system: CentOS 7.3 (or greater) or Ubuntu
- Identity store: local authentication
- Gateway port: 80
- Tableau Server administrator account: admin

**Before you begin**

Review the topic, Before you install.... The procedure here assumes that you have installed Linux on conforming hardware and according to the environmental requirements specified in that topic.

Note that the computer you install on must meet the minimum hardware requirements specified in Minimum Hardware Requirements and Recommendations for Tableau Server. The setup program will not install Tableau Server onto systems that do not meet the minimum hardware requirements.

**Step 1: Install Tableau Server package and start Tableau Services Manager**

Install Tableau Server with your distribution's package manager, then run a script to initialize Tableau Services Manager (TSM). Tableau Services Manager is a the management toolset used to install, configure, and manage Tableau services.
The initialize script is included with the installed package. For more details, see Install and Initialize TSM.

1. Log on as a user with sudo access to the computer where you want to install Tableau Server.

2. Navigate to the directory where you copied the Tableau Server installation package.

3. Use the package manager to install the Tableau Server package.

   - On RHEL-like distributions, including CentOS, run the following commands:

     ```
sudo yum update

sudo yum install tableau-server-<version>.x86_64.rpm
     ```

   **Note:** When you use `yum` to install Tableau Server, all dependent packages are automatically downloaded and installed. This is the preferred method for installing Tableau. If your organization does not allow you to use `yum` and you must install using `rpm -i`, you must also install all dependent packages separately.

   ```
sudo apt-get update

sudo apt-get -y install gdebi-core

sudo gdebi -n tableau-server-<version>_amd64.deb
     ```

4. Navigate to the `scripts` directory:

   ```
cd /opt/tableau/tableau_server/packages/scripts.<version_code>/
   ```

5. Run the following script to start TSM:
sudo ./initialize-tsm --accepteula

6. After initialization is complete, close the terminal session:
   exit or logout

Step 2: Activate and register Tableau Server

Before you can configure Tableau Server you must activate a license and register. For more details, see Activate and Register Tableau Server.

1. Log on as a user with sudo access and log in to TSM. Run the following command:
   
   tsm login -u <username>

2. Activate the Tableau Server license. Run the following command:
   
   tsm licenses activate -k <license_key>

3. Register Tableau Server. Generate a template that you can edit by running the following command:
   
   tsm register --template > /path/to/registration_file.json

4. Open a text editing program, fill in the registration file, save it, then pass it with the following command:
   
   tsm register --file /path/to/registration_file.json

Step 3: Configure local identity store

You must configure the identity store settings. This procedure simplifies installation setting identity store to local authentication. Workbook examples are installed by default. For more details on customizing these defaults, see Configure Initial Node Settings.
Pass the configuration file with the following command:

```
tsm settings import -f /opt/tableau/tableau_server-/packages/scripts.<version_code>/config.json
```

**Step 4: Finalize installation**

The final steps of installation are to apply changes, initialize and start TSM, and then to create the administration account. More details about these steps are at Configure Initial Node Settings.

1. Apply the configurations you made in the previous steps. Run the following command:

   ```
   tsm pending-changes apply
   ```

2. Initialize and start Tableau Server. Run the following command:

   ```
   tsm initialize --start-server --request-timeout 1800
   ```

3. Create the Tableau Server administrator account. Run the following command:

   ```
   tabcmd initialuser --server 'localhost:80' --username 'admin' --password '<password>'
   ```

   Where '<password>' is a strong password. Enclose the password and other arguments in single quotes.

Use the admin account that you created to access the Tableau Server admin web pages. See Sign in to Tableau Server Admin Pages.

**Step 5: Install PostgreSQL drivers**

To validate that Tableau Server is installed and running properly and to review the built-in administrative views, you must install the PostgreSQL driver.

1. Download PostgreSQL drivers from the [Driver Download page](#).

2. Install the drivers on your Tableau Server computer:
On CentOS and RHEL, download the .rpm file and then run the following command:

```
sudo yum install tableau-postgresql-odbc-9.5.3-1.x86_64.rpm
```

On Ubuntu, download the .deb file and then run the following command:

```
sudo dpkg -i tableau-postgresql-odbc_9.5.3_amd64.deb
```

3. To validate that the drivers installed, navigate to the Administrative Views in Tableau Server.

Configure Local Firewall

This topic explains how to configure the firewall on the computer running Tableau Server.

A local firewall should be enabled on the operating system to protect Tableau Server in single and multi-node deployments. In a distributed (multi-node) installation of Tableau Server, communication between nodes does not use secure communication. Therefore, you should enable firewalls on the computers that host Tableau Server.

We recommend that you configure the firewall so that only two ports are accessible to external traffic: the gateway port and the tabadmincontroller port. By default, these are ports 80 and 8850 respectively. Additionally, if you are running in a distributed deployment, then you will need to open the port range, 27000-27009, so licensing can communicate across nodes.

The gateway port is used for HTTP connection to Tableau Server. We recommend that you use SSL for the gateway port. If you will be using SSL, then the port must be 443 because Tableau Server does not support other ports for SSL. The procedures below describe how to configure the firewall for the gateway port. Configure the Tableau Server gateway (Configure Initial Node Settings) to match the port you set here.
The examples below describe how to configure the firewall on single and multi-node deployments of Tableau Server running on RHEL/CentOS distributions. The examples use **Firewalld**, which is the default firewall on CentOS.

**Single-node configuration**

1. Open a bash shell and run the following TSM command to retrieve the port number for the **tabadmincontroller** port:

   ```bash
tsm topology list-ports
   ```

   Make a note of the **tabadmincontroller** port. By default, this port is **8850**.

2. Start **firewalld**:

   ```bash
   sudo systemctl start firewalld
   ```

3. Verify that the default zone is a high-security zone, such as **public**. If it is not, we recommend changing it to a high-security zone.

   ```bash
   sudo firewall-cmd --get-default-zone
   sudo firewall-cmd --set-default-zone=public
   ```

4. **Add ports for the gateway port and the **tabadmincontroller** port. In the example below we use the default ports (80 and 8850).**

   ```bash
   sudo firewall-cmd --permanent --add-port=80/tcp
   sudo firewall-cmd --permanent --add-port=8850/tcp
   ```

5. **Reload the firewall and verify the settings.**

   ```bash
   sudo firewall-cmd --reload
   sudo firewall-cmd --list-all
   ```
Multi-node cluster configuration

In addition to enabling ports, configuring the firewall on a multi-node cluster requires additional steps to ensure that nodes can communicate with each other.

Before you begin

You will need the IP address for each node in the cluster. The example here uses <node1IP> as a placeholder for the initial node IP address, and <node2IP> and <node3IP> as placeholders for the IP addresses of two additional nodes.

Step 1: Configure initial node.

1. Open a bash shell and run the following TSM command to retrieve the port number for the `tabadmincontroller` port:

   tsm topology list-ports

   Make a note of the `tabadmincontroller` port. By default, this port is 8850.

2. Run the following commands to determine the range of port numbers that TSM may dynamically select. You will specify this range later in this procedure. Make a note of the port range.

   tsm configuration get -k ports.range.min
   tsm configuration get -k ports.range.max

   A typical range is 8000 to 9000.

3. Start `firewalld`:

   sudo systemctl start firewalld

4. Verify that the default zone is a high-security zone, such as `public`. If it is not, we recommend changing it to a high-security zone.

   firewall-cmd --get-default-zone
sudo firewall-cmd --set-default-zone=public

5. Add ports for the gateway port and the tabadmincontroller port. In the example below we use the default ports (80 and 8850). You must also add a port range (27000-27010) to enable licensing communication between nodes.

   sudo firewall-cmd --permanent --add-port=80/tcp
   sudo firewall-cmd --permanent --add-port=8850/tcp
   sudo firewall-cmd --permanent --add-port=27000-27010/tcp

6. Configure the firewall to allow all traffic from the other nodes in the cluster. For the ports option, specify the range you noted in Step 2. Run the command for each of the additional nodes in your cluster. For example:

   sudo firewall-cmd --permanent --add-rich-rule='rule family=ipv4 source address=<node2IP>/32 port port=8000-9000 protocol=tcp accept'
   sudo firewall-cmd --permanent --add-rich-rule='rule family=ipv4 source address=<node3IP>/32 port port=8000-9000 protocol=tcp accept'

7. Reload the firewall and verify the settings.

   sudo firewall-cmd --reload
   firewall-cmd --list-all

Step 2: Configure additional nodes

Each node in the cluster must be able to communicate with the initial node and with the other nodes.

Run this procedure on each additional node in the cluster. In this example, the node at IP address, <node2IP>, communicates with the initial node at <node1IP> and a third node at <node3IP>.
1. Start firewalld:

   ```
   sudo systemctl start firewalld
   ```

2. Verify that the default zone is a high-security zone, such as `public`. If it is not, we recommend changing it to a high-security zone.

   ```
   firewall-cmd --get-default-zone
   ```

   ```
   sudo firewall-cmd --set-default-zone=public
   ```

3. Configure the firewall to allow `gateway` and `tabadmincontroller` access from the other nodes in the cluster. For example:

   ```
   sudo firewall-cmd --permanent --add-rich-rule='rule family=ipv4 source address=<node1IP>/32 port port=80 protocol=tcp accept'
   ```

   ```
   sudo firewall-cmd --permanent --add-rich-rule='rule family=ipv4 source address=<node1IP>/32 port port=8000-9000 protocol=tcp accept'
   ```

   ```
   sudo firewall-cmd --permanent --add-rich-rule='rule family=ipv4 source address=<node3IP>/32 port port=80 protocol=tcp accept'
   ```

   ```
   sudo firewall-cmd --permanent --add-rich-rule='rule family=ipv4 source address=<node3IP>/32 port port=8000-9000 protocol=tcp accept'
   ```

   In this example, since the `tabadmincontroller` port (8850) is included in the port range, it is not explicitly specified in a command.

4. Reload the firewall and verify the settings.

   ```
   sudo firewall-cmd --reload
   ```
Automated Installation of Tableau Server

Tableau provides an automated-installer script to automate an install of Tableau Server. The script is community supported. You can download the script and use it as written, or modify it for your specific needs.

Benefits of using the automated installer

- With a single command, you can install, configure and get to a working instance of Tableau Server.
- The command can be run without user input making it suitable for automation.
- The configuration can be set once and used for all your installations, making this a repeatable process.

When not to use the automated installer:

- If you are installing for the first time, we recommend that you manually test the installation before automating the process. Any issues that block installation are easier to resolve interactively, and after you have resolved these issues, you can use the automated installer.
- If you are testing or trying new configuration parameters such as authentication methods, we recommend that you manually run the installation first. TSM validates configuration entities and rejects configuration parameters that are not valid. Once you have the correct parameters identified, you can use the automated installer.
- If you are unable to or do not want to enter passwords into the secrets file, using the automated installer might not be an option for you.
Before you begin

Review the Before you install... topic to make sure you have installed Linux on a computer that meets the operating system requirements and the minimum hardware requirements for Tableau Server.

**Note:** If you are installing Tableau Server in a production environment, review the minimum hardware recommendations. The recommendations represent the minimum hardware configuration you should use for a production installation of Tableau Server.

To perform an automated installation, you have to use the automated installer package, which uses the Tableau Server install package as an input. We recommend that you download **both of these packages** before you begin as follows:

1. Download both the automated installer package and the Tableau Server installer package:
   a. Download the **automated installer package** from GitHub for the distribution you are using. The automated installer packages can be found in the **packages** sub directory.

      **Note:** The version of automated installer package you use must match the version of the Tableau Server installer package. For example, use 10.5.0 version of the automated installer package with 10.5.0 version of the Tableau Server installer package.

   b. Select and download the appropriate **Tableau Server installer package** from the Tableau Server Product Downloads and Release Notes page. The one you choose depends on which Linux distribution you are using. For example, for RHEL like systems, tableau-server-<version>.x86_64.rpm.

   c. Download the config.json, reg_templ.json, and the secrets templates.
2. Copy the packages and templates to a location on or accessible from the computer where you are going to install Tableau Server.

How to use the automated installer

The automated installer installs the Tableau Server installer package, creates the directories, sets the permissions required to run Tableau Server, and starts the Tableau Services Manager (TSM) setup. After the TSM setup is completed, the automated installer runs `tsm` commands to install, configure, and start Tableau Server. By default, during installation, the automated installer activates a trial license. If you have an actual product key, you can provide the product key at the command line or activate the product key after you run the script. Most of the command line options in the automated installer are the same as the options used by the `tsm initialize` command.

To run the automated installer without user input, you must provide the following required command line options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-s <code>&lt;secrets-file&gt;</code></td>
<td>The name of the secrets file. The secrets file should have the user names and passwords for TSM administrator and the Tableau Server administrator accounts.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Providing the password in the secrets file is optional. However, if passwords are not found in the secrets file, you will be prompted to provide them during installation.</td>
</tr>
<tr>
<td></td>
<td>The automated installer package includes the template for the secrets file.</td>
</tr>
<tr>
<td>-f <code>&lt;config-file&gt;</code></td>
<td>The name of the configuration JSON file. The automated installer package includes the template for the configuration file.</td>
</tr>
<tr>
<td>-r <code>&lt;registration-file&gt;</code></td>
<td>The name of the registration file. The automated installer package</td>
</tr>
<tr>
<td><strong>--accepteula</strong></td>
<td>Indicates that you have accepted the End User License Agreement.</td>
</tr>
<tr>
<td>------------------</td>
<td>---------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>&lt;package-file&gt;</strong></td>
<td>The rpm or deb Tableau Server installer.</td>
</tr>
</tbody>
</table>

| **<registration-file>** | Includes the template for the registration file. |

**Use the -h option to see a full list of all the command line options.**

Use the following steps to perform an unattended installation:

**Step 1: Install the automated installer**

1. Log onto the computer as a user with sudo access.

2. Use the package manager to install the script package:

   - **ON RHEL-like distributions, including CentOS, run the following command:**

     ```
     sudo yum install /path/to/tableau-server-automated-installer-<version>.noarch.rpm
     ```

   - **On Ubuntu, run the following commands:**

     ```
     sudo apt-get update
     sudo apt-get -y install gdebi-core
     sudo gdebi -n /path/to/tableau-server-automated-installer-<version>.deb
     ```

The automated installer package download includes templates for the configuration file (config.json), registration file (reg_templ.json) and the secrets (secrets) file that you can use to modify for your requirements as described in the next step. The installer script, and the templates for the initial node configuration, Tableau Server registration, and secrets file are installed to:
Step 2: Create files to provide additional configuration information required to run the automated install

Since the automated installer is meant to run without user interaction, you must provide the following additional information:

1. Run the following command to copy the templates, config.json, regtempl.json, and secrets, to another directory like your home directory. We don’t recommend that you edit the template files directly:

   ```bash
   cp /opt/tableau/tableau_server_automated_installer/automated-installer.<version>/{config.json,regtempl.json,secrets} ~
   ```

2. Edit the configuration template, `config.json`, to provide the initial node configuration settings. You must provide identity store settings for the Tableau Server computer. Depending on your network requirements, you may need to also provide the gateway settings. The caching option is set to cache and reuse data for as long as possible. Sample workbooks are installed by default. The template includes the minimum required information, so the template is a starting point. For more information on configuration settings, see Configure Initial Node Settings.

3. Edit the registration file `regtempl.json` to provide the information needed to register Tableau Server. For more information, see Activate and Register Tableau Server.

4. Edit the secrets file using the `secrets` template with the user name and password for the TSM administrator and Tableau Server administrator accounts.

   - The TSM administrator account should be the same user as the sudo admin running the script. If you do not want to specify the password in the `secrets` file, you can leave it blank, and you will be prompted to provide the password during
The Tableau Server administrator account is the initial account that is created by the installer and is used to administer Tableau Server.

Step 3: Run the automated install

1. Log onto the computer as a user with sudo access.

ON RHEL-like distributions, including CentOS, run the following command:

```
sudo /opt/tableau/tableau_server_automated_installer-/automated-installer.<version>/automated-installer -s
/path/to/secrets -f /path/to/config.json -r /path/to/reg
templ.json --accepteula /path/to/tableau-server-<version>.x86_64.rpm
```

On Ubuntu, run the following command:

```
sudo /opt/tableau/tableau_server_automated_installer-/automated-installer.<version>/automated-installer -s
/path/to/secrets -f /path/to/config.json -r /path/to/reg
templ.json --accepteula /path/to/tableau-server-<version>_.amd64.deb
```

**Important:** You must specify `--accepteula` key to acknowledge and accept the end user license agreement (EULA) in the command that you use the run the script. The EULA is available in the following location: `/opt/tableau/tableau_server/packages/docs.<version_code>/EULA.rtf`. 
Note: If you are adding this machine as an additional node to an existing cluster, you must specify the -b bootstrap flag and the node configuration file from the initial server. For more information on how to generate the node configuration file, see Install and Configure Additional Nodes.

Install Tableau Server in a Disconnected (Air-Gapped) Environment

You can install Tableau Server in a disconnected environment that has no outside network access of any kind. Such disconnected environments, commonly referred to as air-gapped, are used when high security is needed to prevent data breaches or to guard against hacking. Air-gapped environments have no internet access, no outside network access, no outside wireless access, etc. The only means of getting software and data into or out of an air-gapped environment is by using removable media such as USB sticks or writeable optical CDs or DVDs.

Installing Tableau Server in an air-gapped environment is an advanced task for IT administrators who are familiar with the security considerations, best practices, and pitfalls of installing software in air-gapped environments.

The following Tableau Server features will be unavailable or will have reduced functionality in an air-gapped environment:

- Maps – Tableau Server uses externally hosted map data. Maps are unavailable in an air-gapped environment unless you also install a map server in your air-gapped environment. You can use the following workarounds.

- Licensing – Tableau Server needs to connect to the internet in order to activate license keys. However, you can manually activate the license keys.
• **External data** – Any data located outside your air-gapped environment is unavailable.

## Prerequisites

In order to install Tableau Server in an air-gapped environment, you'll need the following:

- Trusted computer with limited access to the internet that you can use to download the installation packages and resources required by Tableau Server. A trusted computer has been scanned and cleared of any viruses and malware.

- Trusted removable media that you can use to transfer the downloaded software to your air-gapped environment. Trusted removable media is removable media that is new and previously unused and comes from a reputable or known source. Trusted removable media has been scanned and verified that it does not contain any viruses or malware.

- Air-gapped environment with computers and storage that meet the requirements for installing Tableau Server.

## Installing Tableau Server on an Air-Gapped Computer Running Linux

The easiest way to install Tableau Server on a computer in an air-gapped environment is to do so before the computer is placed into the air-gapped environment. If that's not possible you’ll need to download the required packages to a trusted computer outside the air gap:

1. On a trusted computer outside the air gap with internet access, download the Tableau Server installation package.

2. Extract the list of dependent packages:

   **On Ubuntu:**
dpkg --field <debfile> Depends (where <debfile> is the name of the .deb package you downloaded from Tableau).

Example command:

dpkg --field tableau-server-linux-1.deb Depends

Example output:

cacertificates, fontconfig, net-tools, bash-completion, cacertificates-java, freerlut3, libegl1-mesa, libfreetype6, libgssapi-krb5-2, libxcomposite1, libxrender1, libxslt1.1, lsb-core

On RHEL and RHEL-like Linux distributions:

yum -q deplist <RPM file> (where <RPM file> is the .rpm package you downloaded from Tableau).

Example command:

yum -q deplist tableau-server-linux_1.rpm

Example output:

package: tableau-server-10400.17.0703.1600.x86_64 10400-17.0703.1600
dependency: /bin/sh
provider: bash.x86_64 4.2.46-21.el7_3
dependency: bash-completion
provider: bash-completion.noarch 1:2.1-6.el7
dependency: cacertificates
provider: cacertificates.noarch 2017.2.14-70.1.el7_3
dependency: fontconfig
provider: fontconfig.x86_64 2.10.95-10.el7
provider: fontconfig.i686 2.10.95-10.el7
dependency: freeglut
provider: freeglut.x86_64 2.8.1-3.el7
provider: freeglut.i686 2.8.1-3.el7
dependency: freetype
provider: freetype.x86_64 2.4.11-12.el7
provider: freetype.i686 2.4.11-12.el7
dependency: krb5-libs
provider: krb5-libs.x86_64 1.14.1-27.el7_3
provider: krb5-libs.i686 1.14.1-27.el7_3
dependency: libXcomposite
provider: libXcomposite.x86_64 0.4.4-4.1.el7
provider: libXcomposite.i686 0.4.4-4.1.el7
dependency: libXrender
provider: libXrender.x86_64 0.9.8-2.1.el7
provider: libXrender.i686 0.9.8-2.1.el7
dependency: libxslt
provider: libxslt.x86_64 1.1.28-5.el7
provider: libxslt.i686 1.1.28-5.el7
dependency: mesa-libEGL
provider: mesa-libEGL.x86_64 11.2.2-2.20160614.el7
provider: mesa-libEGL.i686 11.2.2-2.20160614.el7
dependency: net-tools
provider: net-tools.x86_64 2.0-0.17.20131004git.el7
dependency: redhat-lsb-core
provider: redhat-lsb-core.x86_64 4.1-27.el7.centos.1
provider: redhat-lsb-core.i686 4.1-27.el7.centos.1

3. Download each of the dependent packages:

   On Ubuntu:
apt-get download <package1> <package2>...

On RHEL and RHEL-like Linux distributions:

yumdownloader <package1> <package2>...

4. Transfer the packages to your removable media.

5. On your air-gapped computer, insert the removable media containing the Tableau Server installation package and dependent packages, and then run the installer.

6. After installation is complete, you can activate the Tableau Server license keys. For more information, see Activating Tableau Server in an Air-Gapped Environment.

Activating Tableau Server in an Air-Gapped Environment

Because an air-gapped computer is not connected to the internet, you’ll need to perform the Tableau Server activation process manually.

Step 1. Transcribe data from your air-gapped system into an activation request template.

1. On your Tableau Server in the air-gapped environment, use TSM to obtain the offline activation file. At a command prompt:

   tsm licenses get-offline-activation-file -k <product-key> -o <target-directory>

   The <target-directory> must exist. You can obtain your product key in the Tableau Customer Portal.

2. On a trusted computer that is connected to the internet and is capable of sending files via email, right-click and choose Save link as to download either the server_first-pass_linux.tlq or the server_secondpass_linux.tlq file. The firstpass template is used when the computer has never had Tableau Server installed on it before.

3. Open both the offline.tlq file from the disconnected computer, and the
appropriate `server_firstpass_linux.tlq` or `server_secondpass_linux.tlq` file in an XML text editor such as Notepad++ on the trusted computer that has Internet access. You'll need to write down the values from the disconnected computer in order to copy them to the computer that has Internet access.

4. Update the following XML elements in the appropriate .tlq file (`server_firstpass_linux.tlq` or `server_secondpass_linux.tlq`) with the values for the same elements in `offline.tlq` on the disconnected computer. The template file has X's where you need to change the values. Do not change anything other than the values below.

All the Machine / Hash values in the .tlq files are Hex values. The only valid characters are 0 - 9 and A - F. Use all caps for any letters.

Line 2 - `<EntitlementId>`

Line 5 - `<ClientVersion>`

Line 5 - `<RevisionType>` (This value is only present in the `server_secondpass_linux.tlq` file.)

Line 5 - `<MachineIdentifier>` (This value is only present in the `server_secondpass_linux.tlq` file.)

Line 11 - `<Value>` (If the value is not present, remove the "X" place holder, leaving `<Value></Value>`.)

Line 12 - `<Value>` (If the value is not present, remove the "X" place holder, leaving `<Value></Value>`.)

Line 13 - `<Value>` (If the value is not present, remove the "X" place holder, leaving `<Value></Value>`.)

Line 15 - `<SequenceNumber>`
5. Upload the edited template (offline.tlg) to the Tableau Offline Activation website.

6. The website should say The activation was successful. Please click here to download your activation file.

Download the activation.tlf file and transfer it to your Tableau Server.

Step 2. Initialize or activate your license

1. Move the activation file (activation.tlf) to your disconnected computer using trusted removable media.

2. Run the following command:

   tsm licenses activate -f <path-and-activation-file>

First time license activation

If this is the first Tableau license activated on the computer, you will see this message:

Your license has been initialized. To complete the activation, we need one more exchange. Generate and send to Tableau a second activation request file.

You need to follow the steps below to activate your license. If you are not sure whether you need to repeat the steps, you can run this command:

   tsm licenses list

If you see a message like this one you need to repeat the steps above:

No licenses are currently activated.
Subsequent license activation

If this is not the first Tableau license activated on the computer, or if you have completed the steps above two times, you should see the message "Activation successful," which indicates that Tableau Server is activated.

**Note:** You may have to perform offline activation twice to completely activate your air-gapped Tableau Server. The first offline activation sets up Trusted Storage on the computer if Tableau has never been licensed on it before. The second offline activation propagates the licensing information into Trusted Storage. If you’re upgrading an existing install of Tableau Server, right-click and choose **Save link as** to download the `server_secondpass_linux.tlq` file. It will match all the places to put the values from the generated `.tlq` file.

Displaying Maps in an Air-Gapped Environment

In an air-gapped environment, maps in Tableau Server will be unavailable due to the lack of internet access in the air-gapped environment. You can use the following workarounds to display maps in an offline environment:

- **Option 1** – Use the offline background maps

  To use the offline background map select **Map > Background maps > Offline**. For more information, see **Select Background Maps**.

  **Note:** Due to size limitations with the offline map, zooming in too deep may result in errors as the images for the more close-up maps are not stored offline.

- **Option 2** – Use a map as a background image

  Locate the desired map online and save it as an image file, or copy a map from another location. Set this map image as a static background image in Tableau Desktop. For more information, see **Use Background Images in Your Views**.
**Note:** Zooming in and out will not work with background images.

- **Option 3** – Use a local GeoServer

  For more information, see [Use Web Map Service (WMS) Servers](#).

**Install Tableau Server in the Cloud**

Even if you don’t have your own infrastructure and server hardware, you can deploy an enterprise-level Tableau Server installation in the cloud. Building a cloud-based solution has many benefits over an on-premises installation. For example, the overall total cost of ownership for building a Tableau Server solution in the cloud is normally much less than a similar on-premises solution because you don’t have to buy all of the expensive hardware. In addition, the cloud can provide better uptime, reliability, and fault-tolerance, especially if you deploy your solution across different regions and availability zones.

Looking for Tableau Server on Windows? See [Install Tableau Server in the Cloud](#).

You can build and scale your Tableau environment in the following cloud environments:

- **Tableau Online** - If you don’t want to install software or purchase hardware, you can choose analytics as a service with Tableau Online, the Tableau-hosted environment in the cloud. For more information, see [Tableau Online](#).

- **Amazon Web Services** - You install and manage Tableau Server on Amazon Web Services (AWS). For more information, see [Install Tableau Server in the AWS Cloud](#).

- **Google Cloud Platform** - You install and manage Tableau Server on the Google Cloud Platform. For more information, see [Install Tableau Server on the Google Cloud Platform](#).

- **Microsoft Azure** - You install and manage Tableau Server on Microsoft Azure. For more information, see [Install Tableau Server on Microsoft Azure](#).
Post Installation Tasks

Security Hardening Checklist

The following list provides recommendations for improving the security ("hardening") of your Tableau Server installation.

1. Update to the current version

We recommend that you always run the latest version of Tableau Server. Additionally, Tableau periodically publishes maintenance releases of Tableau Server that include fixes for known security vulnerabilities. (Information regarding known security vulnerabilities can be found on the Security Bulletins page.) We recommend that you review maintenance release notifications to determine whether you should install them.

To get the latest version or maintenance release of Tableau Server, visit the Customer Portal page.

2. Configure SSL/TLS with a valid, trusted certificate

Secure Sockets Layer (SSL/TLS) is essential for helping to protect the security of communications with Tableau Server. Configure Tableau Server with a valid, trusted certificate (not a self-signed certificate) so that Tableau Desktop, mobile devices, and web clients can connect to the server over a secured connection. For more information, see SSL.

3. Disable older versions of TLS

Tableau Server uses TLS to authenticate and encrypt many connections between components and with external clients. External clients, such as browsers, Tableau Desktop, Tableau Mobile connect to Tableau using TLS over HTTPS. Transport layer security (TLS) is an improved version of SSL. In fact, older versions of SSL (SSL v2 and SSL v3) are no longer considered to be adequately secure communication standards. As a result, Tableau
Server does not allow external clients to use SSL v2 or SSL v3 protocols to connect. We recommend that you only allow external clients to connect to Tableau Server with TLS v1.2.

Specifically, we recommend that you disable TLS v1 and TLS v1.1 on Tableau Server. However, before you disable a specific version of TLS, verify that the browsers that your users connect to Tableau Server with support TLS v1.2. In some cases, you may need to preserve support for TLSv1.1.

The following tsm command enables TLS v1.2 (using the "all" parameter) and disables SSL v2, SSL v3, TLS v1, and TLS v1.1 (by prepending the minus [-] character to a given protocol).

```
tsm configuration set -k ssl.protocols -v 'all -SSLv2 -SSLv3 -TLSv1 -TLSv1.1'
```

```
tsm pending-changes apply
```

The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see tsm pending-changes apply.

4. Disable Triple-DES cipher suite

The Triple-DES cipher suite is no longer considered adequate to encrypt sessions on the internet. Specifically, running Triple-DES ciphers leaves the Tableau Server vulnerable to information disclosure and denial of service attacks. You can learn more at the National Vulnerability Database webpage for CVE-2016-2183.

Triple-DES is enabled by default on the version of OpenSSL that is running on Tableau Server. However, other deprecated cipher suites (MD5 and RC4) are disabled. To add Triple-DES to the list of disabled ciphers, run the following commands. (The !aNULL parameter forces clients to use a legitimate cipher.)
tsm configuration set -k ssl.ciphersuite -v
'HIGH:MEDIUM:!aNULL:!MD5:!RC4:!3DES'

tsm pending-changes apply

5. Configure SSL encryption for internal traffic

Configure Tableau Server to use SSL to encrypt all traffic between the Postgres repository and other server components. By default, SSL is disabled for communications between server components and the repository. We recommend enabling internal SSL for all instances of Tableau Server, even single-server installations. Enabling internal SSL is especially important for multi-node deployments. See Configure SSL for Internal Postgres Communication.

6. Enable firewall protection

Tableau Server was designed to operate inside a protected internal network.

**Important:** Do not run Tableau Server, or any components of Tableau Server on the internet or in a DMZ. Tableau Server must be run within the corporate network protected by an internet firewall. We recommend configuring a reverse proxy solution for internet clients that need to connect to Tableau Server. See Configuring Proxies for Tableau Server.

A local firewall should be enabled on the operating system to protect Tableau Server in single and multi-node deployments. In a distributed (multi-node) installation of Tableau Server, communication between nodes does not use secure communication. Therefore, you should enable firewalls on the computers that host Tableau Server. See Configure Local Firewall.

To prevent a passive attacker from observing communications between nodes, configure a segregated virtual LAN or other network layer security solution.
See Tableau Services Manager Ports to understand which ports and services Tableau Server requires.

7. Restrict access to the server computer and to important directories

Tableau Server configuration files and log files can contain information that is valuable to an attacker. Therefore, restrict physical access to the machine that is running Tableau Server. In addition, make sure that only authorized and trusted users have access to the Tableau Server files in the /var/opt/tableau/tableau_server/ directory.

8. Generate fresh secrets and tokens

Any Tableau Server service that communicates with repository or the cache server must first authenticate with a secret token. The secret token is generated during Tableau Server setup. The encryption key that internal SSL uses to encrypt traffic to Postgres repository is also generated at during setup.

We recommend that after you install Tableau Server, you generate new encryption keys for your deployment.

These security assets can be regenerated with the tsm security regenerate-internal-tokens command.

Run the following commands:

tsm security regenerate-internal-tokens

tsm pending-changes apply

9. Disable services that you're not using

To minimize the attack surface of the Tableau Server, disable any connection points that are not needed.
REST API

The REST API interface is enabled by default. If no applications will make REST API calls to your installation of Tableau Server 9.3 (or later), disable it by using the following commands:

```
tsm configuration set -k api.server.enabled -v false
tsm pending-changes apply
```

**Important:** Tableau Prep uses REST API to access Tableau Server. If your organization uses Tableau Prep, do not disable REST API.

JMX Service

JMX is disabled by default. If it’s enabled but you’re not using it, you should disable it by using the following:

```
tsm configuration set -k service.jmx_enabled -v false
tsm pending-changes apply
```

10. Verify session lifetime configuration

By default, Tableau Server does not have an absolute session timeout. This means that client sessions can remain open indefinitely if the Tableau Server inactivity timeout is not exceeded. (The default inactivity timeout is 240 minutes.)

If your security policy requires it, you can set an absolute session timeout. Be sure to set your absolute session timeout in a range that allows the longest-running extract or publishing operations in your organization. Setting the session timeout too low may result in extract and publishing failures for long-running operations.

To set the session timeout run the following commands:
11. Configure a server safelist for file-based data sources

By default, Tableau Server allows authorized Tableau Server users to build workbooks that use files on the server as file-based data sources (such as spreadsheets). In this scenario, files are accessed by the tableau system account.

To prevent unwanted access to files, we recommend that you configure safelist (sometimes referred to as "whitelist") functionality. This lets you limit tableau account access to just the directory paths where you host data files.

1. On the computer running Tableau Server, identify the directories where you will host data source files.

   Important Make sure the file paths you specify in this procedure exist on the server. If the paths do not exist when the computer starts, Tableau Server will not start.

2. Run the following commands:

   tsm configuration set -k native_api.allowed_paths -v "path" , where path is the directory to add to the safelist. All subdirectories of the specified
path will be added to the safelist. If you want to specify multiple paths, separate them with a semicolon, as in this example:

```bash
tsm configuration set -k native_api.allowed_paths -v "/data-sources;/HR/data"
```
```bash
tsm pending-changes apply
```

### 12. Enable HTTP Strict Transport Security for web browser clients

HTTP Strict Transport Security (HSTS) is a policy configured on web application services, such as Tableau Server. When a conforming browser encounters a web application running HSTS, then all communications with the service must be over a secured (HTTPS) connection. HSTS is supported by major browsers.

For more information about how HSTS works and the browsers that support it, see The Open Web Application Security Project web page, [HTTP Strict Transport Security Cheat Sheet](#).

To enable HSTS, run the following commands on Tableau Server:

```bash
tsm configuration set -k gateway.http.hsts -v true
```

By default, HSTS policy is set for one year (31536000 seconds). This time period specifies the amount of time in which the browser will access the server over HTTPS. You should consider setting a short max-age during initial roll-out of HSTS. To change this time period, run:

```bash
tsm configuration set -k gateway.http.hsts_options -v max-age=<seconds>. For example, to set HSTS policy time period to 30 days, enter tsm configuration set -k gateway.http.hsts_options -v max-age=2592000.
```
```bash
tsm pending-changes apply
```

### 13. Disable Guest access

Core-based licenses of Tableau Server include a Guest user option, which allows any user in your organization to see and interact with Tableau views embedded in web pages.
Guest user access is enabled by default on Tableau Servers deployed with core-based licensing.

Guest access allows users to see embedded views. The Guest user cannot browse the Tableau Server interface or see server interface elements in the view, such as user name, account settings, comments, and so on.

If your organization has deployed Tableau Server with core licensing and Guest access is not required, then disable Guest access.

You can disable Guest access at the server or site level.

You must be a server administrator to disable the Guest account at either the server or the site level.

**To disable Guest access at the server level:**

1. In the site menu, click **Manage All Sites** and then click **Settings > General**.

2. For **Guest Access**, clear the **Enable Guest account** check box.

3. Click **Save**.

**To disable Guest access for a site:**

1. In the site menu, select a site.

2. Click **Settings**, and on the Settings page, clear the **Enable Guest account** check box.

For more information, see Guest User.

**Change List**

<table>

Configure SMTP Setup

Tableau Server can email server administrators about system failures, and email server users about subscribed views and data-driven alerts. First, however, you need to configure the SMTP server that Tableau Server uses to send email. After configuring SMTP, complete the steps to configure notifications (Configure Server Event Notification), then when you start or restart the server, it will trigger an email notification, which confirms that you have set up notifications correctly.

Configuring SMTP requires that you restart Tableau Server services.

In this article

- Use the TSM web interface
- Use the TSM CLI

Use the TSM web interface

1. Open TSM in a browser:
   
   https://<tsm-computer-name>:8850. For more information, see Sign in to Tableau Services Manager Web UI.

2. Click **Notifications** on the **Configuration** tab and click **Email Server**.

3. Enter the SMTP configuration information for your organization:
4. Click **Save Pending Changes** after you've entered your configuration information.

5. Click **Apply Changes and Restart**.

**Use the TSM CLI**

For the initial configuration of SMTP, we recommend that you use the configuration file template below to create a json file. You can also set any single configuration key listed below with the syntax described in tsm configuration set.

1. Copy the following json template to a file. Fill in the key values with your SMTP configuration. See the reference section that follows for more information about SMTP key options.

```json
{
  "configKeys": {
    "svcmonitor.notification.smtp.server": "SMTP server url",
    // Other keys as necessary
  }
}
```
"svcmonitor.notification.smtp.send_account": "SMTP user name",
"svcmonitor.notification.smtp.port": 25,
"svcmonitor.notification.smtp.password": "SMTP server password",
"svcmonitor.notification.smtp.ssl_enabled": false,
"svcmonitor.notification.smtp.from_address": "From email address",
"svcmonitor.notification.smtp.target_addresses": "To email address1,address2",
"svcmonitor.notification.smtp.canonical_url": "Tableau Server URL"

2. Run the tsm settings import -f file.json to pass the json file with the appropriate values to Tableau Services Manager to configure Tableau Server for SMTP. Tableau Services Manager will validate the entity values.

3. Run the tsm pending-changes apply command to apply the changes. See tsm pending-changes apply.

Configuration file reference

This table lists all of the options that can be used to configure SMTP.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>svc-monitor.notification.smtp.server</td>
<td>Address of SMTP server. Example: &quot;svc-</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
<tr>
<td><code>monitor.notification.smtp.server</code></td>
<td>User name for SMTP account.</td>
</tr>
<tr>
<td><code>monitor.notification.smtp.send_account</code></td>
<td>Port number for SMTP server. The default is 25.</td>
</tr>
<tr>
<td><code>monitor.notification.smtp.port</code></td>
<td>Password for SMTP server account. Example:</td>
</tr>
<tr>
<td><code>monitor.notification.smtp.password</code></td>
<td>Specifies whether the connection to the SMTP server is encrypted. The default is false.</td>
</tr>
<tr>
<td><code>monitor.notification.smtp.ssl_enabled</code></td>
<td>Email address that will send an notification if there’s a system failure. The email address must have valid syntax (for example, <a href="mailto:ITalerts@bigco.com">ITalerts@bigco.com</a> or noreply@mycompany), but it does not have to be an actual email account on Tableau Server. (Some SMTP servers may require an</td>
</tr>
</tbody>
</table>

**Note:** This should be left as false. Encrypted SMTP connections are not supported for notifications or subscriptions.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>actual email account, however.</td>
<td></td>
</tr>
</tbody>
</table>

**Note:** You can override the system-wide email address on a per-site basis. For more information, see What is a site.

Example:

"svc-monitor.notification.smtp.from_address": "donot-reply@example.com"

<table>
<thead>
<tr>
<th>svc-monitor.notification.smtp.target_addresses</th>
<th>Email address to receive notifications. If email notifications are enabled, you need to include at least one address. Separate multiple addresses with commas.</th>
</tr>
</thead>
</table>

Example:

"svc-monitor.notification.smtp.target_addresses": "iluvdata@example.com"

<table>
<thead>
<tr>
<th>svc-monitor.notification.smtp.canonical_url</th>
<th>URL of the Tableau Server. Enter http:// or https://, followed by the name or IP address of the Tableau server. Used in the footer of subscription email.</th>
</tr>
</thead>
</table>

Example:

"svc-
This topic covers the permissions requirements needed for Tableau Services Manager (TSM) to access and use files. This information is intended for server administrators. This topic does not address permissions used for managing users and content within Tableau Server (permissions for content and users). For information related to these permissions, see Content Permissions and Ownership.

During installation of TSM and Tableau Server, an unprivileged user (tableau) is created and added to a server authorized group (tableau). This user account enables the work done by TSM and Tableau Server processes. You can change the user and group during installation. For more information, see Identity Store.

Permissions requirements for TSM apply to both files, and to the directories in which the files are placed. When TSM creates and manages files, the files get put into specific default locations with the necessary permissions and you don't need to worry about setting permissions. When you create, copy, or move files yourself, or when you put files into non-default locations, you need to be aware of permission requirements so that TSM can properly access the files. Common cases (For information about using non-default locations, see tsm File Paths.)

General rules for permissions and TSM are:

- Files—If the tableau group has access to a file (if it is the group owner and has read access to the file), the users in the group have access to the file. An alternate approach is to give "other" read access.
• Directories—If the *tableau* group has read and execute access to the directory that contains a file, and any parent directories of that directory, the users in the group have access to the file.

Situations that may require you to adjust permissions include server backup files and site import archives that you copy from a different computer or to a non-default location, customization files such as logos or images, and security certificates such as SSL certificates.

For example, if you migrate from Tableau Server on Windows to Tableau Server on Linux, you use a backup created in Windows to restore data to your Linux server. Because this backup file isn't created by TSM, it may not have the correct permissions for the restore process to access it. You need to make sure the backup file and the directory structure you copy it into have the proper permissions. Similarly, if you are copying files like certificates to additional nodes in a cluster, you need to make sure the files and the directories you copy them into have the permissions the *tableau* user needs in order to access them.

**Setting permissions for individual files**

If you are using a file you copy to one of the default locations created by TSM, you need to make sure the ownership and permissions on the file allow TSM access by giving the *tableau* user read access. You can do this in one of two ways:

• You can give the *tableau* user read access by giving the *tableau* group (in a default installation) read and execute access to a file using the `chgrp` and `chmod` commands. For example:

  ```
  chgrp tableau <backup>.tsbak
  chmod g+rx <backup>.tsbak
  ```

• Alternately, you can give world read and execute access to the file:

  ```
  chmod o+rx <backup>.tsbak
  ```
Setting permissions for directories

In addition to setting the proper permissions on the files themselves, TSM also needs permissions for the directory that contains the file, as well as any parent directories. If you are using a non-default location for files that TSM will access, you will need to make sure permissions for the parent directory or directories that contain the file allow read and execute access.

You can address this issue in a couple of ways:

- Change group ownership of the directory to the `tableau` group, and add group read and execute permission to the directory. Doing this makes files in the directory more available to the `tableau` user.

  \[ \text{chgrp tableau <directory-name>} \]

  \[ \text{chmod g+rx <directory-name>} \]

- Alternatively, you can add world read and execute permission to the directory. This makes files in the directory more available to all users on the system. This approach may require additional steps to ensure security of other files in the directory. For example, you may want to make sure other files in the directory are not world readable so other users cannot read them.

  \[ \text{chmod o+rx <directory-name>} \]

**Hint:** You can use `namei -mo` command to list an entire permissions tree. This can make it easier to see what directories need to have permissions adjusted to allow access by the `tableau` group. You can find more information on the internet.

Configure Server Event Notification

You can configure the following server notifications on the following events:
• Content updates
  • Extract failures
  • Subscription views for users
• Server health monitoring
  • Server status changes
  • License reporting
• Drive space
  • Recording usage history
  • Email alerts when space crosses or remains below pre-configured thresholds

**Note:** You need to configure SMTP before you can configure subscriptions or notifications. For more information, see Configure SMTP Setup.

**Content updates**

You can set notifications for extract failures. You can also enable notifications for user subscriptions.

When users subscribe to a workbook or view, a snapshot of the view is email to them on a scheduled basis, so they can see the latest updates without having to sign into Tableau Server.

After you have enabled subscriptions in this procedure, you can configure subscriptions in each site. See Set Up a Server for Subscriptions.

**Server health monitoring**

Server status changes and license reporting.

Server status changes

Tableau Server sends an email when the data engine, repository, or gateway server processes stop or restart, or when the initial Tableau Server node stops or restarts. If you are running a single-server installation (all processes on the same machine), health alerts are only sent when Tableau Server is up. No "down" alerts are sent. If you are running a
distributed installation that's configured for failover, a DOWN alert means that the active repository or a data engine instance has failed and the subsequent UP alert means that the passive instance (repository) or second instance (data engine) of that process has taken over.

License reporting

License reporting is generated at Tableau Desktop and sent to Tableau Server.

Drive space

Enable notifications for remaining drive space on your Tableau Server.

Remaining space thresholds

You can configure Tableau Server to send email alerts when disk space usage on any node crosses a threshold, or remains below the threshold.

There are two thresholds you must set. Thresholds are expressed in percentage of disk space remaining.

You can set a warning threshold and a critical threshold. The critical threshold must be less than the warning threshold.

Setting email interval

Specify how often, in minutes, warning and critical alerts should be sent. The default value is 60 minutes.

Recording usage history

When you configure Tableau Server to record disk space usage, information about free disk space is saved in the repository and you can view the usage history using the Administrative Views.
In this article

Use the TSM web interface
Use the TSM CLI

Use the TSM web interface

1. Open TSM in a browser:

   https://<tsm-computer-name>:8850. For more information, see Sign in to Tableau Services Manager Web UI.

2. Click Notifications on the Configuration tab and click Events.

3. Configure notification settings for your organization:

   ![Event Configuration Screen]

   - **Content updates**
     - Send emails for extract refresh failures
   - Allow users to receive email for views that they have subscribed to
   - **Server health monitoring**
     - Send emails for Tableau Server process events (up, down, and failover)
   - Send emails for Tableau Server license reporting
   - **Drive space**
     - Send emails when unused drive space drops below thresholds
     - Warning threshold: 20 %
     - Critical threshold: 10 %
     - Send threshold alert every: 60 minutes
   - Record disk space usage information and threshold violations for use in custom administrative views

   [Save Pending Changes]
4. Click **Save Pending Changes** after you've entered your configuration information.

5. Click **Apply Changes and Restart**.

**Use the TSM CLI**

The various notification values described above can be set individually with the tsm configuration set command. Alternatively, you can construct a json file and pass all configuration values in one operation. Both methods are described in this section.

Set notification values individually

The following table shows the key/value pairs that map to the notification events described earlier in this topic. Use the tsm configuration set command with the following syntax to set a single key/value pair:

```
tsm configuration set -k <config.key> -v <config_value>
```

For example, to enable extract failure notifications, run the following command:

```
tsm configuration set -k backgrounder.send_email_on_refresh_failure -v true
```

<table>
<thead>
<tr>
<th>Notification option</th>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Extract failures</td>
<td>backgrounder.send_email_on_refresh_failure</td>
<td>true</td>
</tr>
<tr>
<td>Enable subscription views for user</td>
<td>subscriptions.enabled</td>
<td>true</td>
</tr>
<tr>
<td>Server status changes</td>
<td>svcmonitor.notification.smtp.enabled</td>
<td>true</td>
</tr>
<tr>
<td>License reporting</td>
<td>features.DesktopReporting</td>
<td>true</td>
</tr>
<tr>
<td>Remaining space thresholds: enable email notifications</td>
<td>storage.monitoring.email_enabled</td>
<td>true</td>
</tr>
<tr>
<td>-----------------------------------------------------</td>
<td>---------------------------------</td>
<td>-------</td>
</tr>
<tr>
<td>Remaining space thresholds: warning percentage</td>
<td>storage.monitoring.warning_percent</td>
<td>integer value, for example, 20</td>
</tr>
<tr>
<td>Remaining space thresholds: critical percentage</td>
<td>storage.monitoring.critical_percent</td>
<td>integer value, for example, 15</td>
</tr>
<tr>
<td>Set email interval</td>
<td>storage.monitoring.email_interval_min</td>
<td>integer value, in minutes, for example, 25</td>
</tr>
<tr>
<td>Record usage history</td>
<td>storage.monitoring.record_history_enabled</td>
<td>true</td>
</tr>
</tbody>
</table>

After you are done setting values, you must run the following command:

```
tsm pending-changes apply
```

The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

Set all notification values with a single json file

To make all notifications settings with a single configuration, you can pass a json file.

Copy and edit the following template to create a file for your configuration.
After you have saved the file, pass it with the following command:

tsm settings import -f <path-to-file.json>

To apply changes, run the following command:

tsm pending-changes apply

The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

Configure Data Cache

Views published to Tableau Server are interactive and sometimes have a live connection to a database. As users interact with the views in a web browser, the data that is queried gets stored in a cache. Subsequent visits will pull the data from this cache if it is available. By default, Tableau Server will cache and reuse data for as long as possible. You can change
this behavior by configuring the caching option using the `tsm data-access caching set` command.

1. Log in to TSM:

   `tsm login -u <name>

2. Run this command:

   `tsm data-access caching set -r <value>`

   Where `<value>` is one of these options:

   - **low.** This is the default and configures Tableau Server to cache and reuse data for as long as possible.
   - `<value>`. "<value>" specifies the maximum number of minutes data should be cached.
   - **always** or 0 (zero). These values indicates that the cache should be refreshed each time a page is reloaded.

3. Apply changes with the `tsm pending-changes apply` command. This will restart Tableau Server.

### Database Drivers

Tableau connectors require a driver to talk to the database. Before you can connect to data sources from Tableau Server, you must install drivers for the data sources you want to connect to. You can find information about supported data sources for Tableau Server on Linux on the [Tableau Server tech specs page](https://www.tableau.com). You can find driver links and installation instructions for all the supported connectors on the [Driver Download page](https://www.tableau.com).

**Important:** You must install the PostgreSQL driver if you want to use the built-in administrative views.
Install drivers in a cluster

You need to install the drivers for your data sources on the initial node in a Tableau Server cluster. If you install Tableau Server on multiple nodes, you must also install drivers on any node that runs any of the following processes:

- Application Server (Vizportal)
- Backgrounder
- Data Server
- VizQL Server

Server Crash Reporter

The Tableau Server administrator can enable an option to allow logs and related files to be sent to Tableau when the server has an issue that results in a crash. These files are used by Tableau to identify and address issues that cause crashes. By default this option is disabled, and it should only be enabled in organizations that are not subject to regulations related to data privacy.

**Important:** Do not enable crash reporting if your data is subject to privacy regulations.

If Tableau Server has a problem that results in a crash, log files and dump files are generated. If the crash data upload feature is enabled, these files are automatically gathered and zipped into an encrypted package that is sent in the background, at the scheduled time. The encrypted package is sent in small pieces to limit impact to network performance. Only one crash report is packaged and uploaded at a time (a new crash report is not packaged until the previous package has been uploaded) and is sent in a "first in, first out" order. You can schedule the sending for a low-use window to further reduce any impact to your users.

The encrypted package is made up crash dump files and logs that include the following:

- Crash/core dump files
- Error log files related to the crash
• Manifest files related to the crash

The files can contain data that includes:

• Machine-specific information (for example: hardware, operating system, domain).

• A snapshot of the contents of memory at the time of the crash, including application activity details like information about data connections, actions taken by the user in Tableau, and data being worked on in Tableau.

• Tableau information including customer-identifiable information.

See Also:

• Configure Server Crash Reporter

Configure Server Crash Reporter

Server crash reporting is disabled by default. This topic describes how to enable and configure server crash reporting. Crash reports are encrypted and sent to Tableau. See Server Crash Reporter for more information.

Important: Do not enable crash reporting if your data is subject to privacy regulations.

In this article
Use the TSM web interface
Use the TSM CLI

Use the TSM web interface

1. Open TSM in a browser:
https://<tsm-computer-name>:8850. For more information, see Sign in to Tableau Services Manager Web UI.

2. Click the **Maintenance** tab.

3. Under Other Maintenance Tasks, in Server Crash Reporter, select **Enable crash reporting**:

![Server Crash Reporter](image)

4. Specify the scheduled time of day to upload the crash reports to Tableau.

5. When you are finished, click **Pending Changes**, and then click **Apply Changes and Restart**.

**Use the TSM CLI**

Use the configuration file template below to create a json file. After you have filled in the options with the appropriate values, pass the json file and apply settings with the following commands:

```
tsm settings import -f path-to-file.json
```

```
tsm pending-changes apply
```

The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is
stopped, but in that case there is no restart. You can suppress the prompt using the --ignore-prompt option, but this does not change the restart behavior. For more information, see tsm pending-changes apply.

Because the configuration file is using configKey class, the values that you pass are not validated by TSM as they are when you use configEntities class. You can verify and set individual options by using the tsm configuration commands.

Crash reporter settings

The crash reporter settings in the template below specify a range of options for configuring Tableau Server to send crash reports to Tableau.

Configuration template

Use this template to configure the gateway settings.

For more explanation about configuration files, entities, and keys see Configuration File Example.

{  
    "configKeys": {  
        "servercrashupload.enabled": "true",  
        "servercrashupload.scheduled_time": "1:00:00 UTC",  
        "servercrashupload.proxy_server_host": "",  
        "servercrashupload.proxy_server_port": "",  
        "servercrashupload.proxy_server_username": "",  
        "servercrashupload.proxy_server_password": "",  
        "servercrashupload.preserve_upload_packages": "false",  
        "servercrashupload.delete_completed_dumps": "false"  
    }  
}

Configuration file reference

This table includes keys that you can set to configure crash reporting.

servercrashupload.enabled
Default: false.

Set to true to enable crash reporting.

servercrashupload.scheduled_time

Default: 1:00:00 UTC

Specifies the scheduled time that crash uploads will begin. Enter time of day in 24 hour format.

servercrashupload.proxy_server_host

If your organization uses a proxy server to communicate with the internet, specify the host name.

servercrashupload.proxy_server_port

If your organization uses a proxy server to communicate with the internet, specify the port number.

servercrashupload.proxy_server_username

If your proxy server requires authentication, specify the user name with this key.

servercrashupload.proxy_server_password

If your proxy server requires authentication, specify the password with this key.

servercrashupload.preserve_upload_packages

Default: false.

To save all packages that are created for a crash reporting, set this key to true.

By default, packages are saved to /var/opt/tableau/tableau_server-/data/tabsvc/clustercontroller/tabcrashreporter.
servercrashupload.delete_completed.dumps

Default: false.

To delete all dumps after they are sent, set this key to true.

Navigate Server Admin Pages

As a server administrator, you can access all of the menus and pages in Tableau Server for server and site management. If your server is configured for multiple sites, the site menu is available for navigation. Click **Manage All Sites** in the site menu to access server administration pages.

The server administrator pages include server-wide settings that you will use to configure, monitor, and maintain Tableau Server.

Server Administrator Pages

In a single-site deployment, all server and site menus are available to you in the main menu. To create a site, click **Settings > Add a Site**.

On a multi-site server, when a site is selected, you will see these menus:

To access server administration pages, click the site menu, and then select **Manage All Sites**:
On a multi-site server, these are the server administration menus. The site menu text changes to **All Sites** to let you know you are managing server-wide settings.

To return to the site administration menus, click **All Sites**, and the select the site you want to manage.
Server administrators can:

- Monitor server status and activity.
- Generate log files.
- Add sites and edit site settings. Only server administrators can add sites to the server.
- Add users to the server, and assign users to sites.
- Add and manage site groups.

To manage site-related settings, you must first navigate to a specific site. Within each site, you can:

- Manage content and assign permissions.
- Manage schedules for extract refreshes and subscriptions.
- Monitor site activity and record workbook performance metrics.
- Manage storage space limits for content published by users.

- Allow web authoring.

- Enable revision history.

- Allow site administrators to add and remove users.

- Allow users to subscribe to workbooks and views, and allow content owners to subscribe others to workbooks and views.

- Enable offline snapshots for favorites (iOS only).

**Migrate to New Hardware**

Use the following procedure to migrate Tableau Server from one computer to another. Specifically, these steps describe how to move Tableau Server data from your in-production computer to a new computer where Tableau Server is installed. Before you start, make sure you have followed the steps in Prepare for the Upgrade, including creating a backup and gathering any assets that require manual actions. For details, see Perform a Full Backup and Restore of Tableau Server. You'll need these to restore your Tableau Server data and configuration.

**Note:** This operation includes steps that you may need to perform using the TSM command line.

1. Deactivate your product key on your original installation of Tableau Server. You need to do this so you can activate it on the new computer. For more information, see "Tableau Server product key activation" below.

2. Install Tableau Server on the new computer. For details, see Install and Initialize TSM.

3. Copy your backup file .tsbak to the folder location specified by the
basefilepath.backuprestore variable. By default this is: /var/opt/tableau/tableau_server/data/tabsvc/files/backups.

Note: You can change the location for the backup file. For more information, see tsm File Paths.

4. Next, stop Tableau Server:

   tsm stop

5. Restore your in-production data to your new Tableau Server installation using the tsm maintenance restore command:

   tsm maintenance restore -f <filename>

   where <filename> is the name of the .tsbak file you copied in step 3.

   For more information about restoring Tableau Server data, see Restore from a backup.

6. Start the server:

   tsm start

7. Distributed installations only: Install Tableau Server on the new computers you want to add to your new Tableau Server cluster. See Install and Configure Additional Nodes for steps.

8. If you have not deactivated your product key on the old computer, do that after you test your new Tableau Server installation and confirm that it’s ready for production. For details, see "Tableau Server product key activation" below.
Note: If you do not have an internet connection, you are prompted to create an offline activation file to complete the deactivation process. See Activate Tableau Server Offline for steps.

Tableau Server product key activation

You can activate the same Tableau Server product key up to three times. This allows you to test Tableau Server (in a sandbox or QA environments, for example), as well as use Tableau in production. To maximize your activations, you should deactivate your product key when you remove Tableau Server from a computer, unless you will be reinstalling Tableau on the same computer. Doing this gives you the opportunity to use the activation on a different computer. For example, if you move Tableau Server from one computer to another, deactivate the product key, then remove Tableau from the original computer. When you install Tableau on the new computer, you can activate the key there without any conflict. If you are removing Tableau Server to reinstall it on the same computer, you don't need to deactivate the key. Tableau will use the key when reinstalled. For example, if you are moving Tableau from one drive on a computer to a different drive on the same computer. For information on how to deactivate a product key, see tsm licenses deactivate.

Move Tableau Server to Another Drive

By default Tableau Server on Windows is installed to the system drive (usually C:\). This means that all program and data files are installed to that drive. If you need to move Tableau Server to a different drive (if a new policy requires you to not have application data on your system drive, for example, or you are running out of space on the original drive), you can do this by following the procedure below. The steps are intended as an example for moving Tableau Server from one drive to another drive on the same computer, and may not exactly reflect your installation and configuration. For instructions on moving Tableau Server to a new computer, see Migrate to New Hardware.
Before you start

Before starting, make sure you:

- Have a current backup of your data and assets from your existing installation. You’ll need these to restore your installation of Tableau Server on the new drive. For details on creating a backup, see Perform a Full Backup and Restore of Tableau Server.

- Have administrative credentials to the Tableau Server computer. This is where you will be working and you need to be logged on to the computer as an administrator.

- Have a copy of the installation program for the version of Tableau Server you are moving. You need this to install Tableau Server to the new drive.

- Know what authentication methods your current installation is using. For example, if Tableau Server is configured for SSL, SAML, or Kerberos, you will need to back up the related certificate or keytab files separately, and then copy them to the new drive after you reinstall Tableau Server.

When you are ready to move Tableau Server to another drive and have fully backed up your data and all assets and saved those files in a safe location on a different computer:

1. Open a command prompt as an administrator on the initial Tableau Server computer.

2. Change to the scripts directory (By default: C:\Program Files\Tableau\Tableau Server\packages\scripts.<version_code>\) and run the obliterate script to completely remove Tableau Server from the computer:

   tableau-server-obliterate -y -y -y

3. Restart the computer.

4. Install Tableau Server to the new drive. For details, see Install and Initialize TSM.

   At the end of the install process a browser window will open and you will be prompted to create an initial administrative user. Close this without creating the user.
5. **Note:** You can change the location for the backup file. For more information, see tsm File Paths.

6. Open a command prompt as an administrator.

7. Stop Tableau Server:

   tsm stop

8. Restore your Tableau Server data backup and assets you saved earlier. This includes restoring your database, and any assets that need to be restored manually.

   For details, see Restoring core Tableau Server functionality.

9. Start Tableau Server:

   tsm start

**Tableau Server product key activation**

You can activate the same Tableau Server product key up to three times. This allows you to test Tableau Server (in a sandbox or QA environments, for example), as well as use Tableau in production. To maximize your activations, you should deactivate your product key when you remove Tableau Server from a computer, unless you will be reinstalling Tableau on the same computer. Doing this gives you the opportunity to use the activation on a different computer. For example, if you move Tableau Server from one computer to another, deactivate the product key, then remove Tableau from the original computer. When you install Tableau on the new computer, you can activate the key there without any conflict. If you are removing Tableau Server to reinstall it on the same computer, you don't need to deactivate the key. Tableau will use the key when reinstalled. For example, if you are moving Tableau from one drive on a computer to a different drive on the same computer. For information on how to deactivate a product key, see tsm licenses deactivate.

When you remove Tableau Server using the obliterate script, you have the option to have the script deactivate and delete the Tableau product key information by using a "-l" switch.
This will deactivate and remove all Tableau license information, including Tableau Desktop if you have that installed. If you know you want to deactivate the key, we recommend you deactivate the key before running the script. For more information, see Remove Tableau Server from Your Computer.

Distributed and High Availability Tableau Server Installations

The most basic way to run Tableau Server is to install a single node. With this type of installation you have a fully functional Tableau Server, with all Tableau Services Manager (TSM) and Tableau Server processes running on that single node, but this may not be the optimal way to use Tableau Server. You can decide how to install Tableau based on your organization’s needs, and your resources, adding additional nodes and configuring Tableau for high availability. Your installation options include:

- **Single-node installation**—This type of installation is reasonable for testing, running trials, and for environments that can handle occasional downtime and system availability due to lack of redundancy. All server processes are running on a single machine. There is less redundancy and fewer safeguards in the event of a problem with one of the server processes. You also need to make sure the computer you install Tableau Server on has adequate resources to handle the processes and the demands of users and data.

- **Distributed installation**—This type of installation is also called a multi-node installation and requires multiple computers so you can install and run server processes on those distributed nodes. Spreading the server processes out over multiple nodes can extend the reliability and efficiency of Tableau Server by providing redundancy and additional computing power. With the right configuration, a distributed installation can also provide you with automatic repository failover. For more information on failover, see Repository Failover.

- **Highly available (HA) installation**—An HA installation of Tableau Server is a
special type of multi-node installation with a minimum of three nodes and multiple instances of key processes (the Repository, File Store/Data Engine (Hyper), and Coordination Service) on different computers. With an HA installation, there is built-in redundancy of those key processes, including multiple File Stores, and automatic Repository failover. The goal is to minimize system downtime by eliminating single points of failure, and enabling detection of failures with failover where possible.

The first computer you install Tableau on, the "initial node," has some unique characteristics. Two processes run only on the initial node and cannot be moved to any other node except in a failure situation, the License service (License Manager) and TSM Controller (Administration Controller).

Two other processes are initially included on the initial node but can be added or moved to additional nodes, the CFS (Client File Service) and the Coordination Service.

For information about moving the License service and TSM Controller from the initial node to another node, see Recover from an initial node failure below.

**Prerequisite**

These instructions assume that your cluster meets the Distributed Requirements.

**Note:** You cannot install Tableau Server on a combination of Linux and Windows computers.

**Creating a distributed Tableau Server installation**

These are the general steps you follow to create a distributed installation of Tableau Server:

1. Begin by installing Tableau Server on your initial node.
   
   For details, see Install and Configure Tableau Server.

2. Generate a node configuration (bootstrap) file on the initial node.
3. Install Tableau Server on an additional node using the node bootstrap file.

For more information, see Install and initialize an additional node.

4. Configure your additional node with the processes you want to run on it.

For more information, see Configure the additional node.

5. Repeat Steps 3 and 4 for any additional nodes you want to install.

6. Deploy a new Coordination Service ensemble.

For more information, see Deploy a Coordination Service Ensemble.

Creating a highly available (HA) Tableau Server installation

A high availability Tableau Server installation is a special type of distributed installation, designed to accommodate failure in key server components without loss of complete server functionality. To create an HA installation, follow the same steps you take to create a distributed deployment but include additional steps to make the deployment highly available. These additional steps include adding at least two additional nodes (for a minimum of three nodes in the cluster), adding a second instance of the repository, and second instances of the data engine/file store, adding additional gateway processes, and deploying a Coordination Service ensemble. You can also add a load balancer to distribute requests among the gateways.

At a high level, these are the steps you follow to create a highly available installation of Tableau Server:

1. Begin by installing Tableau Server on your initial node.

   For details, see Install and Configure Tableau Server.

2. Generate a node configuration (bootstrap) file on the initial node.
For details, see Generate the node bootstrap file.

3. Install Tableau Server on at least two additional nodes using the node bootstrap file.

For more information, see Install and initialize an additional node.

4. Configure each additional node with the processes you want to run on it. These must include a second copy of the Tableau Server repository, and a second copy of the data engine and file store, as well as additional instances of the gateway.

For more information, see Configure the additional node.

5. Deploy a Coordination Service ensemble.

For more information, see Deploy a Coordination Service Ensemble.

6. (Optional) Configure a load balancer.

For more information, see Add a Load Balancer.

For details on how to create a three-node HA installation, see Example: Install and Configure a Three-Node HA Cluster.

Recover from an initial node failure

With a Tableau Server installation, the initial node includes two services that are only installed on that node, the License service, and the TSM Controller. If there is a problem with the initial node, Tableau Server may not continue to function, even when configured for high availability. To recover from a situation where the initial node fails, you can move the TSM Controller and the License service to one of your already configured nodes. This allows you to recover from the failure while using resources you already have in the cluster. You do not have to configure a standby initial node in case the initial node fails.

For details on how to recover from a failure on the initial node, see Recover from an Initial Node Failure.
Configure Coordination Service ensemble on additional nodes

Configuring a Coordination Service on multiple nodes provides additional duplication of processes and so reduces the possibility of server downtime due to an issue with one of the Coordination Service nodes. For details on how to deploy a Coordination Service ensemble on your cluster, see Deploy a Coordination Service Ensemble.

Tableau Server service license check

A number of processes are installed when you install Tableau Server. Some of these processes are dependent on the existence of a valid Tableau Server license while other installed processes are not. The subset of Tableau Server that require a valid Tableau Server license are considered "licensed processes."

When a licensed process starts or restarts, the process checks with the Tableau Server License Manager service on the initial node to verify there is a valid license. When the License Manager validates the license, the process is fully functional and able to respond to requests from other Tableau Server processes. Once a licensed process has received confirmation from the License Manager, the process does not need to reconfirm the license for 72 hours, or until the process restarts. If the process is not able to verify that it is licensed (if the primary node is unavailable, for example) it cannot run, but it continues to check for a valid license until it confirms the license. To see when the last licensing check occurred, look at the log files in the /var/opt/tableau/tableau_server-/data/tabsvc/logs/licenseservice directory. For more information about licensed processes, see Licensed processes.

Distributed Requirements

Before you start to configure a Tableau Server cluster, make sure you meet the following requirements.
Hardware

While the computers you use in your cluster must meet the requirements described in Before you install..., they do not need to be identical.

Hardware Guidelines for High Availability

Here are some guidelines for the systems you use for failover and high availability:

- **Failover—three computers**: To configure a cluster that provides failover support for the file store and repository processes, you need at least three computers or VMs: one for the initial Tableau Server node and two for additional nodes.

- **Multiple gateways—three computers and a load balancer**: Adding multiple Gateway processes to your Tableau Server installation and using a load balancer to automatically distribute requests to those gateways enhances the reliability of Tableau further. To configure a cluster that provides failover support and multiple gateways, you need to add a load balancer to front your three-node cluster.

- **Failover & multiple gateway support—three computers and a load balancer**: To configure a cluster that provides the above plus support for multiple gateways, you need at least three computers or VMs, and a load balancer to front the cluster.

- **High availability—three computers and a load balancer**: To configure for high availability, you need the resources described above.

- **Initial computers**: If you configure for high availability, the initial Tableau Server node may be running few or no Tableau Server processes. Therefore, the computer that serves as the initial node does not need as many cores as the ones running your additional nodes. You will, however, need adequate disk space for backups because the initial computer is used during the database backup and restore processes. In addition to the amount of space needed for the backup file, you need temporary disk space roughly 10 times the size of the backup file (so if your backup is 4 GB, you should have about 40 GB of temporary disk space available).
Software

- All nodes in a distributed installation must be running the same version of Tableau Server.
- All nodes must be running the same distribution of Linux.

Installation location

When you start Tableau Services Manager (TSM) you can specify a non-default location for the data directory. This location must be the same on all nodes in your distributed Tableau Server installation.

Networking and Ports

- **Ports**: As with any distributed system, the computers or VMs you use need to be able to communicate with one another. For information on how Tableau Services Manager handles port mapping, see Tableau Services Manager Ports.

- **Same subnet**: Do not install a distributed system across multiple subnets. Latency between subnets can cause problems with Tableau server, so all nodes in the cluster should be installed on the same subnet.

  **Note**: When installing a cluster on AWS, this requirement does not apply. For details, see "Install Tableau on Amazon Web Services" in the Tableau Server Help.

- **Static IP addresses**: Any computer running Tableau Server, whether it's a single server installation or part of a cluster, must have a static IP address.

- **Discoverable**: Each node in the cluster must be discoverable from other node computers using DNS or a local host file.

- **Time zone and time**: Each node in the cluster must be in the same timezone, with
their system clocks synchronized. This may happen automatically. For example, if your nodes are all in the Active Directory domain, the domain controller usually handles this. If you are not sure your cluster meets this requirement, consult with your internal IT experts.

Best Practices

Here are some things to keep in mind before you start to install and configure:

- **IP addresses or computer names**: As mentioned above, each computer in the cluster must use a static IP address.

- **Backup**: It’s a best practice to create a backup prior to making significant system changes. See Back up Tableau Server data for steps.

SSL

If you are planning to configure SSL for a highly available Tableau Server cluster with multiple gateways and a load balancer (learn more), make sure that the SSL certificate you use was issued for the load balancer’s host name. See Configure SSL for External HTTP Traffic to and from Tableau Server for other details.

Distributed Installation Recommendations

When you add nodes to a Tableau Server installation, you must decide how many processes to run on each computer. This page provides some general recommendations that are intended only as a starting point.

In addition to these general recommendations, you should also:

- Understand how your organization uses Tableau Server and tune your configuration for your use case—for example, whether you want to optimize for user response or for extract refreshes.
• Perform thorough performance testing to identify the best places to adjust process configuration.

For more information on tailoring a Tableau Server installation to your organization's needs, see Performance Tuning Examples.

For more information on the requirements for a distributed installation and for information on configuring additional nodes, see Distributed and High Availability Tableau Server Installations.

Recommendations for all installations

Although the computers that make up a Tableau Server cluster do not need to have identical hardware, they must all meet the same minimum system requirements. The recommendations on this page assume that the computers where you install Tableau Server have eight cores or more.

The following recommendations apply to all server configurations:

• Run Backgrounder processes on a dedicated computer if you plan on refreshing extracts frequently. Backgrounder processes are generally the most CPU intensive and can slow down other processes on the same computer.

  **Note:** In versions earlier than 10.5, the backgrounder process spun up temporary instances of Data Engine when refreshing extracts. In 10.5, a single instance of Data Engine is installed with the backgrounder during setup. The backgrounder uses this running instance of Data Engine when refreshing extracts.

• If you plan to refresh extracts frequently or if you plan to refresh large extracts, increase the number of processes for Backgrounder processes.

• Run VizQL processes on a different computer than Backgrounder processes. Having them on the same machine means that extract refreshes can affect user views.

• The instance of Data Engine installed on the node where File Store is installed is used...
for querying data for view requests. Consider separating the File Store process from the back grounder processes to help minimize the back grounder tasks from affecting user views.

- Locating the repository (pgsql) and the File Store on the same node as the Administration Controller can reduce the length of time it takes to back up Tableau Server. The Administration Controller is usually on the initial node, unless you have had an initial node failure and had to move the controller to another node.

When the repository is co-located with the controller it eliminates or greatly reduces the need to compress and transfer data between nodes during the backup process. This is also true with the File Store, especially if your organization uses extracts heavily.

Note: In a distributed installation with three or more nodes, you can have a maximum of two repository instances (active and passive). You can also run Tableau Server with one repository, but doing this means there is no failover available for the repository. For more information, see Tableau Server Repository.

Install and Configure Additional Nodes

After you install Tableau Server on one computer (or node), the server is functional and ready for use, but it has no redundancy. If there is a problem with a process or a problem with the computer, Tableau Server may be unavailable. In addition, all processes are running on a single computer, so there can be contention for resources on that computer.

You can extend your Tableau Server installation by adding Tableau to additional nodes, creating a distributed installation. This article describes the general steps for installing Tableau Server on additional nodes and assumes you have already installed Tableau on an initial node. For more information on installing Tableau on the initial node, see Install and Initialize TSM.
If you are installing Tableau Server on multiple nodes, you should install and configure one node at a time. This makes it easier to troubleshoot any issues you might run into.

**Important:** You should add and configure additional nodes when you can fully complete the process by applying pending changes. Adding a node without finishing by applying pending changes can result in users being unable to log into Tableau Server.

In this article

The general steps for installing Tableau Server on an additional node are:

1. Confirm prerequisites
2. Generate the node bootstrap file
3. Install an additional node
4. Configure an additional node
5. Install drivers

Confirm prerequisites

Before you install Tableau Server on any node, ensure that the node meets the system requirements. For more information, see Before you install....

Use the TSM web interface

Use the TSM CLI

Use the TSM web interface
Generate the node bootstrap file

1. Open TSM in a browser:

   https://<tsm-computer-name>:8850

   For more information, see Sign in to Tableau Services Manager Web UI.

2. Click the Configuration tab, and in the Add a Node box, click Download Bootstrap File.

   ![Configuration Tab](image)

   The bootstrap file is created and copied to your local computer.

Install and initialize an additional node

Before you begin, verify that your node bootstrap file is recent. For example, if you have run `tsm security regenerate-internal-tokens` after you generated a bootstrap file, then initialization will fail.
1. Copy the original installer you used on the first computer along with the bootstrap file you generated and put them in a location accessible from the new computer you are adding Tableau Server to. This could be a mounted network share, or directly on the new computer.

2. If you are running a local firewall, then you need to configure firewall rules for all the nodes in the cluster. For more information, see Configure Local Firewall.

3. On the new node, run the Tableau Server Setup program:

   Use the package manager to install the Tableau Server package.

   - On RHEL-like distributions, including CentOS, run the following commands:

     ```
     sudo yum update
     sudo yum install tableau-server-<version>.x86_64.rpm
     ```

     **Note:** When you use `yum` to install Tableau Server, all dependent packages are automatically downloaded and installed. This is the preferred method for installing Tableau. If your organization does not allow you to use `yum` and you must install using `rpm -i`, you must also install all dependent packages separately.

   - On Ubuntu, run the following command:

     ```
     sudo apt-get update
     sudo apt-get -y install gdebi-core
     sudo gdebi -n tableau-server-<version>_amd64.deb
     ```

4. To initialize communications between your new node and the initial node, run the initialize-tsm script that is installed when you install Tableau Server.

   Navigate to the scripts directory:
cd /opt/tableau/tableau_server/packages/scripts.<version_code>/

5. sudo ./initialize-tsm -b /path/to/<bootstrap>.json -u <admin-user-on-first-node> --accepteula

- Use the -b flag to provide the path to the bootstrap file that you copied to the computer. If you have encrypted the bootstrap file, then you must pipe the file as described in Securing secrets for import and export operations.

- Use the -u flag to enter the user name of the administrative user on the initial node. This is the name of an administrative user on the computer, not the Tableau Server administrator. You will be prompted for the user password.

Important: You must enter the credentials of the same user that you used during the installation process on the initial node.

- The --accepteula flag accepts the Tableau Server End User License Agreement (EULA). The EULA is available in the following location:

  /opt/tableau/tableau_server/packages/docs.<version_code>/EULA.rtf

Configure the additional node with Cluster Controller

1. Open TSM in a browser:

   https://<tsm-computer-name>:8850

   For more information, see Sign in to Tableau Services Manager Web UI.

2. Click the Configuration tab. A message should tell you that the new node was added.
Click **Continue** to dismiss the message.

3. Cluster Controller is part of the minimum topology and is already selected. Each node must run Cluster Controller.

   If you only want to set the minimum topology for the node, go to Step 4 below. You might do this if you will be adding additional nodes and are not ready to configure this node beyond the minimum.

   If you want to add additional processes to the minimum topology, specify the processes that should run on the node. Do this by selecting the processes you want, or specifying the number of processes that should run on the node.

   For example, to add a Gateway and two instances of the Backgrounder on the node:

   a. Select **Gateway**.

   b. Set the **Backgrounder** count to 2.

      Adding Backgrounder to a node will also add an instance of Data Engine if one is not already on the node.
The specific processes and process counts you set will depend on your organizational environment and needs. Some processes are added automatically when you add another process. For more information, see Configure Nodes and Tableau Server Processes.

**Note:** The TSM Web UI limits you to a maximum of 8 instances of processes that allow you to select the number of instances. To configure more instances than this, use the command line and the `TSM topology set-process` command. For more information, see `tsm topology set-process`.

4. Click **Pending Changes** at the top of the page:

   ![Pending Changes](image)

   If you are configuring a cluster with three or more nodes, a Coordination Service ensemble warning displays. You can continue. You will deploy a Coordination Service ensemble in a separate step.

5. Click **Apply Changes and Restart** and **Confirm** to confirm a restart of Tableau Server.

   After Tableau Server restarts, the node is included with the minimum topology necessary and any additional processes you configured.

**Use the TSM CLI**

**Generate the node bootstrap file**

To install Tableau Server on additional computers you use the same installer you did for the initial node, along with a "bootstrap" file you generate on the initial node.
Important: The bootstrap file contains a copy of the master keystore file used for encrypting the configuration secrets. We strongly recommend that you take additional measures to secure the bootstrap file using mechanisms as described in Securing secrets for import and export operations.

1. After installing Tableau Server on the initial node, generate the node bootstrap file.

2. On the initial node, open a terminal session.

3. Type this command to generate the bootstrap file:

   ```
   tsm topology nodes get-bootstrap-file --file <path\-file>.json
   ```

Install and initialize an additional node

1. Copy the original installer you used on the first computer along with the bootstrap file you generated and put them in a location accessible from the new computer you are adding Tableau Server to. This could be a mounted network share, or directly on the new computer.

2. If you are running a local firewall, then you need to configure firewall rules for all the nodes in the cluster. For more information, see Configure Local Firewall.

3. On the new node, run the Tableau Server Setup program:

   Use the package manager to install the Tableau Server package.

   - On RHEL-like distributions, including CentOS, run the following commands:

     ```
     sudo yum update
     sudo yum install tableau-server-<version>.x86_64.rpm
     ```
**Note:** When you use `yum` to install Tableau Server, all dependent packages are automatically downloaded and installed. This is the preferred method for installing Tableau. If your organization does not allow you to use `yum` and you must install using `rpm -i`, you must also install all dependent packages separately.

- On Ubuntu, run the following command:

  ```bash
  sudo apt-get update
dsudo apt-get -y install gdebi-core
dsudo gdebi -n tableau-server-<version>_amd64.deb
  ```

4. To initialize communications between your new node and the initial node, run the `initialize-tsm` script that is installed when you install Tableau Server.

   **On the new node:**

   Navigate to the `scripts` directory:

   ```bash
cd /opt/tableau/tableau_server/packages/scripts.<version_code>/
   ```

5. Run the `initialize-tsm` script:

   ```bash
   sudo ./initialize-tsm -b /path/to/<bootstrap>.json -u
   <admin-user-on-first-node> --accepteula
   ```

   - Use the `-b` flag to provide the path to the bootstrap file that you copied to the computer. If you have encrypted the bootstrap file, then you must pipe the file as described in Securing secrets for import and export operations.
   
   - Use the `-u` flag to enter the user name of the administrative user on the initial node. This is the name of an administrative user on the computer, not the Tableau Server administrator. You will be prompted for the user password.
Important: You must enter the credentials of the same user that you used during the installation process on the initial node.

- The `--accepteula` flag accepts the Tableau Server End User License Agreement (EULA). The EULA is available in the following location:

```
/opt/tableau/tableau_server/packages/docs.<version_code>/EULA.rtf
```

Configure the additional node

**Note:** This basic example illustrates how to set the topology on a node. For a more detailed, working multi-node example, see Example: Install and Configure a Three-Node HA Cluster.

On the initial (original) node, set the topology for the newly added node. The topology specifies which processes should run on the node, and how many instances of each process should run. The topology for the node will depend on your environment and organizational needs. The below are just examples of setting the topology.

1. On the new node, open a terminal session.

2. Get the node-id for the new node:

```
tsm topology list-nodes -v
```

   The `-v` option lists the nodes and the processes they are currently running. You can identify the newly added node because it will not have any processes on it.

3. Specify the individual processes that should run on this node.

   Do this with the following command:
tsm topology set-process -n <nodeID> -pr <processname> -c <n>

You must add an instance of the Cluster Controller to each node.

For example, to add the Cluster Controller, two instances of the Backgrounder, and a Gateway to node2:

tsm topology set-process -n node2 -pr clustercontroller -c 1
 tsm topology set-process -n node2 -pr backgrounder -c 2
 tsm topology set-process -n node2 -pr gateway -c 1

The specific processes and process counts you set will depend on your organizational environment and needs. Some processes are added automatically when you add another process. For more information, see Configure Nodes and Tableau Server Processes.

4. Apply the node configuration. The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

   `tsm pending-changes apply`

A warning about deploying a Coordination Service ensemble displays if you have deployed a three- or five-node cluster. If this is the only warning, you can safely override it using the `--ignore-warnings` option to apply the configuration changes in spite of the warning.

   tsm pending-changes apply --ignore-warnings

Install drivers

You need to install drivers so that Tableau Server can connect to data and run extracts. Install these drivers on nodes that are running any of the following processes:
- VizQL Server (vizqlserver)
- Application Server (vizportal)
- Data Server (dataserver)
- Backgrounder (backgrounder)

Drivers and administrative views

If you want to use the built-in administrative views in Tableau Server, you also need to install the PostgreSQL driver on any nodes running any of the above processes.

For more information, see Database Drivers.

Database Drivers

Tableau connectors require a driver to talk to the database. Before you can connect to data sources from Tableau Server, you must install drivers for the data sources you want to connect to. You can find information about supported data sources for Tableau Server on Linux on the Tableau Server tech specs page. You can find driver links and installation instructions for all the supported connectors on the Driver Download page.

**Important:** You must install the PostgreSQL driver if you want to use the built-in administrative views.

Install drivers in a cluster

You need to install the drivers for your data sources on the initial node in a Tableau Server cluster. If you install Tableau Server on multiple nodes, you must also install drivers on any node that runs any of the following processes:

- Application Server (Vizportal)
- Backgrounder
- Data Server
- VizQL Server
Example: Install and Configure a Three-Node HA Cluster

A multi-node high availability installation of Tableau Server can help to maximize the efficiency and availability of Tableau Server. When configuring a multi-node Tableau Server deployment, the steps you perform are designed to build in redundancy, helping to reduce your potential downtime. In addition to simply improving efficiency by moving or adding server processes to additional nodes, you can create a highly available (HA) installation of Tableau Server by satisfying these requirements:

- Add additional nodes for a total of at least three nodes
- Deploy a Coordination Service ensemble on at least three nodes
- Add a second instance of the File Store on one of the additional nodes (Data Engine will be installed automatically, if it is not already on the node)
- Add a second instance of the Repository (pgsql) on one of the additional nodes

A Tableau Server installation that includes these additions will have built-in redundancy and can support failover in the event of a problem with the repository. This example shows how to do this, and more.

A Single Server System

After installing Tableau Server on an initial node, you have a system that is running everything it needs to function. It has at least one instance of all server processes and is the most basic configuration of Tableau Server. It has no redundancy. The server topology looks like this (some TSM-specific processes are not shown):
A Three-Node System

To build in redundancy, you need to add additional nodes on which to host instances of the repository, and the data engine and file store processes. You can add instances of other processes, including multiple instances of a process on a node. In addition, to reduce the system’s vulnerability, you can run multiple gateways and additional instances of some of the server processes. The fewest number of computers required for this configuration is three.

In the diagram below, the data engine/file store processes have been added to both additional nodes. A second, passive instance of the repository has been added to one of the new nodes. Finally, the server processes (shown in blue) have been added to the additional nodes to provide redundancy.
Configuration steps

This procedure describes how to configure a three-node HA Tableau Server cluster with two repository instances and two file store/data engine instances on the additional nodes as pictured above.

Before you begin

Before you install Tableau Server on any additional nodes, ensure that each additional node meets the distributed requirements. See Distributed Requirements for details.

Use the TSM web interface

**Note:** This operation includes steps that you may need to perform using the TSM command line.

Step 1: Install the initial node

See Install and Configure Tableau Server.
Step 2: Generate a bootstrap file for the additional nodes

1. Open TSM in a browser:

   https://<tsm-computer-name>:8850

   For more information, see Sign in to Tableau Services Manager Web UI.

2. Click the Configuration tab, and in the Add a Node box, click Download Bootstrap File.

   ![Configuration Tab](image)

   The bootstrap file is created and copied to your local computer.

Step 3: Install and initialize an additional node

1. Copy the original installer you used on the first computer along with the bootstrap file you generated and put them in a location accessible from the new computer you are adding Tableau Server to. This could be a mounted network share, or directly on the new computer.

2. If you are running a local firewall, then you need to configure firewall rules for all the
nodes in the cluster. For more information, see Configure Local Firewall.

3. On the new node, run the Tableau Server Setup program:

Use the package manager to install the Tableau Server package.

- On RHEL-like distributions, including CentOS, run the following commands:

  ```
  sudo yum update
  
  sudo yum install tableau-server-<version>.x86_64.rpm
  ```

  **Note:** When you use `yum` to install Tableau Server, all dependent packages are automatically downloaded and installed. This is the preferred method for installing Tableau. If your organization does not allow you to use `yum` and you must install using `rpm -i`, you must also install all dependent packages separately.

- On Ubuntu, run the following command:

  ```
  sudo apt-get update
  sudo apt-get -y install gdebi-core
  sudo gdebi -n tableau-server-<version>_amd64.deb
  ```

4. To initialize communications between your new node and the initial node, run the initialize-tsm script that is installed when you install Tableau Server.

**Navigate to the scripts directory:**

```
  cd /opt/tableau/tableau_server/packages/scripts.<version_code>/
```

5. `sudo ./initialize-tsm -b /path/to/<bootstrap>.json -u <admin-user-on-first-node> --accepteula`
• Use the \texttt{-b} flag to provide the path to the bootstrap file that you copied to the computer. If you have encrypted the bootstrap file, then you must pipe the file as described in Securing secrets for import and export operations.

• Use the \texttt{-u} flag to enter the user name of the administrative user on the initial node. This is the name of an administrative user on the computer, not the Tableau Server administrator. You will be prompted for the user password.

\begin{quote}
\textbf{Important:} You must enter the credentials of the same user that you used during the installation process on the initial node.
\end{quote}

• The \texttt{--accepteula} flag accepts the Tableau Server End User License Agreement (EULA). The EULA is available in the following location:

\begin{verbatim}
/opt/tableau/tableau_server/packages/docs.<version_code>/EULA.rtf
\end{verbatim}

Step 4: Install and initialize a second additional node

1. Copy the original installer you used on the first computer along with the bootstrap file you generated and put them in a location accessible from the new computer you are adding Tableau Server to. This could be a mounted network share, or directly on the new computer.

2. If you are running a local firewall, then you need to configure firewall rules for all the nodes in the cluster. For more information, see Configure Local Firewall.

3. On the new node, run the Tableau Server Setup program:

Use the package manager to install the Tableau Server package.

• On RHEL-like distributions, including CentOS, run the following commands:

\begin{verbatim}
sudo yum update

sudo yum install tableau-server-<version>.x86_64.rpm
\end{verbatim}
Note: When you use `yum` to install Tableau Server, all dependent packages are automatically downloaded and installed. This is the preferred method for installing Tableau. If your organization does not allow you to use `yum` and you must install using `rpm -i`, you must also install all dependent packages separately.

- On Ubuntu, run the following command:

  ```bash
  sudo apt-get update
  sudo apt-get -y install gdebi-core
  sudo gdebi -n tableau-server-<version>_amd64.deb
  ```

4. To initialize communications between your new node and the initial node, run the `initialize-tsm` script that is installed when you install Tableau Server.

   **Navigate to the scripts directory:**

   ```bash
   cd /opt/tableau/tableau_server/packages/scripts.<version_code>/
   ```

5. `sudo ./initialize-tsm -b /path/to/<bootstrap>.json -u <admin-user-on-first-node> --accepteula`

   - Use the `-b` flag to provide the path to the bootstrap file that you copied to the computer. If you have encrypted the bootstrap file, then you must pipe the file as described in Securing secrets for import and export operations.

   - Use the `-u` flag to enter the user name of the administrative user on the initial node. This is the name of an administrative user on the computer, not the Tableau Server administrator. You will be prompted for the user password.
Important: You must enter the credentials of the same user that you used during the installation process on the initial node.

- The --accepteula flag accepts the Tableau Server End User License Agreement (EULA). The EULA is available in the following location:

  /opt/tableau/tableau_server/packages/docs.<version_code>/EULA.rtf

Step 5: Configure the new node with a minimum topology

To complete the process of adding new nodes to your cluster, you need to configure them with a minimum topology. With a minimum topology, the only pending change will be the addition of Cluster Controller, which is required on each node. If you want other processes on the nodes you can add most of them at the same time. This example only configures the nodes with Cluster Controller.

1. Open TSM in a browser:

   https://<tsm-computer-name>:8850

   For more information, see Sign in to Tableau Services Manager Web UI.

2. Click the Configuration tab. A message should tell you that new nodes were added.
Click **Continue** to dismiss the message.

3. **Click Pending Changes** at the top of the page:

   If you are configuring a cluster with three or more nodes, a Coordination Service ensemble warning displays. You can continue. You will deploy a Coordination Service ensemble in a separate step.

4. **Click Apply Changes and Restart** and **Confirm** to confirm a restart of Tableau Server.

   When Tableau Server restarts, the nodes are included with the minimum topology necessary.

**Step 6: Deploy a Coordination Service ensemble**

If you install a total of three or more nodes, you should also deploy a Coordination Service ensemble. If you do not, you will get a warning message every time you make changes to the server configuration or topology. You can ignore this message, but as a best practice you should deploy a multi-node Coordination Service ensemble.
When you install Tableau Server, a single instance of the Coordination Service is installed on the initial node. TSM and Tableau Server depend on the Coordination Service to function properly, so to provide redundancy and ensure availability on multi-node installations, configure additional instances of the Coordination Service by deploying a Coordination Service ensemble. Coordination Service ensembles are installed with one, three, or five instances of the Coordination Service. In a three-node installation of Tableau Server, the recommended number of Coordination Service instances is three, one on each node.

**Note:** This operation includes steps that you may need to perform using the TSM command line.

The following steps illustrate how to deploy a new Coordination Service ensemble on an existing three-node Tableau Server cluster and clean up the old ensemble.

1. On the initial node, open a terminal session.
2. Type this command to sign in to Tableau Server as a TSM administrator:
   
   ```bash
   tsm login -u <username>
   ```

   You will be prompted for your password.
3. Type this command to stop Tableau Server:
   
   ```bash
   tsm stop
   ```

   Some TSM processes will continue to run, including the Administration Controller and Administration Agent.
4. Get the node IDs for each node in the cluster:
   
   ```bash
   tsm topology list-nodes -v
   ```
5. Use the `tsm topology deploy-coordination-service` command to add a new Coordination Service ensemble by adding the Coordination Service to specified
nodes. You must specify the node(s) that the Coordination Service should be added to. The command also makes the new ensemble the "production" ensemble (the ensemble in use).

For example, deploy the Coordination Service to all three nodes of a three-node cluster, where the nodes are node1, node2, and node3:

```
tsm topology deploy-coordination-service -n node1,node2,node3
```

6. Wait until the new Coordination Service ensemble is running and the server is ready for the next step.

**Important.** If you attempt to clean up the old Coordination Service ensemble before the server is in the proper state, you can put the server into an unrecoverable state and may need to completely reinstall Tableau.

a. Check the status of the server:

```
tsm status -v
```

If the deployment is not complete, you may see processes showing as running when they are not, and the Coordination Service showing a status of "unavailable" while the service is synchronizing between nodes on the cluster. Tableau Server may show as being in an error state while this is happening. You may also get an error message: "Could not connect to TSM Controller at '<host>:8850'." This is normal when the server is returning to a valid state.

b. Check the status of the server periodically until you are prompted to sign in again.

c. When you are prompted, sign in to TSM and continue to check the server status
until you see a status of "STOPPED" for each node. If the status of a node shows as "ERROR" you need to wait. When each node status is "STOPPED" you should also see the following services running:

On the initial node:

- Two instances of the Coordination Service on the initial node, both with a status of "running".
- The Administration Controller with a status of "running". (The Administration Controller is only installed on the initial node.)
- The Administration Agent with a status of "running".
- Additional services on the initial node, all with a status of "running": Service Manager, License Manager, Client File Service.

On the additional nodes:

- One or more instance of the Coordination Service on each additional node you specified when you deployed the new ensemble, all with a status of "running". If you are deploying a new ensemble to nodes that already had Coordination Service running, you will see two instances of the service.
- The Administration Agent on every node, with a status of "running".

If you do not see a status of "running" for all of the above, wait a few minutes and run the status command again.

Note: If there is a problem with an instance of the Coordination Service (if it shows as stopped for example), you can toggle back to your previous Coordination Service ensemble using the `tsm topology toggle-coordination-service` command. To do this, the rest of the
services should be in the state described above, including Administration Controller and Agent. You can toggle back to the previous ensemble only if you have not run the cleanup-coordination-service command. Tableau Server cannot be running when you use this command.

7. Remove the old ensemble. This step is required. You cannot run Tableau Server with multiple Coordination Service ensembles configured.

   \texttt{tsm topology cleanup-coordination-service}

   Tableau Server must be stopped when you use this command, but some TSM services will be running (see above).

8. Start Tableau Server:

   \texttt{tsm start}

   For more information and details on deploying a new Coordination Service ensemble, see Deploy a Coordination Service Ensemble.

Step 7: Configure processes for the second node

1. Open TSM in a browser:

   https://<tsm-computer-name>:8850

   For more information, see Sign in to Tableau Services Manager Web UI.

2. Click the \textbf{Configuration} tab.

3. Specify the processes and number of instances that should run on the first additional node.

   In this example:
a. Select **Gateway**.

b. Set the **Application Server** (vizportal) count to 2.

c. Set the **VizQL Server** count to 2.

d. Set the **Cache Server** count to 2.

e. Select **Search & Browse**.

f. Set the **Backgrounder** count to 2.

   Adding Backgrounder to a node will also add an instance of Data Engine if one is not already on the node.

g. Set the **Data Server** count to 2.

h. Select **File Store**.

i. Select **Repository** (pgsql).

The specific processes and process counts you set will depend on your organizational environment and needs. Some processes are added automatically when you add another process. For more information, see Configure Nodes and Tableau Server Processes.

**Note:** The TSM Web UI limits you to a maximum of 8 instances of processes that allow you to select the number of instances. To configure more instances than this, use the command line and the `TSM topology set-process` command. For more information, see `tsm topology set-process`.

Step 8: Configure processes for third node

1. In TSM, on the **Configuration** tab, specify the processes and number of instances that should run on the second additional node.

   In this example:
a. Select **Gateway**.

b. Set the **Application Server** (vizportal) count to 2.

c. Set the **VizQL Server** count to 2.

d. Set the **Cache Server** count to 2.

e. Select **Search & Browse**.

f. Set the **Backgrounder** count to 2.

Adding Backgrounder to a node will also add an instance of Data Engine if one is not already on the node.

g. Set the **Data Server** count to 2.

h. Select **File Store**.

2. Click **Pending Changes** at the top of the page:

The Pending Changes list displays.

3. Click **Apply Changes and Restart** and **Confirm** to confirm a restart of Tableau Server.

**Use the TSM CLI**

Step 1: Install the initial node

See Install and Configure Tableau Server.
Step 2: Generate a bootstrap file for the additional nodes

To install Tableau Server on additional computers you use the same installer you did for the initial node, along with a "bootstrap" file you generate on the initial node.

**Important:** The bootstrap file contains a copy of the master keystore file used for encrypting the configuration secrets. We strongly recommend that you take additional measures to secure the bootstrap file using mechanisms as described in Securing secrets for import and export operations.

1. After installing Tableau Server on the initial node, generate the node bootstrap file.
2. On the initial node, open a terminal session.
3. Type this command to generate the bootstrap file:

   ```
   tsm topology nodes get-bootstrap-file --file <path\-file>.json
   ```

Step 3: Install an additional node

1. Copy the original installer you used on the first computer along with the bootstrap file you generated and put them in a location accessible from the new computer you are adding Tableau Server to. This could be a mounted network share, or directly on the new computer.
2. If you are running a local firewall, then you need to configure firewall rules for all the nodes in the cluster. For more information, see Configure Local Firewall.
3. On the new node, run the Tableau Server Setup program:

   Use the package manager to install the Tableau Server package.
   - On RHEL-like distributions, including CentOS, run the following commands:

     ```
     sudo yum update
     ```
sudo yum install tableau-server-<version>.x86_64.rpm

Note: When you use yum to install Tableau Server, all dependent packages are automatically downloaded and installed. This is the preferred method for installing Tableau. If your organization does not allow you to use yum and you must install using rpm -i, you must also install all dependent packages separately.

- On Ubuntu, run the following command:

  ```bash
  sudo apt-get update
  sudo apt-get -y install gdebi-core
  sudo gdebi -n tableau-server-<version>_amd64.deb
  ```

4. To initialize communications between your new node and the initial node, run the initialize-tsm script that is installed when you install Tableau Server.

   On the new node:

   Navigate to the scripts directory:

   ```bash
   cd /opt/tableau/tableau_server/packages/scripts.<version_code>/
   ```

5. Run the initialize-tsm script:

   ```bash
   sudo ./initialize-tsm -b /path/to/<bootstrap>.json -u <admin-user-on-first-node> --accepteula
   ```

   - Use the -b flag to provide the path to the bootstrap file that you copied to the computer. If you have encrypted the bootstrap file, then you must pipe the file as described in Securing secrets for import and export operations.
   - Use the -u flag to enter the user name of the administrative user on the initial
node. This is the name of an administrative user on the computer, not the Tableau Server administrator. You will be prompted for the user password.

**Important:** You must enter the credentials of the same user that you used during the installation process on the initial node.

- The `--accepteula` flag accepts the Tableau Server End User License Agreement (EULA). The EULA is available in the following location:

  /opt/tableau/tableau_server/packages/docs.<version_code>/EULA.rtf

Step 4: Install a second additional node

Install Tableau Server on the second additional node:

1. Copy the original installer you used on the first computer along with the bootstrap file you generated and put them in a location accessible from the new computer you are adding Tableau Server to. This could be a mounted network share, or directly on the new computer.

2. If you are running a local firewall, then you need to configure firewall rules for all the nodes in the cluster. For more information, see Configure Local Firewall.

3. On the new node, run the Tableau Server Setup program:

   Use the package manager to install the Tableau Server package.

   - On RHEL-like distributions, including CentOS, run the following commands:

     ```
     sudo yum update
     sudo yum install tableau-server-<version>.x86_64.rpm
     ```
Note: When you use `yum` to install Tableau Server, all dependent packages are automatically downloaded and installed. This is the preferred method for installing Tableau. If your organization does not allow you to use `yum` and you must install using `rpm -i`, you must also install all dependent packages separately.

• On Ubuntu, run the following command:

```
sudo apt-get update
sudo apt-get -y install gdebi-core
sudo gdebi -n tableau-server-<version>_amd64.deb
```

4. To initialize communications between your new node and the initial node, run the `initialize-tsm` script that is installed when you install Tableau Server.

On the new node:

Navigate to the `scripts` directory:

```
cd /opt/tableau/tableau_server/packages/scripts.<version_code>/
```

5. Run the `initialize-tsm` script:

```
sudo ./initialize-tsm -b /path/to/<bootstrap>.json -u <admin-user-on-first-node> --accepteula
```

• Use the `-b` flag to provide the path to the bootstrap file that you copied to the computer. If you have encrypted the bootstrap file, then you must pipe the file as described in Securing secrets for import and export operations.

• Use the `-u` flag to enter the user name of the administrative user on the initial node. This is the name of an administrative user on the computer, not the Tableau Server administrator. You will be prompted for the user password.
**Important:** You must enter the credentials of the same user that you used during the installation process on the initial node.

- The `--accepteula` flag accepts the Tableau Server End User License Agreement (EULA). The EULA is available in the following location:

```
/opt/tableau/tableau_server/packages/docs.<version_code>/EULA.rtf
```

**Step 5: Add a process to the additional nodes**

1. On the initial node, configure a cluster controller instance on each additional node:

   ```
tsm topology set-process -n <nodeID_second-node> -pr clustercontroller -c 1

tsm topology set-process -n <nodeID_third-node> -pr clustercontroller -c 1
```

2. Apply the node configuration changes:

   ```
tsm pending-changes apply --ignore-warnings
```

   A warning about deploying a Coordination Service ensemble displays because you have deployed a three-node cluster. Use the `--ignore-warnings` option to apply the configuration changes in spite of the warning. You will deploy a new Coordination Service ensemble in the next step.

**Step 6: Deploy a Coordination Service ensemble**

If you install a total of three or more nodes, you should also deploy a Coordination Service ensemble. If you do not, you will get a warning message every time you make changes to the server configuration or topology. You can ignore this message, but as a best practice you should deploy a multi-node Coordination Service ensemble.
When you install Tableau Server, a single instance of the Coordination Service is installed on the initial node. TSM and Tableau Server depend on the Coordination Service to function properly, so to provide redundancy and ensure availability on multi-node installations, configure additional instances of the Coordination Service by deploying a Coordination Service ensemble. Coordination Service ensembles are installed with one, three, or five instances of the Coordination Service. In a three-node installation of Tableau Server, the recommended number of Coordination Service instances is three, one on each node.

**Note:** This operation includes steps that you may need to perform using the TSM command line.

The following steps illustrate how to deploy a new Coordination Service ensemble on an existing three-node Tableau Server cluster and clean up the old ensemble.

1. On the initial node, open a terminal session.

2. Type this command to sign in to Tableau Server as a TSM administrator:

   ```
   tsm login -u <username>
   ```

   You will be prompted for your password.

3. Type this command to stop Tableau Server:

   ```
   tsm stop
   ```

   Some TSM processes will continue to run, including the Administration Controller and Administration Agent.

4. Get the node IDs for each node in the cluster:

   ```
   tsm topology list-nodes -v
   ```

5. Use the `tsm topology deploy-coordination-service` command to add a new Coordination Service ensemble by adding the Coordination Service to specified
nodes. You must specify the node(s) that the Coordination Service should be added to. The command also makes the new ensemble the "production" ensemble (the ensemble in use).

For example, deploy the Coordination Service to all three nodes of a three-node cluster, where the nodes are node1, node2, and node3:

```bash
tsm topology deploy-coordination-service -n node1,node2,node3
```

6. Wait until the new Coordination Service ensemble is running and the server is ready for the next step.

**Important.** If you attempt to clean up the old Coordination Service ensemble before the server is in the proper state, you can put the server into an unrecoverable state and may need to completely reinstall Tableau.

a. Check the status of the server:

```bash
tsm status -v
```

If the deployment is not complete, you may see processes showing as running when they are not, and the Coordination Service showing a status of "unavailable" while the service is synchronizing between nodes on the cluster. Tableau Server may show as being in an error state while this is happening. You may also get an error message: "Could not connect to TSM Controller at '<host>:8850'." This is normal when the server is returning to a valid state.

b. Check the status of the server periodically until you are prompted to sign in again.

c. When you are prompted, sign in to TSM and continue to check the server status
until you see a status of "STOPPED" for each node. If the status of a node shows as "ERROR" you need to wait. When each node status is "STOPPED" you should also see the following services running:

On the initial node:

- Two instances of the Coordination Service on the initial node, both with a status of "running".
- The Administration Controller with a status of "running". (The Administration Controller is only installed on the initial node.)
- The Administration Agent with a status of "running".
- Additional services on the initial node, all with a status of "running": Service Manager, License Manager, Client File Service.

On the additional nodes:

- One or more instance of the Coordination Service on each additional node you specified when you deployed the new ensemble, all with a status of "running". If you are deploying a new ensemble to nodes that already had Coordination Service running, you will see two instances of the service.
- The Administration Agent on every node, with a status of "running".

If you do not see a status of "running" for all of the above, wait a few minutes and run the status command again.

**Note:** If there is a problem with an instance of the Coordination Service (if it shows as **stopped** for example), you can toggle back to your previous Coordination Service ensemble using the `tsm topology toggle-coordination-service` command. To do this, the rest of the
services should be in the state described above, including Administration Controller and Agent. You can toggle back to the previous ensemble only if you have not run the cleanup-coordination-service command. Tableau Server cannot be running when you use this command.

7. Remove the old ensemble. This step is required. You cannot run Tableau Server with multiple Coordination Service ensembles configured.

```
tsm topology cleanup-coordination-service
```

Tableau Server must be stopped when you use this command, but some TSM services will be running (see above).

8. Start Tableau Server:

```
tsm start
```

For more information and details on deploying a new Coordination Service ensemble, see Deploy a Coordination Service Ensemble.

Step 7: Configure processes for the second node

1. On the initial node, set the topology for the second node. The topology specifies which processes should run on the node, and how many instances of each process should run. For details about configuring nodes, see Configure Nodes. Data engine will be added automatically when you add other processes. For details on when data engine is added, see Tableau Server Processes.

   a. Get the node-id for the new node: `tsm topology list-nodes -v`

   b. Specify individual processes that will run on the new node:

      ```
      tsm topology set-process -n <node-id> -pr gateway -c 1
      tsm topology set-process -n <node-id> -pr vizqlserver -c 2
      ```
2. Apply the node configuration changes. You will be prompted with a message that Tableau Server will restart.

```bash
tsm pending-changes apply
```

Step 8: Configure processes for third node

On the initial node, set the topology for the new node. The topology specifies which processes should run on the node, and how many instances of each process should run. Data engine will be added automatically when you add other processes. For details on when data engine is added, see Tableau Server Processes.

1. Get the node-id for the new node:

```bash
tsm topology list-nodes -v
```

2. Specify individual processes that will run on the new node:
3. Apply the node configuration. You will be prompted with a message that Tableau Server will restart.

    tsm pending-changes apply

4. Start the server:

    tsm start

Step 9: Configure firewall rules (optional)

If you are running a local firewall, then you need to configure firewall rules for all the nodes in the cluster. For more information, see Configure Local Firewall. For more information, see Local firewall configuration.

Add a Load Balancer

At this point, all three nodes have gateways, which are used to route requests to available server processes. All gateways are active, but to further reduce the potential for downtime in the cluster, you can configure a load balancer. For more information, see Add a Load Balancer.
Add a Load Balancer

You can enhance the reliability of Tableau Server by running gateways on multiple nodes, and configuring a load balancer to distribute requests across the gateways. Unlike the repository process, which can be active or passive, all gateway processes are active. If one gateway in a cluster becomes unavailable, the load balancer stops sending requests to it. The load balancer algorithm you choose determines how the gateways will route client requests.

**Note:** If you will be using Kerberos authentication, you need to configure Tableau Server for your load balancer before you configure Tableau Server for Kerberos. For more information, see Configure Kerberos.

Note the following as you configure your load balancer to work with Tableau Server:

- **Tested load balancers:** Tableau Server clusters with multiple gateways have been tested with Apache and F5 load balancers.

  If you are using an Apache load balancer and creating custom administrative views, you need to connect directly to the Tableau Server repository. You cannot connect through the load balancer.

- **Tableau Server URL:** When a load balancer is in front of a Tableau Server cluster, the URL that's accessed by Tableau Server users belongs to the load balancer, not the initial Tableau Server node.

- **Trusted host settings:** The computer running the load balancer must be identified to Tableau Server as a trusted host. See the procedure below for how to configure Tableau Server.

- **Proxy server configurations:** The settings used to identify a load balancer to Tableau Server are the same ones that are used to identify a proxy server. If your Tableau Server cluster requires both a proxy server and a load balancer, both must use a single external URL defined in `gateway.public.host` and all proxy servers
and load balancers must be specified in `gateway.trusted` and `gateway.trusted_hosts`. For more information, see Configuring Proxies for Tableau Server.

**Configure Tableau Server to work with a load balancer**

Use the following key-value pairs to configure Tableau Server for a load balancer. You can set the values individually with the `tsm configuration set` command.

Or, use the configuration file template example at the end of this topic to create a configKey json file. After you have filled in the options with the appropriate values, pass the json file and apply settings with `tsm` commands.

**Load balancer configuration key-value pairs**

The key-value pairs described in this section can be set with the `tsm configuration set` command. After you have set all values, run the following command:

`tsm pending-changes apply`

**gateway.public.host**

*Value:* name

The value, name is the URL that will be used to reach Tableau Server through the load balancer.

For example, if Tableau Server is reached by entering `tableau.example.com` in a browser address bar, enter this command:

`tsm configuration set -k gateway.public.host -v "tableau.example.com"

**gateway.public.port**

*Value:* port_number
By default, Tableau assumes that the load balancer is listening on port 80 for external communications. Use this key to specify a different port.

For example, if your load balancer is configured for SSL and listening on port 443, enter the following command:

```bash
tsm configuration set -k gateway.public.port -v "443"
```

gateway.trusted

**Value:** server

Specify the load balancer(s) IPv4 address or computer name.

The value for **server** can be a comma-separated list, for example:

```bash
tsm configuration set -k gateway.trusted -v "10.32.139.45, 10.32.139.46, 10.32.139.47"
```

or

```bash
tsm configuration set -k gateway.trusted -v "proxy1, proxy2, proxy3"
```

gateway.trusted_hosts

**Value:**

Specify alternate names for the load balancer(s), such as its fully-qualified domain name, any non-fully-qualified domain names, and any aliases. These are the names a user might type in a browser. Separate each name with a comma:

```bash
tsm configuration set -k gateway.trusted_hosts -v "name1, name2, name3"
```

**For example:**

```bash
tsm configuration set -k gateway.trusted_hosts -v "lb.example.com, lb, ftp.example.com, www.example.com"
```
Configuration template example

You can configure all of the settings in one operation by customizing the following configuration template example and creating a configKey json file.

Refer to the key-value pair descriptions above to customize the values for your organization.

```
{
  "configKeys": {
    "gateway.public.host": "tableau.example.com",
    "gateway.public.port": "443",
    "gateway.trusted": "proxy1, proxy2, proxy3",
    "gateway.trusted_hosts": "lb.example.com, lb, ftp.example.com, www.example.com"
  }
}
```

When you are finished, save the json file.

Pass the json file with tsm to set the configuration, and then apply settings by running the following commands:

```
tsm settings import -f /path/to/file.json

tsm pending-changes apply
```

For more information about using configKey schemes, see Configuration File Example.

Deploy a Coordination Service Ensemble

The Coordination Service is built on Apache ZooKeeper, an open-source project, and coordinates activities on the server, guaranteeing a quorum in the event of a failure, and serving as the source of "truth" regarding the server topology, configuration, and state. The service is installed automatically on the initial Tableau Server node, but no additional instances are installed as you add additional nodes. Because the successful functioning of Tableau Server depends on a properly functioning Coordination Service, we recommend that for server installations of three or more nodes, you add additional instances of the
Coordination Service by deploying a new Coordination Service ensemble. This provides redundancy and improved availability in the event that one instance of the Coordination Service has problems.

- Hardware requirements
- The Coordination Service Quorum
- Deploy a new Coordination Service ensemble

Hardware requirements

The hardware you use for Tableau Server can have an effect on how well the Coordination Service runs. In particular:

- **Memory.** The Coordination Service maintains state information in memory. By design, the memory footprint is small, and is typically not a factor in overall server performance.

- **Disk speed.** Because the service stores state information on disk, it benefits from fast disk speed on the individual node computers.

- **Connection speed** between nodes. The service communicates continuously between cluster nodes; a fast connection speeds between nodes helps with efficient synchronization.

Because the Coordination Service is I/O intensive, if you are running Tableau Server on computers that meet or just exceed the minimum hardware requirements, you may want to configure a Coordination Service ensemble that puts the service on nodes that are not being used for other server processes. This reduces the chance of delays due to I/O contention between server processes. For information on how to deploy an ensemble on dedicated Coordination Service-only nodes, see Configure Tableau Server for High Availability with Coordination Service-Only Nodes.

The Coordination Service Quorum

To ensure that the Coordination Service can work properly, the service requires a *quorum*—a minimum number of instances of the service. This means that the number of nodes in your
installation impacts how many instances of the Coordination Service you want to configure in your ensemble.

Number of Coordination Service instances to use

The maximum number of Coordination Service instances you can have in an ensemble on Tableau Server depends on how many Tableau Server nodes you have in your deployment. Configure a Coordination Service ensemble based on these guidelines:

<table>
<thead>
<tr>
<th>Total number of server nodes</th>
<th>Recommended number of Coordination Service nodes in ensemble (must be 1, 3, or 5)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-2 nodes</td>
<td>1 node</td>
<td>This is the default and requires no changes unless you want to move the Coordination Service off your initial node and onto your additional node.</td>
</tr>
<tr>
<td>3-4 nodes</td>
<td>3 nodes</td>
<td></td>
</tr>
<tr>
<td>5 or more nodes</td>
<td>5 nodes</td>
<td>Five is the maximum number of Coordination Service instances you can install.</td>
</tr>
</tbody>
</table>

Deploy a new Coordination Service ensemble

If you install a total of three or more nodes, you should also deploy a Coordination Service ensemble. If you do not, you will get a warning message every time you make changes to the server configuration or topology. You can ignore this message, but as a best practice you should deploy a multi-node Coordination Service ensemble.

When you install Tableau Server, a single instance of the Coordination Service is installed on the initial node. TSM and Tableau Server depend on the Coordination Service to function
properly, so to provide redundancy and ensure availability on multi-node installations, configure additional instances of the Coordination Service by deploying a Coordination Service ensemble. Coordination Service ensembles are installed with one, three, or five instances of the Coordination Service. In a three-node installation of Tableau Server, the recommended number of Coordination Service instances is three, one on each node.

**Note:** This operation includes steps that you may need to perform using the TSM command line.

The following steps illustrate how to deploy a new Coordination Service ensemble on an existing three-node Tableau Server cluster and clean up the old ensemble.

1. On the initial node, open a terminal session.

2. Type this command to sign in to Tableau Server as a TSM administrator:

   ```
   tsm login -u <username>
   
   You will be prompted for your password.
   ```

3. Type this command to stop Tableau Server:

   ```
   tsm stop
   
   Some TSM processes will continue to run, including the Administration Controller and Administration Agent.
   ```

4. Get the node IDs for each node in the cluster:

   ```
   tsm topology list-nodes -v
   ```

5. **Use the** `tsm topology deploy-coordination-service` **command to add a new Coordination Service ensemble by adding the Coordination Service to specified nodes. You must specify the node(s) that the Coordination Service should be added to. The command also makes the new ensemble the "production" ensemble (the
ensemble in use).

For example, deploy the Coordination Service to all three nodes of a three-node cluster, where the nodes are node1, node2, and node3:

tsm topology deploy-coordination-service -n node1,node2,node3

6. Wait until the new Coordination Service ensemble is running and the server is ready for the next step.

**Important.** If you attempt to clean up the old Coordination Service ensemble before the server is in the proper state, you can put the server into an unrecoverable state and may need to completely reinstall Tableau.

a. Check the status of the server:

   tsm status -v

   If the deployment is not complete, you may see processes showing as running when they are not, and the Coordination Service showing a status of "unavailable" while the service is synchronizing between nodes on the cluster. Tableau Server may show as being in an error state while this is happening. You may also get an error message: "Could not connect to TSM Controller at '<host>:8850'." This is normal when the server is returning to a valid state.

b. Check the status of the server periodically until you are prompted to sign in again.

c. When you are prompted, sign in to TSM and continue to check the server status until you see a status of "STOPPED" for each node. If the status of a node shows as "ERROR" you need to wait. When each node status is "STOPPED"
you should also see the following services running:

On the initial node:

- Two instances of the Coordination Service on the initial node, both with a status of "running".
- The Administration Controller with a status of "running". (The Administration Controller is only installed on the initial node.)
- The Administration Agent with a status of "running".
- Additional services on the initial node, all with a status of "running": Service Manager, License Manager, Client File Service.

On the additional nodes:

- One or more instance of the Coordination Service on each additional node you specified when you deployed the new ensemble, all with a status of "running". If you are deploying a new ensemble to nodes that already had Coordination Service running, you will see two instances of the service.
- The Administration Agent on every node, with a status of "running".

If you do not see a status of "running" for all of the above, wait a few minutes and run the status command again.

**Note:** If there is a problem with an instance of the Coordination Service (if it shows as **stopped** for example), you can toggle back to your previous Coordination Service ensemble using the `tsm topology toggle-coordination-service` command. To do this, the rest of the services should be in the state described above, including Administration Controller and Agent. You can toggle back to the previous ensemble only if you
7. Remove the old ensemble. This step is required. You cannot run Tableau Server with multiple Coordination Service ensembles configured.

```bash
tsm topology cleanup-coordination-service
```

Tableau Server must be stopped when you use this command, but some TSM services will be running (see above).

8. Start Tableau Server:

```bash
tsm start
```

**Configure Client File Service**

The Client File Service (CFS) manages most shared files in a multinode cluster. For example, authentication related certificates, keys, and files (OpenID, mutual SSL, SAML, and Kerberos), and customization files are managed by CFS.

A single instance of CFS is configured on the initial node when you first install Tableau Services Manager (TSM) and Tableau Server. You can configure additional instances on other nodes, using these limitations and recommendations:

- There must be at least one instance of CFS for any Tableau Server installation. You cannot remove all instances of CFS.
- We recommend you do not configure more than one instance on any one node. Additional instances would not provide any benefit and would be a waste of resources.
- We recommend you configure a CFS instance on each node where you deploy the Coordination Service.

This article explains how to add or remove an instance of CFS. You cannot configure CFS from the Web UI. You must use the CLI to add or remove CFS. The procedure is the same one you use for adding a process to a node.
Configure CFS on additional nodes

1. On the initial node, open a terminal session.

2. Find the node ID for the node you are updating:

   tsm topology list-nodes -v

3. Add CFS on the node by specifying the process and a single instance.

   For example, this command adds one instance of CFS to node1:

   tsm topology set-process -n node1 -pr clientfileservice -c 1

4. Apply the changes:

   tsm pending-changes apply

Repository Failover

In a Tableau Server installation, the repository (pgsql) database is one of the key required processes. The Tableau Server repository stores information about Tableau Server users, groups and group assignments, permissions, projects, data sources, and extract metadata and refresh information. Because it is critical to the server functioning, Tableau Server has a built-in automatic "failover" for the repository when server is installed in a distributed environment that meets certain requirements.

Automatic repository failover

Automatic repository failover means that if there is a problem with the active Tableau Server repository, the server will automatically switch to using the passive repository. This does not happen immediately, to protect against momentary issues with the repository that don't justify a switch, but if the repository is unavailable for more than five minutes, failover occurs.

For automatic repository failover to work, your Tableau Server installation needs:
• A minimum of three nodes

• Two instances of the repository installed
  
  Optional but highly recommended:

  • A multi-node Coordination Service ensemble deployed

With these conditions satisfied, repository failover will occur if the active repository becomes unavailable, either due to a problem with the process, or a problem with the node the process is running on. If the original repository becomes available again (if, for example, the node is restarted and all processes come up properly), it is made the passive repository, available for failover if necessary.

**Manual repository failover**

There may be reasons you want to shift back to the original repository after failover occurs. One reason would be if that instance of the repository is installed on a computer with more resources. To do this, use the `tsm topology repository-failover` command to manually switch back to the original repository. For more information, see `tsm topology failover-repository`.

**Preferred active repository**

When you configure Tableau Server you have the option to specify a node as the preferred active repository. When Tableau Server is configured for repository failover, the preferred active repository node is the one used for the active repository. This is an optional step, and if you do not specify a preferred active repository node, Tableau Server will select the active repository node on startup.

To configure the preferred active repository, use the `tsm configuration set` command to configure the `pgsql.preferred_host` option:

```bash
tsm configuration set -k pgsql.preferred_host -v "<host_name>"
```
Configure a preferred active repository node if you want Tableau Server to select a specific node on startup. You might want to do this if you have a particular server you want to use for your active repository (a computer with more disk space or memory for example), or if you are using custom administrative views. Custom administrative views have embedded connection information that refers to the repository for which you created the views. For more information on connecting to the Tableau Server repository, see Collect Data with the Tableau Server Repository.

**Recover from an Initial Node Failure**

The first computer you install Tableau on, the "initial node," has some unique characteristics. Two processes run only on the initial node and cannot be moved to any other node except in a failure situation, the License service (License Manager) and TSM Controller (Administration Controller).

Two other processes are initially included on the initial node but can be added or moved to additional nodes, the CFS (Client File Service) and the Coordination Service.

If there is a problem with the initial node and you have redundant processes on your other nodes, Tableau Server can continue to run for up to 72 hours before the lack of the licensing service impacts other processes. Your users can continue to sign in and use their content after the initial node fails, but you will not be able to reconfigure Tableau Server because you won’t have access to the Administration Controller. This means you should make a point of moving the two unique processes to another of your running nodes as soon as possible. If your initial node fails for reasons that are recoverable in a relatively short amount of time (for example, a hardware failure you can correct), you should first attempt to bring the node back up without using the procedure below.

---

**Note:** The host_name is case-sensitive and must match the node name shown in the output of tsm status -v.
Note: The steps in this article require server downtime and can be disruptive, and should only be used in the event of a catastrophic failure of the initial node. If you are unable to get your initial node running again, use the following steps to move key TSM processes to another node in your cluster.

Tableau Server includes a script that automates moving these processes to one of your other existing nodes so you can get complete access back to TSM and keep Tableau Server running. Depending on how your installation was configured with CFS and Coordination Service, you may also need to take steps to redeploy these.

General requirements

- If the initial node was running the only instance of the Client File Service (CFS), you need to add that process to another node. Tableau Server requires at least one instance of the CFS. For more information, see Configure Client File Service.
- As part of the process for setting up a multi-node Tableau Server installation you should have deployed a Coordination Service ensemble. The process below assumes there was a Coordination Ensemble deployed before there was a problem with the initial node. For more information about deploying a Coordination Service ensemble, see Deploy a Coordination Service Ensemble.

Note: This operation includes steps that you may need to perform using the TSM command line.

Move the TSM Controller and License Service to another node

If there is a problem with the initial node, the TSM Controller and the Licensing Service need to be started on another node. Follow these steps to get the Controller and Licensing Service working on another node.
1. On a node that is still working, run the Controller recovery script. At a terminal prompt on a working node, type the following command:

   sudo /opt/tableau/tableau_server/packages/scripts.<version_code>/move-tsm-controller -n <nodeID>

   where "nodeID" is the ID for the node you want the TSM Controller to run on. For example:

   sudo /opt/tableau/tableau_server/packages/scripts.10400.17.0802.1319/move-tsm-controller -n node2

2. Verify the Administration Controller is running on the node:

   tsm status -v

3. Stop Tableau Server:

   tsm stop

4. Add the License Service to the node:

   tsm topology set-process -pr licenseservice -n <nodeID> -c 1

5. Remove the old License Service from the original node, where "nodeID" is the initial node that has failed:

   tsm topology set-process -pr licenseservice -n <nodeID> -c 0

6. If the initial node had been running the only instance of CFS, add CFS to this node:

   tsm topology set-process -pr clientfileservice -n node2 -c 1

7. (Optional) You can also add other processes that had been running on the initial node
but are not running on this node. For instance, to add an cache server:

tsm topology set-process -pr cacheserver -n node2 -c 1

8. Apply the changes:

    tsm pending-changes apply

    The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

9. Restart the TSM Administration Controller (as `tableau` system account):

    sudo su -l tableau -c "systemctl --user restart tabadmincontroller_0.service"

    **Note:** It may take a few minutes for `tabadmincontroller` to restart. If you attempt to apply pending changes in the next step before the controller has fully restarted, TSM will not be able to connect to the controller. You can verify that the controller is running by using the `tsm status -v` command. Tableau Server Administration Controller should be listed as "is running".

10. Apply pending changes (there may not appear to be any, but this step is required):

    tsm pending-changes apply

11. Activate the Tableau Server license on the new Controller node:

    tsm licenses activate -k <product-key>

12. Verify the license is properly activated:
tsm licenses list

13. If the initial node was running the Coordination Service, you need to deploy a new Coordination Service ensemble that does not include that node. If you have a three node cluster and the initial node was running the Coordination Service, you must deploy a new, single-instance Coordination Service ensemble on a different node and clean up the old ensemble. In this example, a single instance of the Coordination Service is being deployed to the second node:

```
tsrm topology deploy-coordination-service -n <nodeID2>
```

Wait until the server is completely switched over to the new ensemble.

14. When the server has switched over to the new ensemble, clean up the old ensemble.

Do not do this too soon. You must wait until the server has completely switched to the new ensemble before running the cleanup command or you can permanently break Tableau. For more information about deploying a Coordination Service ensemble, including detailed instructions for determining that the server is ready to, see Deploy a Coordination Service Ensemble.

```
tsrm topology cleanup-coordination-service
```

15. If the initial node was running a File Store instance, you need to remove that instance:

```
tsrm topology filestore decommission -n <nodeID> --delete-filestore
```

Where nodeID is the initial node that has failed.

16. Apply pending changes, using the --ignore-warnings flag if the new Coordination Service ensemble you deployed above is a single node ensemble:

```
tsrm pending-changes apply --ignore-warnings
```

17. Remove the initial node, where nodeID is the initial node that has failed:
tsm topology remove-nodes -n <nodeID>

18. Apply pending changes, using the --ignore-warnings flag if the new Coordination Service ensemble you deployed above is a single node ensemble:

   tsm pending-changes apply --ignore-warnings

19. Start Tableau Server:

   tsm start

   At this point your server should start, and you will be able to use TSM to configure it. The next step is to replace your initial node so your cluster has the original number of nodes. How you do this depends on whether or not you want to reuse the node that failed. We recommend that you only reuse that node if you are able to identify the reason it failed, and take steps to keep the failure from recurring.

20. If you plan to reuse the original node, you first need to completely remove Tableau from it. Do this by running the tableau-server-oblit rate script. For details on doing this, see Remove Tableau Server from Your Computer.

21. On a fresh computer, or on your original computer after completely removing Tableau, install Tableau using your original Setup program and a bootstrap file generated from the node that is now running the Licensing Service and the Administration Controller. For details on how to do this, see Install and Configure Additional Nodes.

   A best practice is to configure any processes you lost when the original node failed, to make sure your cluster is fully redundant. You may want to move processes from your new initial node to the newly added additional node to duplicate your original configuration. For example, if your initial node was only running gateway and File Store, you may want to configure the new initial node the same way.

22. You should also redeploy a new Coordination Service ensemble, once you have your nodes up and running the way you want. For details, see Deploy a Coordination Service Ensemble.
Recover from a Node Failure

If there is a problem with one of your server nodes, and you have redundant processes on your other nodes, Tableau Server can continue to run. Your users can continue to sign in and see and use their content after the node fails, but they may experience performance degradation as a result of the failed node. In addition, your server will be at greater risk of catastrophic failure if the bad node was running processes that are no longer redundant. This means you should make a point of removing the bad node and replacing it as soon as you can. If your node fails for reasons that are recoverable in a relatively short amount of time (for example, a hardware failure you can correct), you should first attempt to bring the node back up without using the procedure below.

Note: If the failed node is your initial node, there are larger implications for your Tableau Server installations. For details on how to recover from the failure of an initial node, see Recover from an Initial Node Failure.

General requirements

- There is still at least one functioning node with an instance of the File Store on it.
- There is still at least one functioning node with a Repository on it.

Note: This operation includes steps that you may need to perform using the TSM command line.

Removing a Failed Node

To remove a failed node from a Tableau Server cluster:

1. Stop Tableau Server:

    tsm stop
2. Identify the failed node:

```
tsm status -v
```

The failed node will have a status of "ERROR" and processes will show as unavailable. The node ID is listed as "node<n>" with the machine name following it. For example, node3:

```
node3: WIN-00915SFASVH
  Status: ERROR
  'Tableau Server Gateway 0' status is unavailable.
```

3. Determine any key processes that were running on the node:

- If the failed node was running the Coordination Service, you need to deploy a new ensemble and clean up the old one before you can remove the node. Do this while Tableau Server is stopped. For detail steps, see Deploy a Coordination Service Ensemble.

- If the failed node was running File Store, you need to force-decommission File Store and remove it before you can remove the node.

```
tsm topology filestore decommission -n <nodeID> --delete-filestore
```

Apply pending changes (use --ignore-warnings option if you had a three node cluster and a single Coordination Service instance):

```
tsm pending-changes apply --ignore-warnings
```

4. If the cluster was a three-node cluster and there are repositories on the remaining working nodes, you need to either remove one repository, or add a new node. This is because you are limited to a single instance of the repository when you have fewer than three nodes.

To remove one repository:
tsm topology set-process -n <nodeID> -pr pgsql -c 0

5. Run the command to remove the failed node. This adds the change to the pending changes list:

   tsm topology remove-nodes -n <nodeID>

6. Verify the node removal is pending:

   tsm pending-changes list

7. Apply pending changes to remove the node:

   tsm pending-changes apply

8. Start Tableau Server:

   tsm start

9. Install Tableau Server on a new node and configure the node with the processes that the old, failed node had been running.

10. On a fresh computer, or on your original computer after completely removing Tableau, install Tableau using your original Setup program and a bootstrap file generated from the initial node. For details on how to do this, see Install and Configure Additional Nodes.

    A best practice is to configure any processes you lost when the original node failed, to make sure your cluster is fully redundant.

11. You should also redeploy a new Coordination Service ensemble, once you have your nodes up and running the way you want. For details, see Deploy a Coordination Service Ensemble.
Configure Nodes

Use the Tableau Services Manager (TSM) Web UI or CLI commands to configure the topology of a node. The initial node is configured with a default that includes all the processes used by TSM and Tableau Server. When you add additional nodes you need to specify which processes will run on those nodes, and how many instances of those processes will run. You may also want to change the topology of the initial node, either adding instances of existing processes, or moving some of those processes to your additional nodes (this is common when setting up a distributed installation of Tableau Server).

**Note:** You cannot remove the File Store or Repository (pgsql) if this is the only instance of that process in your cluster. You must have at least one instance of each of the processes in your Tableau Server installation, and you must add the second instance and allow it to synchronize with the first before you remove the process on the original node. For more information see Move the Repository Process and Move the File Store Process.

**In this article**

Use the TSM web interface

Use the TSM CLI

**Use the TSM web interface**

In most cases, you can make multiple changes to your server configuration. Exceptions are if you are moving or removing a File Store instance or the Repository.

To configure your Tableau Server nodes using the TSM web interface, do the following:

1. Open TSM in a browser:

   https://<tsm-computer-name>:8850
For more information, see Sign in to Tableau Services Manager Web UI.

2. Click the **Configuration** tab.

Your next steps depend on the configuration changes you want to make.

- **Add processes**—Add processes to a node by specifying the number of instances you want on the node, or selecting the box for the process.

For example, to add four instances of the Backgrounder and a Gateway to a node:

a. Select the **Gateway** box:

   ![Gateway configuration](image)

b. Set the **Backgrounder** count to 4:

   ![Backgrounder configuration](image)

Adding Backgrounder to a node will also add an instance of Data Engine if one is not already on the node.
Note: The TSM Web UI limits you to a maximum of 8 instances of processes that allow you to select the number of instances. To configure more instances than this, use the command line and the TSM topology set-process command. For more information, see tsm topology set-process.

- **Change process count**—Change the number of processes on a node by specifying the new number, or selecting the box for the process.

- **Remove a process completely**—Remove all instances of a process from a node by clearing the box for the process, or setting the count to 0 (zero).

In most cases you move a process from one node to another by setting the process instance count on the first node to 0 (zero), and setting the count to a non-zero value on the second node.

If you are attempting to make a configuration that is not allowed (if, for example, you try to remove a File Store that has not been decommissioned), a message displays to let you know this.

3. Click **Pending Changes** at the top right, and **Apply Changes and Restart** to commit the changes and restart Tableau Server.

**Use the TSM CLI**

- Adding processes to a node

- Changing the number of processes on a node

- Removing all instances of a process from a node

- Moving all instances of a process from one node to another node
To configure nodes, run commands from the initial node and use the node ID to specify which node you are configuring. To determine the node ID, use the `tsm topology list-nodes` command. Use the `tsm topology set-process` command to add, update or remove a process on a node. You need to specify the node you are configuring, the process you are adding, updating, or removing, and the number of instances of the process. After setting the topology for a node you need to apply the changes to Tableau Server.

Apply changes using the `tsm pending-changes apply` command. After the changes are applied, Tableau Server is returned to the state it was in before the command was run. This means that if it was running, it will be restarted, and if it was stopped it will remain stopped after pending changes have been applied. In most cases, if Tableau Server is running when you apply pending changes, the server is stopped so that changes can be applied, and then restarted. The exception is if you are changing the number of instances of Backgrounder, or VizQL Server on an existing node. With changes to those processes on an existing node, Tableau Server does not have to be stopped if it is running.

You need the node ID for a node in order to configure the node. To determine the node ID, use this command:

```
tsm topology list-nodes -v
```

**Note:** Examples here show some process names. For a complete list, see Tableau Server Processes.

Adding processes to a node

Use the `tsm topology set-process` command to add a process to a node. You need to specify the node you are configuring, the process you are adding, and the number of instances of the process.

1. On the initial node, open a terminal session.

2. Find the node ID for the node you are changing:
tsm topology list-nodes -v

3. Add processes on the node by specifying the process and the number of instances.
   For example, this command adds two instances of backgrounder to node1:
   
   tsm topology set-process -n node1 -pr backgrounder -c 2

4. Apply the changes:
   
   tsm pending-changes apply

Changing the number of processes on a node

Change the number of processes on a node by specifying an already configured process and providing a new value for the number of instances.

1. On the initial node, open a terminal session.

2. Find the node ID for the node you are changing:
   
   tsm topology list-nodes -v

3. Change the number of processes on the node by specifying an already configured process and providing a new value for the number of instances.
   For example, on a node (node1) that is already running backgrounder, this command changes the number of instances to four:
   
   tsm topology set-process -n node1 -pr backgrounder -c 4

4. Apply the changes:
   
   tsm pending-changes apply

Removing all instances of a process from a node

1. On the initial node, open a terminal session.

2. Find the node ID for the node you are changing:
3. Remove a process from a node by specifying a count of 0 instances for that process on the node.

   For example, this command removes the backgrounder process from node1:
   
   ```
   tsm topology set-process -n node1 -pr backgrounder -c 0
   ```

4. Apply the changes:

   ```
   tsm pending-changes apply
   ```

Moving all instances of a process from one node to another node

In most cases you move a process from one node to another by setting the process instance count on the first node to zero, and setting the count to a non-zero value on the second node.

1. On the initial node, open a terminal session.

2. Find the node ID for the node you are changing:

   ```
   tsm topology list-nodes -v
   ```

3. Move a process from one node to another node by specifying a count of 0 instances for that process on the first node and specifying a count of 1 or greater to the second node.

   For example, these commands remove Backgrounder from node0 and add two instances of it to node1:

   ```
   tsm topology set-process -n node0 -pr backgrounder -c 0
   tsm topology set-process -n node1 -pr backgrounder -c 2
   ```

4. Apply the changes:

   ```
   tsm pending-changes apply
   ```
Install Tableau Server on a Two-Node Cluster

When you install Tableau Server on a two-node cluster, you can install server processes on one or both nodes. A two-node cluster can improve the performance of Tableau Server, because the work is spread across multiple machines.

Note the following about two-node clusters:

- A two-node cluster does not provide failover or support for high availability.
- You can't install more than one instance of the repository on a two-node cluster, and the repository must be on the initial node.

If you need failover or high availability, or want a second instance of the repository, you must install Tableau Server on a cluster of at least three computers. In a cluster that includes at least three nodes, you can configure two instances of the repository, which gives your cluster failover capability.

Maintain a Distributed Environment

After you set up an initial node and one or more additional nodes for a distributed installation, you can perform all subsequent configuration and updates from the initial node, using the TSM CLI, or from any computer using a browser and the TSM Web interface.

When you install additional nodes, they are added by computer name. If the computer name of a node changes, you will need to remove and reinstall the node. For details on removing a node, see Remove a Node.

You can monitor the status of the Tableau Server cluster on the TSM Status page. See View Server Process Status for details.

Additional actions you may need to maintain your distributed environment include:

Move the Repository Process

Tableau Server relies on the PostgreSQL repository to store server data. There must
always be at least one active instance of the repository in any Tableau Server installation, and you can have a maximum of two instances (one active, one passive) if you have at least three nodes in your installation. You cannot remove a repository instance if it is the only instance.

This means that if you want to move the only instance of your repository from one node to another node, you need to add a second instance and synchronize the new repository with the old one before you remove the old one. Synchronize repository instances by starting server. If you've added a new repository, it will automatically synchronize with the existing instance.

If you are deleting a node from your server cluster and that node is hosting the only instance of the repository, you must add a second instance of the repository and synchronize the instances before removing the node.

If you are also moving the file store, you can move the repository at the same time. See Move the File Store Process.

Before making a change to the repository, create a full backup of Tableau Server. For more information, see tsm maintenance backup.

**Important:** You cannot add a second repository instance and remove the first one in the same step. You must have both running so the contents of the first is synchronized with the second, before you remove the original instance.

The steps for moving the repository are:

1. Add a new instance of the repository to another node, start server, and wait for it to synchronize with the first repository.
2. Remove the instance of the repository from the original node.
In this article
Use the TSM web interface
Use the TSM CLI

Use the TSM web interface

To move a repository you need to first add a second instance on a second node, and then after the two instances have synchronized all the data in the original repository, remove the original instance. These steps must be done separately to allow for the synchronization of content between the two instances.

Add a new instance of the repository.

1. Open TSM in a browser:

   https://<tsm-computer-name>:8850

   For more information, see Sign in to Tableau Services Manager Web UI.

2. Click the Configuration tab.

3. For the node you are adding the repository to:

   Select Repository (pgsql).

4. Click Pending Changes at the top of the page:

   The Pending Changes list displays.
If you are configuring a three- or five-node cluster and have not deployed a Coordination Service ensemble, a warning will display. You can continue, and deploy a Coordination Service ensemble in a separate step. For details on deploying a Coordination Service ensemble, see Deploy a Coordination Service Ensemble.

5. Click **Apply Changes and Restart** and **Confirm** to confirm a restart of Tableau Server.

6. After Tableau Server has restarted, on the **Status** tab, verify that all processes are active.

Remove an instance of the repository.

1. In TSM, on the **Status** tab, verify that all processes are active. When both repositories show as Active, you can remove the first one.

2. Click the **Configuration** tab.

3. For the node you’re removing the repository from, clear the **Repository** box.

4. Click **Pending Changes** at the top of the page.

   If you are configuring a three- or five-node cluster and have not deployed a Coordination Service ensemble, a warning will display. You can continue, and deploy a Coordination Service ensemble in a separate step. For details on deploying a Coordination Service ensemble, see Deploy a Coordination Service Ensemble.

5. Click **Apply Changes and Restart** and **Confirm** to confirm a restart of Tableau Server.

**Use the TSM CLI**

To move a repository you need to first add a second instance on a second node, and then after the two instances have synchronized all the data in the original repository, remove the original instance. These steps must be done separately to allow for the synchronization of content between the two instances.
Add a new instance of the repository.

1. Add the repository (pgsql) to another node:

   tsm topology set-process -n <nodeID> -pr pgsql -c 1

2. Apply the changes. The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

   tsm pending-changes apply

3. Wait for the new repository on the second node to synchronize with the repository on the first node.

   tsm status -v

   Wait until the new repository status shows as "passive".

Remove an instance of the repository.

Once the new instance of the repository is fully synchronized and shows as "passive" you can remove the original instance:

1. Remove the repository from the first node by setting the process count to 0 (zero):

   tsm topology set-process -n <nodeID> -pr pgsql -c 0

2. Apply the change. The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

   tsm pending-changes apply
Move the File Store Process

You cannot remove an instance of File Store if it is the only instance on the server. You cannot run Tableau Server without at least one instance of File Store. This means if you need to move the File Store, or if you are deleting a server node that is hosting the only instance of the File Store, you must first move File Store to another node.

Moving the File Store is a two-part process:

- Adding a second instance of File Store (if there is not an existing second instance).
- Decommissioning and removing the original instance of File Store.

This article assumes you have installed Tableau Server on an initial node and at least one additional node. For more information on adding nodes to Tableau Server, see Install and Configure Additional Nodes.

Use the TSM web interface

Adding a second instance of File Store

This procedure assumes you have added an additional node. For more information on adding nodes to Tableau Server, see Install and Configure Additional Nodes.

1. Open TSM in a browser:

   https://<tsm-computer-name>:8850

   For more information, see Sign in to Tableau Services Manager Web UI.

2. Click the Configuration tab.
3. For the node you want to add an instance of File Store on, select **File Store**.

Adding File Store to a node will also add an instance of Data Engine if one is not already on the node.

4. Click **Pending Changes** at the top of the page:

The Pending Changes list displays.

A Coordination Service ensemble warning displays because you are configuring a three-node cluster. You can continue. You will deploy a Coordination Service ensemble in an upcoming step.

5. Click **Apply Changes and Restart** and **Confirm** to confirm a restart of Tableau Server.

Decommissioning and removing an instance of file store

1. In TSM, on the **Status** tab, verify that all processes are active.

2. Click the **Configuration** tab.

3. For the node you’re removing File Store from, clear the **File Store** box.

   This will generate a warning about decommissioning the File Store before removing it. You cannot remove an instance of File Store unless it has been decommissioned. Click **OK** to have TSM decommission the file store for you, or **Cancel** to decommission the File Store from the command line. For more information about decommissioning the File Store using the TSM CLI, see Decommissioning and removing an instance of File Store below.

4. Click the **Status** tab to see the status of the decommission. When the instance of File Store is marked "Ready for removal" you can continue.
5. Click **Pending Changes** at the top of the page.

   Note: If you are configuring a three- or five-node cluster, a Coordination Service ensemble warning will display. You can continue to apply pending changes and deploy a Coordination Service ensemble in a separate step. For information on deploying a Coordination Service ensemble, see Deploy a Coordination Service Ensemble.

6. Click **Apply Changes and Restart** and **Confirm** to confirm a restart of Tableau Server.

### Use the TSM CLI

**Adding a second instance of file store**

1. Create a full backup of Tableau Server. For more information, see Back up Tableau Server data.

2. Add the File Store to a second node.

   ```bash
tsm topology set-process -n <nodeID> -pr filestore -c 1
   ```

   The File Store is automatically added. Data engine is also added if it is not already on the node.

   Apply the configuration changes:

   ```bash
tsm pending-changes apply
   ```

   The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt
using the --ignore-prompt option, but this does not change the restart behavior. For more information, see tsm pending-changes apply.

3. Check the status of the new file store instance.

   tsm status -v

   Wait for the new File Store to synchronize with the File Store on the first node. When synchronization is complete the new File Store has a status of "running" instead of "synchronizing".

Decommissioning and removing an instance of File Store

Once you have a second instance of File Store installed and synchronized you can decommission and remove the original instance. You must decommission the original instance before you remove it. Doing this guarantees that any unique files on the File Store node are duplicated to another file store node.

1. Decommission the original File Store:

   tsm topology filestore decommission -n <nodeID> --override

2. When the decommission command completes, remove the File Store from the node by applying the pending configuration changes. The File Store is automatically removed. Data Engine is also removed unless an instance of one of these processes is installed on the node: VizQL Server, Application Server (Vizportal), Data Server, or Backgrounder.

   tsm pending-changes apply

   The pending-changes apply command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the --ignore-prompt option, but this does not change the restart behavior. For more information, see tsm pending-changes apply.
Remove a Node

If your Tableau Server installation includes a node you no longer need, you can remove it to simplify your installation, and to free up the hardware resources on that node.

You cannot remove a node if:

- It is running the only instance of the Repository. You need to move the Repository to another node before removing the original node. See Move the Repository Process.

- It is running the only instance of the File Store. You need to move the File Store to another node before removing the original node. See Move the File Store Process.

- It is running an instance of the Coordination Service. You need to redeploy a new Coordination Service ensemble that does not include the node before removing the node. See Deploy a Coordination Service Ensemble.

**Important:** Do not use the tableau-server-obliterate script to remove a node. First remove the node using the TSM UI or the tsm topology remove-nodes command. This leaves the rest of the cluster in a good state. Later, if you want to re-add the node to the cluster, run the tableau-server-obliterate script on the node to completely remove Tableau. After removing Tableau from the node, restart the computer and then re-add the node using the normal steps for adding and configuring a node.

In this article

Use the TSM web interface

Use the TSM CLI

Use the TSM web interface

1. Open TSM in a browser:
https://<tsm-computer-name>:8850

For more information, see Sign in to Tableau Services Manager Web UI.

2. Click the **Configuration** tab and, under the node you want to remove, click **Remove Node**:

   ![Remove Node](image)

   If a configuration limitation does not allow you to remove the node (if, for example, it includes a File Store that must first be decommissioned), a message will display letting you know this.

   **Note:** If you just added the node, and have not configured it, you must first apply pending changes before you can remove the node.

3. Click **Pending Changes** at the top right, and **Apply Changes and Restart**.

**Use the TSM CLI**

Use the `tsm topology remove-nodes` command to remove a node from a cluster.

To remove a node from a cluster it must have been configured with a process at some point in the past. If you added a node using the CLI and want to remove it but have not configured any processes, you must add a process on it, run the `tsm pending-changes apply` command, and then remove the node. For example, you might add one instance of Cluster Controller to the node: `tsm topology set-process -n <nodeID> -pr clustercontroller -c 1.`
If you are removing a node you added using the Web UI, the Cluster Controller process is automatically added so you do not need to add it before removing the node.

**Note:** You need to take special steps if the node you are removing hosts the File Store or the Repository processes. You must have at least one instance of each of the processes in your Tableau Server installation, and you must add the second instance and allow it to synchronize with the first before you remove the process on the original node. For more information see Move the Repository Process and Move the File Store Process.

If the node you are removing is hosting the File Store or the repository, move those processes to another node before removing the node. For more information, see Move the File Store Process and Move the Repository Process.

1. On the initial node, open a terminal session.
2. Find the node ID for the node you are changing:
   
   ```bash
   tsm topology list-nodes -v
   ```
3. Remove a node using the remove-nodes command.
   
   For example, to remove `node2` from an existing cluster:
   
   ```bash
   tsm topology remove-nodes --node-names "node2"
   ```
4. Apply the changes:
   
   ```bash
   tsm pending-changes apply
   ```

**Configure Tableau Server for High Availability with Coordination Service-Only Nodes**

The Coordination Service is built on Apache ZooKeeper, an open-source project, and coordinates activities on the server, guaranteeing a quorum in the event of a failure, and
serving as the source of "truth" regarding the server topology, configuration, and state. The service is installed automatically on the initial Tableau Server node, but no additional instances are installed as you add additional nodes. Because the successful functioning of Tableau Server depends on a properly functioning Coordination Service, we recommend that for server installations of three or more nodes, you add additional instances of the Coordination Service by deploying a new Coordination Service ensemble. This provides redundancy and improved availability in the event that one instance of the Coordination Service has problems.

The Coordination Service can generate a large amount of I/O as it communicates with other components of the server, so if you are running Tableau Server on computers that meet or just exceed the minimum hardware requirements, you may want to install Tableau Server in a configuration that uses Coordination Service-only nodes. This means installing Coordination Service on nodes that run no other server processes, and removing Coordination Service from any nodes that are running other server processes. This procedure explains how to do this. You can also run the Coordination Service ensemble on the same nodes running other Tableau Server processes. For details on how to do that, see Deploy a Coordination Service Ensemble.

Prerequisite

Before proceeding with the procedures in this topic, complete the following prerequisites:

- Install and Configure Tableau Server - Install Tableau on your initial node.

- Install and Configure Additional Nodes - Install Tableau on at least two additional nodes.

**Note:** This operation includes steps that you may need to perform using the TSM command line.
Deploy an ensemble on Coordination Service-only nodes

One way to accommodate the high I/O impact of the Coordination Service is to deploy an ensemble on nodes that only run the Coordination Service and the Cluster Controller. The following steps illustrate how to deploy a Coordination Service ensemble on an existing multi-node Tableau Server cluster.

**Note:** For a core-based Tableau Server license, Coordination Service-only nodes do not count against the total count of licensed cores.

1. Add additional nodes to your cluster.

   See Install and Configure Additional Nodes.

2. If you added the new nodes using the TSM CLI, you need to configure the nodes with Cluster Controller (this step is not necessary if you added the nodes using the TSM Web UI because Cluster Controller is automatically added when you add a node with the Web UI).

   On the initial node, open a terminal session.

3. Type this command to sign in to Tableau Server as a TSM administrator:

   ```
   tsm login -u <username>
   ```

   You will be prompted for your password.

4. From the initial node of the cluster, configure the new nodes with an instance of the Cluster Controller:

   ```
   tsm topology set-process -pr clustercontroller -n <node4> -c 1
   tsm topology set-process -pr clustercontroller -n <node5> -c 1
   ```
5. Apply the configuration changes. The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

```bash
tsm pending-changes apply
```

A warning about deploying a Coordination Service ensemble displays because you have deployed a multi-node cluster. If this is the only warning, you can safely override it using the `--ignore-warnings` option to apply the configuration changes in spite of the warning.

```bash
tsm pending-changes apply --ignore-warnings
```

6. Confirm that all nodes are up and running:

```bash
tsm status -v
```

7. On the initial node of the cluster, open a terminal session and type this command to stop Tableau Server:

```bash
tsm stop
```

8. Get the node IDs for each node in the cluster:

```bash
tsm topology list-nodes -v
```

9. Use the `tsm topology deploy-coordination-service` command to add a new Coordination Service ensemble by adding the Coordination Service to specified nodes. You must specify the node(s) that the Coordination Service should be added to. The command also switches Tableau Server to use the new ensemble.

```bash
tsm topology deploy-coordination-service
```
For example, deploy the Coordination Service to three nodes of a six-node cluster:

```bash
tsm topology deploy-coordination-service -n <node4,node5,node6>
```

10. Wait until the new Coordination Service ensemble is running and the server is ready for the next step. **This is important.**

**Important.** If you attempt to clean up the old Coordination Service ensemble before the server is in the proper state, you can put the server into an unrecoverable state and may need to completely reinstall Tableau.

a. Check the status of the server:

```bash
tsm status -v
```

If the deployment is not complete, you may see processes showing as running when they are not, and the Coordination Service showing a status of "unavailable" while the service is synchronizing between nodes on the cluster. Tableau Server may show as being in an error state while this is happening. You may also get an error message: "Could not connect to TSM Controller at '<host>:8850'." This is normal when the server is returning to a valid state.

b. Check the status of the server periodically until you are prompted to sign in again.

c. When you are prompted, sign in to TSM and continue to check the server status until you see a status of "STOPPED" for each node. If the status of a node shows as "ERROR" you need to wait. When each node status is "STOPPED" you should also see the following services running:

On the initial node:
• Two instances of the Coordination Service on the initial node, both with a status of "running".

• The Administration Controller with a status of "running". (The Administration Controller is only installed on the initial node.)

• The Administration Agent with a status of "running".

• Additional services on the initial node, all with a status of "running": Service Manager, License Manager, Client File Service.

On the additional nodes:

• One or more instance of the Coordination Service on each additional node you specified when you deployed the new ensemble, all with a status of "running". If you are deploying a new ensemble to nodes that already had Coordination Service running, you will see two instances of the service.

• The Administration Agent on every node, with a status of "running".

If you do not see a status of "running" for all of the above, wait a few minutes and run the status command again.

Note: If there is a problem with an instance of the Coordination Service (if it shows as stopped for example), you can toggle back to your previous Coordination Service ensemble using the tsm topology toggle-coordination-service command. To do this, the rest of the services should be in the state described above, including Administration Controller and Agent. You can toggle back to the previous ensemble only if you have not run the cleanup-coordination-service command. Tableau Server cannot be running when you use this command.

11. When the new ensemble is running properly, remove the old ensemble. This step is
required. You cannot run Tableau Server with multiple Coordination Service ensembles configured.

tsm topology cleanup-coordination-service

Tableau Server must be stopped when you use this command.

12. Start Tableau Server:

tsm start

Add a Load Balancer

You can enhance the reliability of Tableau Server by running gateways on multiple nodes, and configuring a load balancer to distribute requests across the gateways. Unlike the repository process, which can be active or passive, all gateway processes are active. If one gateway in a cluster becomes unavailable, the load balancer stops sending requests to it. The load balancer algorithm you choose determines how the gateways will route client requests.

Note: If you will be using Kerberos authentication, you need to configure Tableau Server for your load balancer before you configure Tableau Server for Kerberos. For more information, see Configure Kerberos.

Note the following as you configure your load balancer to work with Tableau Server:

- **Tested load balancers**: Tableau Server clusters with multiple gateways have been tested with Apache and F5 load balancers.

  If you are using an Apache load balancer and creating custom administrative views, you need to connect directly to the Tableau Server repository. You cannot connect through the load balancer.

- **Tableau Server URL**: When a load balancer is in front of a Tableau Server cluster, the URL that's accessed by Tableau Server users belongs to the load balancer, not
the initial Tableau Server node.

- **Trusted host settings**: The computer running the load balancer must be identified to Tableau Server as a trusted host. See the procedure below for how to configure Tableau Server.

- **Proxy server configurations**: The settings used to identify a load balancer to Tableau Server are the same ones that are used to identify a proxy server. If your Tableau Server cluster requires both a proxy server and a load balancer, both must use a single external URL defined in `gateway.public.host` and all proxy servers and load balancers must be specified in `gateway.trusted` and `gateway.trusted_hosts`. For more information, see Configuring Proxies for Tableau Server.

Configure Tableau Server to work with a load balancer

Use the following key-value pairs to configure Tableau Server for a load balancer. You can set the values individually with the `tsm configuration set` command.

Or, use the configuration file template example at the end of this topic to create a configKey json file. After you have filled in the options with the appropriate values, pass the json file and apply settings with `tsm` commands.

**Load balancer configuration key-value pairs**

The key-value pairs described in this section can be set with the `tsm configuration set` command. After you have set all values, run the following command:

```
tsm pending-changes apply
```

gateway.public.host

**Value:** name

The value, `name` is the URL that will be used to reach Tableau Server through the load balancer.
For example, if Tableau Server is reached by entering `tableau.example.com` in a browser address bar, enter this command:

```bash
tsm configuration set -k gateway.public.host -v "tableau.example.com"
```

gateway.public.port

**Value:** `port_number`

By default, Tableau assumes that the load balancer is listening on port 80 for external communications. Use this key to specify a different port.

For example, if your load balancer is configured for SSL and listening on port 443, enter the following command:

```bash
tsm configuration set -k gateway.public.port -v "443"
```

gateway.trusted

**Value:** `server`

Specify the load balancer(s) IPv4 address or computer name.

The value for `server` can be a comma-separated list, for example:

```bash
tsm configuration set -k gateway.trusted -v "10.32.139.45, 10.32.139.46, 10.32.139.47"
```

or

```bash
tsm configuration set -k gateway.trusted -v "proxy1, proxy2, proxy3"
```

gateway.trusted_hosts

**Value:**
Specify alternate names for the load balancer(s), such as its fully-qualified domain name, any non-fully-qualified domain names, and any aliases. These are the names a user might type in a browser. Separate each name with a comma:

```bash
tsm configuration set -k gateway.trusted_hosts -v "name1, name2, name3"
```

For example:

```bash
tsm configuration set -k gateway.trusted_hosts -v "lb.example.com, lb, ftp.example.com, www.example.com"
```

Configuration template example

You can configure all of the settings in one operation by customizing the following configuration template example and creating a configKey json file.

Refer to the key-value pair descriptions above to customize the values for your organization.

```json
{
    "configKeys": {
        "gateway.public.host": "tableau.example.com",
        "gateway.public.port": "443",
        "gateway.trusted": "proxy1, proxy2, proxy3",
        "gateway.trusted_hosts": "lb.example.com, lb, ftp.example.com, www.example.com"
    }
}
```

When you are finished, save the json file.

Pass the json file with tsm to set the configuration, and then apply settings by running the following commands:

```bash
tsm settings import -f /path/to/file.json
```

```bash
tsm pending-changes apply
```

For more information about using configKey schemes, see Configuration File Example.
Migrate Tableau Server from Windows to Linux

Customers running Tableau Server on Windows can migrate to Linux by taking a backup of their existing Tableau installation and restoring it to a fresh installation on Linux. This topic describes the steps necessary to do this migration. You cannot migrate or upgrade from a beta version of Tableau Server to an officially released version.

The basic steps to migrate from Tableau Server on Windows to Tableau Server on Linux include:

1. Step 1: Plan your migration—Plan for your migration, including gathering all the information you’ll need to be successful. During this step you should familiarize yourself with potential differences between Tableau Server on Windows and Tableau Server on Linux.

2. Step 2: Create a backup—Create a backup of Tableau Server on Windows.

3. Step 3: Install Tableau Server on Linux and restore the Windows backup—Install a fresh instance of Tableau Server on Linux in a test environment so you can test out the migration, then restore your Windows backup. The restore of your Windows backup will restore the Tableau content (users, projects, sites, workbooks and data sources), but will not restore customizations, so you will need to spend some time configuring Tableau Server on Linux to match the expectations in your organization. If you have a multi-node installation you will need to add nodes and configure them separately.

4. Step 4: Test Tableau Server on Linux—Try Tableau Server on Linux to make sure content is there as you expect, and users are able to perform all the actions they do on Windows. Look specifically at any changes identified as potential differences between Tableau Server on Windows and Tableau Server on Linux. Include key stakeholders in the testing both to leverage their knowledge and to help communicate the upcoming
changes.

5. Step 5: Install Tableau Server on Linux in your production environment and restore the Windows backup—Once you’re satisfied that Tableau Server on Linux gives you the functionality you need, install Tableau in your production Linux environment and restore the Windows backup.

Step 1: Plan your migration

A successful migration from Windows to Linux requires some preparation beforehand. You will need to satisfy the following requirements:

- **Identity store**: You can only restore from a backup that has the same type of identity store as the running server. For example, a backup from a server using local authentication can be restored to a Tableau Server initialized with local authentication, but a backup from a server using Active Directory authentication cannot be restored to a server initialized with local authentication.

- **Server administrator**: You must have password for at least one of the user accounts with Server Administrator privileges from the Tableau Server source (Windows) deployment. You must use the same user as the Server Administrator in the migrated deployment to Linux.

- **Clean installation of Tableau Server for Linux**: When you install Tableau Server on Linux later in this topic, be sure to use the same identity store type as you are using on Windows, and do not create users or content. When you restore the Windows backup file to the Linux deployment of Tableau Server, all user data and content will be replaced from the Windows back up file.

- **Differences between Windows and Linux**: Review the differences between Tableau Server on Windows and on Linux so you are aware of them and can investigate in your test environment.
• If you are migrating from a version of Server on Windows prior to 10.5, approach the migration like an upgrade and familiarize yourself with any changes between your existing version and 10.5 by reading What's Changed in the Server on Windows help.

• Any custom fonts you use may need to be installed on your Linux computer, and may render differently there than on Windows.

• Connection options for Linux are a subset of those available for Tableau Server on Windows. Review the connection types that are available and make sure the ones you need are supported.

• TSM replaces tabadmin. Understand the TSM commands and how they compare to older tabadmin commands. For a list of tabadmin commands and their TSM equivalents, see Migrate from Tabadmin to the TSM CLI.

Step 2: Create a backup

The steps to create a backup depend on what version of Tableau Server on Windows you are running. If you have version 2018.1.x or earlier, you need to use tabadmin to create your backup. If you are running version 2018.2.0 or later, you use TSM to create the backup.

Migrate from 2018.1 or earlier

If you are migrating from Tableau Server on Windows version 2018.1.x or earlier:

1. Log on to the computer running Tableau Server on Windows.

2. Open a command prompt as an administrator.

3. Navigate to the bin directory. For example:

   \cd "C:\Program Files\Tableau\Tableau Server\10.4\bin"

   Run the following command:

4. tabadmin backup tabserver -v -d
Include the `-v` flag to verify the integrity of the backup. Include the `-d` flag to include the date in the file name. In the example, `tabserver` will be used as the base file name of the resulting backup file. The date of the backup will be appended to the file name, for example, `tabserver-2017-12-20.tsbak`.

For more information, see Back Up Tableau Server Data in the Tableau Server on Windows help (version 2018.1).

**Migrate from 2018.2 or later**

If you are migrating from Tableau Server on Windows version 2018.2.0 or later:

1. Log on to the computer running Tableau Server on Windows.
2. Open a command prompt as an administrator.
3. Run the following command:

   ```
   tsm maintenance backup -f <filename> -d
   
   Include the `-d` flag to include the date in the backup file name.
   ```

For more information, see Back up Tableau Server data in the Tableau Server on Windows help.

**Step 3: Install Tableau Server on Linux and restore the Windows backup**

In a test environment, install Tableau Server on Linux:

- Install Tableau Server for Linux according to the procedure, Install and Configure Tableau Server. Use the same identity store as on your Windows deployment, and do not create users or content.

Restore the Tableau Server on Windows backup:
1. Copy the Windows backup file to the computer running Tableau Server on Linux. By default the restore process will look for the file in this location:

/var/opt/tableau/tableau_server/data/tabsvc/files/backups/

You can change the location. For more information, see tsm File Paths.

2. Run the following command to stop Tableau Server:

   tsm stop

3. Run the following command to restore from the backup file:

   tsm maintenance restore -f <filename.tsbak>

   Where <filename.tsbak> is the name of your backup file, for example, tab-server-2017-10-20.tsbak.

   For more information, see tsm maintenance restore

4. Run the following command to start Tableau Server:

   tsm start

After restoring your Tableau content, you may need to configure Tableau Server. For example, if you are migrating from a multi-node installation, you will need to add and configure the additional nodes. You will also need to configure any customizations you made on Windows, including copying over image or logo files if applicable.

**Step 4: Test Tableau Server on Linux**

Once you’ve installed Tableau Server on Linux and restored your Windows backup, you can test the new version of Tableau Server. Because the restore process only restores content to Tableau, you may need to update configuration, topology (adding additional nodes for example), and any customizations you have on your Windows installation.

You’ll want to be familiar with the known differences between Windows and Linux, as well as any potential problem areas. Test basic functionality, along with any special aspects of server that your organization relies on. For example, there may be key data sources that
your organization uses with Tableau. Test these to make sure you’re seeing what you expect.

These are some areas of testing to consider:

- **User access.** Confirm that Tableau Server users, including administrators, can sign in. Test your normal user sign in process. Have some of your users participate in the testing to make sure they are able to sign in as expected, and that they can get to the same content that they have access to in your production environment.

- **Viewing built-in administrative views.** With this release of Tableau Server on Linux, you must install PostgreSQL drivers manually, and the administrative views depend on these. Confirm that you have installed the drivers necessary by accessing the built-in administrative views. For more information, see Administrative Views.

- **Data source availability.** Tableau Server on Linux supports a subset of the data sources on Tableau Server on Windows. You need to confirm that the data sources used by your organization are supported on Linux, and install any drivers required. For details on which data sources are supported, see the Tableau Server tech specs. For information about installing drivers, see Database Drivers.

- **Access to file-based data sources on shared drives.** Data sources such as Excel files on network drives will require special actions in order to be accessible from Linux. You or your IT department will need to mount the drives and update any workbooks using these data sources. For more information on connecting to network drives, see the Tableau Community.

- **Viewing published workbooks.** Have users who are familiar with the content try to view published workbooks to make sure they appear as expected. Test views embedded in web pages (for example, in SharePoint pages). Be especially aware of how fonts may differ between Windows and Linux, and some custom fonts may need to be added to your Linux computer, or replaced with other fonts if they are not available on Linux. Dashboard layouts may appear different as well, due to differences in fonts.

- **Server processes.** Sign in to Tableau Server as a server administrator, and then
open the Server Status page to confirm that all services and processes are running as expected. Be aware of intentional changes due to changes in version 10.5. For more information, see Tableau Server Data Engine.

- **Publishing workbooks and data sources.** Have users publish workbooks and data sources from Tableau Desktop to make sure this goes as you expect. You may need to install drivers to support the data source connections you are using. See Database Drivers.

- **Subscriptions and extract refreshes.** Manually run some extract refreshes to confirm that they complete successfully. Run some key scheduled extract refreshes to confirm that they complete as expected.

- **Permissions.** Confirm that permissions are still set as expected for users and content.

- **Command-line utilities and APIs.** If applicable, test the command line utilities (tsm and tabcmd) and programmatic access via APIs. With Tableau Server on Linux, tabadmin is replaced by TSM. For more information, see Migrate from Tabadmin to the TSM CLI.

**Step 5: Install Tableau Server on Linux in your production environment and restore the Windows backup**

When you have completed testing and have identified those areas that require additional changes on your part, or communication to your users, you are ready to install Tableau Server on Linux in your production environment and restore the Windows backup. To do this, follow the same steps described above.

Important: If you are migrating from Tableau Server version 2018.1 or earlier on Windows - You can take a backup from Tableau Server on Linux and restore that backup to Tableau Server on Windows version 2018.2 or later, but you cannot restore that backup
to Tableau Server on Windows version 2018.1 or earlier. This means that if you migrate to Linux, you cannot easily switch back to Tableau Server on Windows version 2018.1 or earlier. Keep this in mind as you test your migration, and consider keeping your installation on Windows until you are certain that you no longer need it.

Test Workbook Performance

In most cases, you can expect to see similar or better performance after upgrading your Tableau Server from versions 10.4 or earlier to 10.5 or later. However, for workbooks that use complex calculations, you may see performance issues after you upgrade. This article describes how to test performance and troubleshoot these performance issues before you upgrade your production Tableau Server from versions 10.4 and earlier to 10.5 or later.

If you have already upgraded your production Tableau Server to 10.5 or later, and you are seeing performance issues for workbooks that have calculations and use extracts as the data source, see Troubleshoot Performance of Workbooks with Calculations.

Since Linux was first released in 10.5, this only applies when you are migrating from Tableau Server versions 10.4 or earlier on Windows to Linux 10.5 or later.

To make sure your workbook performance is same or better after your upgrade to Tableau 10.5 or later, we strongly recommend that you set up a test environment and do performance testing before you upgrade your production Tableau Server.

Use the following sequence of steps for testing workbook performance:

1. Set up your test environment
2. Capture performance metrics and analyze
3. Troubleshoot performance issues
4. Capture the conclusions and results
Set up your test environment

1. Create a test environment that mirrors your production environment as closely as possible.

   Follow the steps described in Migrate Tableau Server from Windows to Linux.

2. Disable any automated or scheduled extract refresh schedules.

Capture performance metrics and analyze

1. Run Tabjolt or any other tool of your choice to capture performance metrics on your current version of Tableau Server to set a baseline. Use workbooks that have calculations and use extracts as the data source for testing. For more information about how install and use Tabjolt, see the Tabjolt Installation Guide.

2. Perform a full backup to capture the metrics from the first step.

3. Upgrade your test environment to 10.5.3 or later. We are recommending 10.5.3 as the minimum version since the settings you need to enable in order to resolve performance issues later on are only available in 10.5.3 or later versions of Tableau.

4. **Checkpoint:** Run Tabjolt to compare workbook performance before and after upgrade.

   If you see performance degradation after upgrade at this step, it may be due to other Tableau Server issues and might require further investigations. For more information, see Record and Analyze Workbook Performance.

   If you see no difference in performance before and after upgrade, continue to the next step.

5. Select a subset of workbooks and run a full refresh of the extracts. Doing a full refresh will upgrade the extracts from .tde to .hyper.

6. **Checkpoint:** Run the tool again to compare the performance of your workbooks
between step 4 and step 6 which is essentially before and after doing extract refreshes. Specifically, check for workbooks with slower response times or failure to load.

Troubleshoot performance issues

If you find that you are unable to test due to performance issues, or you find that VizQL server is consuming all or most of the available memory on the machine while viewing them, follow **steps 1 through 3**.

For workbooks that load successfully, but have slower response after upgrade, follow **steps 4 and 5**.

1. Enable the following setting that checks the number of query nodes required for Tableau to generate the workbook and displays an error when the set limit is exceeded. This helps prevent VizQL process from consuming the memory resources on the machine that might result in critical Server issues:

   Use TSM CLI to run the following commands:

   ```
   tsm configuration set -k native_api.node_limit_checker.pre_rewrite_disable -v false
   tsm pending-changes apply
   ```

   **Note:** This setting is only available in Tableau Server 10.5.3 or later. While enabling this setting improves the reliability and stability of Tableau Server, you may see errors on a very small percentage of workbooks with when you enable this setting. For example, the Tableau team saw errors on 0.01% of the workbooks with this setting enabled on Tableau Online.

2. Test the workbooks by viewing or interacting with them. You should see an error message informing you about exceeding the node limits on workbooks that have
performance issues - The error message might say something like: "Logical Query tree has 2348182 nodes, maximum number allowed is 1000000...."

3. Use Tableau Desktop to troubleshoot your workbook performance. Run this command to enable the node limit check in your Tableau Desktop:

   ```bash
tableau.exe -DNodeLimitCheckerPreRewriteDisable=false
   ```

   **Note:** This setting is only available in Tableau Desktop 10.5.3 or later.

   In Tableau Desktop, download and open the workbooks that displayed the error message about high node limits in step 2. Try optimizing the performance of workbooks using methods described in the Best Practices for Creating Calculations in Tableau topic. If successful, then publish them to Tableau Server. If you are still experiencing performance issues, continue to the next step.

4. For workbooks that load successfully, but the overall response times is slower after upgrade, try using the Compute Calculations Now option. If you have a large number of workbooks that fall under this category, consider enabling the server wide setting to retain materialized calculations for all extracts when they are upgraded from .tde to .hyper:

   Use TSM CLI to run the following commands:

   ```bash
   tsm configuration set -k native_api.preserve_calculations_on_hyper_refresh_conversion -v true
   tsm pending-changes apply
   ```

   **Considerations for turning on this setting:**

   Turn this setting on only if majority of your workbooks require calculations to be materialized. There are resource and time costs associated with this setting, as described below:
• When this setting is set to true, the extract file size will increase, affecting the overall disk space.

• Extracts with materialized calculations take a longer time to refresh than extracts without materialized calculations.

This setting only affects extracts that are not yet upgraded to .hyper. Extracts already upgraded to .hyper before turning on this setting will not have the calculations materialized. This setting will also not affect workbooks and extracts published from Tableau Desktop, or any new extract refreshes published to Tableau Server that do not use the **Compute Calculations Now** option.

**Note:** This setting is only available in Tableau Server 10.5.3 or later.

5. Enable the extract refresh schedules and monitor the performance of your workbooks to make sure that your workbooks are performing as expected.

**Capture the conclusions and results from your testing**

Make a note of the settings and steps that helped resolve the performance issues to use them to prevent performance degradation when you upgrade your Production Tableau Server.

For example, if during your testing, you found that you needed to set the `native_api.preserve_calculations_on_hyper_refresh_conversion` setting to true, remember to disable your extract refreshes just before you upgrade your production Tableau Server.

**After upgrade, set the** `native_api.preserve_calculations_on_hyper_refresh_conversion` **setting to true, and then re-enable your extract refreshes after you have confirmed that you are not experiencing slow response times after upgrade.**
Migrate from Tabadmin to the TSM CLI

The Tableau Services Manager (TSM) command-line interface (CLI) replaces the tabadmin CLI in Tableau Server on Linux, and in Tableau Server on Windows version 2018.2. This page maps tabadmin commands to TSM commands to help you to migrate to the TSM CLI.

To learn more about the TSM CLI, see tsm Command Line Reference.

Tabadmin commands with a corresponding TSM CLI command

The following table shows which tabadmin commands correspond to commands available in the TSM CLI.

<table>
<thead>
<tr>
<th>Command Description</th>
<th>Tabadmin Command(s)</th>
<th>Comparable TSM CLI Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Activate a license</td>
<td><code>tabadmin activate</code> -- activate</td>
<td><code>tsm licenses activate</code></td>
</tr>
<tr>
<td>Deactivate licenses</td>
<td><code>tabadmin activate</code> -- return</td>
<td><code>tsm licenses deactivate</code></td>
</tr>
<tr>
<td>Activate a trial license</td>
<td><code>tabadmin activate</code> -- trial</td>
<td><code>tsm licenses activate</code> --trial</td>
</tr>
<tr>
<td>Create a backup of the data managed by Tableau Server</td>
<td><code>tabadmin backup</code></td>
<td><code>tsm maintenance backup</code></td>
</tr>
</tbody>
</table>

A backup created using TSM does not include any server configuration data. There is no option to include server configuration data.
<table>
<thead>
<tr>
<th><strong>Clear the server cache</strong></th>
<th><code>tabadmin clearcache</code></th>
<th><code>tsm maintenance cleanup -r</code></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Clean up temporary files and old log files</strong></td>
<td><code>tabadmin cleanup</code></td>
<td><code>tsm maintenance cleanup</code> <strong>Note:</strong> This command was added in version 10.5.1</td>
</tr>
<tr>
<td><strong>Update the server configuration with any changes you’ve made</strong></td>

<td>Command</td>
<td>Notes</td>
</tr>
<tr>
<td>----------------------------------------------------------------------</td>
<td>-----------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>Reset binding between Tableau Server user ID and Open ID Connect identity provider</td>
<td><code>tabadmin reset_openid_sub</code></td>
<td></td>
</tr>
<tr>
<td>Determine whether your environment meets the minimum requirements to run Tableau Server</td>
<td><code>tabadmin validate</code></td>
<td></td>
</tr>
<tr>
<td>Verify that a backup of the Tableau Server repository will restore successfully</td>
<td><code>tabadmin verify_database</code></td>
<td>The <code>tsm maintenance backup</code> command automatically verifies that a backup will restore correctly unless you use the <code>--skip-verification</code> parameter.</td>
</tr>
<tr>
<td>Prepare VizQL processes for fast load times after a Tableau Server restart</td>
<td><code>tabadmin warmup</code></td>
<td>The <code>tabadmin warmup</code> command is no longer necessary, as Tableau Server is now optimized to automatically provide fast load times after a server restart.</td>
</tr>
</tbody>
</table>
Uninstall Tableau Server

Do not uninstall Tableau before upgrading. For details on upgrading, see Upgrade Tableau Server.

You can have multiple versions of Tableau Server installed at the same time. This allows you to run most of an upgrade while an existing version is running, and reduces downtime and impact to users. Once you have upgraded, you can uninstall your previous version. Doing this frees up disk space. You do not have to uninstall the previous version.

This article explains how to uninstall previous versions, after you've upgraded to a newer version.

Uninstalling and completely removing Tableau Server

There are two primary "uninstall" scenarios that Tableau Server on Linux supports:

- **Uninstall Tableau Server**: After you upgrade to a new version of Tableau Server you can uninstall your previous version to free up disk space. Continue reading for information about uninstalling Tableau.

- **Remove Tableau Server**: If you want to completely remove Tableau Server from a computer, you can use a script provided by Tableau to remove Tableau Server and all related files. This removes all data as well as server components, so should only be done if you know you want to reset the computer to a pre-Tableau state. You might need to do this if Technical Support recommends this step when troubleshooting an installation problem. We recommend you create a backup of your data before removing Tableau. Save the backup file to a safe location on a computer that is not part of your Tableau installation. Completely remove Tableau Server without uninstalling any version first. The script will uninstall all existing versions found on the computer. If you have already uninstalled your existing version and now want to completely remove Tableau, you can find the script to do so in a temporary location. For more details, see Remove Tableau Server from Your Computer.
Uninstall a Tableau Server package

Use this procedure to free up disk space by uninstalling packages for previous Tableau Server versions after you have upgraded to a newer version of Tableau Server.

1. Look at the environment.bash file to confirm which version of Tableau Server is currently in use. At a command prompt, type:

   `grep TABLEAU_SERVER_DATA_DIR_VERSION /etc/opt/tableau/tableau_server/environment.bash`

2. Determine which versions of the Tableau Server package are installed on your computer.

   • On RHEL-like distributions, including CentOS, run the following command:

     `yum list installed tableau-server"*"

   • On Ubuntu, run the following command:

     `apt list --installed tableau-server"*"

3. Remove the Tableau Server package with your package manager.

   • On RHEL-like distributions, including CentOS, run the following command:

     `sudo yum remove tableau-server-<version>.x86_64`

   • On Ubuntu, run the following commands:

     `sudo apt-get purge tableau-server-<version>_amd64`

Reinstall a Tableau Server package that was accidentally uninstalled

Do not uninstall the package for your currently running version of Tableau Server. Doing so will make the server unusable. To completely remove Tableau Server and all its files, see Remove Tableau Server from Your Computer.
When you uninstall the Tableau Server package for the current instance of Tableau Server the following operations run:

- All files under /opt/tableau/tableau_server are removed. These files are the unmodified installation files.
- Tableau Server services are stopped and disabled
- Service files for all Tableau Server services are persisted
- Data files are left in place

If you accidentally uninstall the package for your currently running version of Tableau Server, follow this procedure to correct the situation.

To reinstall after uninstalling the running instance of Tableau Server:

1. Reinstall the package for the version you accidentally uninstalled.

2. Run `initialize-tsm`.

Remove Tableau Server from Your Computer

**Warning:** The steps below *completely remove* Tableau Server on Linux, and delete users and groups created by `initialize-tsm`, all related data, configuration information, and logs. This includes any files in `/tmp` or `/var/tmp` that are owned by users configured in `/etc/opt/tableau/tableau_server/environment.bash` as privileged and unprivileged users (by default, `tsmage`nt and `tableau`). Tableau Server licenses are also deactivated, unless you omit the `-l` option when running the command shown below.

If you want to uninstall a particular Tableau Server package to free up disk space (after upgrading, for example), see Uninstall Tableau Server.

As part of the regular installation of Tableau Server, a script is installed that provides you a way to completely remove Tableau and all associated files from your computer. This is
something you would only do if you did not care about your Tableau data, configuration, or log files. The obliterate script will not remove any drivers you installed separately, even those you installed to use with Tableau Server.

The tableau-server-obliterate script is intended for when you want to completely remove Tableau Server from your computer. You might want to do this for a couple of different reasons:

- You no longer want Tableau Server installed on the computer. Use the tableau-server-obliterate script to remove Tableau Server completely.

- Troubleshooting Tableau Server installation problems—If you run into issues installing Tableau, you may need to use the tableau-server-obliterate script to completely remove Tableau Server from your computer before reinstalling. Doing this will clean up any older settings or states (such as the /etc/opt/tableau/tableau_server/environment.bash file) and allow you to reinstall on a "clean" computer. If you are doing this, you can leave off the -l option to preserve licensing information on the computer. When you omit the -l option, you will not need to activate your license when you reinstall Tableau Server.

The script will remove all log files, so if you run into an issue that you want to troubleshoot, or if Tableau Support requests log files for a support case, you should zip up the log files before running the script. For details on gathering log files, see Work with Log Files.

The script will remove all files related to Tableau, so if you have a backup file you want to save, copy it to a safe location on a separate computer.

Running the tableau-server-obliterate script

You can completely remove Tableau Server from a computer, either preserving the licensing information, or removing the licensing information along with all other aspects of Tableau Server. You might want to preserve licensing if you are going to reinstall Tableau Server on the computer.
To completely remove Tableau Server without removing server licensing:

1. Run the `tableau-server-obliterate` script:

   ```
sudo /opt/tableau/tableau_server/packages/scripts.<version_code>/tableau-server-obliterate -y -y -y
   ```

   **Note:** If you have already uninstalled Tableau Server and now you want to remove it, run the copy of the `tableau-server-obliterate` script located in the `/var/tmp` directory. If the script is not in that directory, reinstall the Tableau Server package and then run the `tableau-server-obliterate` script.

   If you have a multi-node (distributed) installation of Tableau Server, run the `tableau-server-obliterate` script on each node in the cluster.

2. Restart each computer you ran the `tableau-server-obliterate` script on.

To completely remove Tableau Server and licensing:

1. Deactivate any active product keys.

   ```
tsml licenses deactivate -k <product_key>
   ```

2. Run the `tableau-server-obliterate` script:

   ```
sudo /opt/tableau/tableau_server/packages/scripts.<version_code>/tableau-server-obliterate -y -y -y -l
   ```

   The `-l` option for the obliterate script removes all licensing files from the computer. The script first attempts to deactivate any active licenses, but it will remove all licensing information whether or not deactivation was successful. This is why we recommend you run the `tsm licenses deactivate` command before running the obliterate script.
Note: If you have already uninstalled Tableau Server and now you want to remove it, run the copy of the tableau-server-obliterate script located in the
/var/tmp directory. If the script is not in that directory, reinstall the Tableau Server package and then run the tableau-server-obliterate script.

If you have a multi-node (distributed) installation of Tableau Server, run the tableau-server-obliterate script on each node in the cluster. You do not need to deactivate licenses on any additional nodes.

3. Restart each computer you ran the tableau-server-obliterate script on.

Upgrade Tableau Server Overview

The articles in this section help you upgrade an existing installation of Tableau Server. They describe the recommended steps of planning and testing before actually performing the upgrade. There's information about best practices, and when you're ready to actually perform your upgrade, steps for upgrading a single node server and a multi-node installation. Where possible, we call out possible pitfalls and help you to avoid these.

Important: Your upgrade steps depend on which version you are upgrading from. When you are ready to actually upgrade, be sure you follow the procedure that applies to your installation:

- Upgrading from Tableau Server on Linux version 10.5 (10.5.0 or later) requires special steps. If you are upgrading from version 10.5, use the Upgrade Tableau Server on Linux from 10.5 procedure.

- Upgrading from Tableau Server on Linux version 2018.1 or later is more straightforward. If
you are upgrading from version 2018.1.0 or later, follow the steps in Upgrade Tableau Server.

For instructions on how to determine your version of Tableau Server, see View Server Version.

Upgrade Tableau Server on Linux

The articles in this section help you upgrade and existing installation of Tableau Server. They describe the recommended steps of planning and testing before actually performing the upgrade. There’s information about best practices, and when you’re ready to actually perform your upgrade, steps for upgrading a single node server and a multi-node installation. Where possible, we call out possible pitfalls and help you to avoid these.

**Important:** Your upgrade steps depend on which version you are upgrading from. When you are ready to actually upgrade, be sure you follow the procedure that applies to your installation:

- Upgrading from Tableau Server on Linux version 10.5 (10.5.0 or later) requires special steps. If you are upgrading from version 10.5, use the Upgrade Tableau Server on Linux from 10.5 procedure.

- Upgrading from Tableau Server on Linux version 2018.1 or later is more straightforward. If you are upgrading from version 2018.1.0 or later, follow the steps in Upgrade Tableau Server.

For instructions on how to determine your version of Tableau Server, see View Server Version.

Research the Upgrade

Before you upgrade Tableau Server, we recommend that you plan the upgrade.

- Learn about the new version of Tableau Server, including what's new and what's changed.
  - Search for "What's New" in the Tableau Server on Linux Help.

- Make sure the computers you are going to upgrade (both for the test environment and the production environment) meet the minimum hardware requirements. Minimum requirements and recommendations can change from version to version.
  - Minimum Hardware Requirements and Recommendations for Tableau Server

    You may need to allocate additional disk space depending on the various factors like whether or not you will be using extracts. For more information, see Disk Space Requirements.

    **Important:** As a best practice, you should never install a beta version of Tableau Server in your production environment. You should also never restore a production Tableau Server installation using a backup of a beta version.

- Confirm licensing requirements

The computers you are going to upgrade (both for the test environment and the production environment) must meet these licensing requirements:

- Trial licenses—When upgrading from one major version to another (version 10.x to version 2018.x for example), you must have a valid license. You cannot directly upgrade to a new major version if your server is running a trial license. If you have a trial license and want to upgrade to a new major version, follow these steps:
1. Backup of your existing Tableau Server. For details, see Back up Tableau Server data.

2. Install the new Tableau Server version on a separate computer and activate a trial license.

3. Restore your backup to the new version. For more information, see Restore from a backup.

• Expired maintenance—You should not upgrade your server if your maintenance is expired. If you attempt to upgrade a server with expired maintenance the upgrade may fail, or, if it succeeds, may result in an unlicensed server. You can refresh your maintenance before upgrading:

  • If you are upgrading Tableau Server on Windows version 2018.1 or earlier, use the Manage Product Keys application. For more details, see Refresh Maintenance Date for the Product Key.

  • If you are upgrading Tableau Server on Windows version 2018.2 or later, or Tableau Server on Linux, run this tsm command:

    tsm licenses refresh

   If refreshing the product key does not update maintenance with a valid date, check in the Tableau Customer Portal to confirm you have a Tableau Server product key with up-to-date maintenance.

• Understand how version compatibility might impact your installation of Tableau Server.

  • Desktop and Server Compatibility in the Tableau Help.
What's New in Tableau Server

This article lists what's new in Tableau Server, beginning with version 10.5. Version 10.5 was the first version of Tableau Server for Linux. If you are looking for a historical list of new features in Tableau Server for Windows versions prior to 10.5, see What's New in Tableau Server for Windows 10.5.

What's new in version 2018.2

User

- Include colleagues on data conversations with @mentions

New features and enhancements related to web authoring and interacting with views on the web are listed in What's New in Tableau for Users and Web Authoring and Tableau Desktop Feature Comparison. For topics related to web authoring and interacting with views, see Using Tableau on the Web.

Server or site administrator

- Backup without compression (added in version 2018.2.5)
- Create a support case from the TSM UI or CLI
- Manage Dashboard Extensions in Tableau Server
- Automated daemon port configuration
- Amazon Linux 2 now supported

Include colleagues on data conversations with @mentions

To engage people in a conversation about compelling data you find in a view, @mention them in comments. As you begin to type a name, matching people with Tableau accounts at
your organization appear in a list you can choose from. For more information, see Comment on Views in Tableau User Help.

Site administrators can disable @mentions in the General section of site settings.

Backup without compression (added in version 2018.2.5)

Tableau Server version 2018.2.9 introduced a new option for the tsm maintenance backup command that allows you to disable compression when doing the backup. This can be beneficial for customers who have backups that take a long time. Using the option speeds up the time for the backup, but results in a larger backup file. If using this command option in a multi-node installation, we strongly recommend you have a File Store instance configured on your initial node to reduce the need to backup across nodes. To learn more about TSM backup, see tsm maintenance backup.

Create a support case from the TSM UI or CLI

You can take a log file snapshot and send it to Tableau Support directly from the Tableau Services Manager UI or CLI. To learn how, see Log File Snapshots (Archive Logs).

Manage Dashboard Extensions in Tableau Server

Dashboard extensions are web applications that provide users new ways to interact with data from other applications directly in Tableau. You can control the dashboard extensions that you allow to run in Tableau. You can manage an extension’s access to data and can block extensions to prevent them from running. To learn more about controlling extensions, see Manage Dashboard Extensions in Tableau Server.
Automated daemon port configuration

In previous versions of Tableau Server on Linux, configuring the licensing daemon port was a required, manual step for multinode deployments. In the 2018.2 version, this process happens automatically. Tableau Server on Linux will automatically detect and configure the appropriate ports for the licensing daemon.

Amazon Linux 2 now supported

Beginning with version 2018.2, Amazon Linux 2 (AL2) is now a supported distro for Tableau Server on Linux.

What's new in version 2018.1

User

- Resize headers on the web
- Streamline discussion threads by deleting comments

New features and enhancements related to web authoring and interacting with views on the web are listed in What's New in Tableau for Users and Web Authoring and Tableau Desktop Feature Comparison. For topics related to web authoring and interacting with views, see Using Tableau on the Web.

Server or site administrator

- New user-based term licenses are now available
- New and renamed site roles are now available
- Improved support for managing web data connectors

Resize headers on the web

When editing a view on the web, you can resize the width of row headers and the height of column headers.
Streamline discussion threads by deleting comments

If a comment on a view is unnecessary or inaccurate, users can quickly delete it by clicking the X in the upper-right corner. For more information, see Comment on Views in Tableau User Help.

To disable the ability to delete comments, change the tsm configuration set option, viz-portal.commenting.delete_enabled, to false.

New user-based term licenses are now available

Tableau offers multiple types of user-based term licenses that grant a range of web authoring and other capabilities at various price points, providing the flexibility for organizations to pay for the data analysis and data visualization capabilities that each type of user in their organization needs. To learn more, see User-based licenses.

New and renamed site roles are now available

Starting in the version 2018.1 release, new and updated site roles are now available. To learn about these site roles, see Set Users’ Site Roles. To learn about changes in the REST API to accommodate new site roles, see What's New in the REST API.

Improved support for managing web data connectors

Tableau Server now provides improved support for web data connectors (WDCs):
A new set of tsm data-access commands are now available to help you manage WDCs.
You can also manage WDCs using the new web-data-connector-settings Entity.

What's new in version 10.5

User

- Extracts use the new .hyper format
- Changes to the way values are computed
- Filtered search hidden by default

New features and enhancements related to web authoring and interacting with views on the web are listed in What's New in Tableau for Users and Web Authoring and Tableau Desktop Feature Comparison. For topics related to web authoring and interacting with views, see Using Tableau on the Web.

Server or site administrator

- Optimized server performance for data alerts
- Nested projects
- Tableau Data Engine with Hyper
- Tableau Services Manager
- Hot topology support
- Lightweight Directory Access Protocol (LDAP) support

Optimized server performance for data alerts

To improve overall performance, Tableau Server now rechecks failing data alerts only when it next checks data conditions for all alerts. You can revert to the previous setting, which
checked failing alerts every 5 minutes, by changing the `tsm configuration set` option, `dataAlerts.retryFailedAlertsAfterCheckInterval`, to `false`.

Nested projects

You can now create project hierarchies when you want to create content segments within a larger area. For example, create a project for each department, say Operations. In each of those top-level projects, separate content based on how the audience uses it, say connecting to certified data versus in-progress collaboration. For more information, see the following articles:

- Use Projects to Manage Content Access
- **Navigate projects** in the article *Navigate Tableau on the Web*

Filtered search hidden by default

Filtered search options are now located on the right side of pages, and are hidden by default. The toggle is a dark icon (●) when the Filters pane is open and a light icon (○) when the Filters pane is closed. For details on searching, see *Search Content*.

To use filtered search, click (●).
Tableau Data Engine with Hyper

Hyper is Tableau’s new in-memory Data Engine technology optimized to bring faster extract and query performance, and increased scalability. You can now analyze large data sets faster and faster extract creation. For more information, see Tableau Server Data Engine.

Extracts use the new .hyper format

Beginning with version 10.5, new extracts use the new .hyper format. Extracts in the new format take advantage of the improved data engine, which supports the same analytical and query performance as the data engine before it, but for even larger extracts. Similarly, when an extract task is performed on a .tde extract using version 10.5, the extract is upgraded to a .hyper extract. For more information, see Extract Upgrade to .hyper Format.

Changes to the way values are computed

To improve data source efficiency and scalability, and produce results that are consistent with commercial databases, values in your data source can be computed differently in version 10.5. In some cases, these changes can cause differences with the values and marks in
your view between version 10.4 (and earlier) and version 10.5 (and later). This applies to extract data sources, and can apply to multi-connection data sources, data sources that use live connections to file-based data, data sources that connect to Google Sheets data, cloud-based data sources, extract-only data sources, and WDC data sources. For more information, see Changes to values and marks in the view in the Tableau User Help.

Tableau Services Manager

Tableau Server version 10.5 features our new web-based server configuration and management application, Tableau Services Manager (TSM). To learn more about TSM, see Tableau Services Manager Overview.

Hot topology support

Tableau Server includes support for hot topology changes. This allows you to change the number of Backgrounder and VizQL processes running on nodes that already have these processes - without the need to restart Tableau Server. To learn more about these and other Tableau Server processes, see Tableau Server Processes.

Lightweight Directory Access Protocol (LDAP) support

Tableau Server now supports Lightweight Directory Access Protocol (LDAP). To learn more about LDAP support in Tableau Server, see Identity Store
What's Changed - Things to Know Before You Upgrade

This article lists important changes in Tableau Server, beginning with version 10.5. Version 10.5 was the first version of Tableau Server for Linux. This list is cumulative. If you are upgrading from an early version (for example, 9.3), read the list of changes for every version between your current version and the version you are upgrading to. If you are upgrading from Tableau Server on Windows to Tableau Server on Linux, read both versions of "What's Changed."

Looking for Tableau Server on Windows? See What's Changed - Things to Know Before You Upgrade.

What Changed in Version 2018.2

Version 2018.2 includes some significant changes you should know about before upgrading.

The following sections summarize the significant changes to Tableau Server 2018.2 and provide links for additional information.

- Updates to Tableau Server Apache Logs
- The Read Only site role is now deprecated
- The tabcmd initialuser command prompts for password
- New ports added
Moving the repository in a two-node cluster not supported

Updates to Tableau Server Apache Logs

Apache log files stored in `/logs/httpd` now contain records with several formatting improvements, including the following:

- Server names are shown according to the `UseCanonicalName` setting, which makes it easier to distinguish between nodes in a multi-node server deployment.
- Date and time are now tracked in a single date-and-time string that can be readily recognized as a single value by a variety of data analysis tools, including Tableau Desktop.
- Time zones are now easier to parse
  - On Linux, the numerical offset from UTC is provided.
  - On Windows, the name of the timezone is enclosed in quotes

Date, time and time zone formatting changes are illustrated by an example log entry from Tableau Server version 2018.1 and earlier releases:

```
::1  -  -  2018-05-09 08:51:48.872 GMT Daylight Time  80 "POST /vizql/w/Re-
gional/v/Obesity/sessions/A971A92AF77A4F4A9813065BDCEB24D6-0:0/-
commands/tabsrv/render-tooltip-server HTTP/1.1" "-" 200 445 "593" 135021 WvKolPH4UcM5Krynamodb593@EwAAA@E
```

For purposes of comparison, here is a log entry from Tableau Server version 2018.2:

```
10.210.24.3 127.0.0.1  -  2018-05-09T16:07:58.120 GMT Daylight Time  80 "POST /vizql/w/Su-
per-store/v/Overview/bootstrapSession/sessions/185CCDC854A44765BB0298E93B403879-
0:3 HTTP/1.1" "-" 200 136026 "784" 2370951 WvMOzgK1hfzh9kFWO@ow2gAAA1Y
```
The Read Only site role is now deprecated

The Read Only site role that was introduced in Tableau Server version 2018.1 is now deprecated. Any users assigned to this site role in version 2018.1 are reassigned to the Viewer site role after an upgrade to version 2018.2. To learn more about site roles, see Set Users’ Site Roles.

The tabcmd initialuser command prompts for password

In previous versions, the tabcmd initialuser command required a --password parameter to set the initial administrator password. In the tabcmd included with this version of Tableau Server, you can leave the --password parameter out of the command to be prompted in the shell instead. See initialuser.

New ports added

We’ve added new service ports in 2018.2.

Automatic port assignment

For installations where automatic port assignment is enabled (this is recommended and the default) there should be no impact to upgrading. The new ports will be automatically selected on upgrade.

Manual port assignment

If you have disabled automatic port assignment, you will need to manually specify the new ports in your configuration before upgrading. For more information about manually assigning ports, see Manual port assignment.

Ports added in 2018.2

<table>
<thead>
<tr>

</table>

**What Changed in Version 2018.1**

Version 2018.1 includes some changes you should know about before upgrading.

The following sections summarize the significant changes to Tableau Server 2018.1 and provide links for additional information.

- Removed tabadmin command options
- Updated tsm commands
- Updated upgrade-tsm script
Removed tabadmin command options

The previously deprecated --license and --administrator options are no longer available when using the `tabcmd createsiteusers`, `tabcmd createusers` and `tabcmd syncgroup` commands. These are breaking changes for any scripts that still use the --license or --administrator options. To update your scripts, use the --role option with these commands to specify the license levels or site roles. For details, see tabcmd Commands.

Updated tsm commands

As of version 2018.1 we have added or expanded the following tsm commands:

- tsm maintenace cleanup—The tsm maintenance cleanup command was added in version 10.5.1. For version 2018.1 it has been enhanced with additional options to give you more flexibility. For details, see tsm maintenance cleanup.
- tsm reset —Added in version 2018.1, this command allows you to reset the initial administrative user. For details, see tsm reset.

Updated upgrade-tsm script

As of version 2018.1 the upgrade-tsm script you run when you upgrade from a previous version now requires you to include the name of a TSM administrator when you run it. For example:

```
sudo /opt/tableau/tableau_server/packages/scripts.<version_code>/upgrade-tsm -u <tsm_system_admin> -p <tsm_system_admin_password> --accepteula
```

where `tsm_system_admin` is a user with administrative permissions on the initial node computer.

What Changed in Version 10.5
Version 10.5 includes some changes you should know about before upgrading.

The following sections summarize the significant changes to Tableau Server 10.5 and provide links for additional information.

- Tableau Server configuration changes
- Changes to extracts
- Version compatibility
- Viewer (can publish) and Unlicensed (can publish) site roles removed
- Nested projects and content navigation
- Nested projects and tabcmd
- Filtered search hidden by default

Tableau Server configuration changes

Hyper powers the new Data Engine in Tableau Server 10.5 and introduces the changes described below. For more information, see Tableau Server Data Engine.

Beginning with version 10.5, Tableau Installer automatically installs Data Engine when you install file store, Vizportal, VizQLServer, data server, or backgrounder and cannot be installed separately. Every node that has an instance of one of these processes will also have a single instance of the data engine process. You can no longer configure more than one instance of data engine on a node. To learn more about Tableau Server Processes see Tableau Server Processes.

Previously, in versions 10.4 and earlier, for distributed installations, the backgrounder process launched temporary instances of data engine (tdeserver64.exe) process during extract creation or refreshes. In Tableau Server 10.5, a single instance of data engine is installed
automatically when you install backgrounder. The backgrounder process uses this single instance of data engine that is installed on the same node. For more information on configuration recommendations, see Distributed Installation Recommendations.

Upgrade may affect your current configuration for a multi-node cluster, especially if you have certain processes isolated on a separate node. For more information, see Tableau Server Data Engine.

Changes to extracts

Beginning with version 10.5, new extracts use the new .hyper format. The improved data engine can read both the .tde and .hyper file formats, so the latest version of Tableau Server can continue to view and read workbooks that are using .tde extracts.

Existing extracts will not automatically be upgraded to the new .hyper format during the Tableau Server or Tableau Desktop upgrade process. Only when certain extract tasks are performed on the .tde extract, the extract is upgraded to the .hyper format. For example, an automatic or scheduled refresh will upgrade a .tde extract to a .hyper extract.

- For more information on extract upgrades, see Extract Upgrade to .hyper Format.
- For recommendation on how to handle automated or schedule refresh tasks before you upgrade, see Prepare for the Upgrade.

NOTE: Use the Extract API 2.0 to create (.hyper) extracts, which requires Tableau 10.5 and later. If you are using Tableau 10.4 and earlier, continue to use the Tableau SDK to create .tde extracts. The Tableau SDK is no longer being maintained. For more information, see Extract API 2.0.

Version compatibility

Upgraded extracts are not backward compatible. After extracts are upgraded from .tde to .hyper format, they cannot be opened or refreshed in Tableau Desktop 10.4 and earlier. Tableau recommends that Tableau Server and all Tableau Desktops in your organization be
on the same version and be upgraded to 10.5 on the same schedule. For more information on specific extract compatibility scenarios, see Impact of extract upgrade.

Viewer (can publish) and Unlicensed (can publish) site roles removed

The site roles **Viewer (can publish)** and **Unlicensed (can publish)** have been deprecated and are no longer available. Users who have either of these site roles on Tableau Server 10.4 or earlier will be reassigned in Tableau Server 10.5.

<table>
<thead>
<tr>
<th>Deprecated site role</th>
<th>In 10.5 is reassigned to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Viewer (can publish)</td>
<td>Viewer</td>
</tr>
<tr>
<td>Unlicensed (can publish)</td>
<td>Unlicensed</td>
</tr>
</tbody>
</table>

Nested projects and content navigation

You can now create project hierarchies when you want to segment content into sub-sections within a larger area. For example, you might create a project for each department. In each of those top-level projects, you can separate content based on how the audience uses it, such as connecting to certified data versus in-progress collaboration. For more information, see the following articles:

- Use Projects to Manage Content Access
- **Navigate projects** in the article *Navigate Tableau on the Web*

Nested projects and `tabcmd`

Using `tabcmd`, you can specify only a top-level project in a project hierarchy. To automate tasks you want to perform on a sub-project or content in a sub-project, you must use the equivalent Tableau REST API call.

Not all actions are available through the REST API. If you use Server on Windows and want to run an unscheduled extract refresh or append a file to an extract, a possible alternative is to use the Tableau Data Extract Command Line Utility.
Filtered search hidden by default

Filtered search options are now located on the right side of pages, and are hidden by default. The toggle is a dark icon (■■) when the Filters pane is open and a light icon (■■) when the Filters pane is closed. For details on searching, see Search Content.

To use filtered search, click ■■ ▼.

Minimum Hardware Requirements and Recommendations for Tableau Server

The following minimum hardware requirements and recommendations apply to all computers running Tableau Server, including physical hardware and virtual machines (VMs):

- **Minimum requirements for testing and prototyping** are the minimum hardware your computer must have in order to install Tableau Server. If your computer does not meet these requirements, the Setup program will not install Tableau Server. These
requirements are appropriate for testing and prototyping, but are not appropriate for most production environments.

- **Minimum recommendations for production** go beyond the minimum requirements, and represent the minimum hardware configuration you should use for a production installation of Tableau Server. If your computer meets the minimum requirements but does not meet these recommendations, the Setup program will display a warning, but you can continue the installation.

In addition, Tableau Server should not be installed on a physical computer or on a VM instance that is also running resource-intensive applications such as databases or application servers.

**Note:** If you install Tableau Server on a computer that meets the minimum requirements but does not have at least 8 cores and 16 GB of system memory, the default number of all processes installed is reduced to one of each process by design. For more information about processes, see Server Process Limits

Minimum Hardware Requirements for Testing and Prototyping

The computer on which you are installing or upgrading Tableau Server must meet the minimum hardware requirements. If the Setup program determines that your computer does not meet the following requirements, you will not be able to install Tableau Server.

These minimum requirements are appropriate for a computer that you use for prototyping and testing of Tableau Server. They apply to single-node installations and to each computer in a distributed installation.
### Minimum Hardware Requirements

**Note:** These minimum requirements are not recommended for use in production environments. For production minimum recommendations, see Minimum Hardware Recommendations for Production.

<table>
<thead>
<tr>
<th>CPU</th>
<th>RAM</th>
<th>Free Disk Space</th>
</tr>
</thead>
<tbody>
<tr>
<td>2-core</td>
<td>8 GB</td>
<td>15 GB</td>
</tr>
</tbody>
</table>

For the requirements:

- Free disk space is calculated after the Tableau Server Setup program is unzipped. The Setup program uses about 1 GB of space. You may need to allocate additional disk space depending on various factors like whether you will be using extracts. For more information, see Disk Space Requirements.

The core Tableau Server bits must be installed in the `/opt` directory where there is at least 15 GB of free disk space. You cannot change the installation path for Tableau Server. If you attempt to install Tableau Server on a computer that does not have enough space, the Tableau Server package will install, but you will be unable to continue with setup.

If you plan to make heavy use of extracts then you may need to allocate additional disk space. You can specify a different directory for data (extract) storage during installation. See Install and Initialize TSM.

- Core count is based on "physical" cores. Physical cores can represent actual server hardware or cores on a virtual machine (VM). Hyper-threading is ignored for the purposes of counting cores.
Minimum Hardware Recommendations for Production

For production use, the computer on which you install or upgrade Tableau Server should meet or exceed the minimum hardware recommendations. These recommendations are general. Actual system needs for Tableau Server installations can vary based on many factors, including number of users and the number and size of extracts. If the Setup program determines that your computer does not meet the following recommendations, you will get a warning, but you can continue with the setup process.

<table>
<thead>
<tr>
<th>Install Type</th>
<th>Processor</th>
<th>CPU</th>
<th>RAM</th>
<th>Free Disk Space</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single node</td>
<td>64-bit</td>
<td>8-core, 2.0 GHz or higher</td>
<td>32 GB</td>
<td>50 GB</td>
</tr>
<tr>
<td>Multi-node and enterprise deployments</td>
<td>Contact Tableau for technical guidance. Nodes must meet or exceed the minimum hardware recommendations, except nodes running backgrounder, where 4 cores may be acceptable.</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

For hardware recommendations for Tableau Server in the cloud, see the following:

- Selecting an AWS Instance Type and Size in the Tableau Server on Linux in the AWS Cloud Administrator Guide
- Selecting a Google Compute Engine Virtual Machine Type and Size in the Tableau Server on Linux in the Google Cloud Platform Administrator Guide
- Selecting a Microsoft Azure Virtual Machine Type and Size in the Tableau Server on Linux in Microsoft Azure Administrator Guide

Prepare for the Upgrade

To properly prepare for a Tableau Server upgrade, gather the following information about your existing installation, key files related to your installation and the upgrade, and complete
the pre-upgrade tasks.

Gather custom configuration information

If you are upgrading on the existing hardware your configuration will be preserved, but it's a good practice to collect this configuration information about your existing installation for several reasons: you need this information when you configure a test environment, you need this information if you are migrating to new hardware, migration as part of the upgrade, and you can use the information to confirm that the upgraded Tableau Server is configured as expected if you notice something unexpected after upgrading.

Collect this information and any associated files and save them to a location that is not on any of the Tableau Server computers.

The following list includes examples of the type of information you should gather:

- **TSM Controller certificate** Verify the certificate for the TSM Controller is still valid.

  To verify your TSM Controller SSL certificate's expiration date:

  1. Open a terminal session.

  2. Type the following commands to display the dates when the certificate is valid:

     openssl s_client -connect <tsm_servername>:8850

     echo | openssl s_client -connect <tsm_servername>:8850 2>/dev/null | openssl x509 -noout -dates

  3. If the certificate is expired, open a case with our Support team, and they will be happy to help with the upgrade.

- **Customizations** This includes non-default ports, timeout values, custom logo images, and fonts.

- **SMTP configuration.**

  For more information, see Configure SMTP Setup.
• **SSL** configuration and certificates.

  For more information, see Configure SSL for External HTTP Traffic to and from Tableau Server.

• **SAML** configuration, certificates and any IdP metadata files.

  For more information, see SAML.

• **Kerberos** configuration.

  For more information, see Configure Kerberos.

• **OpenID** configuration.

  For more information, see Configure Tableau Server for OpenID Connect.

• **Additional node** configurations. Collect the configurations of any additional Tableau Server nodes, including any certificates or other supporting files that you copied to these nodes.

• **Other** values. Note the number of projects, groups, workbooks, views, data sources, and users you have in your production environment. Having this information makes it easy to do a quick check after the upgrade to make sure everything was restored as expected.

Gather the environment configuration

The steps you need to take during the upgrade process depend on whether you're installing the upgrade on the same hardware or you're migrating to new hardware. Upgrading on the same hardware is straightforward and requires a minimum of manual steps (the steps you need to take depend on what version you are upgrading from, what version you are migrating to, and whether or not your existing installation is in the default location). Migrating to new hardware requires you to manually restore your Tableau Server data and reconfigure your settings after you install the new version.
Copy the setup files to a local file share

You will need the following setup files before you upgrade Tableau Server:

- The installer for your existing version of Tableau Server.

You might not need the installer. However, we recommend that you have it available in case there’s a problem during the upgrade. That way you can use the setup program and your server backup to restore your installation to its pre-upgrade state.

**Note:** If you do not have the installer for your existing version, you can download it from the [Alternate Downloads Site](http://example.com). Save the installer in a safe location that is not part of your production or test version of Tableau Server. You will need the Setup program if you need to go back to your existing version after upgrading.

- The setup program for the new version of Tableau Server.

Update tabcmd

A new version of tabcmd is released with every release of Tableau Server. If you install tabcmd on computers that are not part of your Tableau Server installation, you need to update tabcmd on those computers. For more information, see tabcmd.

Back up Tableau Server data

Make a backup of your installation of Tableau Server before beginning the upgrade process, and save the backup file to a safe location (a network share for example). Do not save it on any computer that is part of the Tableau Server installation. This backup provides data that you'll need to set up a test version of the upgraded environment. It also lets you recover if the upgrade process fails.
Notes:

- We recommend you disable subscriptions and scheduling in your production environment immediately before taking the backup, and reenable them after the backup is complete. Doing this will help avoid having your users receive duplicate subscriptions and email messages when you restore your backup in your test environment.

- The full backup can take a while if you have a large installation or a lot of extracts.

- Any changes made between the time you took the backup and the time you do the upgrade are lost because they aren’t included in the backup.

For more information, see Remove Unneeded Files and Back up Tableau Server data.

Save your asset keys file before uninstalling Tableau Server for Windows 2018.1.x or earlier

If you are upgrading from Tableau Server on Windows version 2018.1.x or earlier, and you generated a custom asset key, save a copy of the `asset_keys.yml` file before you uninstall your earlier version. Store this file in a safe place that is not part of your Tableau Server installation (a network share for example).

In most cases you will not need this file. The upgrade process updates asset keys automatically when an upgrade is successful. You only need this file if the upgrade fails and you need to install a new version of Tableau Server and manually restore your backup file. In this case, you also need to specify the asset keys file when doing the restore.

Locating an existing asset keys file

If you generated a custom asset key file, you will have an `asset_keys.yml` file in the data directory. By default this is:

```
\ProgramData\Tableau\Tableau Server\data\tabsvc\config
```

If you do not see an `asset_keys.yml` file, you can skip this.
Restoring a pre-2018.2 Tableau Server for Windows backup and specifying an asset keys file

To manually restore a backup from Tableau Servers for Windows 2018.1.x or earlier, and include asset keys, use tsm, for example:

```
tsm maintenance restore --file <backup> --ak <asset_key_file>
```

For more information, see tsm maintenance restore.

Check your product maintenance status

If you attempt to upgrade a Tableau Server installation that has a product key with expired maintenance, your upgraded Tableau Server will be unlicensed and the upgrade may fail. Before upgrading, make sure that the server’s maintenance hasn't expired.

If your maintenance has expired, select the product key and then click Refresh. If this does not update the maintenance date, check the Tableau Customer Portal for a replacement Tableau Server product key with a later maintenance date. For any questions or concerns, please contact Tableau Technical Support. Reactivating the product key will be part of the upgrade process.

For more information, see Activate and Register Tableau Server. If your server doesn’t have internet access, see Activate Tableau Server Offline.

Disable your extract refreshes

Beginning in 10.5, extracts use .hyper format instead of .tde. Once the file format has been upgraded to .hyper, it cannot be reverted back to .tde format and cannot be opened in Tableau Desktop version earlier than 10.5. For more information, see Extract Upgrade to .hyper Format.

The following tasks on Tableau Server will upgrade a .tde extract to a .hyper extract:

- Manual refresh
- A scheduled full or incremental extract refresh
• Automated refresh tasks that are performed through tabcmd, Extract API 2.0, or through Extract Command Line Utility

• Automated append data to an extract using tabcmd or using the Extract Command Line Utility

**Note:** We recommend that you disable any automated tasks and schedules that result in an extract upgrade. If you have desktop versions that have not yet been upgraded to 10.5, your desktop users will not be able to open the upgraded .hyper extracts. You may also want to first test a few extracts manually after doing the server upgrade, and then reenable any schedules or automated refresh tasks.

For more information about extract refresh scheduling, see Enable Extract Refresh Scheduling and Failure Notification.

**Plan your strategy if you use virtual machines (VMs)**

If you run Tableau Server on VMs, either locally, or in the cloud, be aware of the potential for complications related to licensing. If you are simply upgrading Tableau Server on the VM, you do not need to take any extra action related to licensing. If you plan to clone the VM to create either a new production or test environment to upgrade, you need to deactivate any Tableau Server licenses before cloning. If you do not do this, the new VM environment can end up with an untrusted license, and any attempts to upgrade will fail.

To clone a VM, make sure Tableau is unlicensed (all licenses are deactivated). After cloning the VM, activate the Tableau license there and proceed with the upgrade.

**Test the Upgrade**

The best way to learn what impact a Tableau Server upgrade will have to your current environment is to test it. Knowing how an upgrade will affect your users and your server helps you plan and communicate before the actual upgrade, ensuring that your users will not be caught by surprise.
If you have a Tableau Server test environment this is a great place to test out the upgrade.

We recommend the following sequence for testing a Tableau Server upgrade:

1. Prepare a test environment
2. Upgrade the test environment
3. Confirm that existing functionality works
4. Performance and user acceptance testing
5. Test new features
6. Communicate about the upgrade

Prepare a test environment

To start, create a test environment that mirrors your production environment as closely as possible. The closer your test environment is to the actual environment you will be upgrading, the more accurate a representation you will have of how the upgrade will impact you. This includes identical or similar hardware and operating systems, as well as the same authentication options and network access.

When you’ve got a test computer or virtual machine ready, follow these steps for creating a test environment.

1. On the existing production environment, create a backup of Tableau Server using the `tsm maintenance backup` command.

   For more information, see Create a pre-upgrade backup.

2. On your test environment, install a copy of the same version of Tableau Server as you have in your production environment.
Note: You can download the setup program for your current version from the Alternate Downloads Site.

3. Restore your existing database data using the `tsm maintenance restore` command.

   For more information, see Restore from a backup.

4. Manually replicate your existing Tableau Server configuration.

   You need to manually configure certain aspects of your environment because when you restore the Tableau database it doesn’t include configuration details and customizations.

Upgrade the test environment

Follow the appropriate steps for upgrading the test environment, based on your environment:

- Upgrade Tableau Server
- Upgrade Tableau Server on Linux from 10.5

Confirm that everything works as expected

After you have the new version of Tableau Server installed and configured in your test environment, you are ready to test. You should test basic functionality, along with any special aspects of server that your organization relies on. For example, if there are key subscriptions that your organization relies on, make sure that you test those.

These are some areas of testing to consider:

- **Server processes.** Sign in to Tableau Server as a server administrator, and then open the Server Status page to confirm that all services and processes are running as expected (including on all additional nodes if this is a distributed installation).
• **User access.** Confirm that Tableau Server users can sign in. Test your normal user sign in process. Have some of your users participate in the testing to make sure they are able to sign in as expected, and that they can get to the same content that they have access to in your production environment.

• **Publishing workbooks and data sources.** Have users publish workbooks and data sources from Tableau Desktop to make sure this goes as you expect.

• **Viewing published workbooks.** Have users who are familiar with the content try to view published workbooks to make sure they appear as expected. Test views embedded in web pages (for example, in SharePoint pages).

• **Subscriptions and extract refreshes.** Manually run some extract refreshes to confirm that they complete successfully. Run some key scheduled extract refreshes to confirm that they complete as expected.

• **Permissions.** Confirm that permissions are still set as expected for users and content.

• **Command-line utilities and APIs.** If applicable, test the command line utilities (tsm and tabcmd) and programmatic access via APIs.

**Performance and user acceptance testing**

Use tools like Tabjolt, Replayer, and Scout to do performance and user acceptance testing on your test environment. For more information about these and other performance testing tools, see Performance Resources. If you have workbooks that have calculations and use extracts as the data source, we recommend that you test the performance of these workbooks before you upgrade. For more information, see Test Workbook Performance.

**Test new features**

Take a look at the new features that come with the version you are upgrading to, and at any features that were added between the version you currently have and the new version. Think about how to help your users understand the benefits of the features that apply to your environment.
For more information on new features, see What's New in the Tableau Server Help.

Communicate about the upgrade

The best way to make an upgrade go smoothly is by letting your organization know ahead of time about the upgrade and how it might impact them. If you've had users help test, take advantage of their experience by having them help communicate the changes they saw while testing. You can also provide user access to the test environment if there are key people who should see the upgraded version before the actual upgrade.

Test Workbook Performance

In most cases, you can expect to see similar or better performance after upgrading your Tableau Server from versions 10.4 or earlier to 10.5 or later. However, for workbooks that use complex calculations, you may see performance issues after you upgrade. This article describes how to test performance and troubleshoot these performance issues before you upgrade your production Tableau Server from versions 10.4 and earlier to 10.5 or later.

If you have already upgraded your production Tableau Server to 10.5 or later, and you are seeing performance issues for workbooks that have calculations and use extracts as the data source, see Troubleshoot Performance of Workbooks with Calculations.

Since Linux was first released in 10.5, this only applies when you are migrating from Tableau Server versions 10.4 or earlier on Windows to Linux 10.5 or later.

To make sure your workbook performance is same or better after your upgrade to Tableau 10.5 or later, we strongly recommend that you set up a test environment and do performance testing before you upgrade your production Tableau Server.

Use the following sequence of steps for testing workbook performance:

1. Set up your test environment
2. Capture performance metrics and analyze
3. Troubleshoot performance issues
4. Capture the conclusions and results
Set up your test environment

1. Create a test environment that mirrors your production environment as closely as possible.

   Follow the steps described in Migrate Tableau Server from Windows to Linux.

2. Disable any automated or scheduled extract refresh schedules.

Capture performance metrics and analyze

1. Run Tabjolt or any other tool of your choice to capture performance metrics on your current version of Tableau Server to set a baseline. Use workbooks that have calculations and use extracts as the data source for testing. For more information about how install and use Tabjolt, see the Tabjolt Installation Guide.

2. Perform a full backup to capture the metrics from the first step.

3. Upgrade your test environment to 10.5.3 or later. We are recommending 10.5.3 as the minimum version since the settings you need to enable in order to resolve performance issues later on are only available in 10.5.3 or later versions of Tableau.

4. **Checkpoint:** Run Tabjolt to compare workbook performance before and after upgrade.

   If you see performance degradation after upgrade at this step, it may be due to other Tableau Server issues and might require further investigations. For more information, see Record and Analyze Workbook Performance.

   If you see no difference in performance before and after upgrade, continue to the next step.

5. Select a subset of workbooks and run a full refresh of the extracts. Doing a full refresh will upgrade the extracts from .tde to .hyper.

6. **Checkpoint:** Run the tool again to compare the performance of your workbooks between step 4 and step 6 which is essentially before and after doing extract
refreshes. Specifically, check for workbooks with slower response times or failure to load.

Troubleshoot performance issues

If you find that you are unable to test due to performance issues, or you find that VizQL server is consuming all or most of the available memory on the machine while viewing them, follow steps 1 through 3.

For workbooks that load successfully, but have slower response after upgrade, follow steps 4 and 5.

1. Enable the following setting that checks the number of query nodes required for Tableau to generate the workbook and displays an error when the set limit is exceeded. This helps prevent VizQL process from consuming the memory resources on the machine that might result in critical Server issues:

   Use TSM CLI to run the following commands:

   tsm configuration set -k native_api.node_limit_checker_pre_rewrite_disable -v false

   tsm pending-changes apply

   **Note:** This setting is only available in Tableau Server 10.5.3 or later. While enabling this setting improves the reliability and stability of Tableau Server, you may see errors on a very small percentage of workbooks with when you enable this setting. For example, the Tableau team saw errors on 0.01% of the workbooks with this setting enabled on Tableau Online.

2. Test the workbooks by viewing or interacting with them. You should see an error message informing you about exceeding the node limits on workbooks that have performance issues - The error message might say something like: "Logical Query tree
has 2348182 nodes, maximum number allowed is 1000000..."

3. Use Tableau Desktop to troubleshoot your workbook performance. Run this command to enable the node limit check in your Tableau Desktop:

   \texttt{tableau.exe -DNodeLimitCheckerPreRewriteDisable=false}

   **Note:** This setting is only available in Tableau Desktop 10.5.3 or later.

   In Tableau Desktop, download and open the workbooks that displayed the error message about high node limits in step 2. Try optimizing the performance of workbooks using methods described in the Best Practices for Creating Calculations in Tableau topic. If successful, then publish them to Tableau Server. If you are still experiencing performance issues, continue to the next step.

4. For workbooks that load successfully, but the overall response times is slower after upgrade, try using the Compute Calculations Now option. If you have a large number of workbooks that fall under this category, consider enabling the server wide setting to retain materialized calculations for all extracts when they are upgraded from .tde to .hyper:

   Use TSM CLI to run the following commands:

   \texttt{tsm configuration set -k native_api.preserve_calculations_on_hyper_refresh_conversion -v true}

   \texttt{tsm pending-changes apply}

   **Considerations for turning on this setting:**

   Turn this setting on only if majority of your workbooks require calculations to be materialized. There are resource and time costs associated with this setting, as described below:
When this setting is set to true, the extract file size will increase, affecting the overall disk space.

Extracts with materialized calculations take a longer time to refresh than extracts without materialized calculations.

This setting only affects extracts that are not yet upgraded to .hyper. Extracts already upgraded to .hyper before turning on this setting will not have the calculations materialized. This setting will also not affect workbooks and extracts published from Tableau Desktop, or any new extract refreshes published to Tableau Server that do not use the **Compute Calculations Now** option.

**Note:** This setting is only available in Tableau Server 10.5.3 or later.

5. Enable the extract refresh schedules and monitor the performance of your workbooks to make sure that your workbooks are performing as expected.

Capture the conclusions and results from your testing

Make a note of the settings and steps that helped resolve the performance issues to use them to prevent performance degradation when you upgrade your Production Tableau Server.

For example, if during your testing, you found that you needed to set the `native_api.preserve_calculations_on_hyper_refresh_conversion` setting to true, remember to disable your extract refreshes just before you upgrade your production Tableau Server.

**After upgrade, set the `native_api.preserve_calculations_on_hyper_refresh_conversion` setting to true,** and then re-enable your extract refreshes after you have confirmed that you are not experiencing slow response times after upgrade.
Perform the Upgrade

After you’ve completed the tasks in Prepare for the Upgrade, you’re ready to upgrade your existing Tableau Server installation to version 2018.2

As a best practice, you should always make a backup of your Tableau Server data before upgrading, and save this backup in a safe place that is not part of your Tableau installation. This backup preserves your Tableau data if something unexpected happens during the upgrade, or if you need to go back to your previous version of Tableau Server. For more information, see Back up Tableau Server data.

Upgrade Tableau Server

To upgrade Tableau Server you install the new version while your existing version is running, then run an upgrade script to switch over to the new version. This reduces the amount of downtime for users because the server continues to run while you install the new version. You only stop the server to run the upgrade script.

**Important:** Upgrading Tableau Server on Linux from version 10.5.x (10.5.0 or later) requires special steps that are documented separately. For instructions for how to upgrade from 10.5.x, see Upgrade Tableau Server on Linux from 10.5.

General notes about upgrading:

All upgrades:

- **Backup**—Create a backup. You are responsible for creating a backup of your existing Tableau Server data before upgrading. We strongly recommend creating a backup before upgrading as this provides you with an up-to-date version of your data you can use if you need to go back to your earlier version of Tableau Server. For more information on properly preparing for an upgrade, see Prepare for the Upgrade.

- **Licenses**—
- Trial product keys—You cannot directly upgrade a server that is running a trial product key from one major version to another (for example, from version 10.5.x to version 2018.x). To upgrade from one major version to another with a trial product key, install the new version of Tableau Server on a separate machine, activate a trial key there, and restore a backup from your existing version. For more information, see Confirm licensing requirements.

- Expired maintenance—You cannot upgrade a server with a product key whose maintenance has expired or expires on a date earlier than the release date of the version you are upgrading to. If you attempt to upgrade a server in this state, your server will be unlicensed and the upgrade may fail. If your maintenance has expired or is too old, refresh your product key before you run the upgrade script to upgrade to your new version. If refreshing the key does not update maintenance to a valid date, check in the Tableau Customer Portal for a Tableau Server key with current maintenance.

- Install while running—When you upgrade Tableau Server, you install the new version before uninstalling the old version. The upgrade process will leave the old version in place. You can uninstall the old version after the upgrade is complete to free up disk space, though this is not required.

- Upgrade script—To complete the upgrade and switch to the new version, after installing the new version on all nodes in your cluster, run the upgrade script, upgrade-tsm from the \scripts.<version_code> directory of the new version you just installed.

Multi-node upgrades:

- Node installation—Run the installer on all nodes in a cluster.

The steps below describe the general process for an upgrade of Tableau Server on Linux. Upgrades from beta versions of Tableau Server on Linux are not supported. If you are a Tableau Server on Windows user and want to switch to Tableau Server on Linux, see Migrate Tableau Server from Windows to Linux.
As a best practice you should always make a full backup before upgrading any version of Tableau Server. Save this backup file to a location that is not part of your server installation. Creating and saving a backup preserves your pre-upgrade data and configuration and gives you a rollback option in the event of issues during the upgrade. For more information, see Back up Tableau Server data.

When upgrading Tableau Server on Linux, you do not need to uninstall the previous version. After upgrading you can uninstall the package for the previous version if you choose to do so. One reason to do this is to free up disk space used by the older version. To understand the difference between removing and uninstalling Tableau Server on Linux, see Uninstall Tableau Server.

Upgrading Tableau Server requires a stop and start the server as part of the upgrade process. During this stop/restart Tableau Server is unavailable.

Upgrading will also apply any pending changes. If you have pending changes you do not want applied, you can discard those changes using the `tsm pending-changes discard` command. To see what changes might be pending, use the `tsm pending-changes list` command.

Upgrading Tableau Server on Linux

Follow these steps on each node in your cluster to upgrade Tableau Server.

1. On each node in your cluster:
   a. Copy the new Tableau Server .rpm or .deb package to a location accessible from the computer you are upgrading.

   If you are upgrading a distributed deployment of Tableau Server, then copy the .rpm or .deb package to each node in the cluster or to a location accessible from each node.
b. Log on as a user with sudo access to the computer you are upgrading.

c. Navigate to the directory where you copied the .rpm or .deb Tableau Server package.

d. Use the package manager to install the Tableau Server package.
   - On RHEL-like distributions, including CentOS, run the following command:
     
     ```bash
     sudo yum install tableau-server-<version>.x86_64.rpm
     ```
   
   - On Ubuntu, run the following commands:
     
     ```bash
     sudo gdebi -n tableau-server-<version>_amd64.deb
     ```

2. After you have installed the new package on every node in your cluster, stop Tableau Server:

   ```bash
   tsm stop
   ```

3. With Tableau Server stopped, run the following command on the initial node. Do not run this command on multiple nodes:

   ```bash
   sudo /opt/tableau/tableau_server/packages/scripts.<version_code>/upgrade-tsm -u <system_admin> --accepteula
   ```

   where `<version_code>` is the long form of new version you are upgrading to, for example `scripts.20183.18.1128.2033`, and `<system_admin>` is a user with administrative permissions on the computer where the initial node is installed. You will be prompted for the password for the administrative user.

   The `-u` option was added as of 2018.1. For more information, see Updated upgrade-tsm script. To see all the options available for the `upgrade-tsm` script, use the `-h` option. For example:

   ```bash
   sudo upgrade-tsm -h
   ```
upgrade-tsm -h

4. After the upgrade is completed, exit the terminal session on the initial node and log in again. This ensures that your session will be using the updated TSM version.

5. Start Tableau Server:

   tsm start

- Common Tableau Server Upgrade Issues

Upgrade Tableau Server on Linux from 10.5

When you upgrade Tableau Server on Linux from version 10.5, you need to take several unique steps to complete the upgrade. These are necessary because of a change made after version 10.5.0 released, related to sudo privileges. For more information, see System User, sudo Privileges, and systemd. You only need to do these extra steps once, during the upgrade to 2018.1. This topic describes how to upgrade from version 10.5.0 or 10.5.x (10.5.1 or later) to version 2018.x (2018.1 or later).

If you attempt to upgrade from 10.5.0 or 10.5.x without following these instructions, warnings are displayed and the upgrade is canceled. You will not break your existing Tableau Server installation, but you cannot continue the upgrade.

To identify the version of your installation, see View Server Version.

Follow these steps to upgrade from 10.5.0:

1. Upgrade to 10.5.x—If you are running version 10.5.0, you must first upgrade to 10.5.x (10.5.1 or higher) by installing 10.5.x and running the upgrade-tsm script in the 10.5.x scripts directory.

2. Install 2018.x—With 10.5.x installed and running as expected, install 2018.x but do not upgrade to this version yet.

3. Run TSM commands—Use TSM to stop the server and run three additional
commands.

4. Migrate 10.5.x to single user—Run the migration script in the 2018.x scripts directory. Do this on every node in your cluster.

5. Upgrade to 2018.x—Upgrade Tableau Server by running the upgrade-tsm script from the 2018.x scripts directory.

Upgrade to 10.5.x

If you are running version 10.5.0 of Tableau Server on Linux, the first step you need to take is to upgrade to a later version of 10.5. Beginning with version 10.5.1 changes were made that are needed in order to upgrade to 2018.1 or later. (If you are already on a version of 10.5 that is higher than 10.5.0, you can skip to the Install 2018.x step.)

To upgrade from 10.5.0 to a later version of 10.5:

1. On each node in your cluster:
   a. Copy the Tableau Server version 10.5.x .rpm or .deb package to location accessible from the computer you are upgrading.

      If you are upgrading a distributed deployment of Tableau Server, copy the .rpm or .deb package to each node in the cluster or to a location accessible from each node.

   b. Log on as a user with sudo access to the computer you are upgrading.

   c. Navigate to the directory where you copied the .rpm or .deb Tableau Server package.

   d. Use the package manager to install the Tableau Server package.

      • On RHEL-like distributions, including CentOS, run the following command:
sudo yum install tableau-server-<version>.x86_64.rpm

- On Ubuntu, run the following commands:

  sudo gdebi -n tableau-server-<version>_amd64.deb

2. Stop Tableau Server. If you are upgrading a cluster, do this after you have installed the new package on every node in your cluster.

   tsm stop

3. With Tableau Server stopped, run the following command on any one node. Do not run this command on multiple nodes:

   sudo /opt/tableau/tableau_server/packages/scripts.<version_code>/upgrade-tsm --accepteula

   where <version> is the 10.5.x version you are upgrading to.

   To see all the options available for the upgrade-tsm script, use the -h option. For example:

   upgrade-tsm -h

4. After the upgrade is completed, ensure your session is using the updated TSM version by doing one of the following:

   - Use the source command:

     source /etc/profile.d/tableau_server.sh

   - Exit the terminal session on the initial node and log in again.

5. Start Tableau Server:

   tsm start
Install 2018.x

Install the Tableau Server 2018.x package but do not upgrade to this version yet. Before you do so, you need to run several commands and a migration script. You can install the 2018.x package without stopping the server. When you install the new package you are copying the software to your computer but not changing anything about the currently running version.

To install the 2018.x package, on each node in your cluster:

1. Copy the Tableau Server 2018.x .rpm or .deb package to location accessible from the computer you are upgrading.

   If you are upgrading a distributed deployment of Tableau Server, then copy the .rpm or .deb package to each node in the cluster or to a location accessible from each node.

2. Log on as a user with sudo access to the computer you are upgrading.

3. Navigate to the directory where you copied the .rpm or .deb Tableau Server package.

4. Use the package manager to install the Tableau Server package.

   - On RHEL-like distributions, including CentOS, run the following command:

     ```
     sudo yum install tableau-server-<version>.x86_64.rpm
     ```

   - On Ubuntu, run the following commands:

     ```
     sudo gdebi -n tableau-server-<version>_amd64.deb
     ```

Run TSM commands

Using version 10.5.x of Tableau Server that is installed and running:
1. Stop the server:

   tsm stop

2. Run these three commands:

   tsm configuration set -k service.linux.privileged_user -v 'tableau'

   tsm configuration set -k install.username -v 'tableau'

   tsm pending-changes apply

   where 'tableau' is the user name you specified with the initialize-tsm -- unprivileged-user option when you first installed 10.5.x. If you did not specify a user, the default is 'tableau'.

Migrate 10.5.x to single user

Run this script from the 2018.x scripts directory:

   sudo /opt/tableau/tableau_server/packages/scripts.<version_code>/migrate-to-single-user

   where <version> is your 2018.x version number.

   **Important:** If you have a multi-node installation, you must run this script on every node in your cluster.

At this point Tableau Server is running 10.5.x but configured to work with a single user. This is an interim stage. You should complete the upgrade to version 2018.x before using Tableau.

Upgrade to 2018.x

After completing the above steps:
1. Run the upgrade-tsm script for 2018.x:

```bash
sudo /opt/tableau/tableau_server/packages/scripts.<version_code>/upgrade-tsm -u <tsm_system_admin> -p <tsm_system_admin_password> --accepteula
```

where `<version_code>` is the long version of the 2018.x version you are upgrading to, and `<system_admin>` is a user with administrative permissions on the computer where the initial node is installed. You will be prompted for the password for the administrative user.

The `-u` option was added as of 2018.1. For more information, see Updated upgrade-tsm script. To see all the options available for the `upgrade-tsm` script, use the `-h` option. For example:

`upgrade-tsm -h`

**Note:** If Tableau Server is not stopped the script will not run.

2. After the upgrade is completed, ensure your session is using the updated TSM version by doing one of the following:

   - Use the source command:

     ```bash
     source /etc/profile.d/tableau_server.sh
     ```

   - Exit the terminal session on the initial node and log in again.

3. Start Tableau Server:

   `tsm start`

When desired, you can remove Tableau Server on Linux version 10.5 from your server. Unlike most other programs that run on Linux, previous Tableau Server versions are not
automatically removed as part of a successful upgrade. To learn more, see Remove Tableau Server from Your Computer.

- Common Tableau Server Upgrade Issues

Troubleshoot Tableau Server Install and Upgrade

Follow the suggestions in this topic to resolve common issues with Tableau Server. For additional troubleshooting steps based on process status viewed on the Status page, see Troubleshoot Server Processes.

In this article

- General Troubleshooting Steps
- Common Tableau Server Install Issues
- Common Tableau Server Upgrade Issues
- Troubleshooting connections to TSM
- Starting Tableau Server
- Reindexing Tableau Server Search & Browse
- Activating Tableau Server

General Troubleshooting Steps

Many Tableau Server issues can be addressed with some basic steps:

1. Make sure there is enough disk space on each computer running Tableau Server. Limited disk space can cause a failure to install, a failure to upgrade, or problems running Tableau Server.

2. Restart Tableau Server. Issues related to indexing and processes not fully started can
be resolved by restarting Tableau Server in a controlled way. To restart Tableau Server, use the `tsm restart` command. This will stop all the processes associated with Tableau Server and then restart them.

Common Tableau Server Install Issues

Unable to log into TSM or Tableau Server (sign in screen redisplays after entering credentials)

Using Internet Explorer or Edge, if you enter your credentials into the TSM or Tableau Server sign-in screen and the page redisplays without signing you in, verify that the hostname or domain in your URL does not include an underscore (_). If the hostname or domain of the Tableau Server computer includes an underscore (_) Internet Explorer or Edge browsers will not set a cookie, so the page will redisplay without signing you in. To work around this, use "localhost" or the IP address of the computer in the URL. For example: [https://localhost:8850](https://localhost:8850).

For more information, see the Tableau Knowledge Base.

Multiple install attempts fail

If you attempt to install Tableau Server and the install fails, any subsequent installation attempts are likely to fail unless you run the `tableau-server-obliterate` script to clean Tableau off the computer.

A failed install attempt can leave the computer in a state that causes subsequent attempts to also fail with errors that don’t seem directly related to a previous install attempt. One possible error is:

```
Enabling and starting all services
+ services=(appzookeeper* tabadmincontroller* tabsvc*
licenseservice* fnplicenseservice* tabadminagent* cli-
entfileservice*)
+ systemctl_user enable appzookeeper_0.service
'tabadmincontroller*' 'tabsvc*' 'licenseservice*'
```
fnplicenseservice_0.service 'tabadminagent*' 'clientfileservice*' 
++ id -ru a_tabadminpoc  
+ local unprivileged_uid=222954
+ su -l a_tabadminpoc -c 'XDG_RUNTIME_DIR=/run/user/222954 systemctl --user enable appzookeeper_0.service tabadmincontroller* 
tabsvc* licenseservice* fnplicenseservice_0.service tabadminagent* clientfileservice*' 
Failed to execute operation: No such file or directory

To fix this problem, run the tableau-server-obliterate script to clean up any leftover remnants of the previous install attempt and then restart the computer. For more information, see Running the tableau-server-obliterate script.

**Important:** If you created a backup of Tableau (<file>.tsbak) you want to keep (for example, to restore to your new installation), copy that file to a safe location on another computer to guarantee it is not removed when you clean up your Tableau computer.

Install fails due to hardware requirements

Tableau Server cannot install if the computer you are installing on does not meet the minimum hardware requirements. The requirements apply to all computers on which you are installing Tableau Server. For details on minimum hardware requirements, see Minimum Hardware Requirements and Recommendations for Tableau Server.

Common Tableau Server Upgrade Issues

Upgrade logs location

The upgrade log, app-upgrade.log, is located in /var/opt/tableau/tableau_server/logs.
Upgrade multi-node, initializing additional node fails with "Enter your credentials again" error.

If you attempt to initialize an additional node when upgrading Tableau Server and see this error:

Enter your credentials again. The credentials you enter must provide administrative access to the computer where you generated the configuration file.

this is an indication that the node is unable to connect to or communicate with the initial node. This can happen for multiple reasons:

- The credentials you entered are not valid or you mistyped them. The credentials must be for a user who has administrative permissions on the computer where Tableau Server was first installed. You do not need to use the credentials of the user who created the bootstrap file but doing so will ensure you are using valid credentials.

- The local firewall of the computer you are trying to add is not allowing communication to the initial node. For more information, see Local firewall configuration.

- The nodes are on different subnets. In distributed installations, all nodes should be installed on the same subnet. For more information, see Distributed Requirements.

Upgrading fails due to lack of disk space

If there is not enough disk space for the Tableau Server Setup program to run and do the upgrade, the installation will fail. The amount of disk space required will depend on the size of your repository database and the number and size of your extracts. As a part of upgrading to version 9.0, the Setup program migrates extracts to the new File Store and this takes space.

To free up disk space:
1. Create a log archive snapshot using the `tsm maintenance ziplogs` command.

   After you create the ziplogs file, save it to a safe location that is not part of your Tableau Server installation.

2. Clean up unnecessary files using the `tsm maintenance cleanup` command. For more information, see Remove Unneeded Files.

Troubleshooting connections to TSM

Starting Tableau Server

Tableau Server cannot determine if it fully started

In some instances Tableau Server may report that it could not determine if all components started properly on startup. A message displays: "Unable to determine if all components of the service started properly."

If you see this message after starting, verify that Tableau Server is running as expected by using a `tsm status -v` command.

If the status shows as running ("Status: RUNNING"), then the server successfully started and you can ignore the message. If the status is DEGRADED or STOPPED, see "Tableau Server doesn't start" in the next section.

Tableau Server doesn't start

If Tableau Server does not start or is running in a degraded state, run the `tsm restart` command from a command prompt. This will shut down any processes that are running, and restart Tableau Server.

Reindexing Tableau Server Search & Browse

Problems that can be solved by reindexing Search & Browse

Symptoms of an index that needs to be rebuilt include:
- A blank list of sites when a user attempts to log in
- A blank list of projects when a user tries to select a project
- Missing content (workbooks, views, dashboards)
- Unexpected or inaccurate alerts (for example, an "refresh failed" alert on a workbook that does not include an extract)

If you see any of these behaviors, rebuild the Search & Browse index using the `tsm maintenance reindex-search` command.

Activating Tableau Server

Tableau Server license activation fails

In some instances Tableau Server license activation may fail. Error messages can range from a very generic one:

- An error has occurred

To more specific messages:

- Function flxActCommonLicSpcPopulateFromTS returned error 50030, 71521,

- No license found for 'Tableau Server'

To resolve this issue, try these solutions in the order listed:

Confirm you can access the licensing server

The Tableau licensing service was moved to a new data center on October 6, 2018. This means any environments that required special configuration (static IP safe listing for example) to access licensing.tableau.com or licensing.tableausoftware.com will need to be updated before you can activate, refresh, or deactivate a Tableau product key.

Tableau Server needs to connection to the following internet locations for licensing purposes:
- licensing.tableau.com:443
- atr.licensing.tableau.com:443
- o.ss2.us
- ocsp.rootg2.amazontrust.com
- ocsp.rootca1.amazontrust.com
- ocsp.sca1b.amazontrust.com
- crt.sca1b.amazontrust.com
- crt.rootca1.amazontrust.com
- ocsp.sca0a.amazontrust.com
- crt.sca0a.amazontrust.com
- ocsp.sca1a.amazontrust.com
- crt.sca1a.amazontrust.com
- ocsp.sca2a.amazontrust.com
- crt.sca2a.amazontrust.com
- ocsp.sca3a.amazontrust.com
- crt.sca3a.amazontrust.com
- ocsp.sca4a.amazontrust.com
- crt.sca4a.amazontrust.com

Requests to the above domains may be on port 80 or 443.
Verify the date and time

Verify the date and time on the initial Tableau Server computer is correct. If the clock is set to a time and date earlier than the current date, Tableau Server cannot be activated.

Force the product key to be read again

1. On the initial Tableau Server computer, sign in as administrator and open a command prompt.

2. Change to the Tableau Server bin directory. By default this is:

   `/opt/tableau/tableau_server/packages/bin.<version_code>/`

3. Type the following commands:

   ```
   tsm stop
   ./lmreread
   tsm start
   ```

Send the contents of trusted storage to Tableau Support

If FlexNet Licensing Services is installed and running but you’re still seeing an error, there might be a problem with the Tableau product key information. To resolve this issue, complete the following steps to create a file of the key Tableau licensing information located in trusted storage.

1. On the initial Tableau Server computer, sign in as administrator and open a command prompt.

2. Type the following command:

   ```
   serveractutil -view > <machine_name>-LicResults.txt
   ```

   This creates the `<machine_name>-LicResults.txt` file in your current directory. If you don't have write permissions for that location and see an error, change
to a location where you do have permission to create a file and run the command again.

3. Contact Tableau Support (http://www.tableau.com/support/request) and include the <machine_name>-LicResults.txt file that you created.
What is a site

You might be used to using the term *site* to mean “a collection of connected computers,” or perhaps as the short form of “website.” In Tableau-speak, we use site to mean a collection of users, groups, and content (workbooks, data sources) that’s walled off from any other groups and content on the same instance of Tableau Server. Another way to say this is that Tableau Server supports multi-tenancy by allowing server administrators to create sites on the server for multiple sets of users and content.

All server content is published, accessed, and managed on a per-site basis. Each site has its own URL and its own set of users (although each server user can be added to multiple sites). Each site’s content (projects, workbooks, and data sources) is completely segregated from content on other sites.

**Note:** This article pertains to configuring sites on Tableau Server deployments. For Tableau Online, see [Site Administrator Role and Tasks](#).
In this article

Site administrator tasks
Steps for setting up your site
See also

Site administrator tasks

Where the Server Administrator site role gives a user unrestricted access to the entire Tableau Server deployment, the Site Administrator site roles give a user unrestricted or minimally restricted access at the site level. The differences between Site Administrator Creator and Site Administrator Explorer are in the level of data connection and publishing access. Both site roles allow administering the site itself and managing site users. For more information, see Set Users' Site Roles.

Although a server administrator can work at both the server and site levels, we make a distinction between the two levels of task. The site administrator is typically in charge of creating and maintaining the framework that enables Tableau users in the organization to publish, share, manage, and connect to data sources and workbooks. In this vein, site administrator tasks include any of the following (and both site roles allow this level of access):

- Creating project hierarchies to organize the site’s data sources and workbooks.
  
  This can include delegating project-level management to project leaders.

- Creating groups and assigning permissions that allow users to access only the content they need.

- Adding and removing users, assigning their site roles.
  
  This is allowed by default on a site; however, a server administrator can restrict this access to the server level only.
• Managing the site’s extract and subscription schedules.

• Monitoring site activity.

For more information about the distinction between server administrator and site administrator, see Administrator-level access to sites, in the Manage Server section.

Steps for setting up your site

The table below shows a loose sequence of steps for setting up a site, along with links to topics where you can get more information. You can complete the steps in any order that makes sense for you.

However, before you perform the steps to configure the site, we recommend spending some time with the articles in this section, learning about site authentication, site roles, projects, and permissions. Ideally you would document a plan for your projects, groups, and overall permissions strategy. Then set up a few projects and add a preliminary set of users, to test the plan and resolve issues before you add the remaining users. You can change many site settings after your users are working with the site, but try to go in with the intention of minimizing post-production changes.

If you are a server administrator on your Tableau Server deployment, you can learn more about sites, when to use them (vs. projects), and more in Sites Overview, in the Manage Server section.
Planning a Site

Before you add users and content to a site, we recommend that you plan the following aspects of the site.

- Projects
- Users and groups
- Site roles and permissions
- Extract refresh schedules
- Steps for setting up your site

The subsequent sections go over these site components, assuming that you are familiar with

**Note:** This article and section apply only to self-managed Tableau Server deployments on-premises or in the cloud. If you use Tableau Online, see Manage Content Access.

Projects

You can create projects on a site, which act as containers in which you can organize related content assets (such as data sources and workbooks). For example, you might set up a project to contain all of the certified data sources and workbooks your organization uses for mission-critical decisions. Or you might set up projects by department.

Projects are also useful for managing permissions. Once you know how your users need to access content, it’s usually easier to create projects based on those the type of content, and maintain permissions at the project level.

Every site has a default project named **Default**. When you create projects, the new projects get their initial set of permissions from the default project. In effect, the default project is a template for new projects. As we explain in related articles, for most environments, we
recommend that you use the Default project only as a permissions template, and not as a container for published content.

For more information, see Use Projects to Manage Content Access.

Users and groups

Any user who will publish content or access published content on a site must be able to sign in to the site. If the user already has an account on the server, you’ll need to add that user to the appropriate site. You can add a user to more than one site as well. If the user doesn’t already exist, you need to create a user account. Either way, make a list of the users who will need to be able to sign in to each site.

**Note:** The server license might restrict how many users you can have, or what level of access they can have. Check with the server administrator to make sure that you’ll be able to have an account for all your users.

In general, we recommend that you create groups on the server and then add users to the groups. This helps to make permissions much easier to manage. You can assign permissions on groups, to give those permissions to all users in the group. (See the next section.)

A typical strategy is to create groups for users who use content in similar ways. For example, you might create a group named SalesWBPublishers for all the users in the Sales department who publish workbooks, and a separate group named SalesDSPublishers for people in Sales who publish data sources. Each of these sets of users needs its own set of capabilities, so it makes sense to have a group for each for these needs.

Site roles and permissions

Each user has a site role that determines the maximum permissions that they can have on the site. As part of your site planning, you need to decide each user’s site role. A user with a site role that’s too restrictive might not be able to do the work they need. By the same token,
a security best practice is to limit users’ capabilities to only those that they need to do their work. This is referred to as following the principle of least privilege.

You or a site administrator you delegate this task to must also determine the permissions a user needs to work with content. Each content asset (workbook, data source, project) supports a set of capabilities. For example, you can View or Add Comments to a workbook. Before a user can perform tasks on a workbook, their permissions must allow those capabilities. A recommended practice is to sketch out a mapping of permissions to users outside of Tableau before you try to set this up on the server.

Permissions determine what a user can do within the context of the site role. A user whose site role is Viewer can never publish to the site, regardless of the permissions you grant them. A user whose site role is Creator can publish a workbook to the site, but only if that user has permission to save and view workbooks.

Extract refresh schedules

If users publish data sources or workbooks that include extracts, you usually want to make sure that the extracts are refreshed, so that they contain the latest data. Users can manually refresh an extract, but this isn’t always a good idea if the extract is large, and the refresh takes a long time. Instead, you can set up schedules for when an extract should be refreshed. Another planning task for a site administrator, therefore, is to think about when extracts should be refreshed and to work out schedules.

Manage Users and Groups

Add Users to a Site

Everyone who needs to access Tableau Server—whether to browse, publish, edit content or administer the site—must be added as a user. Administrators have the following options for adding users:
- Add a local user account or a user account from Active Directory, described later in this article.

You can also add users by importing an Active Directory group. See Create Groups via Active Directory.

For Tableau Server on Linux, all external directory communication is configured and managed with a LDAP identity store. In the context of user and group synchronization, Tableau Server configured with LDAP identity store is equivalent to Active Directory. Active Directory synchronization features in Tableau Server function seamlessly with properly configured LDAP directory solutions.

- Import Users via a CSV file that you create using the CSV Import File Guidelines.

Site administrator access to user management

By default site administrators can add and remove users on a site. On the site’s Settings page, server administrators can revoke that capability, so that only server administrators can manage the site’s users.

A site administrator can edit an existing local user account only if the administrator has access to all of the sites the user is a member of. For example, if User1 is a member of sites A and B, an administrator of only site B cannot edit User1’s full name or reset the password.
Add local users to a site

1. Sign in to Tableau Server as an administrator, and if applicable select the site.

2. At the top, select Users. On the Users page, click **Add Users**, and then click **New User**.

3. Enter a user name. If the server is configured for local authentication, using an email address for the user name is the best way to avoid user name collisions (for example, lrodriguez@example.com instead of lrodriguez).
Also enter information in the following fields:

- **Display Name**—Type a display name for the user (e.g., *Laura Rodriguez*).

- **Password**—Type a password for the user.

- **Confirm password**—Retype the password.

- **Email**—This is optional and can be added at a later time in the user profile settings.

4. Select a site role.

   For site role definitions, see Set Users’ Site Roles.

5. Click **Add User**.
Add Active Directory users to a site

Before adding users to a site, be sure to review User Management in Active Directory Deployments to understand how multiple domains, domain naming, NetBIOS, and Active Directory user name format influence Tableau user management.

1. In a site, click Users, and then click Add Users, and then click Active Directory User.

2. Enter one or more user names (separated by semicolons).

   For example, tdavis; jjohnson; hwilson

   If you are adding a user that is from the same Active Directory domain that the server is running on, you can type the AD user name without the domain. The server’s domain will be assumed.

   **Note:** Do not enter the user’s full name in this field; it can cause errors during the importing process.

3. Select a site role.
For site role definitions, see Set Users’ Site Roles.

4. Click **Import Users**.

Remove local users

1. Sign in to Tableau Server as an administrator, select the site, and open the **Users** page.

2. Select the check boxes next to the users’ names, and on the **Actions** menu, select **Remove**.

   If a user is a member only of the current site, and they do not own any content, the user is removed from the server.

   If a user you remove from the current site is a member of other sites on the server, their status remains unchanged on those sites.

Related information

- You can also Add Users to Tableau Server, without site affiliation.

- Upgrading Tableau Server to version 2018.1 or later from a pre-2018.1 version, without activating user-based licenses, affects users who were assigned the **Viewer** site role in the pre-2018.1 server version.

  To learn more, see the section “User-based licenses” in the Licensing Overview and see Set Users’ Site Roles.

Set Users’ Site Roles

When you add users to a site on Tableau Server or Tableau Online, independent of their license type, you must apply a **site role** to them. The site role signifies the maximum level of access a user can have on the site. Along with content permissions, the site role determines who can publish, interact with, or only view published content, or who can manage the site’s users and administer the site itself.

In this article

- How user licenses, site roles, and content permissions work together
- Change a user’s site role
- General capabilities allowed with each site role
- Who can publish content
- Site roles and Active Directory import and synchronization

How user licenses, site roles, and content permissions work together

The intersection of a user’s license type, site role, and content permissions determines the level of access a user has on the Tableau site.

1. The license type is associated with the user. The site role you want to assign to the user determines the license type they will require.

   In a multi-site environment on Tableau Server, a user’s license applies to all sites the user is a member of.

2. The site role is also set at the user level. In a multi-site environment, you assign site roles on each site. For example, the same user can have the Site Administrator Creator site role on one site, and Viewer site role on another site.

   The site role defines the maximum capabilities the user has to work with content on the site, or manage users or the site itself.
3. Whether the site role’s maximum capabilities are available to the user depends on the permissions set on the content resources (projects, data sources, workbooks).

For example, say User A has the following access on a site:

- Creator license
- Explorer site role
- Publisher permissions on a project

In this scenario, even though the license allows connecting to and creating new data sources in the web editing environment or Tableau Desktop, and the content resources allow publishing, the site role denies publishing new content on that site.

Similarly, if User A’s site role and license are both Creator, the user can connect to and save (publish) new data sources only in projects on which permissions settings grant those capabilities.

For more information, see Content Permissions and Ownership.

Change a user’s site role

1. Sign in to the site as a server or site administrator, and go to the Users area.

   If you are a site administrator and do not see the Users area, check with your server administrator on whether they have denied user management capabilities to site administrators.

2. Select the users, and then select Actions > Site Role.
3. Select the new site role, and then click **Change Site Role**.

You can hover the pointer over the information icon to display a matrix that shows the maximum level of general capabilities each site role allows. For more information, continue to General capabilities allowed with each site role.

**General capabilities allowed with each site role**

The following table lists the license types as of version 2018.1, the highest level of site role allowed with each, how each site role maps to its pre-2018.1 equivalent; and summarizes
the maximum capabilities each site role allows. If you want more specific information about which capability can be allowed on each site role for each content type, see

Notes

- This information focuses on site roles and is more generalized. For a list of common specific tasks available per license role, see the matrix on the For Teams & Organizations tab on the Tableau pricing page.

- This information describes site roles as of version 2018.1. To learn more about how core-based licensing relates to user-based licensing, how licenses transfer, or other specific licensing transition scenarios, start with the following topics:

  Migrate from Core-Based to User-Based Licensing

<tr>
<td></td>
<td></td>
<td>- You remove a user who owns content on the site. The user will still own the content but not be able to do anything with it.</td>
</tr>
</tbody>
</table>

**Who can publish content**

The following site roles allow the specified level of publishing access.

- **Server Administrator** (Tableau Server only); **Site Administrator Creator**; and **Creator** allow full connecting and publishing access.

  This includes connecting to data and publishing new workbooks and new data sources from Tableau Desktop and the web editing environment. The site roles also allow editing and saving existing published workbooks, or publishing updates to existing data sources.

- **Explorer (Can Publish)** and **Site Administrator Explorer** have limited publishing
capabilities, as described in General capabilities allowed with each site role.

- **Explorer, Viewer, Read Only**, and **Unlicensed** do not allow publishing.

Site roles and Active Directory import and synchronization

When you import Active Directory users to a site, you can specify the site role. If a user is not yet a member of any site on the server, the user is added to the site with the assigned role. When you synchronize Active Directory groups, the site role is applied through the **Minimum Site Role** setting on the **Groups - Details** page.

**Note:** If you run Tableau Server on Linux, all external directory communication is configured and managed with a LDAP identity store. In the context of user and group synchronization, Tableau Server configured with LDAP identity store is equivalent to Active Directory. Active Directory synchronization features in Tableau Server function seamlessly with properly configured LDAP directory solutions.

If a user already exists in a Tableau Server site, the site role assigned during the import or sync process will be applied if it gives the user more access in a site. Importing or synchronizing AD users and groups can promote a user's site role, but does not demote a user's site role.

If a user already has the ability to publish, that ability is maintained.

The matrix below shows the rules applied for site roles on import.

**Note:** The **Import Site Role** row abbreviated headers indicate the site role specified for import. The **Current Site Role** column headers represent the current user site role. The table values represent the abbreviated resulting site role.
- Site Administrator: SA
- Site Administrator Creator: SC
- Site Administrator Explorer: SE
- Creator: C
- Explorer: E
- Explorer (Can Publish): EP
- Viewer: V

### View, Manage, or Remove Users

Administrators can manage a site’s users such as adding and removing users, setting the groups they’re members of, setting their site roles, and so on. On Tableau Server, server administrators can manage users on multiple sites at a time on the All Sites page.

### View and manage users on a site

Sign in to a site as an administrator, and then select **Users**. On this page you can do any of the following to manage users:

- Set group membership, set site role, or remove the user from the site. If you’ve configured the site for SAML single sign-on, you can set the selected users’ authentication type.

<table>
<thead>
<tr>
<th>Import Site Role</th>
<th>Current Site Role</th>
</tr>
</thead>
<tbody>
<tr>
<td>(V)</td>
<td>SC</td>
</tr>
<tr>
<td>Unlicensed</td>
<td>SE</td>
</tr>
</tbody>
</table>
Select a user name to see details about them, such as content they own, views they subscribe to, and their account settings.

The user Settings page is available when the following conditions are true:

- The user is a member only of sites that the site administrator controls

- Site administrators can manage users. This is always the case for Tableau Online and is the default for Tableau Server; Tableau Server administrators can change this access for site admins.
If the server is configured to use the internal user management system (Local Authentication), you can edit the Display Name, Email, and Password for users after they have been added. If you are making many changes, you may find it easier to import the changes from a CSV file. For details, see Import Users and CSV Import File Guidelines.

View and edit server users

Sign in to Tableau Server as a server administrator. On the site menu, select Manage All Sites, and then select Users.
Manage users’ site membership

By default, server and site administrators can manage users at the individual site level. Server administrators can also manage users and their site roles on multiple sites. You do this at the All Sites level (at the server level).

1. In the site menu, select Manage All Sites, and then select Users.

2. On the Server Users page, select the check boxes next to the users, and then select Actions > Site Membership.

3. Select one or more sites, and a site role for each site, and then click Save.

Search for users

To search for a specific user
Use the filter toggle in the upper right to display the search box and site role filter. Then use the search box or filters to find the users you want.

The search operation checks the display name and user name attributes.

You can use the asterisk (*) character as a search wildcard. For example, searching for John* will return all user names that start with John.

Remove users from a site

You can remove a user only if the user does not own any content (projects, workbooks, views, or data sources). If you attempt to remove a user who owns content, the user site role will be set to Unlicensed, but the user will not removed.

Note: On Tableau Server, when an administrator removes a user from a site (and the user belongs only to that one site), the user is also deleted from the server.

1. Sign in to a site as an administrator, and go to the Users area. Select one or more users to remove, and then select Actions > Remove.
2. Click **Remove** in the confirmation dialog.

**Remove users from the server**

You can remove a user only if the user does not own any content (projects, workbooks, views, or data sources). If you attempt to remove a user who owns content, the user site role will be set to Unlicensed, but the user will not removed.

If a user is a member of multiple sites, and they own content on any of those sites, they are removed from the sites on which they don’t own content. The user remains a member on sites where they own content, but demoted to the Unlicensed site role.

1. In the site menu, click **Manage All Sites**, and then click **Users**. In a single-site environment, click **Users**.

   Select one or more users to delete, and then click **Actions > Delete**.
2. Click **Delete** in the confirmation dialog box.

**Change passwords for users of a single site**

To change the password for a user with membership to a single site, sign in to Tableau Server as a site administrator or a server administrator.

1. Ensure that the correct site is selected in the menu.

2. Click **Users**.

3. Click the display name of a user.

4. Click **Settings**.
5. Click the Change Password link, edit the password, and then click Save Password.

Change passwords for users of multiple sites

To change the password of a user with membership to multiple sites, sign in to Tableau Server as a server administrator.

1. In the site menu, click Manage All Sites.

2. Click Users.

3. Click the display name of a user.
4. Click the **Change Password** link, edit the password, and then click **Save Password**.

![Change Password](image)

**Set the User Authentication Type for SAML**

On a site that has been configured for site-specific SAML, administrators can specify users’ authentication type. For example, if Tableau Server was configured for site-specific SAML and server-wide SAML, administrators can specify which users authenticate with site-specific SAML and which users authenticate with server-wide SAML.

You can assign authentication type at the time you add users to Tableau Server, as well as any time afterward.

1. When you’re signed in to the Tableau Server site, select **Users**.

2. On the **Site Users** page, select the check boxes next to the users you want to assign an authentication type.

3. On the **Actions** menu, select **Authentication**.
4. In the Authentication dialog box, select **Site SAML** or **Server Default**.

**Notes**

- Users that authenticate with site-specific SAML can only belong to one site. If a user needs to belong to multiple sites, set their authentication type to the server default. Depending on how site-specific SAML was configured by the server administrator, the server default is either local authentication or server-wide SAML.

- If you change users’ authentication to site-specific SAML, the next time they sign in, they will be directed to your identity provider’s site to provide their credentials.

**Import Users**

To automate the process of adding users to a site, you can create a CSV file that contains user information, and then import the file.

Site administrators can import users to a particular site; server administrators (Tableau Server only) can import users at the server level, to later add them to multiple sites.

**Note:** This topic contains the steps for importing, assuming that you have already created the CSV file. If you have not created the file yet, see CSV Import File Guidelines for a list of file format requirements and import options.
Add users from a CSV file

The following steps describe how to add users to a site or to the server. The images reflect adding users at the site level.

1. Do one of the following:
   - To add users at the site level, select **Users**, and then **Add Users**.
     - ![Add Users to this Site](image)
     - To add users at the server level on a **single-site** server, select **Users**, and then **Add Users**.
     - To add users at the server level on a **multi-site** server, open the list of sites, and select **Manage All Sites**. Select **Users**, and then **Add Users**.

2. Click **Import From File**, click **Browse** and navigate to the file, and then click **Import Users**.
3. Click **Done**.

**How users’ site roles are assigned or maintained**

When you import at the site level or on a single-site server using `tabcmd`, you can specify the site role for all users in the CSV file. If a user already exists in the Tableau Server site, the site role assigned during the import process will be applied, even if it is more restrictive than users’ existing site role. The exception is that you cannot affect a server administrator’s site role.

For a multi-site server, when you import users in the Server Users page, you create server users with no site affiliation. Because these users do not belong to a site, they cannot have a
site role. The only site role a user can have at the server level is **Unlicensed** or **Server Administrator**.

You can also specify the user’s site role when you assign site membership to a user. For information, see Manage users’ site membership.

**Importing at the server level in multi-site environments**

If the server is running multiple sites and you are a server administrator, you can import a CSV file from two locations. Where existing user accounts are concerned, each location has different capabilities.

- The **Server Users** page appears in a multi-site environment. Only server administrators can access this page.

![Image of Server Users page]

You can import the CSV file from here if you want to update existing user accounts in addition to adding new ones. For example, if you import a file that has a new password for each existing user, their passwords will be reset.

- The **Site Users** page.
Server administrators can add new user accounts with CSV imports. If the CSV file includes existing users, the **Password** and **Display Name** fields must either match the existing or be left blank. If new passwords or full names are used, the import will fail.

**Importing to a single-site environment**

Server and site administrators on a single-site server perform CSV user imports from the **Users** page in a site.

**Multi-site versus single-site import**

Users can belong to more than one site on the same server, but they must use the same credentials for each site. This becomes important when you’re adding users to a site and those users might already be members of a different site. If you try to import a user who already
exists, and if the user’s credentials in the CSV file don’t match the existing credentials, the import fails for that user.

If you’re importing users to a site and think the users might already exist on the server, you can try leaving the **Password** field in the CSV file blank (while including the delimiters for the field). If a user who is defined in the CSV already exists in another site, the user is added to the site where you’re importing. However, if the user *doesn’t* already exist on the server, the user is created, and the CSV import window alerts you that the new user doesn’t have a password. You can then use the server administrator pages to assign a password to any user who doesn’t have one.

**Note:** If the server is configured to use Active Directory for authentication, user passwords are managed by Active Directory, and you can leave the password field in the CSV file blank.

**CSV Import File Guidelines**

You can automate adding users by creating a comma-separated values (CSV) file with user information and then importing the file. You can include attributes in the CSV file, such as license level and the publishing access, to apply to the users at the same time you import them.

To import users, you can use the server or site administration pages or the **tabcmd** utility. Using **tabcmd** provides an option for assigning a site role to all users in the CSV file. For information, see Import Users or createsiteusers filename.csv.

You can import users at the site or server level. If you import users to the server (not to a specific site), the users aren’t assigned to a site and are imported as Unlicensed.

**CSV file format requirements**

When you create the CSV file for importing users, make sure that the file meets the following formatting requirements:
• The file does not include column headings. Tableau Server assumes that every line in
the file represents a user.

• The file is in UTF-8 format, and includes the byte-order mark (BOM).

• Character encodings such as BIG-5 have been converted to UTF-8. You can do this
by opening the file in a text editor and using the Save As command.

• If a user name includes an @ character that represents anything other than a domain
separator, you need to refer to the symbol using the hexadecimal format: \0x40

  For example, user@fremont@mycompany.com should be user-
  \0x40fremont@mycompany.com

Required columns in the CSV file

The following values are required for each user:

• User name

• Password: If Tableau Server is configured to use Active Directory authentication,
  there must be a Password column, but the column itself should be empty. If the
  server is using local authentication, you must provide passwords for new users.

Additional import file options

The CSV file can contain the following fields, in the order shown here:

• User name. The user name. If the server is configured to use Active Directory, this
  value must match a user defined in Active Directory. If the user name is not unique
  across domains, you must include the domain as part of the user name (for example,
  example\Adam or adam@example). This is the only required field.

• Password. A password for the user. If the server is configured to use Active Directory,
  this value is not used.

• Display name. The display name is part of the information used to identify a user on
the server. If the user’s display name is already in use, Tableau Server updates the existing user information with the settings in the CSV file. If the server is configured using Active Directory, this value is not used.

- License level. This can be Creator, Explorer, Viewer, or Unlicensed.

- Administrator level (System, Site, or None). This setting determines whether the user is imported as an administrator.

If you are using the web UI to import users, you can set the administrator site role to **System** only if you import the file at the server (All Sites) level. If you are signed in to a specific site, and if the administrator column for a user in the CSV file is set to **System**, Tableau Server imports the user as a site administrator.

- Publishing capability (**yes/true/1** or **no/false/0**). If you are using the web UI, the publisher setting is used only if you import while signed in to a specific site. If you import users at the server (All Sites) level, this value isn't used.

- Email address. The email address is part of the information used to identify a user on the server. If the email address is already in use, Tableau Server updates the existing user information with the settings in the CSV file.

The order of the columns is significant. The first column is treated as the user name, the second as the password, the third as display name, and so on, regardless of the content in the columns. If you omit values for a field, you must still include the field’s comma delimiter.

Improve performance for large CSV files passed through tabcmd

A server administrator can enable server settings that help to improve performance for importing large CSV files through tabcmd commands. You can do this using the **tsm configuraiton set command** with the following options:

- vizportal.csv_user_mgmt.index_site_users

- vizportal.csv_user_mgmt.bulk_index_users
Essentially, these options index users after the CSV file is processed, instead of one-by-one as they are added to the server’s database. This reduces the number of calls to the database and the memory required to process the file. These `tsm configuration set options` apply to the `tabcmd createsiteusers, deletesiteusers, addusers, and removeusers commands`.

For descriptions for these settings, see `tsm configuration set Options`.

Notes

- If you are not signed in to a specific site and are importing users at the server level, you can assign only the Server Administrator and Unlicensed site roles.

- If you have a user-based server installation, and if adding users would exceed the number of users allowed by your license, the users are added as unlicensed users.

- If you use `tabcmd` and specify the license, but importing users would exceed your license limits, users are imported as Unlicensed.

CSV settings and site roles

The license level, administrator, and publishing settings for a user determine how the user’s site role is set during the import process. The following table shows how the settings are converted to site roles.

<table>
<thead>
<tr>
<th>CSV settings</th>
<th>Site role</th>
</tr>

CSV import example for Tableau Server

The following example shows a CSV file that contains information for several users.

```
henryw,henrypassword,Henry Wilson,Creator,None,yes,henryw@example.com
freds,fredpassword,Fred Suzuki,Viewer,None,no,freds@example.com
alanw,alanpassword,Alan Wang,Explorer,Site,yes,alanw@example.com
michellek,michellepassword,Michelle Kim,Creator,System,yes,michellek@example.com
```

If you import this file while managing a site, four users are added to that site. The Administrator setting for user Michelle is System. However, because you are importing the users into a site, Tableau Server give Michelle the Site Administrator Creator site role. Three of the users are allowed to publish.

If you import this file while managing the server, four users are added to the server, but they are not added to any site. Only one user is imported as a server administrator; the rest are set to Unlicensed.

**Guest User**

Core-based licenses of Tableau Server include a Guest user option, which you can use to let people access Tableau views without an account on the server.

Guest user access is enabled by default when Tableau Server is installed with a core-based license. It is not available with user-based licensing. If you do not intend to use Guest user access, you should disable it.
Guest access allows users only to see and interact with Tableau views. The Guest user cannot browse the Tableau Server interface or see server interface elements in the view, such as user name, account settings, comments, and so on.

**Tip:** To share views with Guest users, either provide URL links or embed views into web pages. For more information, see Tableau User Help.

**Guest user permissions**

A Guest user can have the following maximum capabilities:

- **Workbooks and views:** View, Export Image, Summary Data, View Comments, Filter, Full Data, Web Edit, Download (to save a local copy)

- **Data sources:** View and Download

If you add the Guest user to a group that has a higher level of access to a content resource, the Guest user’s access does not exceed the capabilities listed above. However, the Guest user account will comply with more restrictive permissions settings.

**Enable or disable Guest access**

You must be a server administrator to change Guest account settings at either the server or the site level.

**Note:** Enabling the Guest user for a site can increase the number of potential simultaneous viewers beyond the user list you might be expecting. The administrative view **Status > Traffic to Views** can help you gauge the activity.

1. In the site menu, click **Manage All Sites** and then click **Settings > General**.

2. For **Guest Access**, select or clear **Enable Guest account** to toggle Guest user
3. Click **Save**.

This enables the Guest user on all sites. You can then go to the same setting for a specific site. To disallow Guest access for a site:

1. In the site menu, select a site.
2. Click **Settings**, and on the Settings page, clear the **Enable Guest account** check box.

If the Guest account is enabled on some or all sites, and you turn off Guest access at the server level, it is turned off for all sites as well.

**Note:** You can turn off Guest user access at the server or site level; however, you aren’t able to remove the user. So, although no one can access data or views without signing in to the server, the Guest user still appears in the Site Users list and group lists for groups you’ve added the Guest user to.

### Additional Guest account characteristics

The Guest user is unique in the following additional ways:

- As a single user account, it represents all unauthenticated users accessing Tableau views.
- When enabled, it is a member of the All Users group.
- You can add it as a member of other groups on a site.
- You cannot edit it or select it as the owner of a content resource.
- If the Guest user needs to access a workbook with an extract connection, the Guest must also have the **View** capability on the published data source. (The Guest user is
not allowed to connect to published data sources.)

- The account is not allowed to save custom views.
- Guest cannot be used in a user filter.
- You cannot delete the account; however, you can turn off access to it by clearing the check box described in the steps above.

Manage Licenses

Groups

Add Users to a Group

You can organize Tableau Server users into groups to make it easier to manage multiple users. You can create groups on the server or import groups from Active Directory.

Note: If you run Tableau Server on Linux, all external directory communication is configured and managed with a LDAP identity store. In the context of user and group synchronization, Tableau Server configured with LDAP identity store is equivalent to Active Directory. Active Directory synchronization features in Tableau Server function seamlessly with properly configured LDAP directory solutions.

To keep Active Directory group membership up-to-date:

- Site administrators can synchronize selected groups on demand in a site. For more information, see Synchronize Active Directory Groups on a Site.
- Server administrators can synchronize all Active Directory groups on the server based on a schedule or on-demand. For more information, see Synchronize All Active Directory Groups on the Server.
To add a user to a group, the group must already exist.

Add users to a group (Users page)

1. In a site, click **Users**.

2. Select the users you want to add to a group, and then click **Actions > Group Membership**.

3. Select the groups and then click **Save**.

Add users to a group (Groups page)

1. In a site, click **Groups**, and then click the name of the group.

2. In the group’s page, click **Add Users**.
3. Select the users to be added, and then click **Add Users**.

Create a Local Group

Local groups are created using the Tableau Server internal user management system. After you create a group you can add and remove users.
1. In a site, click **Groups**, and then click **New Group**.

![New Group dialog box](image)

2. Type a name for the group and click **Create**.

**Create Groups via Active Directory**

You can import Active Directory groups to create matching groups on Tableau Server, as well as a user for each member of an Active Directory group that is not already on the server.

**Note:** If you run Tableau Server on Linux, all external directory communication is configured and managed with a LDAP identity store. In the context of user and group synchronization, Tableau Server configured with LDAP identity store is equivalent to Active Directory. Active Directory synchronization features in Tableau Server function seamlessly with properly configured LDAP directory solutions.

Each user is assigned a site role as part of the import process. If any of the users to be imported exist in Tableau Server, the site role assigned during the import process is applied only if it gives the user more access to the server. Importing users does not demote site roles.
Before importing groups, review User Management in Active Directory Deployments to understand how multiple domains, domain naming, NetBIOS, and Active Directory user name format influence Tableau user management.

1. In a site, click **Groups**, and then click **Add Groups**

2. Type the name of the Active Directory group you want to import, and then select the group name in the resulting list.

3. Select the site role for the users.
4. Click **Import**.

**Note:** You cannot change the name of groups imported from Active Directory. The group name can only be changed in Active Directory.

**Synchronize Active Directory Groups in a Site**

At any time, you can synchronize an Active Directory group with Tableau Server to ensure new users in Active Directory are also added in Tableau Server. You can synchronize individual groups or multiple groups at once.

**Note:** If you run Tableau Server on Linux, all external directory communication is configured and managed with a LDAP identity store. In the context of user and group
Synchronization, Tableau Server configured with LDAP identity store is equivalent to Active Directory. Active Directory synchronization features in Tableau Server function seamlessly with properly configured LDAP directory solutions.

1. In a site, click Groups.

On the Groups page, select one or more groups.

2. Click Actions > Synchronize.

Set the minimum site role for users in an Active Directory group

In the Groups - Details page, administrators can set the minimum site role for group users to apply during synchronization.

This setting does not run synchronization; it sets the minimum site role to applied to the group every time synchronization runs. When you synchronize Active Directory groups, new users are added to the site with the minimum site role. If a user already exists, the minimum site role will be applied if it gives the user more access in a site. If you don’t set a minimum site role, new users are added as Unlicensed by default.
**Note:** A user's site role can be promoted but never demoted based on the minimum site role setting. If a user already has the ability to publish, that ability will always be maintained. For more information on minimum site role, see Site roles and Active Directory import and synchronization.

1. In a site, click **Groups**.

2. On the Groups page, select a group, and then select **Actions > Minimum Site Role**.

3. Select the minimum site role, and then click **Change Site Role**.

![Minimum Site Role](image)

What happens when users are removed in the source Active Directory?

Users cannot be automatically removed from the Tableau Server through an Active Directory sync operation. Users that are disabled, deleted, or removed from groups in Active Directory remain on Tableau Server so that administrators can audit and reassign the user's content before removing the user's account completely. For more information, see Sync behavior when removing users from Active Directory.
What happens when a user name changes in the source Active Directory

By default, Tableau Server will not synchronize changes to the user display name after the initial synchronization when the corresponding account is created in Tableau Server. For example, if the user name jsmith is used for the display name John Smith, changing the display name in Active Directory to Joe Smith will not synchronize to the corresponding jsmith user in Tableau Server.

To change this behavior run the following tsm commands:

```bash
tsm configuration set -k vizportal.adsync.update_system_user -v true
tsm pending-changes apply
```

The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

What happens when an Active Directory group is removed from Tableau Server?

Many Tableau administrators use Active Directory groups to import and create users. After the users are imported into Tableau Server, administrators will then delete the group in Tableau Server. Deleting a group does not delete the users in it.

Synchronize All Active Directory Groups on the Server

As a server administrator, you can synchronize all Active Directory groups on a regular schedule or on-demand on the **General** tab of the **Settings** page for the server.

---

**Note:** If you run Tableau Server on Linux, all external directory communication is configured and managed with a LDAP identity store. In the context of user and group synchronization, Tableau Server configured with LDAP identity store is equivalent to Active

The **Last synchronized** time indicates the time that synchronization most recently began.

Synchronize Active Directory groups on a schedule

1. **Single-site**: Click **Settings > General**.

   **Multisite**: In the site menu, click **Manage All Sites** and then click **Settings > General**.

2. Scroll down the page to **Active Directory Synchronization**, and then select **Synchronize Active Directory groups on a regular schedule**.
3. Select the frequency and time of synchronization.

4. Click **Save**.

Synchronize all Active Directory groups on demand

At any time, you can synchronize Active Directory groups with Tableau Server to ensure that new users and changes in Active Directory are reflected in all Active Directory groups on Tableau Server.

1. **Single-site**: Click **Settings > General**.

   **Multisite**: In the site menu, click **Manage All Sites**, and then click **Settings > General**.
2. Under Active Directory Synchronization, click Synchronize All Groups.

View synchronization activity

You can view the results of synchronization jobs in the Background Tasks for Non Extracts administrative view. Queue Active Directory Groups Sync is the task that queues and indicates the number of Sync Active Directory Group tasks to be run.

1. **Single-site**: Click Status.

   **Multisite**: In the site menu, click Manage All Sites and then click Status.

2. Click the Background Tasks for Non Extracts link.

3. Set the Task filter to include Queue Active Directory Groups Sync and Sync Active Directory Group.

You can quickly navigate to this administrative view by clicking the View synchronization activity link in the Settings page for the server.

Set the minimum site role for users in an Active Directory group

In the Groups - Details page, you can set the minimum site role for group users to be applied during Active Directory synchronization.
This setting does not run synchronization; instead, it sets the minimum site role to applied to the group every time synchronization runs. The result is that when you synchronize Active Directory groups, new users are added to the site with the minimum site role. If a user already exists, the minimum site role is applied if it gives the user more access in a site. If you don’t set a minimum site role, new users are added as **Unlicensed** by default.

**Note:** A user’s site role can be promoted but never demoted based on the minimum site role setting. If a user already has the ability to publish, that ability will always be maintained. For more information on minimum site role, see Site roles and Active Directory import and synchronization.

1. In a site, click **Groups**.
2. On the Groups page, select a group. Click **Actions > Minimum Site Role**.
3. Select the minimum site role, and then click **Change Site Role**.
What happens when users are removed in the source Active Directory?

Users cannot be automatically removed from the Tableau Server through an Active Directory sync operation. Users that are disabled, deleted, or removed from groups in Active Directory remain on Tableau Server so that administrators can audit and reassign the user's content before removing the user's account completely. For more information, see Sync behavior when removing users from Active Directory.

Quick Start: Synchronize All Active Directory Groups on a Schedule

After you import Active Directory groups in Tableau Server, you can make sure they stay synchronized in Tableau Server by setting up a schedule. You can also synchronize all Active Directory groups on the server on-demand, at any time. The minimum site role setting for the group is applied when users are synchronized.

**Note:** If you run Tableau Server on Linux, all external directory communication is configured and managed with a LDAP identity store. In the context of user and group synchronization, Tableau Server configured with LDAP identity store is equivalent to Active Directory. Active Directory synchronization features in Tableau Server function seamlessly with properly configured LDAP directory solutions.

1 Set a minimum site role for synchronization

In a site, click **Groups**. Select a group, and then click **Actions > Minimum Site Role**. Select the minimum site role, and then click **Change Site Role**. Server and site administrators can set the minimum site role for group users to be applied during Active Directory synchronization. If you don't set a minimum site role, new users are added as **Unlicensed**.
Synchronizing can promote a user’s site role, but will never demote a user’s site role.

2 Set the schedule

Server administrators can enable synchronization for all Active Directory groups on the General tab of the Settings page for the server. Enable synchronization, select the frequency settings, and then click Save.
All Active Directory groups on the server are synchronized according to the same schedule.

3 Run synchronization on-demand (optional)

On the **General** tab of the **Settings** page, click **Synchronize All Groups** to synchronize all Active Directory groups on Tableau Server immediately. Click this button at any time to ensure new users and changes are reflected in all Active Directory groups on the server.

![Tableau Server Settings](image)

Click **Synchronize All Groups** to synchronize all Active Directory groups on the server outside of a schedule.

4 View the status of synchronization tasks

Server and site administrators can view the results of Active Directory synchronization jobs in the **Background Tasks for Non Extracts** administrative view. On the server or in a site, click **Status**. Under **Analysis**, click **Background Tasks for Non Extracts** and filter on the **Queue Active Directory Groups Sync** and **Sync Active Directory Group** tasks.
Queue Active Directory Groups Sync queues the Sync Active Directory Group tasks to be run.

Delete Groups

You can delete any group from the server (with the exception of the All Users group). When you delete a group, the users are removed from the group but they are not deleted from the server.

1. In a site, click Groups.

2. On the Groups page, select one or more groups to delete.
Dashboard-based Custom Portals

Note: This overview was inspired by the work of Tableau Zen Master Mark Jackson. For more details about the process, check out Mark's blog.

The standard Tableau Online or Tableau Server interface works great for many organizations, but if you want to create a company-branded experience and don't have API developer skills, consider creating a custom portal based on a Tableau dashboard. A custom portal lets you organize content around specific departments or job roles, and you can even incorporate training that helps people interact with data more fully. As the volume of Tableau content grows, a custom portal guides your users directly to the data they need, while providing ready access to related views and Tableau Server search so they can easily explore further.
Sketch out a portal design

Begin outside of Tableau, on paper or in a wireframing application. Consider the structure of your organization and the number of Tableau views that apply to each group of users. Do you simply need one level of navigation that points immediately to content? Or might you need to start with a main page that provides navigational links for separate groups of users or report types, followed by a second level with related dashboards and views?

<table>
<thead>
<tr>
<th>Medical Staff</th>
<th>Illness trend report</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Patient demographics</td>
</tr>
<tr>
<td>Facilities</td>
<td>Hospital occupancy</td>
</tr>
<tr>
<td></td>
<td>Real estate transactions</td>
</tr>
</tbody>
</table>

After you get buy-in on your design from key stakeholders and data consumers, you’re ready to move on to the next phase.

Gather images for logos and navigation elements

Start thinking about images while refining your initial mockup, and then gather them from libraries of clip-art or approved brand graphics, or create them from scratch in an application like Photoshop or SnagIt. PowerPoint can also be a good source if you plan to create navigation thumbnails of common chart types.

Health Group
Lay out text, images, and selected sheets on a dashboard

Create a workbook with a dashboard for the portal, using a tiled layout for more predictable positioning and scaling of elements on different devices. Then start adding Text and Image objects, as well as any sheets for data views you want to highlight right up front in your portal. To refine spacing between these dashboard elements, insert Blank objects and adjust their size. For more information, see Create a Dashboard.

Tip: For dynamic elements that show popular or recently created content, include sheets based on custom administrative views.

Link dashboard elements to content

If you have a second level of navigation in your portal, use filter actions to point to a secondary dashboard from the main one. To create links that directly open data views, right-click Image objects and choose Set URL. (In our example below, each colored arrow and accompanying text is an image that links to a view URL.) You can even point to empty views with preloaded data sources, encouraging users to create new Tableau content in the web-authoring workspace.

Tip: To add hyperlinks to text objects, include the full URL (for example, http://www.tableau.com).
Publish, test, and refine your portal

Publish the workbook to your server and distribute the dashboard URL to your users. Portal design, like data analysis itself, is a cyclical process. Now that your portal is out in the wild, start gathering user feedback so you can continuously improve the experience.
**Tip:** As a finishing touch, hide the Tableau toolbar to give your portal a custom feel. After the question mark at the end of the dashboard URL, add `:embed-d=y&:toolbar=n`

### Data Connection Authentication

**More information**

- [Setting an Oracle Connection to Use TNSNames.ora or LDAP.ora](https://support.tableau.com/topic/setting-an-oracle-connection-to-use-tnsnamesora-or-ldapora) (Tableau Support)

### Enable Kerberos Delegation

Kerberos delegation enables Tableau Server to use the Kerberos credentials of the viewer of a workbook or view to execute a query on behalf of the viewer. This is useful in the following situations:

- You need to know who is accessing the data (the viewer’s name will appear in the access logs for the data source).

- Your data source has row-level security, where different users have access to different rows.

### Requirements

Kerberos delegation requires Active Directory.

- Tableau Server on Linux can only delegate users from a single domain. The domain must be specified in the option `native_api.s4u_domain_override`, as described in Step 4 below.
The Tableau Server information store must be configured to use LDAP - Active Directory.

The computer where Tableau Server is installed must be joined to Active Directory domain.

MIT KDC is not supported.

Configuration process

This section provides an example of the process to enable Kerberos delegation. The scenario also includes example names to help describe the relationships between the configuration elements.

1. Tableau Server will need a Kerberos service ticket to delegate on behalf of the user that is initiating the call to the database. You must create a domain account that will be used to delegate to the given database. This account is referred to as the Run As service account. In this topic, the example user configured as the delegation/Run As account is tabsrv@example.com.

   The account must be configured with Active Directory User and Computers on a Windows Server that is connected to the user domain:

   - Open the Properties page for the Run As service account, click the Delegation tab and select Trust this user for delegation to specified services only and Use any authentication protocol.

2. Create a keytab file for the Run As service account.

   For example, the following commands create a keytab (tabsrv-runas.keytab) using the ktutil tool:

   ```shell
   sudo ktutil
   ktutil: addent -password -p tabsrv@EXAMPLE.COM -k 2 -e <encryption scheme>
   ```
Encryption schemes for this command include RC4-HMAC, aes128-cts-hmac-shal-96, and aes256-cts-hmac-shal-96. Consult your IT team for the correct encryption scheme for your environment and data source.

ktutil: wkt tabsrv-runas.keytab

Tableau Server will use the Run As service account and the associated keytab to authenticate and make a direct connection to the database.

3. Copy the keytab into the Tableau Server data directory and set proper ownership and permissions.

    mkdir /var/opt/keytab
    sudo cp -p tabsrv-runas.keytab /var/opt/keytab

    sudo chown $USER /var/opt/keytab/tabsrv-runas.keytab
    chgrp tableau /var/opt/keytab/tabsrv-runas.keytab
    chmod g+r /var/opt/keytab/tabsrv-runas.keytab

4. Run the following TSM commands to enable Kerberos delegation, set the delegation service account, and associate the keytab file with the service account:

    tsm configuration set -k wgserver.delegation.enabled -v true
    tsm configuration set -k native_api.datasource_impersonation_runas_principal -v tabsrv@example.com
    tsm configuration set -k native_api.datasource_impersonation_runas_keytab_path -v <path-to-file>kerberos.keytab
    tsm configuration set -k native_api.s4u_domain_override -v <EXAMPLE.COM>
In some cases, TSM may return an error mentioning `--force-keys`. If you get this error, run the command again with the `--force-keys` parameter appended to the argument.

5. Run the following TSM command apply the changes to Tableau Server:

```bash
tsm pending-changes apply
```

The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

6. Enable delegation for data connections:

- **SQL Server**—See Enabling Kerberos Delegation for SQL Server in the Tableau Community.
- **MSAS**—See Enabling Kerberos Delegation for MSAS in the Tableau Community.
- **PostgreSQL**—See Enabling Kerberos Delegation for PostgreSQL in the Tableau Community.
- **Teradata**—See Enabling Kerberos Delegation for Teradata in the Tableau Community.

**OAuth Connections**

For Google BigQuery, Google Analytics, Salesforce, OneDrive, Dropbox, and QuickBooks Online, an alternative to storing your sensitive database credentials with Tableau Server is to create connections using the **OAuth 2.0** standard.

From Tableau, when you sign in to data with a provider that uses OAuth, you are redirected to the provider’s sign-in page. After you provide your credentials and authorize Tableau to
access your data, the data provider sends Tableau an **access token** that uniquely identifies requests from Tableau. For more information, see Overview of the OAuth process below.

Using OAuth connections provides the following benefits:

- **Security**: Your database credentials are never known to or stored in Tableau Server, and the access token can be used only by Tableau.

- **Convenience**: Instead of having to embed your data source ID and password in multiple places, you can use the token provided for a particular data provider for all published workbooks and data sources that access that data provider.

In addition, for live connections to Google BigQuery data, each workbook viewer can have a unique access token that identifies the user, rather than sharing a single user name and password credential.

**Overview of the OAuth process**

The following steps describe a workflow in the Tableau environment that calls the OAuth process.

1. You take an action that requires access to a cloud data source.

   For example, you open a workbook that’s published to Tableau Server.

2. Tableau directs you to the cloud data provider’s sign-in page. The information that is sent to the data provider identifies Tableau as the requesting site.

3. When you sign in to the data, the provider prompts you to confirm your authorization for Tableau Server to access the data.

4. Upon your confirmation, the data provider sends an access token back to Tableau Server.
5. Tableau Server presents your workbook and data to you.

The following workflows can use the OAuth process:

- Creating a workbook and connecting to the data source from Tableau Desktop or from Tableau Server.
- Publishing a data source from Tableau Desktop.
- Signing in to Tableau Server from an approved client, such as Tableau Mobile or Tableau Desktop.

Access tokens for data connections

You can embed credentials based on access tokens with data connections, to enable direct access after the initial authentication process. An access token is valid until a Tableau Server user deletes it, or the data provider revokes it.

It is possible to exceed the number of access tokens your data source provider allows. If that's the case, when a user creates a new token, the data provider uses length of time since last access to decide which token to invalidate to make room for the new one.
Access tokens for authentication from approved clients

By default, Tableau Server sites allow users to access their sites directly from approved Tableau clients, after users provide their credentials the first time they sign in. This type of authentication also uses OAuth access tokens to store the users' credentials securely.

For more information, see Disable Automatic Client Authentication

Configure the Server for OAuth Support

Instead of individual usernames and passwords, OAuth works through limited-purpose access tokens. Before you can obtain access tokens needed to create an OAuth connection in Tableau, you need to configure your server so that the data provider sending the token can recognize Tableau Server as a trusted destination. The following section describes how to prepare for setting up OAuth regardless of your data provider. The topics listed below it contain the steps for configuring your server for specific data providers.

Preparing for Configuring OAuth Support

Before you begin the configuration steps specific to your data provider, complete the following prerequisites:

- Obtain the fully qualified domain name of each Tableau Server node that will host views that connect to this data source. For example:

  https://sales.your_domain.com

  If you use Salesforce.com, you will need to provide an https address.

- Make sure at least one of your data-provider accounts is enabled for API access.

  For Google data types, you need access to the developers console on the Google Cloud Platform.

  For Salesforce.com, you need access to the Force.com platform.

  For QuickBooks Online, you need access to the Intuit platform.
Configure Settings for Your Data Provider

When you complete the OAuth-preparation steps, you can configure the appropriate settings with your data provider.

- Set up OAuth for Google
- Set up OAuth for Salesforce.com
- Set up OAuth for QuickBooks Online

Set up OAuth for Google

This topic describes how to set up your Google BigQuery, Google Sheets, and Google Analytics data sources for OAuth.

Complete these steps for each Tableau Server instance.

**Note** Before you complete these steps, make sure you have completed the prerequisites described in Preparing for Configuring OAuth Support.

Set up OAuth by following these three procedures:

- Enable API access and create access token from Google.
- Configure OAuth on Tableau Server.
- Create and edit Google data source.

Obtain a Client ID and Enable Google APIs

**Note** These steps reflect the settings in the Google Cloud Platform console at the time of this writing. For more information, see Using OAuth 2.0 for Web Server Applications in the Google Developers Console Help.

1. Sign in to Google Cloud Platform, and then click Go to my console.
2. On the drop-down menu next to the Google Cloud Platform title, select Create
In the new project form that appears, complete the following:

- Give the project a meaningful name that reflects the Tableau Server instance for which you’ll use this project.

- Determine whether you want to change the project ID.

Note After you create the project, you will not be able to change the project ID. For information, click the question mark icons.

4. Open the new project, and navigate to APIs Manager > Credentials.

Note: You must generate credentials with the Google API Manager for Tableau Server. Do not attempt to use a Service Account, which generates a key, and is not supported.

5. Click the OAuth consent screen tab and then enter a meaningful name for Product name shown to users.

6. Click the Credentials tab, then click the Create credentials drop-down list, and then select OAuth client ID. Complete the following:
- Select **Web Application**.

- For **Authorized JavaScript Origins**, enter the local computer name of your Tableau Server.

- For **Authorized Redirect URI**, replace the existing text with the Internet address for your server, and add the following text to the end of it: `auth/add_oauth_token`. For example:

  
  https://your_server_url.com/auth/add_oauth_token

7. Copy the Authorized Redirect URI, and paste it in a location that you can access from your Tableau Server computer.

8. Click **Create**.

9. Copy the following values that Google returns, and paste them in a location that you can access from your Tableau Server computer:

   - Client ID
   - Client secret

10. In **APIs Manager > Dashboards**, verify that **BigQuery API**, **Google Drive API** (to enable Google Sheets) or **Analytics API** is enabled. To enable APIs, click **ENABLE API** at the top of the page.

Configure Tableau Server for Google OAuth

Using the information you obtained by completing the steps in Obtain a Client ID and Enable Google APIs, configure your Tableau Server:

- On the Tableau Server computer, open the shell and run the following commands to specify the access token and URI:

  
  `tsm configuration set -k oauth.google.client_id -v <your_client_ID>`
tsm configuration set -k oauth.google.client_secret -v <your_client_secret>

tsm configuration set -k oauth.google.redirect_uri -v <your_authorized_redirect_URI>

tsm pending-changes apply

The pending-changes apply command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the --ignore-prompt option, but this does not change the restart behavior. For more information, see tsm pending-changes apply.

Create and edit Google data source

Next, you must publish the Google data sources to the server. See the Tableau Desktop topic, Google BigQuery.

After you've published the data sources, the final step is to edit the data source connection to use the embedded access token that you configured earlier. See Edit Connections on Tableau Server.

Managing access tokens

After you configure the server for OAuth, you can allow users to manage their own access tokens in their profile settings, or you can manage the tokens centrally. For more information, see Allow Saved Access Tokens.

Set up OAuth for Salesforce.com

This topic describes how to set up your Salesforce.com data sources for OAuth. Complete these steps for each Tableau Server instance.
Note: Before you complete these steps, make sure you have completed the pre-requisites described in Preparing for Configuring OAuth Support.

Set up OAuth by following these two procedures:

- Create a Connected App in Salesforce
- Use the information you obtained to configure your server.

Create a Connected Salesforce App

1. Sign in to your Salesforce.com developer account, click your user name in the upper-right, and then select Setup.

2. In the left navigation column, under App Setup, select Create > Apps.

3. In the Connected Apps section, click New.
4. Complete the Basic Information, and in the API section, select Enable OAuth Settings.

5. In the new OAuth settings that appear, for Callback URL, type the fully qualified domain name of your server, using the https protocol, and append the following text to the URL: auth/add_oauth_token.

For example:

https://www.your_server.com/auth/add_oauth_token

6. Move the following items from Available OAuth Scopes to Selected OAuth Scopes:

   - Access and manage your data (api)
   - Access your basic information (id)
   - Perform requests on your behalf at any time (refresh_token)

7. Click Save.

After you save the app, Salesforce populates the API section with the following IDs that you will use to configure Tableau Server:

   - Consumer Key
   - Consumer Secret
   - Callback URL
Configure Tableau Server for Salesforce.com OAuth

1. On the Tableau Server computer, open the bash shell and run the following commands:

   tsm configuration set -k oauth.salesforce.client_id -v <your_client_ID>

   tsm configuration set -k oauth.salesforce.client_secret -v <your_client_secret>

   tsm configuration set -k oauth.salesforce.redirect_uri -v <your_authorized_redirect_URI>

2. (Optional) To change the default login server, type the following command:

   tsm configuration set -k oauth.salesforce.server_base_url -v <URL>

3. Enter the following command to apply changes:

   tsm pending-changes apply

   The pending-changes apply command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the --ignore-prompt option, but this does not change the restart behavior.
   For more information, see tsm pending-changes apply.

Managing access tokens

After you configure the server for OAuth, you can allow users to manage their own access tokens in their profile settings, or you can manage the tokens centrally. For more information, see Allow Saved Access Tokens.
Set up OAuth for QuickBooks Online

This topic describes how to set up your QuickBooks Online data sources for OAuth authentication. Complete these steps for each Tableau Server instance.

**Note:** Before you complete these steps, make sure you have completed the pre-requisites described in Preparing for Configuring OAuth Support.

Setting up OAuth for QuickBooks Online consists of two tasks:

- Create a Connected App on the Intuit developer platform.
- Use the information you get as part of the Connected App to configure your server.

Create a Connected Intuit App

1. Sign in to your Intuit developer account, and then click **My Apps**.
2. In the **Just start coding** section, click **Select APIs**.
3. Select **Accounting** and click **Create App**.
4. In the **Get your app ready for submission** section, click the link to get your production keys.
   
   **Important:** You must use production keys rather than development keys.

5. Copy the app token, OAuth consumer key, and OAuth consumer secret.

Configure Tableau Server for QuickBooks Online

- On the Tableau Server computer, open the bash shell and run the following commands:
tsm configuration set -k oauth.quickbooks.oauth_callback_uri -v http://YOUR-SERVER/auth/add_oauth_token

tsm configuration set -k oauth.quickbooks.consumer_key -v <your_consumer_key>

tsm configuration set -k oauth.quickbooks.consumer_secret -v <your_consumer_secret>

tsm pending-changes apply

The pending-changes apply command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the --ignore-prompt option, but this does not change the restart behavior. For more information, see tsm pending-changes apply.

Managing access tokens

If you run an extract refresh job for your QuickBooks Online data source, Tableau Server attempts to renew access tokens for you. To help ensure that your access tokens do not expire, run your extract refresh jobs more than once a month. Otherwise, the access tokens from QuickBooks Online expire and your extract refresh jobs fail. If your access tokens do expire, you can edit your saved credentials from the Settings page.

The saved credentials can be managed centrally or by your users. For more information, see Allow Saved Access Tokens.

Allow Saved Access Tokens

After you configure Tableau Server for OAuth, you can decide to allow users to manage their own OAuth credentials, or you want to manage them centrally. If you want users to manage their own, you need to enable user profile settings from the server.
Note: If you have not yet configured your server to enable OAuth data connections, see the related topics listed below.

1. Sign in to Tableau Server as a server administrator.

2. **Single-site:** Click Settings > General.

   **Multisite:** In the site menu, click Manage All Sites and then click Settings > General.

3. In the Saved Credentials section, select the following:
   - **Allow users to save passwords for data sources** (allows users to save their individual credentials with data sources).
   - **Allow users to save OAuth access tokens for data sources**

4. Click Save.

After you select these check boxes, users will see a Manage Credentials section in their profile settings, where they can add access tokens for OAuth data connections.
Managing credentials centrally

Server administrators alternatively can manage OAuth credentials centrally. This can work well, for example, if multiple users work from the same data, and you have a dedicated user account for your data provider.

To manage credentials centrally, you do the following:

- Clear the check boxes described in the preceding procedure.
- Edit connection information as data sources are published.

When you edit the connection, you embed credentials that use an OAuth access token instead of an individual’s user name and password.

When the settings for saving passwords and access tokens are not enabled, the Manage Credentials section is excluded from users’ profile settings.

Set up OAuth for Salesforce.com

Set up OAuth for QuickBooks Online

Configure SAP HANA SSO

You can configure Tableau Server to use SAML delegation to provide a single sign-on (SSO) experience for SAP HANA. This scenario is not dependent on SAML authentication.
to Tableau Server. You do not need to use SAML sign on with Tableau Server in order to use HANA SAML delegation. You can sign in to Tableau Server using whatever method you choose.

With SAML delegation for SAP HANA, Tableau Server functions as an identity provider (IdP).

Before you begin

Configuring SAML delegation with SAP HANA requires configuration on both Tableau Server and on SAP HANA. This topic provides configuration information about configuring Tableau Server. Before you configure Tableau Server, you must complete the following:

- Acquire a SAML certificate and key file for Tableau Server. The certificate file must be a PEM-encoded x509 certificate with the file extension .crt or .cert. This file is used by Tableau Server, and must also be installed on HANA. The private key must be a DER-encoded private key file that is not password protected, and that has the file extension .der. This file is only used by Tableau Server.
- Install the certificate in HANA.
- Install the latest version of SAP HANA driver (minimum version is 1.00.9) on Tableau Server.
- Configure network encryption from Tableau Server to SAP HANA (recommended).

For more information about generating the certificate/key pair, encrypting the SAML connection, and configuring SAP HANA, see How to Configure SAP HANA for SAML SSO with Tableau Server in the Tableau Community.

Configure Tableau Server SAML for SAP HANA

The following procedure describes how to configure SAML for SAP HANA on Tableau Server using `tsm data-access set-saml-delegation`. You can also configure SAML for SAP HANA using the sapHanaSettings Entity.

If you are running Tableau Server in a distributed deployment, run the following procedure on the initial node.
1. Place certificate files in a folder named `saml`. For example:

   `/var/opt/saml`

2. Run the following commands to specify the location of the certificate and key files:

   ```bash
   tsm data-access set-saml-delegation configure --cert-key <cert-key> --cert-file <cert-file>
   
   Where `<cert-key>` and `<cert-file>` are file paths to the private key and certificate file, respectively.
   
   For example,
   
   ```bash
   tsm data-access set-saml-delegation configure --cert-key /var/opt/saml/hana_pkey_pkcs8.der --cert-file /var/opt/saml/hana_cert.pem
   
   You can specify other options. For example, you can specify user name format and how credentials are normalized. See `tsm data-access set-saml-delegation`.
   
3. Run the following commands to enable delegation:

   ```bash
   tsm data-access set-saml-delegation enable
   tsm configuration set -k wgserver.sap_hana_sso.enabled -v true
   tsm configuration set -k wgserver.delegation.enabled -v true
   ```

4. When you have finished, run `tsm pending-changes apply`.

   The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt.
using the --ignore-prompt option, but this does not change the restart behavior.
For more information, see tsm pending-changes apply.

Manage Content Access

Set a Site’s Web Authoring Access

Tableau Server administrators can specify at the site level whether to allow users to edit published views in the web environment.

By default web authoring functionality is enabled for all sites. Users with the Web Edit capability to edit workbooks directly on the server. Turn off web authoring if you want users to be able to view and interact with published workbooks but not make any changes to the core information.

The steps below describe how to set web authoring for an entire site. For more granular control over which users can use web editing, you can use projects, groups, and permissions. See Set Web Edit, Save, and Download Access on Content.

Turn web authoring on or off for a site

1. In a web browser, sign in to the server as an administrator and go to the site in which you want web authoring to be enabled. In that site, click Settings.

2. Select Allow users to use web authoring to enable the functionality.

   Clear the check box to turn off web authoring for that site.
Web Authoring

Users with the appropriate permissions can edit workbooks in their browser.

Allow users to use web authoring

3. If your site is already in production, and you want the change to take effect immediately, restart the server.

Otherwise, the change takes effect after server session caching expires or the next time users sign in after signing out.

Notes

- When you enable web authoring, make sure that, on the appropriate workbooks or views, the permission rule for a user or group allows the **Web Edit** capability.

- If you turn off web authoring on a production site and do not complete the last step to restart the server, users might continue to have authoring access until their session caches expire or they sign out.

See which sites allow web authoring

To confirm which sites allow web authoring, on the site-selection menu at the top, select **Manage All Sites**, and then go to the **Sites** page.
Set Web Edit, Save, and Download Access on Content

If you're enabling web authoring functionality on your site, you can configure more precisely which users on the site have access to this functionality. Using site roles and permissions rules at the content level, you can grant or deny Web edit, Save, or Download capabilities on projects, workbooks, and data sources.

**Note:** This document strives to use the phrase *Web edit* only to specify the name of the capability in permissions rules, and *web authoring* to refer to the general functionality of creating and modifying workbooks on the server. However, you might otherwise see these two phrases used interchangably.

Why allow users to work on the server directly

As an administrator, your initial thought about allowing people to populate a site with content, seemingly indiscriminately, might be one of skepticism. However, with a few controls, you can limit where this is done, while providing important benefits that centralized content management offers both you and your users.

Web authoring pros and cons

For publishers and business users, some benefits of web authoring include the following:

- It provides analyst teams who work collaboratively with a central location in which to provide input.

- It enables people who do not have Tableau Desktop to connect to data sources and create workbooks.

- It enables people to access content when they are away from their Tableau Desktop computer or VPN, whether on a computer or a hand-held device.

- It can provide a framework for enabling consistency across Tableau reports.
By making template workbooks available on the server, analysts can download or create new workbooks with data connections, branding, and formatting already in place.

For administrators, benefits can include the following:

- Fewer Tableau Desktop deployments to manage and support.
- Fewer computers that need to have database drivers installed.
- Capacity to govern content.
- More accurate monitoring of what people are doing with Tableau.

Some disadvantages to web editing include the following:

- For analysts, web editing functionality is not as extensive as in Tableau Desktop (although it continues to evolve toward that parity).
- For administrators, more people working on the server might mean upgrading systems.
- Without publishing guidelines, content proliferation on the server is expected.

This can confuse the people who rely on published Tableau dashboards and data sources, degrade server performance and data quality, and potentially affect data security.

Managing permissions to help users avoid content proliferation

To help users to avoid content proliferation on the server, many Tableau administrators use projects to allow varying levels of access to content. For example, one project can allow all users to edit and save workbooks; another can allow only approved publishers to save new content.

To get a better idea how this works, see the following resources:

- Configure Projects, Groups, and Permissions for Managed Self-Service
- Projects and Content Permissions in Everybody’s Install Guide
• **Governed Self-Service at Scale**, a Tableau whitepaper by Rupali Jain.

To view the PDF, you might need to provide your Tableau website credentials. These are the same ones you use for the community forums or to submit support cases.

Coordinate edit and save capabilities with site roles for the appropriate level of access

To edit, save, and download workbooks, users must have a site role that allows those actions, along with the capabilities—defined in permissions rules—that grant or deny editing-related access.

Site role access

• When the appropriate permissions are set at the content level, the **Creator** or **Explorer (Can Publish)** site role allows both **Save** (overwrite) and **Save As/Download**.

Users with these site roles can save (overwrite) only workbooks that they own. If they edit a workbook owned by another user, only the **Save As** command is available, and they can save the workbook with a new name.

• The **Explorer** site role allows downloading but not saving (neither overwriting existing nor saving changes to a new workbook).

Capabilities set on content

These capabilities coordinate with the site role to allow levels of editing and saving.

• **Web Edit** determines whether users can edit workbooks directly on the server.

• **Download Workbook/Save As** determines whether users have access to the **Save As** option while they are editing a workbook, or can download a workbook as a Tableau packaged workbook (.twbx).
**Save As** allows users to save changes they’ve made to an existing workbook as a new workbook on the server. It also determines whether they can open a workbook on the server from Tableau Desktop.

Tableau treats saving like publishing, so to save new workbooks, users must have a site role of **Creator** or **Explorer (Can Publish)**.

- **Save** determines whether users can save changes to an existing workbook on the server (overwrite a workbook).

To overwrite a workbook with changes made on the server, a user must have a site role of **Creator** or **Explorer (Can Publish)**.

**Configure site roles and permissions**

Use the tables in the following sections to coordinate the site role with saving and editing capabilities.

Set these capabilities at the project level, using permissions rules.

Allow users who can publish to edit, save changes to, and download existing and new workbooks.

Apply these capabilities to users who have the **Creator** or **Explorer (Can Publish)** site role.

<table>
<thead>
<tr>
<th>Capability</th>
<th>For the project</th>
<th>For specified workbooks in the project</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web Edit</td>
<td>-</td>
<td>Allowed</td>
</tr>
<tr>
<td>Download Workbook/Save As</td>
<td>-</td>
<td>Allowed</td>
</tr>
<tr>
<td>Save</td>
<td>Allowed</td>
<td>Allowed</td>
</tr>
</tbody>
</table>
Allow users who can publish to edit, save changes to, and download new workbooks, but not overwrite existing workbooks

Apply these capabilities to users who have the Creator or Explorer (Can Publish) site role.

<table>
<thead>
<tr>
<th>Capability</th>
<th>For the project</th>
<th>For specific workbooks in the project</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web Edit</td>
<td>-</td>
<td>Allowed</td>
</tr>
<tr>
<td>Download Workbook/Save As</td>
<td>-</td>
<td>Allowed</td>
</tr>
<tr>
<td>Save</td>
<td>Allowed</td>
<td>Denied</td>
</tr>
</tbody>
</table>

**Important:** In the “save but not overwrite” case above, allowing Save access at the project level is required for publishers to be able to publish workbooks from Tableau Desktop. To deny overwriting existing workbooks, you must deny the Save capability explicitly on each relevant workbook, and not lock permissions to the project. If project permissions are locked, permissions set on the project apply to all workbooks in it.

Allow explorers to download workbooks

Apply these capabilities to users who have the Explorer site role.

<table>
<thead>
<tr>
<th>Capability</th>
<th>For the project</th>
<th>For specific workbooks in the project</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web Edit</td>
<td>-</td>
<td>Allowed</td>
</tr>
<tr>
<td>Download Workbook/Save As</td>
<td>-</td>
<td>Allowed</td>
</tr>
<tr>
<td>Save</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

The Save and Save As capabilities will be denied by the Explorer

Configure Projects, Groups, and Permissions for Managed Self-Service

Tableau Online and Tableau Server each provide an environment for easy open publishing and collaborative analysis of visualizations created in Tableau Desktop or web authoring. With that flexibility comes the challenge of making sure the right content is easy to find for the people who rely on it for their work. Likewise, making sure the access you allow doesn’t create performance or management nightmares on the site.

To address these challenges, many administrators set up their Tableau sites for what we’ll refer to as managed self-service. This is just a way of saying that the site allows areas of open collaboration and web editing, alongside areas in which access to data and reports is more controlled. As the site administrator, you put guidelines in place to help users figure out where to go for the type of work they need to do.

To get started with a managed self-service approach, the following sections discuss how you as the site administrator can meet the following objectives:

- Create projects on the Tableau Server or Tableau Online site to match the ways people need to work with content.

  For example, some projects are open to all for collaboration; others are visible only to authorized publishers.

- Create user groups based on the type of access users need to the content.

- Create a clear and scalable permissions strategy.
Note: The information provided here is adapted and simplified from practices of existing Tableau Zen Masters and customers who have shared their experiences. Links to their talks are available at the bottom of this page.

Start by creating a project team and adopting a permissions strategy

We recommend that you recruit users from various segments of your Tableau population, to create a project team of people who have differing uses for Tableau content.

Your permissions strategy will help your environment scale as you add new Tableau users. Make sure it incorporates two important practices: manage permissions only for groups, and set permissions only at the project level. Setting permissions at the individual user level and on individual content resources becomes unmanageable quickly. If you need to deviate from this practice, make sure you document and communicate your strategy to other administrators and project leaders.

Steps to coordinate projects and groups

To get projects and permissions (content) to work together with groups (people) in a managed self-service environment, you generally take the following steps:

1. Plan your permissions: Find common themes in the type of access users need. This helps determine projects and groups.

2. Remove permissions that will cause ambiguities

3. Create groups

4. Assign permissions to the groups

5. Create projects and adjust permissions

6. Lock permissions in each project
If you decide to follow the guidelines described here, you might want to Automate working with groups and projects.

1. Plan your permissions

Before you create groups and start assigning permissions, create a list of people who need access to content, and arrange them in groups according to what they’ll want to do.

For example, someone who publishes or moves a data source to a certified content project would need different level of access than someone who only consumes published reports. (We use the term “certified” to mean “trusted” — these are the data sources or reports that your Tableau community can trust to be a source of truth for your organization.)

Keep in mind also that you can set permissions differently for each project. So someone who is a data steward for the Ops department might not get the equivalent access to the Marketing content.

This exercise, done outside of the Tableau environment, can be the most challenging part of setting up a site.

Use a closed permissions model for managed content

General models for setting permissions are open or closed. In an open model, users get a high level of access, and you explicitly deny capabilities. This model can work when your organization is very small, and everyone has a similar level of responsibility.

In a closed model, users get only the access they need to do their jobs. This is the model security professionals advocate, and the examples in this article will attempt to show.

2. Remove permissions that will cause ambiguities

Every site has a Default project and an All Users group. The Default project works as a template for new projects in the site. Creating groups and setting baseline permissions here helps you to know and manage exactly who gets what level of access for each new project.
In the managed self-service context, setting baseline permissions means removing the permissions from the All Users group, so that the permissions are enabled only on groups you create and have control over.

1. In the menu at the top of the page, select Projects.

2. Open the permissions for the Default project. Open the Actions menu (…), and then select Permissions.

3. Next to the All Users group name, select . . . , and then select Edit.

4. In the drop-down lists under Project, Workbooks, and Data Sources, select None.
5. Select **Delete** to apply the changes.

3. **Create groups**

You create groups to match what people need to do with a set of content. In this case “a set of content” refers to the workbooks and data sources in a project.

When you create your groups, use descriptive names that make sense for your organization. For example, one possible set of groups might be as follows:

- **Project leaders.** You might also think of these as project-level administrators. Users who can perform all available capabilities on data sources, with the possible exception of setting permissions on them. People in this group can be site administrators, or users whose job it is to approve or certify data models or reports.

  To grant administrator capabilities at the project level, you can assign the **Project Leader** permissions role to users with the appropriate site roles. To learn more, see Project-level administration.

- **Analysts/Publishers.** This group is for users who can publish workbooks to production and other open projects, use web editing on some projects, and connect to data sources certified by the data stewards. This group is not allowed to set permissions on content or move it between projects.

- **Business Users.** This group is the most likely to include people who do not use Tableau Desktop, but use data to answer questions and make business decisions. They can view and interact with workbooks only in specific projects, and they can’t publish, edit, save, or delete anything.
• **Administrators.** Depending on the size of your deployment, managing site or server administrators as a group helps you keep track of who has that level of access.

  **Note:** Users with the Server Administrator or Site Administrator Creator site role have access to everything on the site, regardless of the groups you add them to.

If you have multiple Tableau roles per department, creating corresponding groups manually can be labor intensive. For alternatives, see Automate working with groups and projects later in this article.

**Learn more:** Add Users to a Group

### 4. Assign permissions to the groups

After you create groups, you can assign permissions in one of the following ways:

- In the Default project, apply a core set of permissions on each group that will stay more or less the same for all projects. You can then make minor adjustments in specific projects.

  Or

- Keep the Default project clean and apply permissions only on projects you create.

For the example we’re using, it makes more sense to set permissions templates in the Default project. You will want to explicitly deny some capabilities across the board, and then allow them on only a few projects where you want to allow more open access.

**Set permissions templates**

1. While you have the Default project open, on the **Actions** menu (...), select **Permissions**.

   The **Permissions** pane shows only the All Users group that has no permissions.
2. Create a permission rule for each group as follows:
   a. Select Add a user or group rule, and then select one of your groups.
      This adds the group to the User/Group column, open for editing.
   b. Select a permission role in the Project, Workbook, and Data Source columns.
      Permission roles are predefined sets of capabilities that make setup easier.
   c. Refine permissions in any of the columns by selecting the expand icon (>>) to display individual capabilities and set them explicitly.

3. Lock permissions to the project.

Example

For the groups defined in 3. Create groups, here is one way you might set default permissions.

**Project leader roles**

- Project: **Project Leader**
- Workbooks: **Editor**
- Data Sources: **Editor**

This gives site administrators and data stewards full access to a project and its content. If you’re an IT admin, this enables you to delegate Tableau content administration to people who are closer to that content.

**Analyst Publisher roles**

- Project: **Publisher**
- Workbooks: **Editor**
- Data Sources: **Connector**

**Business Users roles**
- Project: **Viewer**
- Workbooks: **Interactor**
- Data Sources: **Denied**

**Default project settings for individual capabilities**

- Under Workbooks, set **Web Edit** and **Download Full Data** to **Deny**.

  This assumes you want to allow web editing and downloading data only on select projects. When you create those projects, you can refine the permissions.

- If you want to put more than a couple of users in the Project administrators group for each project, consider denying the **Set Permissions** capability for that group. An alternative for delegating the task of setting permissions is to set individual users’ site roles to Site Administrator.

- Leave capabilities in the Edit category set to **None**.

- If you want to allow other capabilities only as an exception, set those to **Deny** here as well.

<table>
<thead>
<tr>
<th>Permissions</th>
<th>Edit permissions for the project “Default”</th>
</tr>
</thead>
<tbody>
<tr>
<td>User / Group</td>
<td>Project</td>
</tr>
<tr>
<td>All Users (1)</td>
<td>None</td>
</tr>
<tr>
<td>Analyst/Publishers (1)</td>
<td>Publisher</td>
</tr>
<tr>
<td>Business Users (2)</td>
<td>Viewer</td>
</tr>
<tr>
<td>Data Analysts (3)</td>
<td>Project Leader</td>
</tr>
</tbody>
</table>

5. Create projects and adjust permissions

After the Default project is set with your custom permissions template, you can create projects that allow the content use cases you identified. For each project, you can adjust the default permissions as appropriate.
Example project structure

One way to structure projects could be to reflect the following use cases:

**Workbooks shared for open collaboration on the server**

Anyone in the department can publish to the open-collaboration project while their content is in development. Colleagues can collaborate using web editing on the server. Some people call this a sandbox, some call it staging, and so on. On this project you can allow web editing, saving, downloading, and so on.

Here you want not only to enable collaboration, but also to enable people who don’t have Tableau Desktop to contribute and provide feedback.

**Shared reports that cannot be edited**

This could be a project that people who create workbooks and data sources (Analysts and Data Stewards) could publish to when they want to make content available to business users for viewing, with confidence that their work cannot be "borrowed" or modified.

For this type of project, you would deny all capabilities that allow editing or getting the data off of the server for reuse. You would allow viewing and interacting capabilities.

**Vetted data sources for Analysts to connect to**

This would be where Data Stewards publish the data sources that are meet all of your data requirements and become the "source of truth" for your organization. Project leaders on this project can certify these data sources, so that they rank higher in search results and are included in recommended data sources.

You would allow authorized Analysts (that is, the Publishers group described earlier) to connect their workbooks to data sources in this project, but not download or edit them. You would deny capabilities to the Business Users group, so those users would not even see this project.

**Inactive content**
Another possibility is to segregate workbooks and data sources that the site’s administrative views show haven’t been used for a period of time. You could give content owners a time limit before their content is removed from the server.

Whether you do this or delete directly from the working projects is up to your organization. In an active environment, don’t be afraid to be intentional about removing content that is not being used.

Source for workbook templates

This is a project that people can download from but not publish or save to, where authorized publishers or project leaders make template workbooks available. Templates that have your organization’s approved fonts, colors, images, and even data connections built in can save authors a lot of time and keep your reports looking consistent.

Help project leaders manage content and users find it

- Devise a scalable project-naming scheme that makes sense in your organization.
  
  For example, basic structure might be `<Department> - <ContentUse>;` such as **Ops - Production**.

- Use the project’s **Description** field.

  The description you enter when you create a project appears on the project thumbnail, as well as the project-specific Details tab.
6. Lock permissions in each project

After you refine the capabilities for each group in a project, you can lock the project’s permissions. Do this on the Default project, too.

1. With a project’s Permissions page open, select the button next to Permissions for workbooks and data sources are

2. In the dialog box that appears, select Locked to the project.
Locking permissions prevents publishers from setting permissions explicitly as part of the publishing process in Tableau Desktop. Instead, content inherits permissions set on the project it’s published to, and only administrators and project leaders can set permissions.

Automate working with groups and projects

Creating multiple groups and projects and setting permissions manually can get tedious. To automate these processes, as well as make them repeatable for future updates, you can perform these tasks using REST API or tabcmd commands.

Next steps

Besides projects, groups, and permissions, other data governance themes include:

User education

Help all of your Tableau users become good data stewards. The most successful Tableau organizations create Tableau user groups, have regular training sessions, and so on.

For a common approach to orienting users to the site, see Dashboard-based Custom Portals.

For publishing and data certification tips, see the following topics:

- Use Certification to Help Users Find Trusted Data
- Prepare for Publishing a Workbook (links to Tableau Help)
- Best Practices for Published Data Sources (links to Tableau Help)

Optimize extract refresh and subscription activity

If you use Tableau Server, create policies for extract refresh and subscription schedules, to avoid them dominating the site’s resources. The TC customer presentations by Wells Fargo and Sprint address this subject in detail. In addition, see the topics under Tuning & Operations.
If you use Tableau Online, see the following topics to become familiar with the ways people can refresh extracts:

- Keep Data Fresh
- Use Tableau Bridge to Expand Data Freshness Options

**Monitoring**

Use administrative views to keep an eye on the site’s performance and content use.

**Administrative Views**

Learn how Tableau and some of our customers address governance and self-service.

The following list contains links to data governance and Center of Excellence (COE) presentations given at the Tableau Conference over recent years. Even if Tableau versions have evolved, the principles remain the same. You can explore the playlists for other videos related to COE, managing Tableau at scale.

- **Creating a Centre of Excellence in Tableau** (TC Europe 2018)
- **Server Admins: Don’t Fear Web Authoring** (Sprint, TC16)
- **The Past, Present, & Future at Charles Schwab** (TC 17)
- **Content Strategies in Tableau** (TC 17)

**Use Projects to Manage Content Access**

When Tableau Desktop users publish a workbook or data source to a site on Tableau Server, they can select a *project* to publish it to. If they don’t specify a project, their content is published to the **Default** project.

As an administrator, you can create projects to hold and organize related *content resources*, or to delegate content management. Content resources on Tableau Server are workbooks, views, and data sources, and the projects that hold them.
In this article

Why use projects

Project-level administration

How the Default project acts as a permissions template

Prevent publishers from changing permissions on content they own

Next steps

Why use projects

Projects help you to create a scalable process for managing access to the content published to Tableau Server. Advantages they have include:

- They enable administrators to delegate content management to project leaders who work with the content more closely, without having to give them administrator access to site or server settings.

  Project leaders can create nested projects under their top-level project, enabling them to maintain their team’s content within a single hierarchy.

- They can make the site easier to navigate for self-service users.

  They segment the Tableau Server site into areas that give users access based on how they use the data published to those areas, or on the Tableau user group they work with.

  You can hide projects from groups who don’t need to use them, create a distinguishable project-naming scheme, and take advantage of project descriptions to clarify how to use the project.

- They enable you to track permissions effectively.
You can create groups based on the level of content access users in the group need, and set default permissions on projects, so you know exactly which capabilities new users get by default, and likewise which capabilities all users get when a new project is created.

When to create project hierarchies (example)

Many organizations have several or more distinct groups of Tableau users, each with its own priorities and leaders. These groups might share some organization-wide content (or even draw from an org-wide pool of data sources), but primarily they use data and reports that are specific to their team. In this or similar scenario, an example for using project hierarchies might look as follows:

1. You, as a site or server administrator, can create top-level projects for each of your distinct Tableau teams.

2. On each top-level project, you assign the Project Leader role to team leads, and change project ownership.

   Project leaders effectively are the content administrators, so it’s important that they understand how permissions work in Tableau, along with Tableau content management best practices.

3. Each project leader takes over their project, creating the structure within the project that works for their team.

   That is, they can create child projects they need, based on how their team members collaborate and share data and reports.

The benefit to you as the site administrator is that you can focus on system health. The benefit to your Tableau users is that people who know the best practices for working with Tableau and data can manage these things for their teams, without having to submit IT requests to change permissions or add projects.
Why not use sites?

If you manage your own Tableau Server deployment, you can create as many sites as you want. However, for managing data and reports across your company, projects allow the flexibility you need to administer shared data and reports, and users who might belong to multiple groups. Many Tableau administrators configure projects as described in the previous section, to expose only what’s necessary to users who need to work with it. Projects work better than sites for evolving content from development to staging to production.

Sites work well when content can remain completely separate during all phases, and there is little to no user overlap. A good (and common) example for using multiple sites is to create a site for each of multiple external clients, whose published content you manage as a consultant or vendor. Our own Tableau Online is an example of this on a large scale. Another example might be to use a separate site for sensitive content that you want only specific Human Resources or medical staff to use.

Project-level administration

As a server or site administrator, you can delegate administration of projects and their content, without exposing access to your site or server settings. You can do this by changing the ownership of a project or granting a group or user the Project Leader permissions role on a project.

The project owner is always one individual user. By default, the user who creates a project is its owner. The project owner has administrative access to the project and content in it—including making someone else the owner and assigning Project Leader permissions.

The Project Leader permissions role provides a way to allow multiple users administrative access to a project, its child projects, and all workbooks and data sources in those projects.

A project leader does not have to be a project owner or administrator. In addition to server and site administrators, the full scope of Project Leader permissions is available to users with a Creator or Explorer (Can Publish) site role.
Project ownership and project leader access in project hierarchies

In a multi-level project hierarchy, a user or group that is given the Project Leader permissions role to a project, at any level within the hierarchy, is implicitly given Project Leader access to all of that project’s child projects and their content items.

To remove the Project Leader access, you must do so at the parent level in the hierarchy on which the ownership or role was explicitly assigned.

Similarly, the owner of a project at any level has project leader access to all content in that project, as well as to any of its child projects, even if they do not own the child projects.

Only a project owner or administrator can change ownership of a content resource, and this can be done regardless of whether the project permissions are locked at the top level.

Actions project-level administrators can take on projects

Project leaders and owners can perform the tasks in the following list, as can server or site administrators.

- Create and delete projects as follows:

  Server or site administrators can create or delete top-level or nested projects anywhere on the site.

  Project owners and project leaders can create and delete child (nested) projects in projects they own, or on which they have Project Leader permissions.

  **Note:** Project owners can delete top-level projects that they own.

- Project owners can change ownership of their projects. Both project owners and project leaders can assign the Project Leader permissions to groups or users.

  As a project leader or owner, if you assign the Project Leader permissions role to someone else, remember that full access to this role’s capabilities depends on the user’s site role, as specified earlier in this section.

- Set permissions for a project, as well as the child projects, workbooks, and data
sources in it.

- Lock permissions to apply the top-level project's default settings to all workbooks, data sources, and child projects and their content. Permissions can be modified only from the project on which they're locked.

In a locked project hierarchy, only the owner or project leader of the top-level project in the hierarchy can change permissions.

- Move workbooks and data sources to another project to which they have Project Leader or owner access.

Moving the project can affect permissions. For information, see Move a project or project hierarchy.

- Run, add, or remove extract refresh schedules.

See also Permissions in Project Hierarchies

How the Default project acts as a permissions template

Tableau creates a Default project with every site.
The Default project serves as a template for new top-level projects you create on the site. When you create a new top-level project, settings and permissions from the Default template are applied to the new project, including permissions set on the project’s workbooks and data sources.

**Note:** Nested projects (projects you create within other projects) take the permissions set at their parent project, not the Default project.

Before you create other top-level projects, you can take steps to set up the Default project, to help you to know exactly:

- Which type of user gets what level of access for each new project.
- How you might need to modify permissions for each new project.

For more information, see Steps to coordinate projects and groups in the topic Configure Projects, Groups, and Permissions for Managed Self-Service.
Prevent publishers from changing permissions on content they own

Administrators and project leaders can prevent users from changing the permissions for workbooks and data sources in a project hierarchy. For example, you can disable the option to set permissions during the publishing process, and prevent publishers and content owners from changing them after publishing. To do this, you lock content permissions to the project. For more information, see the links below.

Next steps

- Add Projects and Move Content Into Them
- Permissions in Project Hierarchies
- Set Project Default Permissions and Lock the Project

Add Projects and Move Content Into Them

A content resource (workbooks and data sources) can live in only project. Server and site administrators can add or remove top-level projects on a site, and move published content from one project to another. Project leaders with appropriate site roles can add or remove child projects and move content between projects on which they have Project Leader access.

This article contains the steps for creating and moving projects. We recommend becoming familiar with the following related content as well:

- To learn about projects and when or why to use them, see Use Projects to Manage Content Access.
- Before you create project hierarchies, become familiar with Permissions in Project Hierarchies.
- To see the specific site roles that allow full Project Leader access, see Project-level administration.
In this article

Add a top-level or child (nested) project
Move a workbook or data source to another project
Move a project or project hierarchy
Delete a project

Required access level for moving content

Add a top-level or child (nested) project

1. While you’re signed in to Tableau Server as an administrator or project leader, select Content > Projects.

2. In the Projects page, do one of the following:

   ● (Administrators only) To add a top-level project, click New Project.

   ● To add a child project under a top-level project, select the top-level project, and on its Projects tab, click New Project.

3. Enter a name and description for the project, and then click Create.
You can include formatting and hyperlinks in the project description. Select **Show formatting hints** for syntax.

**Note:** To edit a project description later, select it to open it, navigate to **Details**, and then click **Edit Description**.

Move a workbook or data source to another project

The following procedure is specific to workbooks; however, you follow similar steps for data sources on the **Data Sources** page.
1. Go to the **Workbooks** place, select one or more workbooks, and then select **Actions > Move**.

2. Select the new project for the workbook, and then click **Move**.
Move a project or project hierarchy

1. In the thumbnail or list view, navigate to the project you want to move, select the
   **Actions** button, and then select **Move**.
2. Select the destination project and then click **Move Project**.
How moving projects affects Project Leader permissions

When you move a project, Project Leader permissions adapt to the new project environment.

- When the target project hierarchy is **locked**, previous Project Leader permissions are removed, and new Project Leader permissions are granted according to those set at the top-level of the target hierarchy.

- When the target project hierarchy is **unlocked** (managed by owner), previous implicitly granted Project Leader permissions are removed, explicitly set Project Leader permissions are retained, and new Project Leader permissions are granted according to those set at the top-level of the target hierarchy.

Delete a project

When you delete a project, all of the workbooks and data sources in the project are also deleted from the site. If you want to delete a project but not its content, move the content to another project, and then delete the project.

**Important**

- You cannot undo deleting a project.

- Deleting a project deletes all content in it, including child projects and their content.

- You cannot delete the Default project.

To delete a project:

1. Click **Content > Projects**. On the **Projects** page, do the following:
   a. Select the check box next to a top-level project.

   Or navigate to a child project, and on its **Projects** page, select the check box for the child project you want to delete.

   b. Select **Actions > Delete**.
2. Confirm that you want to delete the project.

Required access level for moving content

Moving content is effectively like removing it from one project and publishing it to another. For non-administrators, the permissions needed on the source project are different than those needed on the destination project.

**Note:** The term *permissions role* refers to the collection of related capabilities you can assign as a set.
Required site role

To move content, users must have one of the following site roles:

- Server Administrator (Tableau Server only)
- Site Administrator Creator or Site Administrator Explorer
- Creator or Explorer (Can Publish)

Users with a Server Administrator or Site Administrator site role do not need any additional capabilities.

Required permissions for the project that users move content to

Non-administrators must have the Publisher or higher permissions role set on the project that is the move destination.

Required permissions for the project that users move content from

Non-administrator users must have these additional capabilities on the project:

- Ownership of the project or the Project Leader or Publisher permissions role.
  
  OR

- In a project hierarchy, project owner of, or Project Leader permissions role on the project or a parent project higher in the hierarchy.

If they have the Publisher permissions role on the project, and they are not the project owner (or owner or leader of a parent project), they must have the following capabilities:

**Data sources:** Data source owner

**Workbooks:** Workbook owner or Move capability set explicitly on the workbook.

You can grant the **Move** capability individually, or along with related capabilities allowed through the **Editor** permissions role.
Set Project Default Permissions and Lock the Project

As an administrator or project leader, you can organize a related workbooks and data sources in projects. You can then set a project’s permissions—including the default permissions that will be set on child projects you create under that project, and workbooks and data sources published anywhere in that project hierarchy. You can further lock the top-level project, at which point only administrators and project leaders can change permissions, and only at the top-level project.

Administrators and users with an appropriate site role plus the Project Leader permission can lock permissions to a project. For more information, see Permissions in Project Hierarchies.

In this article

Set the default permissions for a project
Lock or unlock permissions on a project
Permissions roles you can set at the project level
Capabilities you can set for a project

Prerequisites

The remaining sections in this article assume the following:

- You have already created your user groups.
  
  For a best practice recommendation for creating groups, see Steps to coordinate projects and groups in the topic Configure Projects for Managed Self-Service.

- You understand which site roles allow access to all Project Leader capabilities. For information, see Project-level administration.
Set the default permissions for a project

These steps focus on our recommended practice of assigning permissions to groups; however, you can assign permissions to individual users the same way.

Before you can complete these steps, you must create your groups, as mentioned in Pre-requisites.

1. While you’re signed in to Tableau Server as an administrator or project leader, select Content > Projects.

2. In the Projects page, on the actions menu (….) for a project, select Permissions.

3. Click Add a user or group rule, select Group, and then select the group or name from the list.

   ![Permission Table]

   For an existing group, open the actions menu, and then select Edit.
4. Select a permissions role for **Project, Workbooks, or Data Sources**, and then click **Save**.

To create a custom set of capabilities, select the **Project, Workbooks, or Data Sources** labels to expand the permissions view. Click capabilities to set them to **Allowed, Denied, or Unspecified**. Click **Save**.

The following image shows how to set project permissions. The same general steps apply for workbooks and data sources.
Note: To change the settings after saving, open the group’s or user’s actions menu (…), and then select Edit.

5. View the effective permissions:

Select a group name or user name in the permission rules to see the resulting user permissions.

Expand the Project, Workbooks, or Data Sources permissions views to see individual capabilities.
Hover over a capability box to see a tooltip with details on whether a capability is allowed or denied.

6. Follow the same steps to configure additional permission rules for more groups.

Lock or unlock permissions on a project

1. Sign in to your Tableau Server site as an administrator or project leader, in the Projects area, click a project’s Actions (…) menu, and then select Permissions.
2. Click **Edit Content Permissions**.

3. In the **Content Permissions in Project** dialog box, select **Locked to the project**, and then click **Save**.
4. To unlock content permissions for the projects, click **Edit Content Permissions** again, and select **Managed by owner**.
Content Permissions in Project

Permissions for workbooks and data sources in the project “Ops” are:

-  
  **Locked to the project**
  Workbooks and data sources in this project always use the default permissions. Permissions for individual workbooks and data sources in this project cannot be modified.

-  
  **Managed by the owner**
  Workbooks and data sources in this project start with the default permissions. Permissions for individual workbooks and data sources in this project can be modified.

Click for a user or select a permission rule above to view user permissions.

The default permissions are reapplied to workbooks and data sources in the project, and their permissions are now editable.

Permissions roles you can set at the project level

Permissions roles are built-in templates that assign a common set of capabilities on content. You can assign them only at the project level, for the project itself, and the workbook and data sources in it.

<table>
<thead>
<tr>
<th>Template</th>
<th>Description</th>
</tr>
</thead>
</table>
| Project Leader | Combined with the appropriate site role, allows the user or group full access to the project, its child projects, and content published into that project hierarchy.  
To learn more, see Project-level administration. |
| Editor      | Allows the user or group to connect to, edit, download, delete, and set permissions for data sources or workbooks in the project.              |
They can also publish data sources, and as long as they are the owner of a data source they publish, can update connection information and extract refresh schedules. This permission is relevant for views when the view they access connects to a data source.

<table>
<thead>
<tr>
<th>Capability</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Publisher</td>
<td>Allows the user or group to publish workbooks and data sources to the project.</td>
</tr>
<tr>
<td>Connector</td>
<td>Allows the user or group to connect to data sources in the project.</td>
</tr>
<tr>
<td>Viewer</td>
<td>Allows the user or group to view the workbooks and views in the project.</td>
</tr>
<tr>
<td>None</td>
<td>Sets all capabilities for the permission rule to Unspecified.</td>
</tr>
<tr>
<td>Denied</td>
<td>Sets all capabilities for the permission rule to Denied.</td>
</tr>
</tbody>
</table>

Capabilities you can set for a project

The three capabilities you can set specifically for a project are: View, Save, and Project Leader.

<table>
<thead>
<tr>
<th>Capability</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>View</td>
<td>Allows the user or group to view the workbooks and views in the project. The View capability must also be allowed for the individual workbooks and views in the project.</td>
</tr>
<tr>
<td>Save</td>
<td>Allows the user or group to publish workbooks and data sources to the server and overwrite content on the server. The Save capability must also be allowed for the individual workbooks and data sources in the project.</td>
</tr>
</tbody>
</table>
When allowed, the user with a site role that supports publishing can re-publish a workbook or data source from Tableau Desktop, thereby becoming the owner and gaining all permissions.

Subsequently, the original owner’s access to the workbook is determined by that user’s group permissions and any further permissions the new owner might set.

This permission also determines the user’s or group’s ability to overwrite a workbook after editing it on the server. For related information, see Set Web Edit, Save, and Download Access on Content.

Project Leader

Combined with the appropriate site role, allows the user or group to set permissions for all items in the project, lock project permissions, and edit default permissions.

To learn more, see Project-level administration.

Content Permissions and Ownership

Use Projects to Manage Content Access

Configure Projects, Groups, and Permissions for Managed Self-Service

Permissions in Project Hierarchies

As an administrator or project leader, you can decide how permissions are set in a project hierarchy you manage. On the top-level project in a hierarchy, you can set the project to one of two available states: locked and managed by owner. Locking permissions can help you maintain a predictable permissions model within a project hierarchy. For example, it denies publishers the option to set explicit permissions on workbooks and data sources they own.
In this article

- Project permissions states: locked and managed by owner
- How permissions are evaluated in project hierarchies

Project permissions states: locked and managed by owner

You can lock permissions in project hierarchies at the top level of the hierarchy. When you lock permissions, the top-level project’s permissions settings are applied to all workbooks, views, and data sources in the hierarchy.

In a locked project hierarchy, only administrators and project leaders with an appropriate site role can modify permissions, and they can do so only on the top level. Publishers cannot set permissions on their content during or after publishing from Tableau Desktop.

When permissions are managed by the owner (“unlocked”), they become editable by content owners and other users with the appropriate access level. During publishing, users have the option to set permissions explicitly on the workbook or data source they are publishing, unless you explicitly deny this capability on groups they are members of or individual users.

To clarify, owners always get full read, write, and other access to the content they publish, but in a locked state, they cannot change permissions on it.

**Note:** If a workbook, data source, or project with editable permissions is moved to a locked project, the permissions set on the locked project are applied to that content. The moved content’s permissions are then locked.

When to use each state

In general permissions are easier to manage when you lock projects. You need to go only to one place to see how they’re set for all content in that project’s hierarchy.
However, this requires that all child projects have the same permissions as set at the top level. The following common scenarios are possible only when you keep the project hierarchy unlocked:

- You want to create projects for different types of access your team needs for content in child projects. This strategy is described in Configure Projects, Groups, and Permissions for Managed Self-Service, and it requires setting unique permissions on each child project.

If you keep permissions unlocked, you can still set permissions at a parent project level that you want all child projects to take by default. And you can use groups to set capabilities explicitly, including denying the Set Permissions capability, so that users cannot set permissions on content they own.

- In web editing, you want to allow publishers to save changes to workbooks but not overwrite them.

For more information, see Allow users who can publish to edit, save changes to, and download new workbooks, but not overwrite existing workbooks.

How permissions are evaluated in project hierarchies

The following diagram shows how ownership and Project Leader permissions are applied in a hierarchy.

- PL = Project Leader
- O = Owner
- Dotted line indicates implicit permissions “inherited” at a parent level.
- * = Owner was assigned explicitly by the owner of the parent project.
How permissions are applied in locked project hierarchies

You can lock permission only at the top-level in a project hierarchy, and the following behavior applies:

- All child projects you create within a top-level project use the default permissions set at that top-level project (not the Default project), and you cannot modify permissions at the child-project level.

- Workbooks, views, and data sources also use the default permissions set on the top-level project.

- Users, including content owners, cannot edit permissions for individual workbooks, views, or data sources.

When users publish workbooks and data sources from Tableau Desktop, they cannot set permissions in the Publish dialog box, and their content gets the default permissions for the project they publish it to.

- Users or groups that have an appropriate site role and are assigned the Project role can...
Leader permissions role at the top-level project get project leader access to all child projects and their workbooks and data sources.

- Administrators and content owners can change ownership at any level in the hierarchy.

- Administrators and project leaders can edit permissions at the top-level project, and those changes propagate to all child projects.

How permissions are applied in unlocked project hierarchies

If the top-level project’s permissions are not locked, you can set permissions on its child projects in the same way you can on top-level projects, with the exception of locking the child project.

When you create a child project, it takes default permissions from the parent project. Users implicitly get the same permissions they have on the parent project.

If you set permissions at the child level, those settings take precedence over permissions set at the parent level.

See also

For a couple of best-practice steps for how to implement permissions, see the following:

- Configure Projects, Groups, and Permissions for Managed Self-Service

- Structure Content Projects, Groups, and Permissions (links to Everybody’s Admin Guide)

Add a Project Image

Projects can have images that are displayed in thumbnail view in Tableau Server.
Set a project image

1. Sign in to a site on Tableau Server. On the Content tab, select Projects, and then select a project.

2. Navigate to Details, and then click Edit Description.
3. In the **About** field, add the URL for your image, using the following syntax:

!http://www.example.com/image.png!
Select **Show formatting hints** to see how you can format description text.

4. Click **Save**.
Content Permissions and Ownership

In Tableau Server, you set content permissions to specify who is allowed to work with which content resources on a particular site.

For example, you can tightly restrict who has access to your company’s financial information, but widely share organizational development content.

Content resources on which you will generally assign permissions include the following:

- Projects
- Workbooks
- Data sources

Views in a workbook inherit permissions from the workbook, although you might have an edge case for which you want to set permissions for a single view.
What makes up a user's permissions

When Tableau determines which tasks (or capabilities) a user is allowed to perform on a content resource, it takes the following pieces into account:

**Site roles:** At the time that you add users to a site, you must apply a site role to them. This is the only setting that you apply to users (as opposed to content) to affect permissions. The site role determines whether the user can publish, interact with, or only view published content on that site. See Set Users’ Site Roles.

**Permission rules and templates:** You assign content access through permission rules. These rules describe the capabilities that you want a user or group to be able to perform on a set of content. Examples of capabilities include editing a view or connecting to a data source. Tableau provides a set of templates for common permission roles, such as Editor, Project Leader, and so on.

**Content ownership:** By default, the person who publishes a data source or workbook to the server is the owner of that content. Ownership changes when another publisher updates the content on the server, or republishes it from Tableau Desktop. An administrator or project leader can change ownership or set defaults for the project.

**User permissions:** are the effective permissions that are the result of evaluating rules and settings, and which ultimately determine what a user can do with the content.

Who can set permissions

Users can have the **Set Permissions** capability. By default, these are:

- Administrators, for all content on the site.
- Project leaders, for all content in the project and its child projects.
- Content owners, generally those who create projects or publish data sources or workbooks.
Quick Start: Permissions

You can use permission rules to control access to content on a site. A permission rule is a set of capabilities that defines the level of access a group or user has on a content item. Content items are projects you create, and the workbooks and data sources published to them.

The most efficient way to manage permissions is to create permission rules for groups, and assign the permissions at the project level.

1 Add users to groups

Create groups for users based on who should have the same permissions, and then add users to those groups. Within a site, select Groups. Select a group name, and then select Add Users.
2 Select a project

On the Content page for a site, navigate to the **Projects** page. On the Actions menu, select **Permissions** to view the permission rules for the project. By default, only an All Users group is defined, with pre-defined permissions roles applied to the group.

The image below shows an All Users group that was modified to remove those pre-defined permissions, in preparation for creating new groups for your own environment.

3 Create a Permission Rule

Click **Add a user or group rule**, select **Group**, and then find and select the group.

Select a permission role template to apply an initial set of capabilities for the group. Click a capability to set it to **Allowed** or **Denied**, or leave it **Unspecified**. Click **Save** when you are done.
Whether a user can set permissions is based on their site role and how their **Set Permissions** capability is set.

4 View User Permissions

After you save the permission rule for the group, you can view the effective permissions for that content.

Click a group name to see the group’s users and their permissions. Hover over a capability box to see a tooltip with details on whether a capability is allowed or denied.
Custom indicates a user's capabilities have been changed from the initial settings for their site role or content role.

Site roles

A user’s site role determines the maximum permissions allowed for that user.

- Server and site administrators can access all site content with full permissions.
- Owners always get full access to the content they’ve published, but can change permissions for their workbooks and data sources only when the parent project permissions are not locked.

For more information, see Set Users’ Site Roles.

Permissions evaluation

- **Denied** takes precedence over **Allowed**.
- **Unspecified** results in **Denied** if no other permissions are specified.
- Specific user permissions on content take precedence over group permissions on content. In other words, user permissions trump group permissions.
For a couple of best-practice steps for how to implement permissions, see the following:

- Configure Projects, Groups, and Permissions for Managed Self-Service
- Projects and Content Permissions (links to Everybody’s Admin Guide)
Manage Content Ownership

When you publish a data source or workbook on Tableau Server or when you create a project, you become its owner. A content owner, a project leader with an appropriate site role, or an administrator can change ownership of a content asset. After ownership is reassigned, the original owner has no special connection to the content item, and their ability to access it is determined by their permissions on the project or that specific item.

In this article
Who can change or be given ownership, by content type
Considerations for changing content ownership
Change a workbook or data source owner
Change a project owner

Who can change or be given ownership, by content type

Whether you can change or be given ownership depends on your permissions and your relationship to the content asset, as described in the following table.

Note: Full project leader access is available only with some site roles. For information, see Project-level administration.

<table>
<thead>
<tr>
<th>Content asset type</th>
<th>Who can change ownership</th>
<th>Who can be given ownership</th>
</tr>
</thead>
<tbody>
<tr>
<td>Top-level projects</td>
<td>Server administrator¹</td>
<td>Server administrator</td>
</tr>
<tr>
<td></td>
<td>Site administrator</td>
<td>Site administrator (Creator and Explorer)</td>
</tr>
<tr>
<td></td>
<td>Creator</td>
<td></td>
</tr>
<tr>
<td>--------------------</td>
<td>------------------------------------------------------------------------</td>
<td></td>
</tr>
</tbody>
</table>
| **Child (nested) projects** | Server administrator  
Site administrator  
Project leader or owner | Any administrator or user of the site, excluding users with a Read Only site role. |
| **Workbooks and data sources** | Server administrator  
Site administrator  
Workbook or data source owner  
Project leader or owner of the project that contains the item | Any administrator or user of the site, excluding users with a Read Only site role. |

1 The Server Administrator site role applies to Tableau Server only; not Tableau Online.

Considerations for changing content ownership

- Before you remove a user from Tableau Server, make sure they do not own any content assets.

  If the user does own content, you must first reassign ownership of those assets before you can delete the user. Otherwise, their site role is set to Unlicensed, but they are not deleted, and only an administrator can take certain actions on that content.

- If you change the ownership of a workbook or data source that includes embedded credentials, to connect to underlying data, the embedded credentials will be deleted.

  You can update the embedded credentials by editing the connection information on Tableau Server. For more information, see Edit Connections. Alternatively, the new owner can download the workbook or data source, and open the item in Tableau.
Desktop to update the embedded credentials, and then re-publish the workbook or data source.

- If you do not lock permissions to projects, make sure users you give content ownership to know your permissions guidelines, or you account for permissions as you change ownership. In unlocked projects, by default, content owners can set permissions on their content. For more information, see Permissions in Project Hierarchies.
Change a workbook or data source owner

1. On the Content page for a site, select **Workbooks** or **Data Sources**.

2. Select one or more workbooks or data sources, and then select **Actions > Change Owner**.

3. Type the name of a user or select a user from the list.
4. Click **Change Owner**.

Change a project owner

1. On the Content page for a site, select **Projects**.

2. Select one or more projects, and then select **Actions > Change Owner**.
3. Type the name of a user or select a user from the list.
4. Click **Change Owner**.

View or Edit Permissions

When you specify permissions for a project, workbook, view, or data source, you use a **permissions rule** to express who is allowed to work with that resource. Permissions rules are the explicit capabilities that can be set for an individual user, or for a group—for each resource.

You work with these rules in the **Permissions** window, described in the steps below. You define permissions rules in the upper section. The **User Permissions** section below it shows the effective, or resulting, permissions after Tableau evaluates your rule.

View or edit a permissions rule for a selected content resource

1. On the Content page for a site, select **Projects, Workbooks, Views, or Data Sources** to display all items of that content type.

2. Select the check box for the item, and then select **Actions > Permissions**.
This shows the current permissions rules.

3. To edit a rule, do the following:

   a. Select the actions menu (…) next to the rule name, and then select Edit.

   b. Select a permissions role to assign a set of capabilities and leave the rest unspe-
      cified.

      See How the permissions rules settings work together below for more inform-
      ation.

   c. Select an individual capability to cycle through Allowed or Denied, or Unspe-
      cified settings.

   d. Click Save.

4. To see the resulting permissions for the selected group or user, do the following:

   a. In the permissions rules area, select the group or user name.

   b. In the User Permissions area, hover over a capability box to show a tooltip
      that indicates the capability name, its resulting setting, and how the result was
The following image shows permissions on a selected workbook for Andrew Allen in the Finance group. The tooltip indicates that a rule assigned to a group he is a member of denies the web edit capability.

How the permissions rules settings work together

In the Permissions window, the settings that appear depend on the type of content you select, and some are not available until you edit the rule, as described earlier in this article.

The following settings apply to permissions on projects. Data sources and workbooks show similar sections:

- **User / Group**: Lists users or groups that a rule applies to. If the permissions are not locked to the top-level project, you can select Add a user or group rule to configure permissions on the selected project, which then become default settings for this project's child projects.

- **Project**: Lists available permissions-role templates for projects. Each template contains a predefined set of capabilities for the rule.

- **Workbooks / Data Sources**: Similar to Project, lists the permissions-role templates
for assigning predefined sets of capabilities for workbooks or data sources.

- **View / Interact / Edit**: These are categories of capabilities that you can set to **Allowed**, **Denied**, or **Unspecified**. Setting **Unspecified** evaluates to **Denied** if no other permissions are specified for a user or group on the content.

Although some of the permissions-role names are the same as or similar to site role names, the permissions roles are separate, and they indicate groups of capabilities that are typically configured as a set.

What determines users’ effective permissions

Effective user permissions for a content resource are determined by the following:

- The maximum capabilities allowed for a user’s site role. The site role acts as the “ceiling” for what permissions are allowed. For more information, see Set Users’ Site Roles.

- Whether the user is a project leader for a project hierarchy or is shown as the owner of a content asset.

- The evaluation of each permissions rule that applies to that user, or a group the user is a member of, for the selected content type or content item.

For example, if a user is granted the Editor permissions role for workbooks in a project (which allows all available workbook capabilities), but has the site role of Viewer and does not own any workbooks, the user will be allowed only the capabilities of **View, Download Image, Download Summary Data, View Comments**, and **Add Comments**.

In the following example, a permissions rule has been created for the Finance group. Initially, the administrator applied the **Editor** permissions role to the group. This granted all capabilities. Then the admin set the **Save** capability to **Denied**. This changed the name of the permissions role to **Custom**. The **User Permissions** (effective permissions) section for the Finance group reflects these actions. You can also see that one user has fewer capabilities, because that user has a site role of Viewer.
Tip: The All Users group permissions rule in this example has been set to None, which leaves all of the permissions as Unspecified for the All Users group. This approach requires the administrator to specifically assign permissions only to the groups or users that should have access to content assets, which makes for more predictable effective permissions. For more information, see 2. Remove permissions that will cause ambiguities in the topic Configure Projects, Groups, and Permissions for Managed Self-Service.

Set Permissions on Individual Content Resources

As an administrator, or as a user granted the Set Permissions capability on a specific resource, you can change permissions on that resource (data source or workbook).
Generally we recommend setting permissions at the project level for all content in the project. A reason you might want to deviate from this practice, for example, is to explicitly deny the some capabilities on a data source or workbook that has a data source or user filter that enables a form of row-level security.

In this article
Capabilities you can set on data sources
Capabilities you can set on workbooks and views
Set permissions on a content resource

Capabilities you can set on data sources

Use permission rules to set the following capabilities for a data source:

<table>
<thead>
<tr>
<th>Capability</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>View</td>
<td>View the data source on the server.</td>
</tr>
<tr>
<td>Connect</td>
<td>Connect to the data source. The Connect permission allows a user to connect to a data source from an editor (in Tableau Desktop or Tableau Server web editing). Note: If a workbook author embeds credentials in a workbook or view, users who also have the Web Edit permission will be able to access to the workbook’s data source regardless of their Connect permissions.</td>
</tr>
<tr>
<td>Save</td>
<td>Publish data sources to the server and overwrite data sources on the server.</td>
</tr>
<tr>
<td>Download Data</td>
<td>Download the data source from the server.</td>
</tr>
</tbody>
</table>
Note: Cube data sources, like those for Microsoft Analysis Services or Oracle Essbase connections, must be used locally. To download the published data source to Tableau Desktop, the user must have the Download capability. You must explicitly grant the Download permissions regardless of the permissions role you apply. For more information, see Cube Data Sources.

<table>
<thead>
<tr>
<th>Source</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Note:</strong> Cube data sources, like those for Microsoft Analysis Services or Oracle Essbase connections, must be used locally. </tr>
<tr>
<td>Editor</td>
<td>Allows the user or group to connect to, download, delete, and set permissions on data sources on the server. They can also publish data sources, and as long as they are the owner of a data source they publish, they can update connection information and extract refresh schedules. (The latter two capabilities are no longer available if an administrator or project leader changes data source ownership.)</td>
</tr>
<tr>
<td>None</td>
<td>Sets all capabilities for the permission rule to <strong>Unspecified</strong>.</td>
</tr>
</tbody>
</table>
Denied | Sets all capabilities for the permission rule to **Denied**.

Capabilities you can set on workbooks and views

The list of capabilities and the available permission role templates vary depending on whether you are setting permissions for a workbook or a view. For information about capability definitions, see Permissions Reference.

Editing view-level permissions

When a Tableau Desktop author publishes a workbook with the **Show Sheets as Tabs** enabled, these tabbed views take on the workbook permissions rules. Changes you make to the workbook permissions affect all of its tabbed views.

To edit an individual view’s permissions, save the workbook again without tabs (or hide sheets). The default permissions are applied to the workbook, and you can then edit view permissions.

We recommend that you set view-level permissions sparingly, as an exception. Try to manage permissions at the project level as much as possible. When permissions are locked to a project, views in a workbook use the workbook permissions.

Permission role templates for workbooks and views

<table>
<thead>
<tr>
<th>Template</th>
<th>Applies to...</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Viewer</td>
<td>workbooks, views</td>
<td>Allows the user or group to view the workbook or view on the server.</td>
</tr>
<tr>
<td>Interactor</td>
<td>workbooks, views</td>
<td>Allows the user or group to view the workbook or view on the server, edit workbook views, apply filters, view underlying data, export images, and export data. All other permissions are inherited from the user’s or group’s project permissions.</td>
</tr>
<tr>

</tr>
</tbody>
</table>

**Set permissions on a content resource**

1. In the Data Sources, Workbooks, or Views page, select the check boxes for each resource, and then select **Actions > Permissions**.

The following image shows how this looks on the Data Sources page.

![Data Sources page](image)

**Note**: If you select multiple items and some of the items are read-only, you cannot view the permissions. Instead, select one item at a time.

2. Click **Add a user or group rule**, select **Group** or **User**, and then select the group or user name from the list.
3. Select a permission role template to apply an initial set of capabilities for the group or user, and then click **Save**.

4. To further customize the rule, click the actions menu (…) next to the rule name, and then click **Edit**. Click a capability in the rule to set it to **Allowed** or **Denied**, or leave it unspecified. Click **Save** when you are done.
5. Configure any additional rules you want for other users or groups.

6. View the resulting permissions.

Click a group name or user name in the permission rules to see the resulting permissions. Hover over a capability box to see a tooltip that shows whether a capability is allowed or denied, and what determined that result.

How data access is evaluated for workbooks that connect to Tableau data sources

How Permissions are Evaluated

Permissions in Tableau Server are assigned to content assets—projects, workbooks, data sources, and occasionally to individual views. You use permissions rules to specify who can work with a content asset.

Each user’s level of access to content published to a site is determined by the following:

- **Site role.** A user’s site role determines whether a user can publish, interact with, or only view content assets. For more information, see Set Users’ Site Roles.

- **Content permissions.** Every project, workbook, data source, or view theoretically can have a unique set of permissions rules.

  A permissions rule includes the user or group, and the set of capabilities you want to grant users for an asset or set of assets. An example of a capability is Download Data Source.

  Each permissions role template (such as Editor, Interactor, Viewer) specifies a pre-defined set of capabilities.

  Available capabilities vary depending on the content type. Capabilities can be set to Allowed, Denied, or Unspecified. Denied always takes precedence over Allowed; Unspecified results in Denied if no other permissions rules allow a capability for a user.

- **Ownership.** Content owners always get full access to the content they’ve published, including setting permissions on it. In locked project hierarchies, you can prevent content owners from modifying permissions on their workbooks and data sources. For information, see Set Project Default Permissions and Lock the Project.

A user’s effective permissions for a given content asset are determined by the following:
• The maximum capabilities allowed through the site role.

• Whether the user owns the content item.

• The result after Tableau evaluates permissions rules applied to that user and all groups the user is a member of.

You can set permissions rules for an individual user or group for each content asset. This diagram illustrates how permission rules are evaluated in Tableau Server.

![Diagram illustrating permission evaluation in Tableau Server]

Notes on permissions

• You cannot set permissions at the site level; permissions are assigned to only to content.

• Individual user permissions take precedence over group permissions.

• Workbook permissions serve as templates for view permissions. In a locked project, when a workbook uses tabbed views, views inherit workbook permissions. In an unlocked project, when a workbook is saved without tabs, the workbook and view permissions can be edited independently.

• For each content item, every site user is automatically included in the All Users group. As a result, when you create additional group permissions rules for a content item, the All Users permissions rules affect how permissions are evaluated. For more information, see 2. Remove permissions that will cause ambiguities in the topic “Configure Projects, Groups, and Permissions for Managed Self-Service.”
The order of precedence in which Tableau evaluates permissions

Tableau steps through the following rules, continuing to the next rule if the current one evaluates to “denied.” If any rule evaluates to “allowed,” the capability is allowed, and Tableau stops evaluating.

1. **Administrator site roles**: People with a site role of Server Administrator (Tableau Server only) or Site Administrator Creator can access all site content with full permissions, regardless of the permissions set on projects or individual content assets.

2. **License denies capabilities**: If a user’s license type explicitly denies the capability, the user is denied. For example, a user with a Viewer license cannot connect to data sources.

3. **Project Owner**: If the user owns a project that contains a content asset, the capability is allowed.

4. **Project Leader**: If the user has, or is in a group that has, the Project Leader permissions role on a project, the user has administrative access to content in that project.

5. **User is content owner**: If a user is the owner of a content asset, they are allowed all access. However, in locked projects, administrators or project leaders can deny capabilities at the project level, such as setting permissions on content the user owns. In locked project hierarchies, content assets inherit permissions set on the top-level project.

6. **User - capability denied**: If the user has been explicitly denied the capability on a content asset, they are denied.

7. **User - capability allowed**: If the user has been explicitly allowed the capability for the content, they are allowed.

8. **Group - capability denied**: If the user belongs to a group that has been explicitly denied the capability for the content, they are denied.
9. **Group - Capability Allowed:** If the user belongs to a group that has been explicitly allowed the capability for the content, they are allowed.

10. The user is denied access to the content.

**Permissions Reference**

This article lists the user and content settings that make up a given user’s ability to access published data sources and workbook on a given site on Tableau Server.

In this article
Site and permissions roles that allow full content access
Capabilities available for each content type
How data access is evaluated for workbooks that connect to Tableau data sources

Site and permissions roles that allow full content access

The following list describes roughly who gets full access to content and the scope of that access:

- Server administrators (Tableau Server only) are allowed all capabilities on all content published to the server.

- Site administrators are allowed all capabilities on content published to the site they administer.

  Users with the Site Administrator Creator site role can also publish or save new content from any Tableau client that supports publishing functionality. For example, Tableau Desktop, the web authoring environment.

- In groups to which you apply the Project Leader role, users with the appropriate site roles are allowed all capabilities on content in the project.
To learn more about Project Leader permissions, see Project-level administration.

- Publishers become the owners of content they publish, and, by default, they are allowed all capabilities on that content. If they publish to a locked project hierarchy, they cannot set permissions on their content after publishing, unless they also are the top-level project owner or leader.

Capabilities available for each content type

The following table shows how permissions apply to content and describes each capability.

**How data access is evaluated for workbooks that connect to Tableau data sources**

When a Tableau Desktop user publishes a workbook that connects to a data source published to the server (a Tableau data source), the user can set the data authentication type to **Embed password** or **Prompt users**. In this specific publishing case, data authentication refers to the workbook’s connection to the Tableau data source. This is independent of the authentication set in the published data source’s connections to the underlying data.
When a user subsequently opens the workbook on the server, the workbook-specific data authentication is evaluated along with the Connect capability, set in permissions rules. Whether the user can see the data in the workbook is determined as follows:

- When the workbook publisher selects the **Embedded password** option, they effectively embed their own Connect permissions, allowing anyone who can view the workbook to see the data it connects to. How the viewer’s Connect capability is set on the data source does not affect this outcome.

- When the publisher selects the **Prompt users** option, viewers who are allowed the Connect capability are on the data source are prompted for their credentials. Users who are denied the Connect capability are denied access the data.

The following table summarizes the two bullet points above.

<table>
<thead>
<tr>
<th>Workbook</th>
<th>Data source authentication</th>
<th>Connect capability</th>
<th>Resulting access to data in the workbook</th>
</tr>
</thead>
<tbody>
<tr>
<td>Embedded password</td>
<td>Embedded password or Prompt user</td>

Manage Data

Tableau Server Data Sources

When your Tableau users want to share data connections they’ve defined, they can publish data sources to Tableau Server. When a data source is published to the server, other users can connect to it from their own workbooks, as they do other types of data. When the data in the Tableau data source is updated, all workbooks that connect to it pick up the changes.

Looking for Tableau Server on Windows? See Tableau Server Data Sources.

A Tableau Server data source consists of metadata that describes the following:

- **The connection information**: Defines whether the data is in a live database or an extract, and which of that data to bring in to Tableau.

- **Customization and cleanup**: Includes information that facilitates efficient use of the data. For example, calculations, sets, groups, bins, parameters, custom field formatting, and so on.

- **Data access and refresh instructions**: Includes the location of the underlying database server (whether on-premises or in the cloud), network paths for file-based data, security information such as credentials or access tokens, and related information.

In addition to helping your users create data consistency and reliability, using Tableau data sources offers advantages to you as the administrator. Because multiple workbooks can connect to one data source, you can minimize data source proliferation and save on storage space and processing time. When someone downloads a workbook that connects to a Tableau data source that in turn has an extract connection, the extract stays on the server, reducing network traffic. Finally, if a connection requires a database driver, you need to install and maintain the driver only on the server, instead of on each user’s computer. (If you
use Tableau Online, all supported drivers are available to data sources published to your site.)

Managing data sources

You can perform some or all management tasks on a data source if you have one of the following levels of access:

- Site or server administrator
- Project leader or owner of the project the data source is published to
  - Full project leader access is available only with some site roles. For information, see Project-level administration.
- Data source owner

Unless you’re a site or server administrator, you might not have access to all management tasks. For example, if the Permissions menu is not available, chances are that the project permissions are locked, which denies setting permissions on individual workbooks and data sources.

Tip: A best practice is to designate a person or team to manage all data sources published to a project or to the whole site, so that all data sources can be maintained under the same set of guidelines.

To perform the management tasks that you have access to, do the following:

1. Sign in to the site, go to the Data Sources page, select the check box next to the data source, and in the upper-left of the Data Sources page, select Actions.
• **Edit and view permissions**: Permissions can specify which users or groups can connect to, modify, or download data sources. As mentioned at the beginning of this section, if this action is not available, it’s likely that the project permissions are locked.

• **Edit connection information**: Update embedded credentials or other metadata that describes the connections to the underlying data.

• **Create a new workbook or download**: You can start a new workbook in the browser environment by connecting to a Tableau data source. Or download the data source to use locally.

• **Change the data source owner**

• **View the data source’s revision history**

• **Refresh extracts**: If a data source includes an extract, you can assign the extract to a refresh schedule.

  For information, see Refresh Data on a Schedule.

• **Add or remove keyword tags**: Tags can contain a single word or multiple words,
 delimited by a comma.

- **Delete**: Deleting a data source affects workbooks that connect to the data source. Before you delete a data source, ensure that there are no workbooks that connect to the data source or edit the workbooks to use another data source.

- **Move**: Move a data source from one project to another. This requires specific settings on each project. For information, see Required access level for moving content.

In addition, for data sources that are proxy connections, administrators can stay aware of how users authenticate to the database, and whether the appropriate drivers are installed. For information, see Database Drivers and Data Security.

**Extract Upgrade to .hyper Format**

Beginning in version 10.5, new extracts use the .hyper format instead of the .tde format. Extracts in the .hyper format take advantage of an improved data engine, which supports the same fast analytical and query performance as the data engine before it, but for even larger extracts.

This article covers what you and your users should be aware of as a result of the extract format change in version 2018.2 and how the change impacts your users.

**In this article**

Changes to extracts in version 10.5
Tasks that cause extract upgrade
Impact of extract upgrade
What to expect after extract upgrade
Changes to extracts in version 10.5

With the introduction of Tableau’s improved data engine technology, Hyper, comes a change to the extract format. As mentioned above, extracts created in version 2018.2 use the .hyper format. Though Tableau version 2018.2 can continue to read .tde extracts, it cannot create new .tde extracts. The impact of this format change means that when certain extract tasks are performed either by a user or by Tableau Server, such as an extract refresh or append data, the .tde extract is automatically upgraded and converted to a .hyper extract.

After an extract is upgraded to a .hyper extract, your users can interact with the .hyper extract as they would a .tde extract. However, your users should be aware of the following backward limitations:

- The upgrade can't be reversed. An upgraded extract can't be converted back to a .tde extract.
- The upgraded extract can't be opened in Tableau Desktop 10.4 and earlier.
- Workbooks that contain upgraded extracts can't be published as an older version from Tableau Desktop to Tableau Server.
- Workbooks that contain upgraded extracts can't be downgraded as an older version in Tableau Desktop.
- Workbooks that contain an upgraded extract, which are downloaded from Tableau Server using the Download Tableau Workbook option, cannot be opened in Tableau Desktop 10.4 and earlier.

Tasks that cause extract upgrade

There are three distinct ways a .tde extract can get upgraded to a .hyper extract: 1.) during an extract refresh (full or incremental), 2.) when appending data to an extract, and 3.) when an extract is upgraded manually using Tableau Desktop 2018.2. After an extract has been upgraded, the original .tde extract is automatically removed from Tableau Server if it's not being reference by other workbooks.
The followings tasks on Tableau Server automatically upgrades and converts a .tde extract to a .hyper extract:

- Manual extract refresh
- Scheduled extract refresh
- Automated refresh task that's performed through tabcmd
- Automated refresh task that's performed through the Extract Command-Line Utility
- Automated append data to an extract using tabcmd
- Automated append data to an extract using the Extract Command-Line Utility

Impact of extract upgrade

Tableau recommends that the Tableau Desktop version in your environment be upgraded to match Tableau Server 2018.2. If they don't match, extract compatibility can be an issue depending on the task your users want to perform.

To get a better understanding of when extract upgrades can occur and potential compatibility issues your users might experience, review a detailed explanation of the extract compatibility scenarios on the Tableau Support page or a summary explanation below.

**Note:** In the tables below, "10.4" represents Tableau 10.4 and earlier and "10.5" represents Tableau 10.5 and later.

Performing tasks on Tableau Server 10.5

When working with extracts created in Tableau Desktop 10.4 and earlier, your users should be aware of the following extract-related compatibility scenarios around common tasks performed on Tableau Server 10.5.
<table>
<thead>
<tr>
<th>Task</th>
<th>10.4 workbook</th>
<th>10.5 workbook</th>
<th>.tde extract</th>
<th>.tde extract</th>
<th>.hyper extract</th>
</tr>
</thead>

<td>√</td>
</tr>
</tbody>
</table>

Automating refresh and append tasks

When working with extracts created in Tableau Desktop 10.4 and earlier, your users should be aware of the following extract-related compatibility scenarios around automating refresh and append tasks using tabcmd or the Tableau Command-Line Utility.
<table>
<thead>
<tr>
<th>Task</th>
<th>10.4 workbook</th>
<th>10.5 workbook</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>.tde extract</td>
<td>.tde extract</td>
</tr>
<tr>
<td><strong>Refresh or append</strong></td>
<td>using 10.4 tabcmd</td>
<td>Workbook version remains unchanged, but extract upgrades to .hyper format</td>
</tr>
<tr>
<td></td>
<td>using 10.5 tabcmd</td>
<td>Workbook version remains unchanged, but extract upgrades to .hyper format</td>
</tr>
<tr>
<td><strong>Publish</strong></td>
<td>using 10.4 tabcmd</td>
<td>✓</td>
</tr>
<tr>
<td></td>
<td>using 10.5 tabcmd</td>
<td>Not possible</td>
</tr>
<tr>
<td><strong>Refresh or append</strong></td>
<td>using 10.4 Tableau Command-Line Utility</td>
<td>✓</td>
</tr>
<tr>
<td></td>
<td>using 10.5 Tableau Command-Line Utility</td>
<td>Workbook version remains unchanged, but extract upgrades to .hyper format</td>
</tr>
</tbody>
</table>

**Why keep an extract in .tde format?**

If the version of Tableau Desktop cannot be upgraded to match Tableau Server 2018.2, your users will need to keep their extracts in .tde format.
How to keep an extract in .tde format

To keep an extract in the .tde format, the extract should not be upgraded. To help your users keep their extracts from upgrading, advise them against performing any of the tasks listed above in the Extract Upgrade to .hyper Format section. Then, consider the following suggestions to maintain a .tde version of an extract:

- Disable existing extract refresh schedules on Tableau Server until you can identify which extracts should and shouldn't be upgraded.

  **Note:** To access an extract's refresh schedule, you must be a data source owner, or be a server administrator, site administrator, or Project Leader. For more information about which site roles allow full Project Leader capabilities, see Project-level administration.

- Continue to perform extract refresh and append data tasks using Tableau Server 2018.2, but maintain an earlier version of Tableau Desktop and the ability to connect to the original data in case you need to recreate the .tde extract.

- Use an earlier version of Tableau Desktop to perform extract tasks, such as extract refresh or append data.

What to expect after extract upgrade

After an extract upgrade has taken place, your users should expect some additional changes when working with extracts in version 2018.2. For more information, see *After an extract upgrade* section in Tableau Help.

View Data Source Attributes

On the Data Sources page, you can filter the view to data sources or connections and see attributes for each.

View data sources by name

To filter by data source name, in the View list, select Data Sources.
Attributes in the data source name list include the following:

- **Icon/Name**—The icon next to the data source name indicates whether the data source is published (✓) or embedded in a workbook (🗑).
  
  - Select the name of a published data source to open its data source page, with tabs for viewing connections and workbooks that connect to it.
  
  - Select the name of an embedded data source to open the workbook associated with it, as well as tabs for viewing other data it connects to.
  
- **Connects To**—Indicates the name of the database server or data file. This could be a database outside of Tableau Server, an extract, or a published data source.
  
- **Live or Last Extract**—This column tells you whether the connection to the data is live, or, if it is a connection to an extract, when the extract was last updated.

**View a list of connections**

To filter by connection type, in the **View** list, select **Connections**.
Connection attributes include:

- **Connects to**—Indicates the name of the database server or data file. This could be a database outside of Tableau Server, an extract, or a published data source.

- **Connection type**—Shows the type of data. **Tableau Server** indicates that the connection is to a data source published on the site. **Tableau Data Engine** means the data source has an extract stored on the Tableau data server.

**Use Certification to Help Users Find Trusted Data**

In a self-service environment with multiple publishers, it’s common for a project on Tableau Server to contain a variety of data sources that are named similarly, or are based on the same or similar underlying data, or are published without any descriptive information about them. When this is the case, analysts who create views in Tableau Desktop or web authoring can’t be confident knowing which data source is the right one to connect to.

To help your users find the data that’s trusted and recommended for their type of analysis, you can **certify** the data sources that comply with your organization’s data standards.

Certification complements the Recommendations Trainer feature, by offering a way to promote data sources through curation.

**In this article**

- How certification helps users find trusted data
Who can certify data sources
Certify a data source

How certification helps users find trusted data

When you certify a data source, a certification badge appears next to it on the Data Sources page, and in data source lists, such as when connecting to data in web authoring or from Tableau Desktop.

Certified data sources rank higher in search results and are added to recommended data sources.

In addition, you can provide notes about the certification status, which appear in a tooltip when users hover over the certification badge. The tooltip also shows who certified the data source and the data source’s connection type.

For more information, see the Certify a data source steps below.
Create guidelines for selecting data sources to certify

As with most Tableau functionality, certification is flexible. You can define for your organization the criteria you use to determine when to certify a data source. As you do this, you might want to document and share your guidelines. As new data sources are published, the guidelines can help you and other administrators or project leaders to be consistent with your certification choices. They can also help users understand what certification means.

Whether you use the same certification criteria across all projects, or define unique criteria for each project, the important thing is to be clear about what certification means in your environment.

Who can certify data sources

To access data source certification, a user must have either of the following permissions levels on Tableau Server:

- Site Administrator site role.
- Creator site role with the Project Leader permissions role on the project that contains the data sources.

Certify a data source

1. Sign in to Tableau Server and select the Data Sources tab.
2. Select the name of the data source, and then select the Details tab.
3. Next to Certification, select Edit Certification Status, and then do the following:
   a. Select the This data is certified check box.
   b. Add a note that gives users context for the certification status, intended use for the data, or other helpful information.
Information you add to the Note section appears in the certification badge tooltip, mentioned earlier in How certification helps users find trusted data.

Keep Data Fresh

Manage Refresh Tasks

Administrators can change the priority of scheduled extract refreshes relative to other server tasks, manually refresh extracts, or delete their schedules.

1. Sign in to the site that has the schedules you want to manage, and then click **Tasks**.

2. Select one or more scheduled extract refreshes.

3. From the **Actions** menu, do any of the following:

   - Select **Change Schedule**, and choose a new schedule from the list.
   - Select **Run Now** to refresh manually.

   **Note**: If an extract does not have a scheduled refresh, you can refresh it on demand from the Data Connections page.

   - Select **Change Priority**, and enter a number between 1 and 100 to move the extract up or down in the priority list.
Select **Delete** to completely remove the schedule for the selected data sources.

See also

Enable Extract Refresh Scheduling and Failure Notification

Refresh Data on a Schedule

You can schedule refresh tasks for published extract data sources and published workbooks that connect to extracts.

**Note:** When a refresh is performed on extracts created in Tableau 10.4 and earlier (that is, a .tde extract), the extract is upgraded to .hyper extract automatically. While there are many benefits of upgrading to a .hyper extract, your users won't be able open the extract with earlier versions of Tableau Desktop. For more information, see Extract Upgrade to .hyper Format.

1. When you’re signed in to Tableau Server, go to **Content > Data Sources** or **Content > Workbooks**, depending on the type of content you want to refresh.

2. Select the check box for the data source or workbook you want to refresh, and then select **Actions > Extract Refresh**.

3. In the Refresh Extracts dialog, select **Schedule a Refresh**, and complete the following steps:
• Select the schedule you want.

• If available, specify whether you want a full or incremental refresh.

By default, and if this option is not shown, a full refresh is performed. Incremental refresh is available only if you configured it in Tableau Desktop before publishing the extract. For information, see Refreshing Extracts in the Tableau Help.

• Click the Schedule Refresh button.

Note: If you want to add a new schedule, you can do so on the Schedules page.

Quick Start: Refresh Extracts on a Schedule

For published workbooks that connect to data extracts, you can set up the server to refresh the extracts on a recurring schedule, so all workbooks connected to them always show the most up-to-date data.
To schedule refreshes you need to have administrator or data owner permissions.

**Note:** This topic applies to extracts published to Tableau Server. For Tableau Online, how you refresh extracts depends on the underlying data they connect to. For more information, see [Keep Data Fresh](#).

1. **Set up a schedule on the server**

   Sign in to the server, go to the **Schedules** page, and click **New Schedule**.

   ![Schedules page](image)

   Tableau provides a few refresh schedules. You create additional schedules you need.

2. **Enable scheduled extract refreshes and failure emails**

   As a server or site administrator, you can enable schedules, as well as email notification when extract refreshes fail.

   Select **Settings**, and then go to the **General** page.

   - Under Email Notification, select **Send email to data source and workbook owners when scheduled refreshes fail**.

   - Under **Embedded Credentials**, select both check boxes to allow publishers to
embed credentials and schedule extract refreshes.

3 Publish a workbook with an extract

In Tableau Desktop, select Server > Publish Workbook. Sign in to the server if you’re not already. In the Publish Workbook to Tableau Server dialog box, click Schedules & Authentication. Under Extract Schedule, select the schedule from the list.
If the original data requires authentication, you will also need to select how you want people to access it.

4 Monitor refresh performance

You can monitor scheduled tasks by viewing **Background Tasks for Extracts** on the **Status** page.
Automate Refresh Tasks

You can associate extract refresh tasks with schedules in Tableau Server to automate refreshing extracts. You can also automate extract refreshes using tabcmd, a command line utility that you can download for use with Tableau Server. In particular, you can use the `refreshextracts` command in combination with other commands in your own script. For example:

```
tabcmd login - http://mytabserver -u jsmith -p P@ssw0rd!
refreshextracts --datasource salesq4
```

**Note:** When an extract refresh is performed on extracts created in Tableau 10.4 and earlier (that is, a .tde extract), the extract is upgraded to .hyper extract automatically. While there are many benefits of upgrading to a .hyper extract, your users won’t be able open the extract with earlier versions of Tableau Desktop. For more information, see Extract Upgrade to .hyper Format.

For information about downloading the tabcmd utility, see tabcmd.

Handle Extract Refresh Alerts

When Tableau Server cannot complete a scheduled refresh, an alert appears to indicate that the refresh has failed. If a scheduled refresh fails five consecutive times, Tableau Server suspends the refresh. When a refresh is suspended, Tableau Server does not try to run it again until someone takes an action that attempts to correct the cause of the failure.

**Note:** The number of consecutive failures for a refresh is set to five by default, but can be changed by a Tableau Server administrator, using the `backgrounder.failure_threshold_for_run_prevention` option. For more information, see `tsm configuration set Options`.
You will see the Alerts menu only if an extract refresh failed and you are:

- A system or site administrator
- The author of the workbook or data source that couldn't be refreshed
- The author of a workbook that connects to a data source that couldn’t be refreshed

When you open the Alerts menu you can see more information about the refresh failure(s):

![Alerts menu example]

When a Data source is listed as Embedded it means that the data source definition (which includes things like the data source credentials or the database name) is embedded, or resides, within the workbook itself, originally created in Tableau Desktop.

When a data source name or workbook name is listed as the Data source (for example, Data source: sales_data), it means that the data source is a Tableau Server data source. The data source definition resides on Tableau Server.

In the Data pane on Tableau Desktop, you can determine whether the data source is on Tableau Server or is local. If the data source is on the server, a Tableau icon is displayed next to the data source name instead of a database icon:
Resolving Extract Refresh Problems

To resolve refresh issues, you can take any of these actions, based on the cause indicated in the alert:

- **Errors related to access token validation or user credentials**

  You can resolve some extract refresh problems by clicking the **Connection Details** in the alert. Select the check box next to the problematic data source, click **Actions > Edit Connection**, and then enter the missing information. Click **Save** when you’re done. After you update the connection information, Tableau Server restarts the refresh schedule.

  If you originally embedded the credentials or other data connection information when you published the workbook or data source from Tableau Desktop, you can also republish the workbook or data source. As part of the publishing process, you can choose to set a new refresh schedule. If you don’t choose a new schedule, Tableau Server restarts the existing schedule.

- **Errors that indicate the database was unreachable**

  Confirm that the database is online and that you can sign in to access the data. You can use the **Try again** link in the alert to restart the refresh schedule.

- **Errors when using user filters or impersonation**

  See the **Tableau Knowledge Base**.

If the problem cannot be corrected by editing the data connection, you will need to resolve it in Tableau Desktop and republish the workbook.
Tip: Administrators can edit data connections at any time on the Data Connections page, accessible from each site by clicking the Content tab and Data Connections.

Edit Connections on Tableau Server

Administrators and data source owners can manage the information that describes how a published data source connects to the underlying data. This information includes the database server name or address, the server port, the database user name, and whether or not the password is embedded in the connection.

Note: Ability to edit connections is determined primarily by your site role, rather than by your permissions on the data source. To edit connections, your site role must be Server Administrator, Site Administrator, or Creator. If your role is Creator, you also must be the data source owner.

1. Sign in to the site that has the data sources you want to modify, and open the Data Sources page.

2. Select the name of the data source with the connection you want to update.
   
   Use the search box or filters on the left to narrow the data source list. The values you type into the Server and Database username fields are treated as regular expressions.

3. In the Connections view, select the check box for the connection, and then click Actions > Edit Connection.
4. Update the connection information.

For **Server name**, if you want to use an IP address, make sure the database or its driver supports that type of connection. If it doesn’t, enter the database server name.

For connections to Google, Salesforce, and web data connector (WDC) data, see Authentication types for Google, Salesforce, and WDC data later in this topic.
5. Click **Save**.

6. Refresh the browser page for your changes to take effect.

**Authentication types for Google, Salesforce, and WDC data**

Google BigQuery, Google Analytics, Salesforce.com, and many web data connector (WDC) connections use the OAuth authentication standard, which uses secure access tokens instead of “raw” user name and password credentials. With OAuth, database credentials do not need to be stored in Tableau, and all users connect through this access token, including Tableau Desktop users who want to create or edit workbooks that connect to the data source.

The following sections describe Google and Salesforce connection options. Web data connector options vary, but all involve signing in through the provider’s web-based sign-in form to establish the access token.

**Google authentication options**

When you edit Google BigQuery or Google Analytics connections, select either of the following options in the **Edit Connection** dialog box:

- Select **Embed Google BigQuery (or Google Analytics) credentials in the connection** to authenticate through a designated account, and then select an existing account from the list or select **authenticate account now...** to add a new one.

  When you add a new account, the Google sign-in page appears. After you provide your database credentials, Google prompts you to confirm Tableau access to the data. When you click **Accept**, Google returns an access token to use for connecting to the data.

  **Note:** If you create extracts of your Google data source, select this first option, so that you can schedule refresh tasks.

- Select **Prompt user for Google BigQuery/Analytics credentials** to require users
to connect through their own individual access tokens or sign in each time they connect.

Salesforce.com authentication options

When you edit Salesforce.com connections, you can select any of the following options in the Edit Connection dialog box:

- Select **Embed a Salesforce username and password** to use a traditional authentication method.

- Select **Embed Salesforce credentials in the connection** to use an OAuth connection and schedule refresh tasks, and then select an existing account from the list or click **Add a Salesforce Account** to add a new one.

When you add a new account, the Salesforce.com sign-in page appears. After you provide your database credentials, Salesforce.com prompts you to confirm Tableau access to the data. When you allow Tableau access, Salesforce.com creates an access token through which it connects to the data.
- Select **No Salesforce authentication** to require users to sign in to Salesforce.com each time they connect. (This option does not allow scheduled extract refreshes.)

**Monitor progress**

When you save your changes in the Edit Connection dialog box, the dialog displays the progress. If you close the dialog box, the modifications continue to run in the background until completed. Tableau Server will make as many changes as possible. Any failures will be skipped, but they will not impede other changes. For example, if you try to change the server name and add a password to several connections, the server names will be changed, and the passwords on workbooks will be changed. However, because you cannot add a password to a data source, the passwords for the data sources will not be changed.

For information about checking the progress of these tasks, see Background Tasks for Extracts.
Cube Data Sources

Cube (multidimensional) data sources have certain characteristics that make them unique in Tableau.

Cube data sources do not support pass-through connections. This means that when a cube data source is published, you cannot make a connection from Tableau Server using the data source. It also means you cannot create a workbook using the data source in Tableau Server.

Publishing a cube data source to Tableau Server gives you the ability to store the data source on the server. However, to use the data source, you must download the data source to Tableau Desktop and use it locally. To download a published data source you need:

- The **Download/Web Save As** permission for the data source. For more information, see Set Permissions on Individual Content Resources.
- Correct drivers installed and ports opened on computer running Tableau Desktop.

Web Data Connectors in Tableau Server

Web data connectors (WDCs) are web pages that provide a data connection that is accessible over HTTP for data sources that don’t already have a connector in Tableau. WDCs allow users to connect to almost any data that is accessible over the web and to create extracts for their workbooks. Data sources for a WDC can include internal web services, JSON data, REST APIs, and other sources that are available over HTTP or HTTPS. Users can create their own WDC or use connectors that were created by others.

For information about how to use a WDC in Tableau Desktop, see Web Data Connector in the Tableau Desktop documentation.

For information about how to create a WDC, see the Web Data Connector documentation on Github.

- Before you run connectors on Tableau Server
Before you run connectors on Tableau Server

As a security measure, Tableau Server won't run WDCs unless you approve the connector, as explained in this topic.

**Note:** You must be a server administrator to approve WDCs for use on Tableau Server.

WDCs require your approval because they contain executable code and typically make requests to third-party websites. Before a user can use a WDC with Tableau Server, you must either add the domain and port used by the connector to a safe list (whitelist) and also include the domains that a connector can send requests to and receive requests from on a secondary safe list (secondary whitelist). Before you do this, we recommend that you vet and test the connector so that you know what the connector does and what sites it connects to. For more information, see Testing and Vetting Web Data Connectors.

When you add a connector to the safe lists (whitelists), you configure Tableau Server to allow connections to a particular URL where the connector is hosted and from a URL which the connector can query. This is the only way to allow Tableau Server to run WDCs. The connectors can then be hosted on a server inside your organization's firewall or on an external domain. Importing WDCs is not supported for Tableau Server.

Manage connectors in a safe list

To add a WDC to the safe list, use the `tsm data-access web-data-connectors add` command. This command and the related commands described below let you perform the following tasks:
- Add WDCs to the safe list and secondary safe list.
- Allow or disallow all WDCs, or WDC refreshes.
- Remove one or more connectors from the safe list.
- List all WDCs on the safe list and secondary safe list.

Updating WDC safe lists requires a server restart

After running any commands that make changes to WDCs, you need to apply your pending changes using the `tsm pending-changes apply` command.

The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

Add connectors to the safe list and secondary safe list

To add a connector to the safe list and secondary safe list, use the `tsm data-access web-data-connectors add` command, providing the name, safe list URL, and secondary safe list URLs. You can also manage WDCs using the web-data-connector-settings Entity. After running this command, you need to apply your pending changes using the `tsm pending-changes apply` command.

```
```

Notes on formatting:

- Be sure to use straight quotes (" and "), not curly or "smart" quotes, around the name of the WDC.
For many WDCs, the port specified for the --url option is 443 or 80, but you can check the value for your connector by looking at the data source details on Tableau Server.

If a WDCs send requests to and receive data from multiple domains, use a comma-delimited list of URL for the --secondary option.

To add an entire domain to the secondary safe list, end the domain URL with a wildcard character (*).

Allow or disallow WDCs or WDC extract refreshes

To allow or disallow WDCs, or WDC extract refreshes, use the following command before running tsm pending-changes apply:

```
tsm data-access web-data-connectors allow
```

Remove one or more WDCs from the safe list

To remove one or more WDCs from the safe list, use the following command before running tsm pending-changes apply:

```
tsm data-access web-data-connectors delete
```

List all WDCs on the safe list

To list all WDCs on the safe list, use the following command:

```
tsm data-access web-data-connectors list
```

Refresh the extract for a connector

When a user creates a workbook that uses a WDC, Tableau Server creates an extract from the data returned by the connector. If the user then publishes the workbook, the publish process sends the workbook and the data extract to the server.

Tableau can refresh an extract that was created by a WDC, the same as it can refresh any extract. If the connector requires credentials to sign in to the web-based data source, you need to ensure that the credentials are embedded with the data source, and that the WDC is on the safe list for the server. Tableau Server cannot refresh the extract if the connector
requires credentials and they are not embedded with the data source. This is because the refresh can occur on a schedule or in some other background context, and the server cannot prompt for credentials.

Currently, there is no way to re-authenticate a data source from Tableau Server directly. If the data source has credentials that expire, or was published without embedding the credentials, the workbook and data extract need to be published again with the new embedded credentials.

If the background process that performs the refresh operation fails, it creates an alert and a log entry that indicates this issue. Users will be able to see that the timestamp on the extract does not change.

To disable refresh for all WDCs, use the `tsm data-access web-data-connectors allow -r false` command.

Troubleshooting

If the server experiences problems with adding connectors to the safe list, you can examine the log files. Be sure to check the log files on both the initial server node and on the other nodes that are running the gateway process. For more information about log files, Server Log File Locations.

If the issue is that Tableau Server will not refresh an extract that was created by a WDC, make sure that the `webdataconnector.refresh.enabled` configuration setting has been set to `true`. If it is set to `false`, run the following command to allow extract refreshes for all WDCs on the server:

`tsm data-access web-data-connectors allow -r true`

**Note:** The safe list is the only way of allowing Tableau Server to run web data connectors. Importing web data connectors was deprecated starting with version 10.5.
Testing and Vetting Web Data Connectors

Web Data Connectors (WDCs) contain JavaScript that typically connects to data on another site. Because of this, you should test and vet web data connectors before users use them as data sources for a workbook, and before you use them with Tableau Server.

This topic includes some suggestions for testing and vetting web data connectors.

- Examine the source
- Test the web data connector in an isolated environment
- Monitor the traffic created by the connector
- Test the performance and resource usage of the connector

Examine the source

The code in a web data connector is in JavaScript, so you can open the file (and any external files that the connector uses) and examine the source code.

Many connectors reference external JavaScript libraries, such as the jQuery library or API libraries for third parties. Validate that the URL for external libraries points to a trusted location for the library. For example, if the connector references the jQuery library, make sure that the library is on a site that is considered standard and safe. If it is practical for you to change the source code of the connector, use HTTPS protocol (https://) to reference external libraries (if the source site supports HTTPS) to help verify the site's authenticity.

To the extent possible, make sure you understand what the code is doing. In particular, try to understand how the code is constructing requests to external sites, and what information is being sent in the request.

**Note:** Experienced JavaScript programmers often compress (minify) their code to reduce the size of the code for download. Dense blocks of code that use cryptic function and variable names are not uncommon. While this can make it more difficult to examine...
the code, it is not a sign that the code was written to be deliberately difficult to understand.

Test the web data connector in an isolated environment

If possible, test the web data connector in an environment that is isolated from your production environment and from user computers. For example, add a web data connector to a safe list on a test computer or virtual machine that's running a version of Tableau Server that is not used for production.

Monitor the traffic created by the web data connector

When you test a web data connector, use a tool like Fiddler, Charles HTTP proxy, or Wireshark to examine the requests and responses that the connector makes. Make sure that you understand what sites the connector makes requests to and what content the connector is requesting. Similarly, examine the responses and their content to be sure that the connector is not reading data or code that is not directly related to the connector's purpose.

Test the performance and resource usage of the web data connector

When you test a web data connector, use tools to monitor its CPU and memory usage. Remember that the web data connector will run on Tableau Server, which is an environment in which many processes are already running. You want to make sure that when the connector fetches data, the connector does not have an undue impact on server performance.

Check whether the connector writes to disk. If it does, check how much disk space it occupies, and examine the output to make sure you understand what it's writing and why.

Creators: Connect to data on the web

Before you can create a new workbook and build a view on the web to analyze your data on the web, you need to connect to your data. Tableau supports connecting to data sources on
the web published through Tableau Desktop, or, connecting to data directly through Tableau Online or Tableau Server.

**Note:** Data connections created in Tableau Online or Tableau Server are *live connections* only. If you need to use an extract for web authoring, you can publish your data source through Tableau Desktop. To publish through Tableau Desktop, see *Publish Data Sources and Workbooks*.

To create a new workbook, sign into Tableau Online or Tableau Server.

In the Content tab, do either of the following:

- Go to the Projects section, select a project, and select New Workbook.
- Go to the Workbooks section and select New Workbook.

A Connect to Data window opens, which contains several tabs: Files, Connectors, On this Site, and, if you’re connected to Tableau Online, Dashboard Starters.
As a Creator, you can create a new workbook or add a new data source to an existing workbook in several ways:

- Upload Excel or text-based data from the Files tab
- Connect to server or cloud data with Connectors
- Connect to published data sources with On This Site
- On Tableau Online, quickly author and analyze data from Oracle Eloqua, Salesforce, ServiceNow ITSM, and QuickBooks Online from the Dashboard Starters tab

**Connect to Files**

Tableau supports uploading Excel or text-based data sources (.xlsx, .tsv, .csv) directly in your browser. In the Files tab of the Connect to Data window, connect to an Excel or text file by dragging and dropping it into the field or clicking "Upload from computer."

When Tableau successfully connects to your data, the Data Source page opens so that you can prepare the data for analysis and begin building your view. To learn more, see [Creators: Prepare Data on the Web](#).

**Use connectors**

From the Connectors tab, you can connect to data housed in a cloud database or on a server in your enterprise. You need to supply connection information for each data connection that you make. For example, for most data connections, you need to supply a server name and your sign-in information.

**Connect to Your Data** has information on how to connect Tableau to each of these connector types to set up your data source. If your connector doesn't appear in the Connectors tab, you can connect to data through Tableau Desktop and publish your data source to Tableau Online or Tableau Server for web authoring. Learn more about how to [Publish a Data Source](#) in Tableau Desktop.
Tableau web authoring supports connecting to your data through Tableau Online and Tableau Server using the following connectors:

- Amazon Aurora
- Google Cloud SQL
- PostgreSQL
- Amazon Redshift
- MemSQL
- Snowflake
- Denodo
- Microsoft SQL Server
- Vertica
- EXASOL
- MySQL

If your site is in Tableau Server, you may see more connectors than are on this list.

When Tableau successfully connects to your data, the Data Source page opens so that you can prepare the data for analysis and begin building your view. To learn more, see Creators: Prepare Data on the Web.

**Note:** If you're unable to connect to your data from Tableau Online, check to see if the database is publicly accessible. Tableau Online can only connect to data that's accessible from the public internet. If your data is behind a private network, you can connect using Tableau Bridge. To learn more, see Publishers: Use Tableau Bridge to Keep Tableau Online Data Fresh.

**Connect to published data sources "On this Site"**

Tableau supports connecting to published data saved to your site with the **On this Site** tab. If you or another user has saved a data source or published to the web through Tableau Desktop, it will appear in Tableau Online or Tableau Server as a published data source.

When Tableau successfully connects to your data, the Data Source page opens so that you can prepare the data for analysis and begin building your view. To learn more, see Creators: Prepare Data on the Web.
Keeping data fresh in web authoring

**Update uploaded files in Tableau Online or Tableau Server:** If you manually upload a file (Excel or text) for web authoring, Tableau can’t refresh the file automatically. To update your data, select “Edit Connection” to upload a new version of the file.

**Update file-based published data sources in Tableau Online:** If you have a published data source in Tableau Online (published through Tableau Desktop) that uses file-based data, you can keep it fresh using Tableau Bridge. For more information, see Expand Data Freshness Options by Using Tableau Bridge.

Dashboard Starters

Dashboard Starters help you quickly author and analyze data from cloud-based systems like Salesforce, ServiceNow ITSM, Oracle Eloqua, and Marketo. Simply create a new workbook and choose from several beautiful, informative designs that are tailor-made for key business metrics. For more information, see Dashboard Starters for Cloud-based Data Sources.

Navigate Site Admin Pages

When you sign in to Tableau Server as a site administrator, you see menus for site and content management that are not available to other users.

A site administrator can:

- Manage content and assign permissions.
- View and manually run schedules for extract refreshes and subscriptions.
- Manage extract refreshes and subscriptions.
- Add and manage site users (if allowed by the server administrator; see Add or Update Sites).
• Add and manage site groups.

• Monitor site activity.

For information about navigating content (workbook, data source, project) pages in Tableau Server, see Navigate Tableau on the Web and Manage Web Content in the Tableau Help.

Site administrator pages

Site administrators manage all site content and access on a per-site basis.

If you work with a single site on Tableau Online, or your Tableau Server deployment has one site, you’ll see menus for managing that site’s content, users, groups, schedules, and tasks, and for monitoring its status.

If you work with multiple sites, the menus across the top include a site menu on the left side.

The site menu displays the name of the current site. To go to another site, select the site menu, and then select the site name.
Create, Interact with, and Embed Views on the Web

You can create and interact with views on Tableau Server. For more information, see the following topics in the Tableau Help for users.

Authentication

Authentication verifies a user’s identity. Everyone who needs to access Tableau Server—whether to manage the server, or to publish, browse, or administer content—must be represented as a user in the Tableau Server identity store. The method of authentication may be performed by Tableau Server (“local authentication”), or authentication may be performed by an external process. In the latter case, you must configure Tableau Server for external authentication technologies such as Active Directory, SAML, or OpenID. In all cases, whether authentication takes place locally or is external, each user identity must be represented in the Tableau Server identity store, which is managed by the repository.

Looking for Tableau Server on Windows? See Authentication.
Access and management permissions are implemented through site roles. Site roles define which users are administrators, and which users are content consumers and publishers on the server. For more information about administrators, site roles, groups, Guest User, and user-related administrative tasks, see Users and Site Roles for Users.

**Note:** In the context of authentication, it’s important to understand that users are not authorized to access external data sources through Tableau Server by virtue of having an account on the server. In other words, in the default configuration, Tableau Server does not act as a proxy to external data sources. Such access requires additional configuration of the data source on Tableau Server or authentication at the data source when the user connects from Tableau Desktop.

Local authentication

If the server is configured to use local authentication, then Tableau Server authenticates users. When users sign-in and enter their credentials, either through Tableau Desktop, tabcmd, API, or web client, Tableau Server verifies the credentials.

To enable this scenario, you must first create an identity for each user. To create an identity, you specify a username and a password. To access or interact with content on the server, users must also be assigned a site role. User identities can be added to Tableau Server in the server UI, using tabcmd Commands, or using the REST API.

You can also create groups in Tableau Server to help manage and assign roles to large sets of related user groups (e.g., “Marketing”).

When you configure Tableau Server for local authentication, you cannot set password policies or account lockout on failed password attempts. If you require these account safeguards, then you should use Active Directory or other supported authentication.
Active Directory

If Tableau Server is configured to use Active Directory authentication, then credentials are managed and verified by Active Directory. When a user logs onto Tableau Server from Tableau Desktop or a web client, the credentials are passed through to Active Directory, which then verifies them and sends an access token to Tableau Server. Tableau Server will then manage user access to Tableau resources based on the site roles stored in the local identity store.

In this scenario, Tableau Server must be installed in a domain in Active Directory. Tableau Server will sync user and group metadata from Active Directory to the identity store. You do not have to manually add users. However, after the data is synchronized, you will need to assign site and server roles. You can assign these individually, or at the group level. Tableau Server does not synchronize any data back to Active Directory. Tableau Server manages content and server access according to the site role permission data is stored in the repository.

If you are already using Active Directory to manage users in your organization, then we recommend selecting Active Directory authentication during Tableau setup to make user provisioning and management easier. For example, by synchronizing Active Directory groups, you can set minimum site role Tableau permissions for users that are synchronized in the groups. You can synchronize specific Active Directory groups, or you can synchronize them all. For more information, see Synchronize All Active Directory Groups on the Server.

Be sure to review User Management in Active Directory Deployments to understand how multiple domains, domain naming, NetBIOS, and Active Directory user name format influence Tableau user management.

LDAP identity store

You can also configure Tableau Server to use LDAP as a generic way to communicate with the identity store. For example, OpenLDAP is one of several LDAP server implementations with a flexible schema. Tableau Server can be configured to query the OpenLDAP server.
See Identity Store. Authentication in this scenario maybe be provided by the native LDAP solution, or with one of the single sign-on solutions discussed later in this topic.

**Data connection authentication**

You can configure Tableau Server to support a number of different authentication protocols to various different data sources. Data connection authentication may be independent of Tableau Server authentication. For example, you may configure user authentication to Tableau Server using local authentication, while configuring Kerberos delegation, OAuth, or SAML authentication to specific data sources. See Data Connection Authentication.

**Other authentication options for Tableau Server**

Tableau Server supports several types of single sign-on (SSO) and other authentication methods. In most SSO scenarios, users don't have to explicitly sign in to Tableau Server. Instead, the credentials they've used to authenticate already (for example, by signing in to your corporate network) are used to authenticate them to Tableau Server, and they can skip the step of entering a username and password to access Tableau Server. In the following authentication methods, users' identities as established externally are mapped to a user identity defined in the Tableau Server identity store.

When you configure Tableau Server to use an SSO or alternative authentication solution, all authentication is handled by the external solution. However, Tableau Server will manage user access to Tableau resources based on the site roles stored on Tableau Server.

Tableau Server supports these authentication methods:

- **SAML.** You can configure Tableau Server to use SAML (security assertion markup language) for SSO. With SAML, an external identity provider (IdP) authenticates the user's credentials, and then sends a security assertion to Tableau Server that provides information about the user's identity.

  You can use SAML to access Tableau Server if you have configured Active Directory or local authentication on Tableau Server. For more information, see SAML.
• **Kerberos.** If Kerberos is enabled in your environment and if the server is configured to use Active Directory authentication, you can provide users with access to Tableau Server based on their Windows identities. For more information, see Kerberos.

• **Mutual SSL.** Using mutual SSL, you can provide users of Tableau Desktop, Tableau Mobile, and other approved Tableau clients a secure, direct-access experience to Tableau Server. With mutual SSL, when a client with a valid SSL certificate connects to Tableau Server, Tableau Server confirms the existence of the client certificate and authenticates the user, based on the user name in the client certificate. If the client does not have a valid SSL certificate, Tableau Server can refuse the connection. For more information, see Configure Mutual SSL Authentication.

• **OpenID.** OpenID Connect is a standard authentication protocol that lets users sign in to an identity provider (IdP) such as Google. After they've successfully signed in to their IdP, they are automatically signed in to Tableau Server. To use OpenID Connect on Tableau Server, the server must be configured to use local authentication. Active Directory authentication is not supported. For more information, see OpenID Connect.

• **Trusted Authentication.** Trusted authentication lets you set up a trusted relationship between Tableau Server and one or more web servers. When Tableau Server receives requests from a trusted web server, it assumes that the web server has already handled whatever authentication is necessary. Tableau Server receives the request with a redeemable token or ticket and presents the user with a personalized view which takes into consideration the user’s role and permissions. For more information, see Trusted Authentication.

**Related topics**

• REST API: [Signing In and Out (Authentication)]

• Mobile device authentication: [Single sign-on for Tableau Mobile]
SAML

SAML (Security Assertion Markup Language) is an XML standard that allows secure web domains to exchange user authentication and authorization data. You can configure Tableau Server to use an external identity provider (IdP) to authenticate users over SAML 2.0. No user credentials are stored with Tableau Server, and using SAML enables you to add Tableau to your organization’s single sign-on environment. Tableau Server supports all SAML 2.0 features including multi-factor authentication (MFA), forcing password change on first login, password complexity requirements, account lockout, and more.

You can use SAML server wide, or you can configure sites individually. Here’s an overview of those options:

- **Server-wide SAML authentication.** A single SAML IdP application handles authentication for all Tableau Server users. Use this option if your server has only the Default site.

- **Server-wide local authentication and site-specific SAML authentication.** In a multi-site environment, users who are not enabled for SAML authentication at the site level can sign in using local authentication.

- **Server-wide SAML authentication and site-specific SAML authentication.** In a multi-site environment, all users authenticate through a SAML IdP configured at the site level, and you specify a server-wide default SAML IdP for users that belong to multiple sites.

If you want to use site-specific SAML, you must configure server-wide SAML before you configure individual sites.

User authentication through SAML does not apply to permissions and authorization for Tableau Server content, such as data sources and workbooks. It also does not control access to underlying data that workbooks and data sources connect to.
**Note:** Tableau Server supports both service provider initiated and IdP initiated SAML in browsers only. Connections from Tableau Desktop or the Tableau Mobile app require that the SAML request be service provider initiated.

The following image shows the steps to authenticate a user with single sign-on in a typical service provider initiated flow:

1. User navigates to the Tableau Server sign-in page or a published workbook.
2. Tableau Server starts the authentication process and redirects the request to the registered IdP.
3. The IdP requests the user's username and password and authenticates the user to the IdP.
4. The IdP returns a SAML success response to Tableau Server.
5. Tableau Server verifies that the username in the response matches what is stored in Tableau and displays the page the user requested in Step 1.
SAML Requirements

Before you configure SAML on Tableau Server, make sure your environment meets the requirements.

Certificate and identity provider (IdP) requirements

To configure Tableau Server for SAML, you need the following:

- **Certificate file.** A PEM-encoded x509 certificate file with a .crt extension. This file is used by Tableau Server, not the IdP. If you have an SSL certificate, it is possible in some circumstances to use the same certificate with SAML. For more information, see Using SSL certificate and key files for SAML later in this article.

- **Certificate key file.** An RSA or DSA private key file that has the .key extension. RSA keys must be in PKCS#1 format. The PKCS#1 RSA key file cannot be password protected. To use a password protected key (PKCS#8 RSA key file), you must upgrade to Tableau Server 2018.3 or later.

- **IdP account that supports SAML 2.0 or later.** You need an account with an external identity provider. Some examples are PingFederate, SiteMinder, and OpenAM.

- **IdP provider that supports import and export of XML metadata.** Although a manually created metadata file might work, Tableau Technical Support cannot assist with generating the file or troubleshooting it.

Using SSL certificate and key files for SAML

If you are using a PEM-encoded x509 certificate file for SSL, you can use the same file for SAML. For SSL, the certificate file is used to encrypt traffic. For SAML, the certificate is used for authentication.

In addition to the requirements listed in Certificate and identity provider (IdP) requirements above, to use the same certificate for both SSL and SAML, the certificate must also meet the following condition to work for SAML:
• Confirm that the certificate includes only the certificate that applies to Tableau Server and not any other certificates or keys.

To do this, you can create a backup copy of the certificate file, and then open the copy in a text editor to review its contents.

User management requirements

When you enable SAML, user authentication is performed outside of Tableau, with the IdP. However, the user management is performed either by Active Directory or by Tableau Server (called local authentication even though Tableau Server is not performing authentication in this scenario).

Note: If you run Tableau Server on Linux, all external directory communication is configured and managed with a LDAP identity store. In the context of user and group synchronization, Tableau Server configured with LDAP identity store is equivalent to Active Directory. Active Directory synchronization features in Tableau Server function seamlessly with properly configured LDAP directory solutions.

When you configure user authentication, you select the option that reflects how you want to use SAML. If you want to use site-specific SAML, you must configure server-wide SAML before you configure individual sites.

• **For site-specific SAML:** If you have multiple sites on Tableau Server and want to set up each site for a particular IdP or IdP application (or configure some sites to not use SAML), configure Tableau Server to use local authentication. For site-specific SAML, Tableau Server relies on the IdP for authentication and does not use passwords.

• **For server-wide SAML:** If you configure server-wide SAML with a single IdP, you can configure Tableau Server to use local authentication or Active Directory for user management.

• **Server-wide SAML authentication and site-specific SAML authentication.** In a
multi-site environment, all users authenticate through a SAML IdP configured at the site level, and you specify a server-wide default SAML IdP for users that belong to multiple sites. To configure this scenario, the Tableau Server identity store must be configured for local authentication.

**Note:** The REST API and tabcmd do not support SAML single-sign (SSO). To sign in, you must specify the name and password of a user who has been created on the server. The user could have a local or Active Directory account, depending on how you have configured Tableau Server. For Tableau Online, you can specify the TableauID credentials of the user. REST API or tabcmd calls will have the permissions of the user you sign in as.

SAML compatibility notes and requirements

- **Matching usernames:** The user name stored in Tableau Server must match the user name stored in the IdP. For example, if the user name for Jane Smith is stored in PingFederate as *j smith*, it must also be stored in Tableau Server as *j smith*.

  If you are configuring SAML as part of the initial Tableau Server setup, make sure the account you plan to use exists in your IdP before you run setup. During Tableau Server setup you create the server administrator account.

  If you use Active Directory authentication with Tableau Server and have multiple Active Directory domains (that is, users belong to multiple domains, or your Tableau Server installation includes multiple domains), the IdP must send both the username and domain for a user, and they must match exactly in Tableau Server. Although these can be sent as either domain\username or username@domain.com, we recommend using domain\username.

  For more information, see User Management in Active Directory Deployments.

- **Default signature algorithm:** Tableau Server uses SHA1 signature algorithm. Many IdPs default to SHA256. A mismatch between the IdP and Tableau Server
signature algorithms will cause SAML authentication failures. To change to SHA256, set the SHA256Enabled configuration entity to true during your initial configuration. See samlSettings Entity. You can also change to SHA256 by running the following TSM command:

tsm configuration set -k wgserver.saml.sha256 -v true

• **External authentication types**: Tableau Server supports using one external authentication type at a time.

• **Mutual SSL**: Tableau Server does not support mutual SSL (two-way SSL) and SAML together. If you want to use mutual SSL, you can configure it on the IdP.

• **Encryption and site-specific SAML assertions**: Although Tableau Server does not support encrypted SAML assertions from the IdP, all SAML requests and responses are sent over HTTPS.

• **User identity in Tableau Server for tabcmd users**: As described in User management requirements section above, to use tabcmd, you must sign in as a user defined on the server. You cannot use SAML accounts with tabcmd.

• **Using SAML SSO with Tableau clients**: By default, both Tableau Desktop and the Tableau Mobile app allow SAML authentication.

If your IdP does not support this functionality, you can disable SAML sign-in for Tableau clients using the following commands:

tsm authentication saml configure --desktop-access disable
tsm authentication saml configure --mobile-access disable

**Note**: The --mobile-access disable option is ignored by devices running Tableau Mobile app version 19.225.1731 and higher. To disable SAML for
devices running these versions you must disable SAML as a client login option on Tableau Server.

For more information, see tsm authentication saml <commands>.

- **Distributed installations**: Tableau Server clusters configured for SAML must have the same SAML certificate, SAML key, and SAML IdP metadata files on each node configured for an Application Server (vizportal) process. These files should also be in the same file path on each node.

- **Login URL**: For users to be able to sign in, your IdP must be configured with SAML Login endpoint that sends a POST request to the following URL:

- **Logout URL**: To enable users to sign out after signing in with SAML (single logout, or SLO), your IdP must be configured with a SAML Logout endpoint that sends a POST request to the following URL:

- **Post-logout redirect URL**: By default, when a user signs out of Tableau Server, the sign-in page is displayed.

  To display a different page after sign-out, use the tsm authentication saml configure command with the -su or --signout-url option.

    - To specify an absolute URL, use a fully-qualified URL starting with http:// or https://, as in this example:

      tsm authentication saml configure -su https://example.com

    - To specify a URL relative to the Tableau Server host, use a page starting with a
// (slash):

tsm authentication saml configure -su /our-
logoutpage.html

- **Active Directory Federation Service (AD FS):** You must configure AD FS to return additional attributes for Tableau authentication with SAML. The **Name ID** and **username** attributes can be mapped to the same AD attribute: **SAM-Account-Name**.

Using SAML SSO with Tableau client applications

Tableau Server users with SAML credentials can sign in to the server from Tableau Desktop or the Tableau Mobile app. For full compatibility, we recommend that the Tableau client application version matches that of the server. To connect using site-specific SAML, users must run version 10.0 or later of the Tableau client application.

Connecting to Tableau Server from Tableau Desktop or Tableau Mobile uses a service provider (SP) initiated connection.

Redirecting authenticated users back to Tableau clients

When a user signs in to Tableau Server, Tableau Server sends a SAML request (**AuthnRequest**) to the IdP, which includes the Tableau application’s **RelayState** value. If the user has signed in to Tableau Server from a Tableau client such as Tableau Desktop or Tableau Mobile, it’s important that the RelayState value is returned within the IdP’s SAML response back to Tableau.

When the RelayState value is not returned properly in this scenario, the user is taken to their Tableau Server home page in the web browser, rather than being redirected back to the application they signed in from.

Work with your Identity Provider and internal IT team to confirm that this value will be included as part of the IdP’s SAML response, and then preserved by any network appliance (such as a proxy or load balancer) that resides between your IdP and Tableau Server.
XML data requirements

As part of SAML configuration, you exchange XML metadata between Tableau Server and the IdP. This XML metadata is used to verify a user’s authentication information when the user initiates the Tableau Server sign-in process.

Tableau Server and the IdP each generates its own metadata. Each set of metadata must contain the information described in the following list. If either set is missing information, errors can occur when you configure SAML or when users try to sign in.

- **HTTP POST**: Tableau Server accepts only HTTP POST requests for SAML communications. HTTP Redirect is not supported.

- With the Binding attribute set to HTTP-POST, the SAML metadata that Tableau Server and the IdP each export must contain the following elements.

  - The element that specifies the URL that the IdP redirects to after successful authentication. This is required in the Service Provider metadata, not the Identity Provider metadata.

    For Site SAML, the Location endpoint is /saml/service/public/sp/metadata?alias=<site alias>.

  - The logout endpoint element appears in Tableau Server metadata and specifies the URL that the IdP will use for Tableau Server’s logout endpoint. If this element is not in the IdP metadata, Tableau Server cannot negotiate a logout endpoint with the IdP and the SAML Logout feature will not be available within the Tableau Server:
<md:SingleLogoutService Binding="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST"
    Location="https://SERVER-NAME:9031/idp/slo"/>

- Verify that the metadata XML from the IdP includes a **SingleSignOnService**
  element, in which the binding is set to **HTTP-POST**, as in the following example:

```xml
<md:SingleSignOnService Binding="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST"
    Location="https://SERVER-NAME:9031/idp/SSO.saml2"/>
```

- This element should appear in IdP metadata and specifies the URL that
  Tableau Server will use for the IdP's logout endpoint.

```xml
<md:SingleLogoutService Binding="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST"
    Location="https://SERVER-NAME:9031/idp/slo"/>
```

- **Attribute named username**: You must configure the IdP to return an assertion that
  includes the **username** attribute in the **saml:AttributeStatement** element.
  The assertion's attribute type must be **xs:string** (it should **not** be typed as
  **xs:any**).

  The following example shows what this might look like.

```xml
<saml:Assertion assertion-element-attributes>
    <saml:Issuer>issuer-information</saml:Issuer>
    <Signature xmlns="http://www.w3.org/2000/09/xmldsig#">
        ...
    </Signature>
    <saml:Subject>
        ...
    </saml:Subject>
</saml:Assertion>
```
<saml:Conditions condition-attributes >
...
</saml:Conditions>
<saml:AuthnStatement authn-statement-attributes >
...
</saml:AuthnStatement>

<saml:AttributeStatement>
<saml:Attribute Name="username" NameFormat- t="urn:oasis:names:tc:SAML:2.0:attrname-format:basic">
user-name
</saml:AttributeValue>
</saml:Attribute>
</saml:AttributeStatement>
</saml:Assertion>

By default, Tableau Server will read the username attribute in the AuthNResponse returned from the Idp. However, some IdPs may return a different attribute that is intended to identify the user. In this case, you may need to change the attribute that Tableau Server reads for the username. To authenticate successfully, the attribute's value that is returned from the IdP must match an actual username value of a Tableau Server user.

To change the SAML attribute that passes the username value, run the following TSM command:

tsm authentication saml map-assertions --user-name <USER-NAME>.

See tsm authentication.

Configure Server-Wide SAML

Configure server-wide SAML when you want all single sign-on (SSO) users on Tableau Server to authenticate through a single SAML identity provider (IdP), or as the first step to configuring site-specific SAML in a multi-site environment.

If you have configured server-wide SAML and are ready to configure a site, see Configure Site-Specific SAML.

The SAML configuration steps we provide make the following assumptions:

- You are familiar with the options for configuring SAML authentication on Tableau Server, as described in the SAML.
- You have verified that your environment meets the SAML Requirements, and obtained the SAML certificate files described in those requirements.

Before you begin

Gather the certificate files and place them on the Tableau Server.

In the Tableau Server folder, create a new folder named SAML, and place copies of the SAML certificate files in that folder. For example:

/var/opt/tableau/tableau_server/data/saml

(Keep the certificate files in a safe location outside of the Tableau Server directory tree as well.)

**Note:** If you use the same certificate files for SSL, you could alternatively use the existing certificate location for configuring SAML, and add the IdP metadata file to that directory when you download it later in this procedure. For more information, see Using SSL certificate and key files for SAML in the SAML requirements.
If you are running Tableau Server in a cluster, then the SAML certificates, keys, and metadata file will be automatically distributed across the nodes when you enable SAML.

Use the TSM web interface

**Note:** Where indicated, you will also need to obtain metadata from your IdP. Information for how to do this will be in the IdP’s documentation.

1. Open TSM in a browser:

   https://<tsm-computer-name>:8850. For more information, see Sign in to Tableau Services Manager Web UI.

2. On the **Configuration** tab, select **User Identity & Access**, and then select the **Authentication Method** tab.

3. For **Authentication Method**, select **SAML**.

4. In the SAML section that appears, complete Step 1, entering the following settings (do not yet select the check box to enable SAML for the server):
**Tableau Server return URL**—The URL that Tableau Server users will access, such as https://tableau-server.

Using https://localhost or a URL with a trailing slash (for example, http://tableau_server/) is not supported.

**SAML entity ID**—The entity ID uniquely identifies your Tableau Server installation to the IdP.

You can enter your Tableau Server URL again here. If you plan to enable site-specific SAML later, this URL also serves as the base for each site’s unique ID.

**SAML certificate and key files**—Enter the path you created in Configure Server-Wide SAML.

After you provide the information required in Step 1, the Download XML Metadata File button in Step 2 becomes available. If you are using a passphrase-protected key file, you will need to enter the passphrase with TSM CLI. See the final step in this procedure.

5. Now select the **Enable SAML authentication for the server** check box above Step 1.

6. Complete the remaining SAML settings.
   
a. For Steps 2 and 3, exchange metadata between Tableau Server and the IdP. (Here’s where you might need to check in with the IdP’s documentation.)

   Select **Download XML Metadata File**, and specify the file location.

   For other IdPs, go to your IdP account to add Tableau Server to its applications (as a service provider), providing the Tableau metadata as appropriate.

   Follow the instructions in the IdP’s website or documentation to download the IdP’s metadata. Save the .xml file to the same location that holds your SAML certificate and key files. For example:
b. Return to the TSM web UI. For Step 4, enter the path to the IdP metadata file, and then select **Upload**.

![Image](https://example.com/image.png)

b. Return to the TSM web UI. For Step 4, enter the path to the IdP metadata file, and then select **Upload**.

```xml
/var/opt/tableau/tableau_server/data/saml/idp-metadata.xml
```

c. For Step 5: In some cases, you may need to change the assertion values in the Tableau Server configuration to match the assertion names that are passed by your IdP.

You can find assertion names in the IdP's SAML configuration. If different assertion names are passed from your IdP, then you must update Tableau Server to use the same assertion value.

**Tip:** “Assertions” are a key SAML component, and the concept of mapping assertions can be tricky at first. It might help to put this in a tabular-data context, in which the assertion (attribute) name is equivalent to a column heading in the table. You enter that “heading” name, rather than an example of a value that might appear in that column.

d. For Step 6, select the Tableau applications in which you want to give users a single sign-on experience.

**Note:** The option to disable mobile access is ignored by devices running Tableau Mobile app version 19.225.1731 and higher. To disable SAML for
devices running these versions you must disable SAML as a client login option on Tableau Server.

e. Finally, for the SAML sign-out redirect, if your IdP supports single logout (SLO), enter the page you want to redirect users to after they sign out, relative to the path you entered for the Tableau Server return URL.

7. Click Save Pending Changes after you've entered your configuration information.

8. Click Pending Changes at the top of the page:

9. Click Apply Changes and Restart.

Use the TSM CLI

Before you begin

- Go to your IdP’s website or application, and export the IdP’s metadata XML file.

Confirm that the metadata XML from the IdP includes a SingleSignOnService element, in which the binding is set to HTTP-POST, as in the following example:

```xml
```
Configure return URL, SAML entity ID, and specify certificate and key files

1. Open the command prompt shell and configure the SAML settings for the server (replacing placeholder values with your environment path and file names).

   For more information, see tsm authentication saml configure.

2. If SAML is not already enabled on Tableau Server; for example, you’re configuring it for the first time, or you have disabled it, enable it now:

   tsm authentication saml enable

3. Apply the changes:

   tsm pending-changes apply

   The pending-changes apply command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the --ignore-prompt option, but this does not change the restart behavior. For more information, see tsm pending-changes apply.

Generate Tableau Server metadata and configure the IdP

1. Run the following command to generate the required XML metadata file for Tableau server.

   tsm authentication saml export-metadata -f <file-name.xml>
You can specify a file name, or omit the \(-f\) parameter to create a default file named `samlmetadata.xml`.

2. On your IdP’s website or in its application:

   - Add Tableau Server as a Service Provider.

     Refer to your IdP’s documentation for information about how to do this. As part of the process of configuring Tableau Server as a Service Provider, you will import the Tableau Server metadata file you generated from the `export-metadata` command.

   - Confirm that your IdP uses `username` as the attribute to verify users.

**Match assertions**

In some cases, you may need to change the assertion values in the Tableau Server configuration to match the assertion names that are passed by your IdP.

You can find assertion names in the IdP’s SAML configuration. If different assertion names are passed from your IdP, then you must update Tableau Server to use the same assertion value.

**Tip:** “Assertions” are a key SAML component, and the concept of mapping assertions can be tricky at first. It might help to put this in a tabular-data context, in which the assertion (attribute) name is equivalent to a column heading in the table. You enter that “heading” name, rather than an example of a value that might appear in that column.

The following table shows the default assertion values and the configuration key that stores the value.

<table>
<thead>
<tr>
<th>Assertion</th>
<th>Default value</th>
<th>Key</th>
</tr>
</thead>
<tbody>
<tr>
<td>Username</td>
<td><code>username</code></td>
<td><code>wgserver.saml.idpattribute.username</code></td>
</tr>
<tr>
<td>Display name</td>
<td><code>displayName</code></td>
<td><code>wgserver.saml.idpattribute.displayname</code></td>
</tr>
</tbody>
</table>
To change a given value, run the `tsm configuration set` command with the appropriate key:value pair.

For example, to change the `username` assertion to the value, name, run the following command:

```
tsm configuration set -k wgserver.saml.idpattribute.username -v name
```

After you have updated the assertions, you must run the following command to apply the changes:

```
tsm pending-changes apply
```

**Optional: Disable client types from using SAML**

By default, both Tableau Desktop and the Tableau Mobile app allow SAML authentication.

If your IdP does not support this functionality, you can disable SAML sign-in for Tableau clients using the following commands:

```
tsm authentication saml configure --desktop-access disable
```

```
tsm authentication saml configure --mobile-access disable
```

**Note:** The `--mobile-access disable` option is ignored by devices running Tableau Mobile app version 19.225.1731 and higher. To disable SAML for devices running these versions you must disable SAML as a client login option on Tableau Server.
After you have updated the assertions, you must run the following command to apply the changes:

```bash
tsm pending-changes apply
```

Test the configuration

1. In your web browser, open a new page or tab, and enter the Tableau Server URL.

   ![Tableau Server URL](image)

   The browser redirects you to the IdP’s sign-in form.

2. Enter your single sign-on user name and password.

   ![Sign-in Form](image)

   The IdP verifies your credentials and redirects you back to your Tableau Server start page.
Configure SAML with AD FS on Tableau Server

You can configure Active Directory Federation Services (AD FS) as a SAML identity provider, and add Tableau Server to your supported single sign-on applications. When you integrate AD FS with SAML and Tableau Server, your users can sign in to Tableau Server using their standard network credentials.

Prerequisites

Before you can configure Tableau Server and SAML with AD FS, your environment must have the following:

- A server running Microsoft Windows Server 2008 R2 (or later) with AD FS 2.0 (or later) and IIS installed.

- We recommend that you secure your AD FS server (for example, using a reverse proxy). When your AD FS server is accessible from outside your firewall, Tableau Server can redirect users to the sign in page hosted by AD FS.

- SSL certificate encrypted using SHA-2 (256 or 512 bit) encryption, and that meets the additional requirements listed in the following sections:
  - SSL certificate requirements
  - SAML Certificate and identity provider (IdP) requirements

Step 1: Verify SSL connection to AD FS

AD FS requires an SSL connection. If you haven’t done so yet, complete the steps in Configure SSL for External HTTP Traffic to and from Tableau Server, using a certificate that meets the requirements as specified above.

Alternatively, if Tableau Server is configured to work with a reverse proxy or load balancer where SSL is being terminated (commonly referred to as SSL off-loading), then you do not need to configure external SSL.
Step 2: Configure SAML on Tableau Server

Complete the steps in Configure Server-Wide SAML through downloading the Tableau Server metadata to an XML file. At that point, return here and continue to the next section.

Step 3: Configure AD FS to accept sign-in requests from Tableau Server

**Note:** These steps reflect a third-party application and are subject to change without our knowledge.

Configuring AD FS to accept Tableau Server sign-in requests is a multi-step process, starting with importing the Tableau Server XML metadata file to AD FS.

1. Do one of the following to open the Add Relying Party Trust Wizard:

   **Windows Server 2008 R2:**
   
   a. Select **Start menu > to Administrative Tools > AD FS 2.0**.
   
   b. In **AD FS 2.0**, under **Trust Relationships**, right-click the **Relying Party Trusts** folder, and then click **Add Relying Party Trust**.

   **Windows Server 2012 R2:**
   
   a. Open **Server Manager**, and then on the **Tools** menu, click **AD FS Management**.
   
   b. In **AD FS Management**, on the **Action** menu, click **Add Relying Party Trust**.

2. In the **Add Relying Party Trust Wizard**, click **Start**.

3. On the **Select Data Source** page, select **Import data about the relying party from a file**, and then click **Browse** to locate your Tableau Server XML metadata file. By default, this file is named **samlspmetadata.xml**.

4. Click **Next**, and on the **Specify Display Name** page, type a name and description for
the relying party trust in the Display name and Notes boxes.

5. Click Next to skip the Configure Multi-factor Authentication Now page.

6. Click Next to skip the Choose Issuance Authorization Rules page.

7. Click Next to skip the Ready to Add Trust page.

8. On the Finish page, select the Open the Edit Claim Rules dialog for this relying party trust when the wizard closes check box, and then click Close.

Next, you’ll work in the Edit Claim Rules dialog, to add a rule that makes sure the assertions sent by AD FS match the assertions Tableau Server expects. At a minimum, Tableau Server needs an email address. However, including first and last names in addition to email will ensure the user names displayed in Tableau Server are the same as those in your AD account.

1. In the Edit Claim Rules dialog box, click Add Rule.

2. On the Choose Rule Type page, for Claim rule template, select Send LDAP Attributes as Claims, and then click Next.

3. On the Configure Claim Rule page, for Claim rule name, enter a name for the rule that makes sense to you.

4. For Attribute store, select Active Directory, complete the mapping as shown below, and then click Finish.

The mapping is case sensitive and requires exact spelling, so double-check your entries.

<table>
<thead>
<tr>
<th>LDAP Attribute</th>
<th>Outgoing Claim Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAM-Account-Name</td>
<td>Name ID</td>
</tr>
<tr>
<td>SAM-Account-Name</td>
<td>username</td>
</tr>
</tbody>
</table>
If you are running AD FS 2016 or later, then you must add a rule to pass through all claim values. If you are running an older version of AD FS, skip to the next procedure to export AD FS metadata.

1. Click **Add Rule**.
2. Under **Claim rule template**, choose **Pass Through or Filter an Incoming Claim**.
3. Under **Claim rule name**, enter **Windows**.
4. On the **Edit Rule - Windows** pop-up:
   - Under **Incoming claim type**, select **Windows account name**.
   - Select **Pass through all claim values**.
   - Click **OK**.

Now you will export AD FS metadata that you’ll import to Tableau Server later. You will also make sure the metadata is configured and encoded properly for Tableau Server, and verify other AD FS requirements for your SAML configuration.

1. Export AD FS Federation metadata to an XML file, and then download the file from `https://<adfs server name>/FederationMetadata/2007-06/FederationMetadata.xml`.

2. Open the metadata file in a text editor like Sublime Text or Notepad++, and verify that it is correctly encoded as UTF-8 without BOM.

   If the file shows some other encoding type, save it from the text editor with the correct encoding.

3. Verify that AD FS uses forms-based authentication. Sign-ins are performed in a browser window, so you need AD FS to default to this type of authentication.

   Edit `c:\inetpub\adfs\ls\web.config`, search for the tag, and move the line so it appears first in the list. Save the file so that IIS can automatically reload it.
Note: If you don’t see the `c:\inetpub\adfs\ls\web.config` file, IIS is not installed and configured on your AD FS server.

4. (Optional) This step is required only if AD FS is configured as an IDP for site-specific SAML. This step is not required if AD FS is configured as the IDP for server-wide SAML.

Configure an additional AD FS relying party identifier. This allows your system to work around any AD FS issues with SAML logout.

Do one of the following:

**Windows Server 2008 R2:**

a. In AD FS 2.0, right-click on the relying party you created for Tableau Server earlier, and click Properties.

b. On the Identifiers tab, in the Relying party identifier box, enter `https://<tableauservername>/public/sp/metadata` and then click Add.

**Windows Server 2012 R2:**

a. In AD FS Management, in the Relying Party Trusts list, right-click on the relying party you created for Tableau Server earlier, and click Properties.

b. On the Identifiers tab, in the Relying party identifier box, enter `https://<tableauservername>/public/sp/metadata` and then click Add.

**Note:** AD FS can be used with Tableau Server for a single relying party to the same instance. AD FS cannot be used for multiple relying parties to the same instance, for example, multiple site-SAML sites or server-wide and site SAML configurations.
5. Turn off AD FS assertion encryption for the relying party. Tableau Server does not currently support assertion encryption.

On the AD FS server, use Windows PowerShell to run the following command, replacing `<MyRelyingPartyName>` in the example command below to the name of the ADFS relying party display name:

```
Set-ADFSRelyingPartyTrust -TargetName <MyRelyingPartyName> -EncryptClaims 0
```

**Note:** If you receive the error **Set-ADFSRelyingPartyTrust Cmdlet cannot be found**, you must add the AD FS PowerShell snap-in. At the command prompt type: `Add-PSSnapin Microsoft.Adfs.PowerShell`, and then repeat this step.

Step 4: Provide AD FS metadata to Tableau Server

1. Return to the TSM web UI, and navigate to **Configuration > User Identity & Access > Authentication Method** tab.

2. In Step 4 of the SAML configuration window, enter the location of the XML file you exported from AD FS, and select **Upload**.

3. Complete the remaining steps (matching assertions and specifying client type access) as specified in Configure Server-Wide SAML. Save and apply changes.

4. Stop Tableau Server, open TSM CLI, and run the following commands, so that AD
FS can properly redirect to Tableau Server after it accepts users’ SAML credentials:

```bash
tsm configuration set -k wgserver.saml.sha256 -v true
```

3. Apply the changes:

```bash
tsm pending-changes apply
```

The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

Use SAML SSO with Kerberos Database Delegation

In a Windows Active Directory (AD) environment, you can enable SAML single sign-on (SSO) to Tableau Server, along with Kerberos database delegation. This provides authorized users direct access to Tableau Server, as well as to the underlying data defined in their published workbooks and data sources.

In this article

- Overview of the process
- Configure Tableau Server for SAML with Kerberos
Overview of the process

In a typical scenario:

1. One of your Tableau analysts publishes a dashboard to Tableau Server. That dashboard contains a connection to a Hadoop cluster, for example, that is configured to accept Kerberos credentials.

   Then the workbook publisher sends a link to colleagues for review.

2. When a colleague clicks the link, Tableau Server authenticates the user through the SAML SSO process. Then it looks at the user’s authorization scheme, and if allowed, uses the Tableau Server keytab to accesses the underlying database on behalf of the user. This populates the dashboard with the Hadoop data that the user is authorized to see.
Configure Tableau Server for SAML with Kerberos

Using SAML with Kerberos works inherently when you complete the processes to enable each separately:

1. Configure Tableau Server for SAML, as described in Configure Server-Wide SAML.

2. Configure Tableau Server and your underlying databases to accept Kerberos credentials, as described in Enable Kerberos Delegation and related articles.

Configure Site-Specific SAML

Use site-specific SAML in a multi-site environment when you want to enable single sign-on, and you also use multiple SAML identity providers (IdPs) or IdP applications. When you enable site SAML, you can specify the IdP or IdP application for each site, or configure some sites to use SAML and the others to use the default server-wide authentication method.

If you want all server users to use SAML and sign in through the same IdP application, see Configure Server-Wide SAML.

Prerequisites for enabling site-specific SAML

Before you can enable SAML single sign-on at the site level, complete the following requirements:

- The Tableau Server identity store must be configured for local authentication.
  
  You cannot configure site-specific SAML if Tableau Server is configured with an external identity store such as Active Directory or OpenLDAP.

- Make sure your environment and your IdP meet the general SAML Requirements.

- Note the location of the SAML certificate files. You will provide this when you Configure the server to support site-specific SAML.

  For more information, see Put metadata and certificate files in place in the topic on configuring server-wide SAML.
• Add Tableau Server as a service provider to your IdP. You can find this information in the documentation the IdP provides.

• Confirm that the system clocks of the computer hosting the site-SAML IdP and the computer hosting Tableau Server are within 59 seconds of each other. Tableau Server does not have a configuration option to adjust the response skew (time difference) between the Tableau Server computer and the IdP.

Server-wide settings related to site-specific SAML

In the server’s workgroup.yml file, server-wide settings that are used in some way for site-specific SAML include:

• `wgserver.saml.returnurl` and `wgserver.saml.entityid`: In the settings for configuring site-specific SAML, Tableau provides a site-specific return URL and entity ID based on these settings. The site-specific return URL and entity ID cannot be modified.

• `wgserver.saml.domain`, `wgserver.saml.port`, and `wgserver.saml.protocol` are used for SAML requests at the site level.

Server-wide settings `wgserver.saml.maxauthenticationage` and `wgserver.saml.responseskew` do not apply to site-specific SAML.

Configure the server to support site-specific SAML

After you complete the prerequisites listed above, you can run the following commands to configure the server to support site-specific SAML.

1. Configure entity, set return URL, and add certificate files. Run the following command (if you have already configured server-wide SAML, skip to Step 2):

```bash
 tsm authentication saml configure --idp-entity-id <tableau-server-entity-id> --idp-return-url <tableau-server-return-url> --cert-file <path-to-saml-certificate.crt> --key-file <path-to-saml-keyfile.key>
```
2. Enable site SAML. Run the following commands:

   tsm authentication sitesaml enable

   tsm pending-changes apply

About the commands

The sitesaml enable command exposes the Authentication tab on each site’s Settings page in the Tableau Server web UI. After you configure the server to support site SAML, you can continue to Configure SAML for a site to work through the settings on the Authentication tab.

The pending-changes apply command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the --ignore-prompt option, but this does not change the restart behavior. For more information, see tsm pending-changes apply.

If you want to review the commands and settings that will be carried out when you run pending-changes apply, you can run the following command first:

   tsm pending-changes list --config-only

Configure SAML for a site

This section takes you through the configuration steps that appear on the Authentication page in the Tableau Server web UI. In a self-hosted Tableau Server installation, this page appears only when support for site-specific SAML is enabled at the server level. It is enabled by default in Tableau Online.

Note: To complete this process, you will also need the documentation your IdP provides. Look for topics that refer to configuring or defining a service provider for a SAML connection, or adding an application.
Step 1: Export metadata from Tableau

To create the SAML connection between Tableau Server and your IdP, you need to exchange required metadata between the two services. To get metadata from Tableau Server, do either of the following steps. See the IdP’s SAML configuration documentation to confirm the correct option.

- Select **Export metadata** to download an XML file that contains the Tableau Server SAML entity ID, Assertion Consumer Service (ACS) URL, and X.509 certificate.

  The entity ID is site-specific, and based on the server-wide entity ID that you specified when you enabled site SAML on the server. For example, if you specified `https://tableau_server`, you might see the following entity ID for the site:

  `https://tableau_server-/samlservice/public/sp/metadata?alias=48957410-9396-430a-967c-75bdb6e002a0`

  You cannot modify the site-specific entity ID or ACS URL that Tableau generates.

- Select **Download signing and encryption certificate** if your IdP expects the required information in a different way. For example, if it wants you to enter the Tableau Server entity ID, ACS URL, and X.509 certificate in separate locations.

  The following image has been edited to show that these settings are the same in
Steps 2 and 3: External steps

For Step 2, to import the metadata you exported in step 1, sign in to your IdP account, and use the instructions provided by the IdP’s documentation to submit the Tableau Server metadata.

For Step 3, the IdP’s documentation will guide you also in how to provide metadata to a service provider. It will instruct you to download a metadata file, or it will display XML code. If it displays XML code, copy and paste the code into a new text file, and save the file with a .xml extension.

Step 4: Import IdP metadata to the Tableau site

On the Authentication page in Tableau Server, import the metadata file that you downloaded from the IdP or configured manually from XML it provided.

Step 5: Match attributes

Attributes contain authentication, authorization, and other information about a user. In the Identity Provider (IdP) Assertion Name column, provide the attributes that contain the
information Tableau Server requires.

- **Username or Email**: (Required) Enter the name of the attribute that stores user names or email addresses.

- **Display name**: (Optional but recommended) Some IdPs use separate attributes for first and last names, and others store the full name in one attribute.

Select the button that corresponds to the way your IdP stores the names. For example, if the IdP combines first and last name in one attribute, select **Display name**, and then enter the attribute name.

![Match attributes](image)

**Step 6: Manage users**

Select existing Tableau Server users, or add new users you want to approve for single sign-on.
When you add or import users, you also specify their authentication type. On the Users page, you can change users’ authentication type any time after adding them.

For more information, see Add Users to a Site or Import Users and Set the User Authentication Type for SAML.

**Important:** Users that authenticate with site-specific SAML can belong only to one site.

If a user needs to access multiple sites, set their authentication type to the server default. Depending on how site-specific SAML was configured by the server administrator, the server default is either local authentication or server-wide SAML.

---

**Default authentication type for embedded views**

Part of enabling SAML on your site is to specify how users access views embedded in web pages.

- **Allow users to choose their authentication type**

  When you select this, two sign-in options appear where a view is embedded: a sign-in button that uses single sign-on authentication and a link to use TableauID as an alternative.

  **Tip:** With this option, users need to know which alternative to choose. As part of notification you send your users after you add them to the single sign-on site, let them know which type of authentication to use for a variety of sign-in scenarios. For example, embedded views, Tableau Desktop, Tableau Bridge, Tableau Mobile, and so on.

- **TableauID**
This option requires users to sign in using a TableauID even if SAML is enabled on the site. Generally it’s reserved for administrators for troubleshooting issues with embedded views and SAML.

- **Single sign-on with SAML**

  If your IdP doesn't support signing in from an iframe, select **Authenticate in a separate pop-up window**. When a user goes to the web page with the embedded view, the pop-up window appears when they select the sign-in button.

  If your IdP supports signing in from an iframe, select **Authenticate using an inline frame (less secure; not supported by all IdPs)**. Iframe embedding can provide a more seamless user experience. For example, if a user is already authenticated with your IdP, and iframe embedding is enabled, the user seamlessly authenticates with Tableau Server when browsing to pages that contain embedded Tableau views.

  **Caution:** Because iframes can be vulnerable to clickjacking attacks, not all IdPs support signing in through an iframe. With clickjacking, the attacker tries to lure users into clicking or entering content. They do this by displaying the page to attack in a transparent layer over an unrelated page. For Tableau Server, an attacker might try to capture user credentials or to get an authenticated user to change settings. For more information, see Clickjacking on the Open Web Application Security Project website.

**Troubleshoot SAML**

This topic provides information about resolving issues that can occur when you configure SAML authentication.

**SAML and Enable Automatic Logon**

If you are using SAML and if Tableau Server is also configured to use Active Directory, do not also select **Enable automatic logon**. **Enable automatic logon** and SAML cannot both be used on the same server installation.
HTTP Status 500 error when configuring SAML

Under some circumstances you might get an HTTP status 500 error and see the following error after enabling SAML and navigating to the Tableau Server URL in a browser:

```
org.opensaml.saml2.metadata.provider.MetadataProviderException: User specified binding is not supported by the Identity Provider using profile urn:oasis-is:names:tc:SAML:2.0:profiles:SSO:browser
```

To help resolve this error, make sure of the following:

- The IdP URL for the SSO profile specified in the SAML tab is correct.
- The IdP URL for the SSO profile provided while creating the service provider in the IdP is correct.
- The IdP is configured to use HTTP-POST requests. (Redirect and SOAP are not supported.)

If any of these settings were not correct, make appropriate updates and then perform the SAML configuration steps again, starting with generating and exporting the XML metadata document from Tableau Server.

If these settings are correct, but you still see the error, examine the metadata XML that is produced by Tableau Server and by the IdP, as described in SAML Requirements.

Signing In from the Command Line

SAML is not used for authentication when you sign in to Tableau Server using tabcmd or the Tableau Data Extract command line utility (provided with Tableau Desktop), even if Tableau Server is configured to use SAML. These tools require the authentication configured when Tableau Server was originally installed (either local authentication or AD).

Login Failed

Login can fail with the following message:
Login failure: Identity Provider authentication successful for user <username from IdP>. Failed to find the user in Tableau Server.

This error typically means that there is a mismatch between the usernames stored in Tableau Server and provided by the IdP. To fix this, make sure that they match. For example, if Jane Smith’s username is stored in the IdP as jsmith it must be stored in Tableau Server as jsmith.

SAML Error Log

SAML authentication takes place outside Tableau Server, so troubleshooting authentication issues can be difficult. However, login attempts are logged by Tableau Server. You can create a snapshot of log files and use them to troubleshoot problems. For more information, see Log File Snapshots (Archive Logs).

**Note:** To log SAML-related events, `vizportal.log.level` must be set to debug. For more information, see Change Logging Levels.

Check for SAML errors in the following files in the unzipped log file snapshot:
`\vizportal\vizportal-<n>.log`

In Tableau Server 9.0 and later, the application process (vizportal.exe) handles authentication, so SAML responses are logged by that process.

Trailing Slash

On the SAML tab, confirm that the **Tableau Server return URL** does not end with a trailing slash.

Correct: `http://tableau_server`

Incorrect: `http://tableau_server/`
Confirm Connectivity

Confirm that the Tableau Server you are configuring has either a routeable IP address or a NAT at the firewall that allows two-way traffic directly to the server.

You can test your connectivity by running telnet on Tableau Server and attempting to connect with the SAML IdP. For example: `C:\telnet 12.360.325.10 80`

The above test should connect you to the HTTP port (80) on the IdP and you should receive an HTTP header.

Kerberos

Kerberos is a three-way authentication protocol that relies on the use of a trusted third-party network service called the Key Distribution Center (KDC) to verify the identity of computers and provide for secure connections between the computers through the exchange of tickets. These tickets provide mutual authentication between computers or services, verifying that one has permission to access the other.

Tableau Server supports Kerberos authentication in an Active Directory Kerberos environment, with authentication to Tableau Server being handled by Kerberos.

**Note:** The Kerberos support in Tableau Server is for user authentication. It does not handle internal permissions and authorization related to Tableau Server content, such as workbooks.

How Kerberos works

When you configure Tableau Server for Kerberos in an Active Directory (AD) environment, the AD domain controller also serves as the Kerberos Key Distribution Center (KDC) and issues Ticket Granting Tickets to the other nodes in the domain. Users authenticated by the KDC do not have to authenticate further when connecting to Tableau Server.

The following is a diagram of the authentication workflow.
User logs into their Active Directory domain.

The Kerberos KDC authenticates the user and sends a Ticket Granting Ticket (TGT) to the user's computer.

The user connects to Tableau Server in Tableau Desktop or in a web browser.

Tableau Server authenticates the user.

Kerberos Requirements

You can configure Kerberos authentication for Tableau Server running in either Active Directory or LDAP directory environments.

General requirements

- **External Load Balancer/Proxy Server:** If you are going to use Tableau Server with Kerberos in an environment that has external load balancers (ELBs) or proxy server, you need to set these up before you configure Kerberos in the Tableau Server.
Configuration utility. See Configuring Proxies for Tableau Server.

- **iOS Browser Support:** An iOS user can use Kerberos authentication with mobile Safari if a Configuration Profile specifying the user’s Kerberos identity is installed. See Configuring an iOS Device for Kerberos Support in the Tableau Mobile Help. For more information about browser support for Kerberos SSO, see Browser Support for Kerberos SSO.

- **Tableau Server requires constrained delegation,** where the Tableau data access account is specifically granted rights to the target database SPNs. Unconstrained delegation is not supported.

- The supported data sources (SQL Server, MSAS, PostgreSQL, Hive/Impala, and Teradata) must be configured for Kerberos authentication.

- A keytab file that is configured with the service provider name for the Tableau Server for user authentication. If you are using Kerberos authentication for datasources then those credentials should be included in the single keytab file that you will specify during Kerberos configuration on Tableau Sever.

**Active Directory requirements**

You must meet the following requirements to run Tableau Server with Kerberos in an Active Directory environment:

- **Tableau Server must use Active Directory (AD) for authentication.**

- **The domain must be an AD 2003 or later domain for Kerberos connections to Tableau Server.**

- **Smart Card Support:** Smart cards are supported when users sign into their workstations with a smartcard and this results in a Kerberos TGT being granted to the user from Active Directory.

- **Single-Sign On (SSO):** Users must be granted a Kerberos Ticket Granting Ticket
(TGT) from Active Directory when they sign into their computers. This is standard behavior for domain-joined Windows computers and standard for Mac computers that use AD as their network account server. For more information on using Mac computers and Active Directory, see Join your Mac to a network account server in the Apple Knowledge Base.

**Kerberos delegation**

For Kerberos delegation scenarios the following are required:

- If the domain is AD 2003 or later, single domain Kerberos delegation is supported. The users, Tableau Server, and backend database must be on the same domain.

- If the domain is AD 2008, there is limited cross domain support. Users from other domains can be delegated if the following conditions are met. Tableau Server and the backend database must be on the same domain, and a two way trust is required between the domain where Tableau Server resides and the user’s domain.

- If the domain is 2012 or later, full cross-domain delegation is supported. AD 2012 R2 is preferred because it has a dialog for configuring constrained delegation, while 2012 non-R2 requires manual configuration.

**Understanding Keytab Requirements**

Kerberos authentication relies on credentials that are stored in specially formatted files called keytab files. You may need to generate keytab files for your Tableau Server deployment. This topic describes the keytab files that Tableau Server uses to access various services in a typical organization.

If your organization includes IT professionals who handle identity, authentication, and/or security, then you should work with them to create a plan for generating appropriate keytabs for your Tableau Server deployment.
Operating system

If your organization uses Kerberos for authentication, then the computer where Tableau Server is running must be authenticated with the Kerberos realm in which it's running.

If you are running Tableau Server on Windows, and the computer is joined to the Active Directory, then you do not need to manage or generate a keytab file. Windows Active Directory handles all keytab and Kerberos configuration.

If you are running Tableau Server on Linux in a Kerberos realm (MIT KDC or Active Directory), then you will need to generate a keytab file specifically for the computer operating system. The keytab you create for the computer should be specifically for OS authentication. Do not use the same keytab file for OS authentication that you will be using for the other services described later in this topic.

Directory service

If your organization uses a directory service, such as OpenLDAP or Active Directory, to manage user identity, then Tableau Server requires read-only access to the directory.

Alternatively, you can configure Tableau Server to manage all accounts by installing with a local identity store.

The following table summarizes keytab requirements:

<table>
<thead>
<tr>
<th>Tableau is running on...</th>
<th>Directory service</th>
<th>Need to manually generate a keytab?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows in AD domain</td>
<td>Active Directory</td>
<td>No</td>
</tr>
<tr>
<td>Windows</td>
<td>OpenLDAP</td>
<td>Yes</td>
</tr>
<tr>
<td>Linux</td>
<td>Active Directory or OpenLDAP</td>
<td>Yes</td>
</tr>
</tbody>
</table>

If you need to manually generate a keytab for this scenario, then you will use it for GSSAPI bind to the directory. Follow these recommendations:
• Create a service account in your directory for Tableau Server.

• Create a keytab specifically for the Tableau Server service account. Do not reuse the keytab file that the computer account/OS uses to authenticate.

• Upload the keytab file as part of the json configuration of the Tableau Server identity store. See identityStore Entity.

User authentication (SSO) in Windows Active Directory

If you will be using Active Directory as the identity store for Tableau Server, and you want users to authenticate with Kerberos SSO, then you will need to generate a keytab file for Tableau Server.

Follow these recommendations (for Windows and Linux versions of Tableau Server):

• Create a service account in your directory for Tableau Server.

• Create a keytab specifically for the Tableau Server service account. Do not reuse the keytab file that the computer account/OS uses to authenticate. You may use the same keytab for Kerberos SSO as you use for the directory authentication in the scenario above.

• You must create service principal names (SPN) in Active Directory for the Tableau Server service.

• Use the batch file in the next section to create the SPNs and the keytab file.

• After you have created the SPNs, upload the keytab file as described in Configure Kerberos.

Batch file: Set SPN and create keytab in Active Directory

You can use a batch file to set the service principal names (SPN) and create a keytab file. These operations are a part of the process to enable Kerberos SSO for Tableau Server running in Active Directory.
In previous versions of Tableau Server (before 2018.2), the configuration script was generated from the Tableau Server Configuration utility.

To generate a configuration script, copy and paste the following batch file contents into a text file. The batch file creates service principal names (SPN) for Tableau Server and will create a keytab file for the user you specify in the file.

Follow the directions in the file contents. After you have finished customizing the file, save it as a .bat file.

This file must be run in an Active Directory domain by a Domain admin, who will be prompted for the service account password of the account you specify in the file.

**SPN and keytab batch file contents**

```batch
@echo off
setlocal EnableDelayedExpansion

REM ******

REM This script generates the Service Principal Names (SPNs) and keytab files required for
REM Kerberos SSO with Apache.
REM This script executes setspn and ktpass, utilities included in any Windows Server
REM Operating System from 2003 on.
REM Before running this script you must enter configuration information for the setspn and
REM ktpass commands.
REM Elements that require your configuration information are enclosed in as such:
REM  ! -- and --!.  
REM After you customize this file, save it as a .bat file, and
```
run on a domain-joined
REM computer.
REM This script must be run by a Domain admin.

REM ***********

REM The following set command will prompt the domain admin for credentials of the
REM Tableau Server service account.
REM This account must be a valid domain user account.
REM If the password contains a literal " (blackslash - double quote), all backslashes
REM immediately before the double quote must be
REM duplicated when typed for the password to work, e.g. if password contains
REM \" replace with \"", if passwords contains \" replace with \\\\\n
set /p adpass= "Enter password for the Tableau Server service account."
set adpass=!adpass:"="!

REM ***********

REM The following setspn commands create the SPN in the domain.
REM More information on setspn can be found here:
(WS.10).aspx
REM Enter the canonical FQDN and the host names for Tableau Server followed by the
REM Tableau Server service account name.
REM Use this syntax: HTTP/hostname domain\service_account_name.
REM The example below shows syntax for a computer named
"tableau01" in the "example.lan"
REM domain, with service account, "tab-serv-account":
REM setspn -s HTTP/tableau01 example\tab-serv-account
REM setspn -s HTTP/tableau01.example.lan example\tab-serv-
account
REM DNS and AD are not case sensitive, but the keytab files
are. Verify that host names
REM match letter case as stored in DNS.
REM Use Windows Server's DNS Manager utility to verify host
name case.
REM **********

echo Creating SPNs...
setspn -s HTTP/!-replace with canonical host name and service
account --!
setspn -s HTTP/!-replace with canonical FQDN and service
account --!
REM **********

REM The following commands create the keytab file in the same
directory where the
REM bat file is run. More information on ktpass can be found
here:
REM Note: keytab files are case-sensitive.
REM The realm following the FQDN should be all uppercase.
REM Syntax is:
REM ktpass /princ HTTP/!--FQDN--!@!-Kerberos_Rolem--! /pass
!adpass!
REM /pttype KRB5_NT PrincipaL /out keytabs\kerberos.keytab
REM the following example shows the ktpass syntax with the
example.lan configuration from above:
REM ktpass /princ HTTP/tableau01.example.lan@EXAMPLE.LAN /pass
!adpass! /ptype KRB5_NT_PRINCIPAL /out keytabs\kerberos.keytab

REM ************

echo Creating Keytab files in %CD%\keytabs
mkdir keytabs
ktpass /princ HTTP/!--FQDN--!@!--Kerberos_Realm--! /pass !adpass! /ptype KRB5_NT_PRINCIPAL /out keytabs\kerberos.keytab

Datasource delegation

You can also use Kerberos delegation to access data sources in an Active Directory. In this scenario, users can be authenticated to Tableau Server with any supported authentication mechanism (SAML, local authentication, Kerberos, etc), but can access datasources that are enabled by Kerberos.

Follow these recommendations:

- The keytab file that you use for Kerberos delegation can be the same keytab that you use for Kerberos SSO.
- The keytab must be mapped to the service principal for Kerberos delegation in Active Directory.
- You may use the same keytab for multiple data sources.

For more information, see the following configuration topics:

- Tableau Server on Linux: Enable Kerberos Delegation
- Tableau Server on Windows: Enabling Kerberos Delegation

See also

- MIT Kerberos Support for Tableau Server on Linux
Configure Kerberos

You can configure Tableau Server to use Kerberos. This allows you to provide a single sign-on (SSO) experience across all the applications in your organization. Before you configure Tableau Server for Kerberos make sure your environment meets the Kerberos Requirements.

**Note:** Kerberos constrained delegation for SSO to Tableau Server is not supported. (Constrained delegation for data sources is supported.) For more information, see Single-Sign On (SSO) in Kerberos Requirements.

To configure Kerberos, you must first enable Kerberos, and then specify a keytab file for user authentication. The keytab file you specify must be configured with the service provider name for the Tableau Server for user authentication. If you are using Kerberos authentication for data sources, those credentials should be included in the single keytab file that you will specify during Kerberos configuration on Tableau Server.

In this article

- Use the TSM web interface
- Use the TSM CLI
- Confirm your SSO configuration

### Use the TSM web interface

1. **Open TSM in a browser:**

   https://<tsm-computer-name>:8850. For more information, see Sign in to Tableau Services Manager Web UI.

2. **Click User Identity & Access on the Configuration tab and then click**
Authentication Method.

3. Under **Authentication Method**, select **Kerberos** in the drop-down menu.

4. Under Kerberos, select **Enable Kerberos for single sign-on (SSO)**.

5. To copy the keytab file to the server, click **Select File**, and then browse to the file on your computer.

![Authentication Method](image)

6. Click **Save Pending Changes** after you’ve entered your configuration information.

7. Click **Apply Changes and Restart**.

Use the TSM CLI

1. Copy the keytab file to the computer running Tableau Server and run the following command to set permissions on the file:

   ```bash
   chmod 644 "/path/keytab_file"
   ```

   If you are running Tableau Server on in a distributed cluster deployment, then you will need to manually distribute the keytab file to each node and then set the permissions. Copy the keytab file to the same directory on each node in the cluster. After you have copied the keytab file to each node and set permissions on the file, then run the following TSM commands on one node. The configuration will propagate to each node.
2. Type the following command to specify the location and name of the keytab file:

   tsm authentication kerberos configure --keytab-file <path-to-keytab_file>

3. Type the following command to enable Kerberos:

   tsm authentication kerberos enable

4. Run `tsm pending-changes apply` to apply changes.

   The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

Confirm your SSO configuration

Once Tableau Server has restarted, test your Kerberos configuration from a web browser on a different computer by typing the Tableau Server name in the URL window:

![Tableau Server](image)

You should be automatically authenticated to Tableau Server.

Browser Support for Kerberos SSO

To use browser-based Kerberos Single Sign-on (SSO), the following must be true:
Kerberos must be enabled on Tableau Server
The user must have permission to access Tableau Server (they can log in using a user name and password)
The user must be authenticated to Active Directory through Kerberos on the client computer. Specifically, this means that they have a Kerberos Ticket Granting Ticket (TGT).

**Note:** If Kerberos SSO fails you can still sign in to Tableau Server with your user name and password.

Desktop clients

The following combinations of operating system and Tableau Desktop or browser support Kerberos authentication to Tableau Server. In some cases, additional configuration is required.

**Windows**
- Tableau Desktop 8.3 or newer
- Internet Explorer - supported, may require configuration, see Note 1
- Chrome - supported, may require configuration, see Note 1
- Firefox - requires configuration, see Note 2
- Safari - not supported

**Mac OS X**
- Tableau Desktop 8.3 or newer
- Safari - supported
- Chrome - see Note 3
- Firefox - see Note 2
- Internet Explorer - not supported

**Mobile clients**

The following combinations of operating system and Tableau App or browser support Kerberos authentication to Tableau Server:

**Mac iOS**
- Tableau App 8.3 or newer - see Note 4
- Safari - see Note 4
- Chrome - not supported

Android - see Note 5
- Tableau App 8.3 or newer
- Android Browser
- Chrome

Note 1: Internet Explorer and Google Chrome on Windows desktop

Kerberos SSO is supported on both Internet Explorer and Google Chrome but requires configuration in Windows Internet Options:

- Enable Integrated Windows Authentication.
- Verify that Tableau Server URL is in the local intranet zone. The Tableau Server URL must be in the local internet zone. In many cases Internet Explorer’s automatic detection of intranet zones will automatically configure this. If the URL has not been detected and configured, then you will need to manually add the URL to the local intranet zone.

To enable Integrated Windows Authentication:

1. In Windows Control Panel, open Internet Options.
2. On the Advanced tab scroll down to the Security section.
4. Click Apply.

To verify or add the Tableau Server URL to the local intranet zone:

1. In Windows Control Panel, open Internet Options.
2. On the Security tab, select Local intranet, and then click Sites.
3. On the Local intranet dialog box, click Advanced.
4. The internal Tableau Server URL should be listed in the Websites field. In some organizations, IT administrators will use a wildcard (*) to specify internal URLs. For example, the wildcard, https://*.example.lan, includes all servers in the
internal example.lan namespace in the local intranet zone.

- If the Tableau Server URL or a wildcard URL for the Tableau Server namespace is listed in the Websites field, then click Close. You do not need to update the local intranet zone.
- If the Tableau Server URL or a wildcard URL is not specified in the Websites field, Enter the Tableau Server name (URL) in the Add the website to the zone field, click Add, and then click OK.

Note 2: Firefox on Windows and Mac OS X desktop

Kerberos SSO is supported in Firefox on both Windows and Mac, but requires that you configure two URL settings to enable Kerberos. Both of those settings are described in the following procedure:

1. In Firefox, enter about:config in the address bar.
2. Click I'll be careful, I promise when warned about changing advanced settings.
3. Enter negotiate in the Search box.
4. Double-click `network.negotiate-auth.allow-non-fqdn`, and then set the value to `true`.

5. Double-click `network.negotiate-auth.trusted-uris` and enter the Tableau Server fully qualified domain name (FQDN). For example, `tableau.example.com` or `example.com`.

**Note 3: Chrome on Mac OS X desktop**

According to Chrome documentation, Kerberos SSO works on a Mac when you launch Chrome from a terminal window with the following command:

```
open -a "Google Chrome.app" --args --auth-server-whitelist="tableau-server.example.com"
```

where `tableauserver.example.com` is the URL for Tableau Server in your environment.

However, we have found inconsistent results in our testing and therefore recommend using Safari or Firefox if you want to use Kerberos SSO on a Mac. See the Integrated Authentication section at [HTTP authentication](http://www.chromium.org) on The Chromium Projects site for more information.
Note: Chrome on Mac OS X continues to be supported with Tableau Server, but users may be prompted to log in with their user name and password (single sign-on may not work).

Note 4: Mobile Safari and Tableau App on Mac iOS

Kerberos SSO is supported if iOS is configured for Kerberos. The iOS device must have a Kerberos authentication configuration profile installed. This is usually done by an enterprise IT group. Tableau Support cannot assist with configuring iOS devices for Kerberos.

Note 5: Android platform

Kerberos SSO is not supported on the Android operating system because there is no platform-level support for Kerberos. You can still use your Android device and the Tableau App or a supported browser to connect to and log in to Tableau Server.

Troubleshoot Kerberos

The troubleshooting suggestions in this topic are divided into issues related to single sign-on (SSO) on the server and issues with the delegated data sources.

Single sign-on to Tableau Server

Kerberos authentication failed (unable to connect automatically to Tableau Server)

In a Kerberos SSO environment, a user signing in to Tableau Server from a web browser or Tableau Desktop might see the following error:

Tableau Server could not authenticate you automatically. Sign in using your Tableau Server credentials.
Troubleshoot the error on the client computer

- **General access to Tableau Server**—Sign in to Tableau Server using the user’s name and password. If these credentials fail, the user might not be a user on Tableau Server. For Kerberos SSO to work, the user must be able to access Tableau Server, and they must be granted a Ticket Granting Ticket (TGT) by Active Directory.

- **Other user accounts**—Try to connect with SSO to Tableau Server using other user accounts. If all users are affected, the problem might be in the Kerberos configuration.

- **Computer location**—Kerberos does not work when you sign in to Tableau Server on localhost. Clients must be connecting from a computer other than the Tableau
Server computer.

- **URL address**—You cannot use an IP address to sign in to Tableau Server using Kerberos SSO. In addition, the server name you use to access Tableau Server must match the name used in the Kerberos configuration (see Key table entry, below).

- **TGT (Ticket Granting Ticket)**—Confirm that the client computer has a TGT from the Active Directory domain. Kerberos requires a TGT to sign in. Constrained delegation, with the proxy granting a ticket, is not supported.

For more information, see Single-Sign On (SSO) in Kerberos Requirements.

To confirm the client computer has a TGT, do the following:

- On Windows, open a command prompt and type the following: `klist tgt`
- On the Mac, open a terminal window and type the following: `klist`

The output should show a TGT for the user/domain trying to authenticate to Tableau Server.

The client computer might not have a TGT in the following circumstances:

- The client computer is using a VPN connection.
- The client computer is not joined to the domain (for example, it is a non-work computer being used at work).
- The user signed into the computer with a local (non-domain) account.
- The computer is a Mac that is not using Active Directory as a network account server.

- **Browser**—Check the browser the user is using to access the server.
• Internet Explorer (IE) and Chrome work “out of the box” on Windows.

• Safari works “out of the box” on the Mac.

• Firefox requires additional configuration.

For more information Browser Support for Kerberos SSO.

Troubleshooting on the server

If you cannot solve the problem from the client computer, your next steps are to troubleshoot on the computer running Tableau Server. The administrator can use the request ID to locate the sign-in attempt in the Apache logs on Tableau Server.

• **Log files**—Check the Apache error.log for an error with the exact time/date of the failed sign-in attempt.

• **Key table entry**—If the error.log entry says "No key table entry matching HTTP/<servername>.<domain>.<org>@", for example:

  [Fri Oct 24 10:58:46.087683 2014] [:error] [pid 2104:tid 4776]
  [client 10.10.1.62:56789] gss_acquire_cred() failed: Unspecified GSS failure. Minor code may provide more information (, No key table entry found matching HTTP/server-name.domain.com@)

This error is a result of a mismatch between any of the following:

• **Tableau Server URL** - The URL used by the client computer to access the server.

  This is the name that you type into Tableau Desktop or a browser address bar. It could be a shortname (http://servername) or a fully-qualified domain name (http://servername.domain.com)
• **DNS reverse lookup** for the server IP address

  This looks up a DNS name using an IP address.

  At a command prompt type:

  ```
  ping servername
  ```

  with the IP address returned by pinging the server, do a reverse DNS lookup type:

  ```
  nslookup <ip address>
  ```

  The nslookup command will return network information for the IP address. In the *Non-authoritative answer* portion of the response, verify that the fully qualified domain name (FQDN) matches the following configured values:

  - The Kerberos .keytab file
  - Service Principal Name (SPN) for the server

  For more information about configuring these values, see Understanding Keytab Requirements.
Data source SSO

Delegated data source access failures

Check the vizqlserver log files for "workgroup-auth-mode."

Look for "workgroup-auth-mode" in the log files. It should say "kerberos-impersonate" not "as-is".

Kerberos delegation multi-domain configuration

Tableau Server has the ability to delegate users from other Active Directory domains. If your database uses MIT Kerberos, you may need to adjust your Kerberos principal to database user mapping. Specifically, you will need to update krb5.conf with rules for each Kerberos realm that users will connect from. Use the auth_to_local tag in the [realms] section to map principal names to local user names.

For example, consider a user, EXAMPLE\jsmith, whose Kerberos Principal is jsmith@EXAMPLE.LAN. In this case, Tableau Server will specify a delegated user, jsmith@EXAMPLE. Tableau Server will use the Active Directory legacy domain alias as the Kerberos Realm.

The target database may already have a rule such as the following to map the user, jsmith@EXAMPLE.LAN to the database user, jsmith.

```
EXAMPLE.LAN = {
    RULE:[1:$1@$0]({*@EXAMPLE.LAN}s/@.*//
    DEFAULT
}
```

To support delegation, you must add another rule to map jsmith@EXAMPLE to a database user:

```
EXAMPLE.LAN = {
    RULE:[1:$1@$0]({*@EXAMPLE.LAN}s/@.*//
    RULE:[1:$1@$0]({*@EXAMPLE}s/@.*//
```
See the MIT Kerberos Documentation topic, `krb5.conf`, for more information.

Cross-domain constrained delegation

In some cross-domain scenarios where the KDC is running on a Windows Server prior to Windows 2012, delegation may fail. Errors you may see include:

- SQL Server Network Interfaces: The system cannot contact a domain controller to service the authentication request. Please try again later.
- SQL Server Native Client: Cannot generate SSPI context
- The Domain Controller returns: KRB-ERR-POLICY error with a status \texttt{STATUS\_CROSSREALM\_DELEGATION\_FAILURE} (0xc000040b).

“Cross-domain” refers to a scenario where Tableau Server is running in a different domain than the data source with different service accounts. For example:

- Tableau Server runs on DomainA with DomainA service account.
- SQL Server runs on DomainB with DomainB service account.

Traditional constrained delegation only works if both servers are in the same domain. The user can come from other domains.

If you are seeing the errors noted above, then to enable this scenario, your Active Directory administrator should remove any traditional constrained delegation which is configured on the delegating account. Removing delegation can be achieved with Active Directory management tools or by removing the values associated with the Active Directory property, `msDS-AllowedToDelegateTo`.

If you wish to preserve an existing single domain delegation alongside cross-domain delegation, then you must configure both using resource-based constrained delegation.

The article, How Windows Server 2012 Eases the Pain of Kerberos Constrained Delegation, Part 2, provides a detailed description of how Microsoft KDC and Active Directory
handle delegated scenarios. To configure these scenarios, refer to the Microsoft Kerberos documentation.

**Configure Mutual SSL Authentication**

Using mutual SSL, you can provide users of Tableau Desktop and other approved Tableau clients a secure, direct-access experience to Tableau Server. With mutual SSL, when a client with a valid SSL certificate connects to Tableau Server, Tableau Server confirms the existence of the client certificate and authenticates the user, based on the user name in the client certificate. If the client does not have a valid SSL certificate, Tableau Server can refuse the connection. You can also configure Tableau Server to fall back to username/password authentication if mutual SSL fails.

Mutual SSL authentication is not supported on Tableau Mobile.

In this article

Use the TSM web interface

Use the TSM CLI

**Use the TSM web interface**

1. Configure SSL for External HTTP Traffic to and from Tableau Server.

2. Open TSM in a browser:

   https://<tsm-computer-name>:8850. For more information, see Sign in to Tableau Services Manager Web UI.

3. On the **Configuration** tab, select **User Identity & Access** > **Authentication Method**.

4. Under **Authentication Method**, select **Mutual SSL** in the drop-down menu.

5. Under Mutual SSL, select **Use mutual SSL and automatic sign in with client**
certificates.

6. Click Select File and upload your certificate authority (CA) issued certificate to the server.

This certificate must be a valid PEM-encoded x509 certificate with the extension .crt.

7. Enter remaining SSL configuration information for your organization.

Username format: When Tableau Server is configured for mutual SSL, the server gets the user name from the client certificate, so it can establish a direct sign-in for the client user. The name that Tableau Server uses depends on how Tableau Server is configured for user authentication:

- Local Authentication—Tableau Server uses the UPN (User Principal Name) from the certificate.
- Active Directory (AD)—Tableau Server uses LDAP (Lightweight Directory Access Protocol) to get the user name.

Alternatively, you can set Tableau Server to use the CN (Common Name) from the client certificate.

8. Click Save Pending Changes after you've entered your configuration information.

9. Click Apply Changes and Restart.
Use the TSM CLI

1 Require SSL for external server communication

To configure Tableau Server to use SSL for external communication between Tableau Server and web clients, run the `external-ssl enable` command as follows, providing the names for the server certificate’s .crt and .key files:

```bash
tsm security external-ssl enable --cert-file <file.crt> --key-file <file.key>
```

- For `--cert-file` and `--key-file`, specify the location and file name where you saved the server’s CA-issued SSL certificate (.crt) and key (.key) files.

- The above command assumes the you are signed in as a user that has the Server Administrator site role on Tableau Server. You can instead use the `-u` and `-p` parameters to specify an administrator user and password.

- If the certificate key file requires a passphrase, include the `--passphrase` parameter and value.

2 Use mutual SSL

Add mutual authentication between the server and each client, and allow for Tableau client users to be authenticated directly after the first time they provide their credentials.

1. Run the following command:

```bash
tsm authentication mutual-ssl configure --cert-file <file.crt>
```

For `--cert-file`, specify the location and file name of the server’s CA certificate (.crt) file, as in the previous step for external SSL.

See the remaining sections in this article for any additional options you might want to include with the `mutual-ssl configure` command.
2. Run the following commands to enable mutual SSL and apply the changes:

   tsm authentication mutual-ssl enable
   tsm pending-changes apply

   The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

Additional options for mutual SSL

You can use `mutual-ssl configure` to configure Tableau Server to support the following options.

For more information, see `tsm authentication mutual-ssl <commands>`.

Fallback authentication

When Tableau Server is configured for mutual SSL, authentication is automatic and a client must have a valid certificate. You can configure Tableau Server to allow a fallback option, to accept user name and password authentication.

   tsm authentication mutual-ssl configure -f true

User name mapping

When Tableau Server is configured for mutual SSL, the server authenticates the user directly by getting the user name from their client certificate. The name that Tableau Server uses depends on how the server is configured for user authentication:

- **Local Authentication**—uses the UPN (User Principal Name) from the certificate.
- **Active Directory (AD)**—uses LDAP (Lightweight Directory Access Protocol) to get the user name.
You can override either of these defaults to set Tableau Server to use the common name.

```
tsm authentication mutual-ssl configure -m cn
```

For more information, see Mapping a Client Certificate to a User During Mutual Authentication

**Certificate Revocation List (CRL)**

You might need to specify a CRL if you suspect that a private key has been compromised, or if a certificate authority (CA) did not issue a certificate properly.

```
tsm authentication mutual-ssl configure -rf <revoke-file.pem>
```

Mapping a Client Certificate to a User During Mutual Authentication

When you use mutual (two-way) SSL authentication, the client presents its certificate to Tableau Server as part of the authentication process. Tableau Server then maps user information in the client certificate to a known user identity. The strategy that Tableau Server uses to perform client mapping depends on the content of your organization’s client certificates.

This topic discusses the ways information in a client certificate can map to a user identity and how to change the way Tableau Server performs that mapping. To understand how the mapping happens and whether you need to change it, you must know how client certificates are structured in your organization.

- User-name mapping options
- Change the certificate mapping
- Address user-name ambiguity in multi-domain organizations

User-name mapping options

Tableau Server uses one of the following approaches to map a client certificate to a user identity:
• **Active Directory.** If Tableau Server is configured to use Active Directory for user authentication, when Tableau Server receives a client certificate, it passes the certificate to Active Directory, which maps the certificate to an Active Directory identity. Any explicit user name information in the certificate is ignored.

**Note:** This approach requires client certificates to be published for the user accounts in Active Directory.

• **User principal name (UPN).** A client certificate can be configured to store the user name in the user principal name field. Tableau Server reads the UPN value and maps it to a user in Active Directory or to a local user.

• **Common name (CN).** A client certificate can be configured to store the user name in the common name field of the certificate. Tableau Server reads the CN value and maps it to a user in Active Directory or to a local user.

If you configure the server for Active Directory authentication and UPN or CN user-name mapping, put the user name in one of the following formats:

username, domain/username, or username@domain.

*For example:* asmith, example.org/asmith, or asmith@example.org.

If the server uses local authentication, the format of the name in the UPN or CN fields is not predetermined, but the name in the field must match a user name on the server.

Change the certificate mapping

You use the following command to map a client certificate to a user identity in Tableau Server:

```bash
tsm authentication mutual-ssl configure -m <value>
```

Possible values are **ldap** for Active Directory mapping, **upn** for UPN mapping, or **cn** for CN mapping.
When you first install and configure Tableau Server, the server sets the default user-name mapping to match the server’s authentication type:

- If the server is configured to use Active Directory, it also uses Active Directory for mapping the certificate to the user identity.

- If the server is configured to use local authentication, the server gets the user-name value from the UPN field in the certificate.

If the default behavior for how Tableau Server maps a user name to an identity is not correct for your server configuration, run the following set of commands to change the mapping to use the CN value:

```
tsm authentication mutual-ssl configure -m cn

tsm pending-changes apply
```

The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

Address user-name mapping ambiguity in multi-domain organizations

Under some circumstances, the user name in a certificate’s UPN or CN field can be ambiguous. This ambiguity can lead to unexpected results when the user name is mapped to a user identity on the server.

For example, if Tableau Server is presented with a user name that does not include a domain, the server maps the user name to an identity using the default domain. This can cause an incorrect user-name mapping, potentially assigning a user a different user’s identity and permissions.

This can occur particularly in environments where the following conditions apply:
• Your organization supports multiple Active Directory domains.

• The server is configured to use Active Directory authentication.

• The server is configured to use UPN or CN mapping.

• Some users have the same user name but different domains. For example, asmith@example.org and asmith@example.com.

• The user name in the certificate’s UPN or CN fields does not include the domain as part of the user name—for example, it shows asmith.

To avoid incorrect user-name mapping, make sure the client certificates include fully qualified user names with the domain, using the format asmith@example.org or example.org/asmith.

`tsm authentication mutual-ssl <commands>`

**OpenID Connect**

You can configure Tableau Server to support OpenID Connect for single sign-in (SSO). OpenID Connect is a standard authentication protocol that lets users sign in to an identity provider (IdP) such as Google. After they've successfully signed in to their IdP, they are automatically signed in to Tableau Server.

Configuring OpenID Connect involves several steps. The topics in this section provide general information about using Tableau Server with OpenID Connect, and provide a sequence for configuring the IdP and Tableau Server.

**Authentication overview**

This section describes the OpenID Connect authentication process with Tableau Server.
Step 1: A user requests a resource on Tableau Server.

Step 2: Tableau Server redirects the request to the IdP gateway for authentication.

Step 3: The user is prompted and successfully authenticates with the IdP. The IdP redirects the session back to Tableau Server. Included with the URL is an authorization code for the user.

Step 4: Tableau Server presents the user's authorization code back to the IdP. As an IdP client, the Tableau Server includes its own client credentials to prevent spoofing.

Step 5: The IdP returns a web token and an ID token to Tableau Server.

- **JSON Web Token (JWT) validation**: By default Tableau Server performs a validation of the IdP JWT. During discovery, Tableau Server retrieves the public keys specified by the `jwks_uri` in the IdP configuration discovery document. Tableau Server validates the ID token for expiry and then verifies the JSON web signature (JWS), the issuer (IdP), and the client ID. You can learn more about the JWT process in the OpenID documentation, [10. Signatures and Encryption](#), and the IETF proposed standard, [JSON Web Token](#). We recommend leaving JWT validation enabled, unless your Idp does not support it. Use the `tsm authentication openid configure` command...
-ignore-jwk true command to disable validation.

- The ID token is a set of attribute key-pairs for the user. The key-pairs are called claims. Here is an example IdP claim for a user:

"sub" : "7gYhRR3HiRRCaRcgvY50ubrtjGQB4MjW4rXbpPFp-g2cprtHP62m2sqowM7G1LwjN5"
"email" : "alice@tableau.com",
"email_verified" : true,
"name" : "Alice Adams",
"given_name" : "Alice",
"family_name" : "Adams",
"phone_number" : "+359 (99) 100200305",
"profile" : "https://tableau.com/users/alice"

Step 6: Tableau identifies user from IdP claim. Tableau Server searches the user account records stored in the repository. By default, Tableau Server will use the subject identifier, or sub, claim to identify a user account. If no user record is storing the sub claim value, then Tableau Server will search for username matches using the email claim. When a username match is found, Tableau Server will write the corresponding sub claim to the user record in the repository. You can configure Tableau Server to use different claims for this process. See Requirements for Using OpenID Connect.

Step 7: Tableau Server authorizes the user.

How Tableau Server Works with OpenID Connect

OpenID Connect is a flexible protocol that supports many options for the information that's exchanged between a service provider (here, Tableau Server) and an IdP. The following list provides details about the Tableau Server implementation of OpenID Connect. These details can help you understand what types of information Tableau Server sends and expects, and how to configure an IdP.
- Tableau Server supports only the OpenID Authorization Code Flow as described in the OpenID Connect final specification.

- Tableau Server relies on using discovery or a provider URL to retrieve the OpenID Provider metadata. Alternatively, you can host a static discovery document on Tableau Server. For more information see Configure Tableau Server for OpenID Connect.

- Tableau Server supports only the client_secret_jwt Client Authentication method specified in the OpenID Connect specification. In addition, Tableau Server supports only RSA Asymmetric Encryption for handling the JWT. However, you can turn off JWT validation. See tsm authentication openid <commands>.

- Tableau Server expects a kid value in the id_token attribute’s JOSE Header. This value is matched with one of the keys found in the JWK Set document, whose URI is specified by the jwks_uri value in the OpenID discovery document. A kid value must be present even if there is only one key in the JWK Set document.

- Tableau Server does include OpenID support for the JWK x5c parameter or for using X.509 certificates.

For more information about OpenID Connect, see the following:

- OpenID Connect Core 1.0 incorporating errata set 1
- OpenID Connect Discovery 1.0 incorporating errata set 1

Requirements for Using OpenID Connect

This topic describes the requirements to use OpenID Connect with Tableau Server.

IdP account

You must have access to an identity provider (IdP) that supports the OpenID Connect (OIDC) protocol. You must also have an account with the IdP. OpenID Connect is supported by many identity providers. The OIDC protocol is an open and flexible standard, and as
such, not all implementations of the standard are identical. As you configure Tableau Server for OIDC, work with your IdP.

The Google IdP implementation has been extensively tested with Tableau Server and is the model IdP for the configuration documented in these topics.

Local authentication

To use OpenID Connect on Tableau Server, the server must be configured to use local authentication—that is, the server must be configured so that you explicitly create users on the Tableau Server, rather than importing them from Active Directory. Active Directory authentication is not supported with OpenID.

IdP claims: mapping users

To sign in successfully to Tableau Server, a given user must be provisioned in OpenID and then mapped to a user account on Tableau Server. OpenID uses a method that relies on claims to share user account attributes with other applications. Claims include user account attributes such as email, phone number, given name, etc. To understand how Tableau Server maps IdP claims to user accounts, see Authentication overview.

Tableau Server relies on the IdP claims to map user accounts from the IdP to those hosted on Tableau Server. By default, Tableau Server expects the IdP to pass the email claim. Depending on your IdP, you may need to configure Tableau Server to use a different IdP claim.

If you are using Google as an IdP, then use the default, email claim to map IdP identities to Tableau Server user accounts. If you are not using Google as an IdP, then work with your IdP to determine the claim for which you should configure Tableau Server.

Default: using email claim to map users

By default, the user’s user name in Tableau Server must match the email claim in the IdP ID token. Therefore, in the default configuration, you must use email addresses (also referred to as UPN) as the username in Tableau Server. If you use Google as the IdP, the user name in Tableau Server must be the user’s Gmail address (alice@gmail.com).
Using a complete email address helps to guarantee the uniqueness of the user name in Tableau Server, even when two users have the same email but are on different email hosts.

**Note:** When you create a user identity in Tableau Server, you specify a user name, password, and optionally an email address. For using OpenID Connect in the default configuration, the user name (expressed as an email address) is the value that must match the user’s name in the IdP. The optional email address in the Tableau Server user identity is not used for OpenID authentication.

### Ignoring the domain name

You can configure Tableau to ignore the domain portion of an email address when matching the IdP email claim to a user account on Tableau Server. In this scenario, the email claim in the IdP might be alice@example.com, but this will match a user named alice in Tableau Server. Ignoring the domain name might be useful if you already have users defined in Tableau Server that match the user names portion of the email claim, but not the domain portions.

**Important:** We do not recommend ignoring the user domain name without taking precautions. Specifically, verify that user names are unique across the configured domains that you've created in your IdP.

Setting Tableau Server to ignore the user domain name has the potential to result in unintended user log on. Consider the case where your IdP has been configured for multiple domains (example.com and tableau.com). If two users with the same first name, but different user accounts (alice@tableau.com and alice@example.com) are in your organization, then the first one to complete the OpenID provisioning sequence will claim the sub mapping in the IdP. If the wrong user is mapped, then the other user will be unable to log on until the associated sub value is reset.

To configure Tableau Server to ignore domain names in user names from the IdP, set `tsm`
authentication openid configure --ignore-domain to true. For more information, see tsm authentication openid <commands>.

When you change the tsm authentication openid configure --ignore-domain option to ignore the domain in user names, all user names in Tableau Server must have a domain name.

Using custom claims to map users

As referenced in Authentication overview, the sub claim is often included in IdP claims. Typically, the sub claim is a unique string that identifies a given user account. The benefit of using a sub claim is that it will not change, even if you or another admin updates other user attributes or IdP claims (email, phone number, etc) associated with that account. By default, Tableau Server identifies and verifies OpenID users according to the sub claim in the IdP ID token.

The OpenID sub claim value must be mapped to the corresponding user in Tableau Server. Since the sub claim is an arbitrary string, a different claim is used to associate accounts during the first sign-in session. The first time a user signs in to Tableau Server with OpenID, Tableau will match the OpenID user account to a corresponding user account on Tableau. By default, Tableau will use the IdP claim, email, to identify the Tableau user. Tableau will then update that user’s record with the sub claim from OpenID. Since the ID token always includes the sub claim along with other claims, on subsequent sessions, Tableau will identify that user with the sub claim only.

For some organizations, mapping user names with the email address is not reliable or not supported by the IdP. Beginning with Tableau Server 10.2, you can map user accounts from any arbitrary IdP claim to the Tableau Server username.

The IdP claim you are using must map exactly to a corresponding Tableau Server username. In the example below, the username is kwilliams.
To change the IdP claim that is used to map identity on Tableau Server, use the `tsm authentication openid map-claims --user-name` command. For more information, see `tsm authentication openid <commands>`.

**Changing the `sub` claim**

As described above, the `sub` claim is the identifier that Tableau Server uses to identify users after the initial mapping session. The `sub` claim is written to the corresponding user account in Tableau Server. If your IdP does not provide a `sub` claim, then you can specify an arbitrary claim to use instead. Like `sub`, the claim value you specify must be unique and should not change when other user claims are updated.
To specify a different IdP claim for default sub claim, use the `tsm authentication openid map-claims --id` command. For more information, see `tsm authentication openid <commands>.

Where `arbitraryClaim` is the name of the IdP claim that you want to use as the replacement for the sub claim.

Configure the Identity Provider for OpenID Connect

This topic provides information about configuring an identity provider (IdP) to use OpenID Connect with Tableau Server. This is one step in a multi-step process. The following topics provide information about configuring and using OpenID Connect with Tableau Server.

- OpenID Connect
- Configure the Identity Provider for OpenID Connect (you are here)
- Configure Tableau Server for OpenID Connect
- Signing In to Tableau Server Using OpenID Connect

Configure the IdP

Before you can use OpenID Connect with Tableau Server, you must have an account with an identity provider (IdP) and a project or application with the IdP. When you configure Tableau Server, you will need to be able to provide the following information:

- Provider client ID. This is the identifier that the IdP assigned to your application.
- Provider client secret. This is a token that is used by Tableau to verify the authenticity of the response from the IdP. This value is a secret and should be kept securely.
- Provider configuration URL. This is the URL at the provider’s site that Tableau Server should send authentication requests to.
Redirect URL

Some IdPs will require a redirect URL for your Tableau Server. You can manually construct your URL for the IdP using the following syntax:

<protocol>://<host>/vizportal/api/web/v1/auth/openIdLogin

For example, https://tableau.example.com/vizportal/api/web/v1/auth/openIdLogin.

Example IdP process

The following procedure provides an outline of the steps that you follow with the provider. As an example, the procedure discusses using Google as a provider. However, each provider has a somewhat different flow, so the specifics of the steps (and their order) might vary depending on your provider.

1. Register at the provider’s developer site and sign in. For example, for Google, you can go to the Developers Console at this URL: https://console.developers.google.com

2. Create a new project, application, or relying party account.

3. In the developer dashboard, follow the steps for getting an OAuth 2.0 client ID and client secret. Record these values for later.

   **Note:** Keep the client secret in a secure place.

4. On the developer site, find the URL of the endpoint that the IdP uses for OpenID Connect discovery. For example, Google uses the URL https://accounts.google.com/.well-known/openid-configuration. Record this URL for later.

   Alternatively, if your IdP has provided you with a static discovery document, copy that file to a local directory on the Tableau Server for later.
Configure Tableau Server for OpenID Connect

This topic describes how to configure Tableau Server to use OpenID Connect for single-sign on (SSO). This is one step in a multi-step process. The following topics provide information about configuring and using OpenID Connect with Tableau Server.

- OpenID Connect
- Configure the Identity Provider for OpenID Connect
- Configure Tableau Server for OpenID Connect (you are here)
- Signing In to Tableau Server Using OpenID Connect

Note: Before you perform the steps described here, you must configure the OpenID identity provider (IdP) as described in Configure the Identity Provider for OpenID Connect.

In this article
Use the TSM web interface
Use the TSM CLI

Use the TSM web interface

1. Open TSM in a browser:

   https://<tsm-computer-name>:8850. For more information, see Sign in to Tableau Services Manager Web UI.

2. Click User Identity & Access on the Configuration tab and then click Authentication Method.

4. Under OpenID Connect, select **Enable OpenID authentication for the server**.

5. Enter the OpenID configuration information for your organization:

   ![Authentication Method](image)

   **Note:** If your provider relies on a configuration file hosted on the local computer (rather than a file hosted at a public URL), you can specify the file with the tsm authentication openid <commands>. Use the `--metadata-file <file_path>` option to specify a local IdP configuration file.

6. Click **Save Pending Changes** after you've entered your configuration information.

7. Click **Apply Changes and Restart**.

Use the TSM CLI
The procedure in this section describes how to use TSM command line interface to configure OpenID Connect. You can also use a configuration file for the initial configuration of OpenID Connect. See openIDSettings Entity.

1. Use the configure command of tsm authentication openid <commands> to set the following required options:

   --client-id <id>: Specifies the provider client ID that your IdP has assigned to your application. For example, “laakjwdlnaoiloadjkwla”.

   --client-secret <secret>: Specifies the provider client secret. This is a token that is used by Tableau to verify the authenticity of the response from the IdP. This value is a secret and should be kept securely. For example, “fwahfkjaw72123=".

   --config-url <url> or --metadata-file <file_path>: Specifies location of provider configuration json file. If the provider hosts a public json discovery file, then use --config-url. Otherwise, specify a path on the local computer and file name for --metadata-file instead.

   --return-url <url>: The URL of your server. This is typically is the public name of your server, such as "http://example.tableau.com".

   For example, run the command:

   

   There are additional, optional configurations that you can set for Open ID Connect using either openIDSettings Entity or tsm authentication openid <commands>. In addition, if you need to configure IdP claim mapping, see Options for openid map-claims.

2. Type the following command to enable Open ID Connect:

   tsm authentication openid enable
3. Run `tsm pending-changes apply` to apply changes.

The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

Signing In to Tableau Server Using OpenID Connect

This topic provides information about signing in to Tableau Server using OpenID Connect. The following topics provide information about configuring and using OpenID Connect with Tableau Server.

- OpenID Connect
- Configure the Identity Provider for OpenID Connect
- Configure Tableau Server for OpenID Connect
- Signing In to Tableau Server Using OpenID Connect (you are here)

Signing in using OpenID Connect

After Tableau Server has been configured to use OpenID Connect, users who access the server and aren’t already signed in are redirected to the IdP site, where they are prompted to sign in. Users enter the credentials that they have with the IdP. In many cases, the user is also asked to authorize the IdP to share information with Tableau Server, as in the following example:
When a user signs in using OpenID Connect, the IdP sends a unique user identifier (known in OpenID as the sub value) as part of the information that's redirected to Tableau Server. This sub value is associated with the user's Tableau user identity.

Restricting sign-in to server administrators for command-line tools

Command-line tools for working with Tableau Server (tabcmd, TSM, and tableau.com) do not support sign-in using OpenID Connect. When OpenID Connect is enabled for the server, these tools still require sign-in using a Tableau Server username and password.

Even if users normally authenticate using OpenID Connect, each user has a Tableau Server username and password. This means that users could use command-line tools like tabcmd. As a security measure, you can make sure that only server administrators can use command-line tools. To do this, use `tsm configuration set to set wgserv-er.authentication.restricted` to `true`. When this setting is true, only server administrators can sign in to Tableau Server using a username and password; all other users must sign in to the server using a single sign-on (SSO) option like OpenID Connect.
The effect is that users who are not administrators also cannot then use command-line tools. To make this change, run the following sequence of TSM commands:

```bash
tsm configuration set -k wgserver.authentication.restricted -v true
tsm pending-changes apply
```

OpenID Connect Authentication Request Parameters

The OpenID authentication request sent from Tableau Server passes information using a limited set of parameters, as listed in this topic. If your OpenID IdP requires parameters that are not on the list above, it is not compatible for use with Tableau Server.

- **scope.** This value specifies a profile that tells the IdP what user information claims to return. This value can be configured by a Tableau Server administrator. The default value is "openid email profile". For more information, see Configure the scope value later in this document.

- **response_type.** OpenID Connect supports multiple flows. This value tells the IdP which flow Tableau Server expects. Tableau supports only the authorization code flow, and the value is always set to "code".

- **client_id.** This value specifies the server’s ID (Provider client ID in the Tableau Server Configuration dialog box), which lets the IdP knows where the request came from. It is provided by the IdP when the service is registered. The value is configurable by a Tableau Server administrator.

- **redirect_uri.** This value specifies the URL that the IdP redirects to after the user has authenticated using OpenID Connect. The URL must include the host and protocol (for example, http://example.tableau.com), but Tableau provides the URL endpoint.

- **nonce.** Tableau Server generates a nonce value to verify that the client that it redirected to matches the entity that comes back from the IdP.
Configure the scope value

The scope value indicates to the IdP the information that Tableau Server requests about the user. By default, Tableau Server sends the value "openid profile email". This indicates that Tableau uses OpenID to authenticate (this part of the scope attribute value must always be included ) and that Tableau Server is requesting the user profile and email information during the exchange of the user authorization code.

If this default scope is not appropriate for your scenario, you can have Tableau Server request custom information about the user. To do so, you configure the IdP with a custom profile (for example, something like "tableau-scope"). You can then configure Tableau Server to send the scope request using the name of the custom profile.

To change the scope value that Tableau Server requests, use the following TSM CLI command:

```
 tsm authentication openid configure --custom-scope-name custom-scope-name
```

**Note:** Tableau Server always includes "openid" as part of the scope value (even if you don't include it in the custom_scope setting).

Troubleshoot OpenID Connect

Use the following topics to troubleshoot OpenID Connect (OIDC) issues in Tableau Server.

OpenID Connect protocol is supported by many identity providers. The OIDC protocol is an open and flexible standard, and as such, not all implementations of the standard are identical. Most issues that administrators encounter when configuring Tableau Server for OIDC are the result of how different identity providers implement OIDC. If you encounter errors as you set up OIDC with Tableau Server, we recommend that you work with your IdP to resolve them.
Signing In from the Command Line

Even if Tableau Server is configured to use OpenID, it is not used if you sign in to Tableau Server using tabcmd, the REST API, or the Tableau Data Extract command line utility (provided with Tableau Desktop).

Login Failed

Login can fail with the following message:

Login failure: Identity Provider authentication successful for user <username from IdP>. Failed to find the user in Tableau Server.

This error typically means that there is a mismatch between a username stored in Tableau Server and the username provided by the IdP. To fix this, make sure that they match. For example, if Jane Smith's username is stored in the IdP as jsmith it must be stored in Tableau Server as jsmith as well.

Error 69: "Unable to Sign In"

An error 69 may be returned when you attempt to sign in to Tableau Server with a web browser and receive an error, "Unable to Sign In. Sign in failed. Contact your Tableau Server administrator." The URL that returns this message is https://example.com/#/error/signin/69?redirectPath=%2.

If you receive this error and you have configured OIDC for the Salesforce IdP, then you must set the vizportal.openid.client_authentication parameter. See tsm configuration set Options for more information.

OpenID Error Log

OpenID authentication takes place outside Tableau Server, so troubleshooting authentication issues can be difficult. However, sign-in attempts are logged by Tableau Server. You can create a snapshot of log files and use them to troubleshoot problems. For more information, see Server Log File Locations.
Note: To log OpenID-related events, vizportal.log.level must be set to debug with tsm configuration set Options.

Check for OpenID errors in the following files in the unzipped log file snapshot:

\vizportal\vizportal-<n>.log

Trusted Authentication

When you embed Tableau Server views into webpages, everyone who visits the page must be a licensed user on Tableau Server. When users visit the page they are prompted to sign in to Tableau Server before they can see the view. If you already have a way of authenticating users on the webpage or within your web application, you can avoid this prompt and save your users from having to sign in twice by setting up trusted authentication.

Trusted authentication simply means that you have set up a trusted relationship between Tableau Server and one or more web servers. When Tableau Server receives requests from these trusted web servers it assumes that your web server has handled whatever authentication is necessary.

If your web server uses SSPI (Security Support Provider Interface), you do not need to set up trusted authentication. You can embed views and your users will have secure access to them as long as they are licensed Tableau Server users and members of your Active Directory.

Note: Client browsers must be configured to allow third-party cookies if you want to use trusted authentication with embedded views.

How Trusted Authentication Works

The diagram below describes how trusted authentication works between the client's web browser, your web server(s) and Tableau Server.
1 **User visits the webpage:** When a user visits the webpage with the embedded Tableau Server view, the webpage sends a GET request to your web server for the HTML for that page.

2 **Web server POSTS to Tableau Server:** The web server sends a POST request to the trusted Tableau Server (for example, [https://tabaserver/trusted](https://tabaserver/trusted), not [https://tabserver](https://tabserver)). That POST request must have a `username` parameter. The `username` value must be the username for a licensed Tableau Server user. If Tableau Server is hosting multiple sites and the view is on a site other than the Default site, then the POST request must also include a `target_site` parameter.

3 **Tableau Server creates a ticket:** Tableau Server checks the IP address or host name of the web server (192.168.1.XXX in the above diagram) that sent the POST request. If the web server is listed as a trusted host then Tableau Server creates a ticket in the form of a unique string. Tickets must be redeemed within three minutes after they are issued.
Tableau Server responds to the POST request with that ticket. Or if there is an error and the ticket cannot be created, then Tableau Server responds with a value of −1.

4 Web server passes the URL to the browser: The web server constructs the URL for the view and inserts it into the HTML for the page. The ticket is included (for example, https://tabserver/trusted/<ticket>/views/requested_view_name). The web server passes the HTML back to the client’s web browser.

5 Browser requests view from Tableau Server: The client web browser sends a GET request to Tableau Server that includes the URL with the ticket.

6 Tableau Server redeems the ticket: Tableau Server redeems the ticket, creates a session, logs the user in, removes the ticket from the URL, and then sends the final URL for the embedded view to the client.

The session allows the user to access any of the views that the user would have if they logged onto the server. In the default configuration, users authenticated with trusted tickets have restricted access such that only views are available. They cannot access workbooks, project pages, or other content hosted on the server.

To change this behavior, see the wgserver.unrestricted_ticket option at tsm configuration set Options.

How is a trusted ticket stored?

Tableau Server stores trusted tickets in the Tableau Server repository using the following process:

1. Tableau Server generates a two-part ticket: the first part is a Base64-encoded unique ID (UUID) and the second part is a 24-character random secret string.
2. Tableau Server hashes the secret string and stores it with the unique ID in the repository. Hashing takes the secret string as input, and uses an algorithm to compute a unique string. This unique string protects the security of the secret string from unauthorized users.
3. Tableau Server sends the Base64 UUID and the original 24-character random string to the client.
4. The client returns the Base64 UUID and the original 24-character secret string to Tableau Server as part of the request for a view.
5. Tableau Server locates the string pair with the Base64 UUID, and then hashes the secret string to verify that it matches the hash stored in the repository.

This process ensures that any trusted ticket content stored on Tableau Server cannot be used to impersonate users or access content protected by authentication. However, because the full trusted ticket is sent over HTTP between Tableau Server and the client, the process relies on secure and encrypted transmission of HTTP data. Therefore, we recommend that you only deploy trusted tickets over SSL/TLS or another layer of network encryption.

Add Trusted IP Addresses or Host Names to Tableau Server

The first step in setting up trusted authentication is to configure Tableau Server to recognize and trust requests from one or more web servers:

In this article
Use the TSM web interface
Use the TSM CLI

Use the TSM web interface

1. Open TSM in a browser:

   https://<tsm-computer-name>:8850. For more information, see Sign in to Tableau Services Manager Web UI.

2. Click User **Identity & Access** on the Configuration tab and then click **Trusted Authentication**.

3. Under **Trusted Authentication**, for each trusted host, enter the name or IP address
and then click **Add**:

![Trust Auth Configuration](image)

**Notes:**

The values you specify completely overwrite any previous setting. Therefore, you must include the full list of hosts if you want to amend an existing list.

Static IP addresses are required: The web servers you specify must use static IP addresses, even if you use host names.

If you have one or more proxy servers between the computer that is requesting the trusted ticket (one of those configured in Step 2 as shown at Trusted Authentication) and Tableau Server, you also need to add them as trusted gateways using the `tsm configuration set gateway.trusted option`. See Configuring Proxies for Tableau Server for steps.

4. Enter a value in **Token Length** (Optional).

The token length determines the number of characters in each trusted ticket. The default setting of 24 characters provides 144 bits of randomness. The value can be set to any integer between 9 and 255, inclusive.

5. Click **Save Pending Changes** after you've entered your configuration information.
6. Click **Apply Changes and Restart**.

## Use the TSM CLI

1. Enter the following command:

   ```
   tsm authentication trusted configure -th <trusted IP address or host name>
   ```

   In the command above, `<trusted IP address>` should be a comma-separated list of the IPv4 addresses or host names of your web server(s), with each host name or IP address in quotes.

   **Note:** The values you specify completely overwrite any previous setting. Therefore, you must include the full list of hosts in the `tsm authentication trusted configure -th` command. (You cannot amend the list of hosts by running the `tsm authentication trusted configure -th` command repeatedly.)

   For example:

   ```
   tsm authentication trusted configure -th "192.168.1.101", "192.168.1.102", "192.168.1.103"
   ```

   or

   ```
   tsm authentication trusted configure -th "webserv1", "webserv2", "webserv3"
   ```

   **Notes:**
   
   Each host name or IP address in the list must be in double-quotes, followed by a
comma and one space after each comma.
The web servers you specify must use static IP addresses, even if you use host names.

2. If you have one or more proxy servers between the computer that is requesting the trusted ticket (one of those configured in Step 2 as shown at Trusted Authentication) and Tableau Server, you also need to add them as trusted gateways using the tsm configuration set gateway.trusted option. See Configuring Proxies for Tableau Server for steps.

3. Type the following command to save the changes to all the server configuration files:

   tsm pending-changes apply

   The pending-changes apply command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the --ignore-prompt option, but this does not change the restart behavior. For more information, see tsm pending-changes apply.

   There are other optional trusted authentication configurations (legacy support, logging, and timeout settings) that you can make by passing a json file to Tableau Server. See trustedAuthenticationSettings Entity.

Next, you need to configure your web server to receive tickets from Tableau Server.

Get a Ticket from Tableau Server

After you’ve added trusted IP addresses to Tableau Server, you’re ready to configure your web server to get tickets from Tableau Server via POST requests (step 3 in the diagram). The POST request must be sent to http://<server name>/trusted, not http://t-abserv. For example http://tabserv/trusted.
Note: If SSL is enabled you must use https instead of http. For example: https://tabserver/trusted.

Here’s the data you can use in a POST request to Tableau Server:

- **username=<username>** (required): The username for a licensed Tableau Server user. If you are using Local Authentication the username can be a simple string (for example, `username=jsmith`). If you are using Active Directory with multiple domains you must include the domain name with the user name (for example, `username=MyCo\jsmith`).

- **target_site=<site_id>** (required if view not on Default site): Specifies the site containing the view if Tableau Server is running multiple sites and the view is on a site other than the Default site (for example, `target_site=Sales`). The value you use for `<site_id>` should be the Site ID that was provided when the site was created. This value is case sensitive. If the Site ID is `SAles`, then the `target_site=SAles`.

- **client_ip=<IP address>** (optional): Used to specify the IP address of the computer whose web browser is accessing the view (for example, `client_ip=123.45.67.891`). It is not the IP address of the web server making the POST request of Tableau Server. If you decide to use this parameter, see Optional: Configure Client IP Matching for more information.

Tableau Server’s response to the POST request will be a unique string (the ticket). If Tableau Server isn’t able to process the request, the return will be -1. See Ticket Value of -1 Returned from Tableau Server for tips on how to correct this. Also, in order for users to successfully authenticate when they click an embedded view, their browsers must be configured to allow third-party cookies.

The ticket format changed in Tableau Server 10.2. The ticket format is now a string composed of two parts. Each part is a 128 bit string that is encoded before it is returned to the client. The first part is a universally unique ID (UUID v4) that is Base64-encoded. The second part is a 24-character secure random string. The concatenation of these parts can be
expressed as Base64(UUIDv4):SecureRandomString. An example of a ticket might look like this: 9D1ObyqDQmSI0yQpKdy4Sw==:dg62g CsSE0QRArXNT0p6mlJ5.

Next, you need to add code that allows the web server to construct an URL for the view that includes the view’s location and the ticket.

Display the View with the Ticket

After you create the POST request, you need to write code that provides the web server with the view’s location and the ticket from Tableau Server. It will use this information to display the view. How you specify it depends on whether the view is embedded, and if Tableau Server is running multiple sites.

Tableau Server View Examples

Here’s an example of how to specify a view that users only access via Tableau Server (the view is not embedded):

http://tabserver/trusted/<ticket>/views/<workbook>/<view>

If Tableau Server is running multiple sites and the view is on a site other than the Default site, you need to add t/<site ID> to the path. For example:

http://t- abserver/trusted/<ticket>/t/Sales/views/<workbook>/<view>

Use the same capitalization that you see in the Tableau Server URL.

Embedded View Examples

Here are some examples of how to specify embedded views. Because there are two approaches you can take with embed code, both ways are provided below. Regardless of which you use, there is some information unique to trusted authentication that you must provide. For more information, search for "Writing Embed Code" in the Tableau Server Help.
Note: The examples below use embed code parameters. For more information, see Embed Code Parameters in the Tableau Help.

Script Tag Examples

This example uses the ticket object parameter:

```html
<script type="text/javascript" src="http://myserver/javascripts/api/viz_v1.js"></script>
<object class="tableauViz" width="800" height="600" style="display:none;">
  <param name="name" value="MyCoSales/SalesScoreCard" />
  <param name="ticket" value="9D1ObyqDQmSIOyQpKdy4Sw==:dg62gCsSE0QRArXNTOp6mlJ5" />
</object>
```

Here's what the above example looks like for a multi-site Tableau Server, where the view is published on the Sales site:

```html
<script type="text/javascript" src="http://myserver/javascripts/api/viz_v1.js"></script>
<object class="tableauViz" width="800" height="600" style="display:none;">
  <param name="site_root" value="/t/Sales" />
  <param name="name" value="MyCoSales/SalesScoreCard" />
  <param name="ticket" value="9D1ObyqDQmSIOyQpKdy4Sw==:dg62gCsSE0QRArXNTOp6mlJ5" />
</object>
```

Instead of using ticket, you can use the path parameter to state the full path of the view explicitly. When path is used, you do not also need the name parameter, which is usually a required parameter in Tableau JavaScript embed code:
Here's the same example, but for a multi-site server. Note that /<site ID> is used here:

```
<script type="text/javascript" src="http://myserver/javascripts/api/viz_v1.js"></script>
<object class="tableauViz" width="900" height="700" style="display:none;">
   <param name="path" value="trusted/9D1ObyqDQmSIOyQpKdy4Sw==:dg62gCsSE0QRArXNTOp6mlJ5/t/Sales/views/MyCoSales/SalesScoreCard"/>
</object>
```

**Iframe Tag Example**

```
<iframe src="http://tabserver/trusted/9D1ObyqDQmSIOyQpKdy4Sw==:dg62gCsSE0QRArXNTOp6mlJ5/views/MyCoSales/SalesScoreCard?:embed=yes" width="800" height="600"></iframe>
```

**Optional: Configure Client IP Matching**

By default, Tableau Server does not consider the client web browser IP address when it creates or redeems tickets. To change this, you need to do two things: specify an IP address using the `client_ip` parameter in the POST request that obtains the ticket, and follow the steps below to configure Tableau Server to enforce client IP address matching.
1. Open a bash shell as an administrator and type the following command:

```bash
tsm configuration set -k wgserver.extended_trusted_ip_checking -v true
```

2. Then type the following command:

```bash
tsm pending-changes apply
```

The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

Test Trusted Authentication

The steps below provide a method you can use to test retrieving a trusted ticket from your web server. This simple test can help evaluate connectivity between the web server and Tableau Server, and whether or not trusted authentication has been configured correctly.

- **Step 1: Add a test user**
- **Step 2: Create a test HTML page**
- **Step 3: Retrieve a trusted ticket from Tableau Server**
- **Step 4: Test access with trusted ticket**

**Step 1: Add a test user**

Create a user on the Tableau Server that you can use to test trusted ticket functionality. See Add Users to Tableau Server. Add that user to a site on the server, and set the user’s site role to **Explorer**.
Step 2: Create a test HTML page

Paste the following code into a new .html file that you save on the web server you specified in Step 1. You can change the labels and style attributes as you prefer.

```html
<html>
<head>
<title>Trusted Ticket Requester</title>
<script type="text/javascript">
    function submitForm()
    {
        document.getElementById('form1').action = document.getElementById('server').value + "/trusted";
    }
</script>
<style type="text/css">
    .style1 {width: 100%;}
    .style2 {width: 429px;}
    #server {width: 254px;}
</style>
</head>
<body>
<h3>Trusted Ticketer</h3>
<form method="POST" id="form1" onSubmit="submitForm()">
    <table class="style1">
        <tr>
            <td class="style2">Username</td>
            <td><input type="text" name="username" value="" /></td>
        </tr>
        <tr>
            <td class="style2">Server</td>
            <td><input type="text" id="server" name="server" value="https://" /></td>
        </tr>
    </table>
</form>
</body>
</html>
```
<h4>Be sure to add your IP as a Trusted IP address to the server</h4>

Step 3: Retrieve a trusted ticket from Tableau Server

The following procedure will return a trusted ticket from Tableau Server.
1. Open the web page that you created in the previous step.

   ![Trusted Ticketer](image)

   This operation requires JavaScript, so the web browser might prompt you to allow scripts to run.

2. In the text boxes, enter the following:
   
   - **Username**: The test user that was created in Step 2.
   - **Server**: the address of your Tableau Server, e.g., `https://server_name`.
   - **Client IP (optional)**: The IP address of the user’s computer, if it's configured for client trusted IP matching.
   - **Site**: The name of the Tableau Server site that the test user is a member of.

3. Click **Get Ticket**. One of the following will be returned:
   
   - **A unique ticket**: A trusted ticket is a string composed of a base64-encoded UUID and a 24-character random string, for example,
     
     `9D101xmDQmSIOyQpKdy4Sw==:dg62gCsSE0QRArXNTOp6m1J5`.
   - `-1`: If the value, -1 is returned, the configuration contains an error. See Ticket Value of -1 Returned from Tableau Server.

   **Step 4: Test access with trusted ticket**

   Now that you have a ticket, you can use it to access content on Tableau Server.

   Construct a URL with the unique ticket that you generated in the previous step to verify access with the trusted ticket. The URL syntax is different if you are accessing a Tableau Server with a single site vs a server that hosts multiple sites.

   **Single (Default) site server url**
Non-default site server url

https://<server-name>/trusted/<unique-ticket>/t/<site-name>/views/<workbook-name>/<view-name>

Variables in the URLs are indicated by angle brackets (< and >). All other syntax is literal.

Troubleshoot Trusted Authentication

This section includes some common issues and errors you might encounter when you're configuring trusted authentication.

Trusted authentication information is written to /var/opt/tableau/tableau_server-opt/tableau_server-data/tabsvc/logs/vizqlserver/vizqlserver_vizqlserver_vizqlserver_vizqlserver_vizqlserver.log.

To increase the logging level from info to debug, use the tsm configuration set Options setting vizqlserver.trustedticket.log_level.

To test your trusted authentication deployment, see Test Trusted Authentication.

Ticket Value of -1 Returned from Tableau Server

Tableau Server returns -1 for the ticket value if it cannot issue the ticket as part of the trusted authentication process. The exact reason for this message is written to the vizqlserver_log files in the following folder:

/var/opt/tableau/tableau_server/data/tabsvc/logs/vizqlserver

Here are some things to confirm:

- All web server host names or IP addresses are added to trusted hosts

The IP address or host name for the computer sending the POST request must be in the list of trusted hosts on Tableau Server. See Add Trusted IP Addresses or Host Names to Tableau Server to learn how to add IP addresses or host names to this list.
- IP addresses are IPv4

If you are using IP addresses to specify trusted hosts, they must be in Internet Protocol version 4 (IPv4) format. An IPv4 address looks like this: 123.456.7.890. IPv6 addresses (for example, fe12::3c4a:5eab:6789:01c%34) are not supported as a way of inputting trusted hosts.

- Username in POST request is a valid Tableau Server user

The username you send in the POST request must be a licensed Tableau Server user with a Viewer or Explorer license level. You can see a list of users and their license levels by signing in to Tableau Server as an administrator and clicking the Licensing link on the left side of the page.

- Username in POST request includes domain

If Tableau Server is configured to use Local Authentication, the username that you send in the POST can be a simple string. However, if the server is configured for Active Directory you must include the domain name with the user name (domain\username). For example, the username parameter might be: username=dev\jsmith

- Content-Type is specified

If you are designing an ASP.NET or C# application, you need to declare the content type in your HTTP request. For example:

```java
http.setRequestHeader("Content-Type","application/x-www-form-urlencoded; charset=UTF-8")
```

If you do not specify content type and Tableau Server returns a -1, the log files contain the error: "missing username and/or client_ip".

HTTP 401 - Not Authorized

If you receive a 401- Not Authorized error, you may have configured Tableau Server to use Active Directory with SSPI. If your web server uses SSPI, you do not need to set up trusted
authentication. You can embed views and your users will have access to them as long as they are licensed Tableau server users and members of your Active Directory.

See tsm authentication sspi <commands>.

If you see a 401 error (or a 302 - Redirect error) after you have deployed Tableau Server 2018.2, then it’s likely the trusted ticket code you have written to construct the URL for the client has not been updated to account for the two-part ticket URL format.

See Get a Ticket from Tableau Server.

HTTP 404 - File Not Found

You may receive this error if your program code references a Tableau Server URL that does not exist. For example, your web server may construct an invalid URL that cannot be found when the webpage tries to retrieve it.

Invalid User (SharePoint or C#)

You may encounter this error if you’ve configured Tableau Server for trusted authentication.

The example code for the SharePoint .dll references the following GET request:

The above request will return the display name of the current Windows Active Directory user. If you want to use the login ID, then you will need to change the code to:

After you make the change, recompile the SharePoint .dll.

Attempting to Retrieve the Ticket from the Wrong IP Address

You may encounter this error if you’ve configured Tableau Server for trusted authentication.

The client web browser IP address is not considered by default when redeeming the ticket. If Tableau Server is configured to enforce client IP address matching, make sure that the client’s web browser IP address that is sent in the POST to Tableau Server is the same as
when the browser tries to retrieve the embedded view. For example, in the Trusted Authentication diagram, if the POST request in step 3 sends the parameter client_ip=74.125.19.147, then the GET request in step 5 must come from that same IP address.

See Optional: Configure Client IP Matching to learn how to configure Tableau Server to enforce client IP address matching.

Cookie Restriction Error

When a user signs in to Tableau Server, a session cookie is stored in their local browser. The stored cookie is how Tableau Server maintains that the signed in user has been authenticated and can access the server. Because the cookie is set with the same domain or subdomain as the browser's address bar, it is considered a first-party cookie. If a user's browser is configured to block first-party cookies, they will be unable to sign in to Tableau Server.

When a user signs in to Tableau Server via an embedded view, or in an environment where trusted authentication has been configured, the same thing happens: a cookie is stored. In this case, however, the browser treats the cookie as a third-party cookie. This is because the cookie is set with a domain that's different from the one shown in the browser's address bar. If a user's web browser is set to block third-party cookies, authentication to Tableau Server will fail. To prevent this from occurring, web browsers must be configured to allow third-party cookies.

An error occurred communicating with the server (403)

If Tableau Server is configured for trusted authentication, you may receive this error after opening a new view in a browser and attempting to navigate back to views you'd opened earlier. Tableau Server provides protection against unauthorized reuse of VizQL sessions through the tsm configuration set Optionsvizqlserver.protect_sessions, which is set to true by default. Because Tableau Server is configured for trusted authentication, you may not also need to enable vizqlserver.protect_sessions. To disable it, use tsm configuration set Options to change it to false.

Data Connection Authentication
More information

- Tableau Server on Linux - Connecting to a Windows Shared Directory (Tableau Community)
- Setting an Oracle Connection to Use TNSNames.ora or LDAP.ora (Tableau Support)

Enable Kerberos Delegation

Kerberos delegation enables Tableau Server to use the Kerberos credentials of the viewer of a workbook or view to execute a query on behalf of the viewer. This is useful in the following situations:

- You need to know who is accessing the data (the viewer's name will appear in the access logs for the data source).
- Your data source has row-level security, where different users have access to different rows.

Requirements

Kerberos delegation requires Active Directory.

- Tableau Server on Linux can only delegate users from a single domain. The domain must be specified in the option, native_api.s4u_domain_override, as described in Step 4 below.
- The Tableau Server information store must be configured to use LDAP - Active Directory.
- The computer where Tableau Server is installed must be joined to Active Directory domain.
- MIT KDC is not supported.

Configuration process

This section provides an example of the process to enable Kerberos delegation. The scenario also includes example names to help describe the relationships between the configuration elements.
1. Tableau Server will need a Kerberos service ticket to delegate on behalf of the user that is initiating the call to the database. You must create a domain account that will be used to delegate to the given database. This account is referred to as the Run As service account. In this topic, the example user configured as the delegation/Run As account is tabsrv@example.com.

The account must be configured with Active Directory User and Computers on a Windows Server that is connected to the user domain:

- Open the **Properties** page for the Run As service account, click the **Delegation** tab and select **Trust this user for delegation to specified services only** and **Use any authentication protocol**.

2. Create a keytab file for the Run As service account.

For example, the following commands create a keytab (tabsrv-runas.keytab) using the ktutil tool:

```
sudo ktutil
ktutil: addent -password -p tabsrv@EXAMPLE.COM -k 2 -e <encryption scheme>
```

**Encryption schemes for this command include** RC4-HMAC,aes128-cts-hmac-shal-96, and aes256-cts-hmac-shal-96. Consult your IT team for the correct encryption scheme for your environment and data source.

```
ktutil: wkt tabsrv-runas.keytab
```

Tableau Server will use the Run As service account and the associated keytab to authenticate and make a direct connection to the database.

3. Copy the keytab into the Tableau Server data directory and set proper ownership and permissions.

```
mkdir /var/opt/keytab
sudo cp -p tabsrv-runas.keytab /var/opt/keytab
```
sudo chown $USER /var/opt/keytab/tabsrv-runas.keytab

chgrp tableau /var/opt/keytab/tabsrv-runas.keytab

chmod g+r /var/opt/keytab/tabsrv-runas.keytab

4. Run the following TSM commands to enable Kerberos delegation, set the delegation service account, and associate the keytab file with the service account:

```bash
tsm configuration set -k wgserver.delegation.enabled -v true
tsm configuration set -k native_api.datasource_imper-sonation_runas_principal -v tabsrv@example.com
tsm configuration set -k native_api.datasource_imper-sonation_runas_keytab_path -v <path-to-file>kerberos.keytab
tsm configuration set -k native_api.s4u_domain_override -v <EXAMPLE.COM>
```

In some cases, TSM may return an error mentioning `--force-keys`. If you get this error, run the command again with the `--force-keys parameter appended to the argument.

5. Run the following TSM command apply the changes to Tableau Server:

```bash
tsm pending-changes apply
```

The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

6. Enable delegation for data connections:
• **SQL Server**—See Enabling Kerberos Delegation for SQL Server in the Tableau Community.

• **MSAS**—See Enabling Kerberos Delegation for MSAS in the Tableau Community.

• **PostgreSQL**—See Enabling Kerberos Delegation for PostgreSQL in the Tableau Community.

• **Teradata**—See Enabling Kerberos Delegation for Teradata in the Tableau Community.

OAuth Connections

For Google BigQuery, Google Analytics, Salesforce, OneDrive, Dropbox, and QuickBooks Online, an alternative to storing your sensitive database credentials with Tableau Server is to create connections using the OAuth 2.0 standard.

From Tableau, when you sign in to data with a provider that uses OAuth, you are redirected to the provider’s sign-in page. After you provide your credentials and authorize Tableau to access your data, the data provider sends Tableau an **access token** that uniquely identifies requests from Tableau. For more information, see Overview of the OAuth process below.

Using OAuth connections provides the following benefits:

- **Security**: Your database credentials are never known to or stored in Tableau Server, and the access token can be used only by Tableau.

- **Convenience**: Instead of having to embed your data source ID and password in multiple places, you can use the token provided for a particular data provider for all published workbooks and data sources that access that data provider.

In addition, for live connections to Google BigQuery data, each workbook viewer can have a unique access token that identifies the user, rather than sharing a single user name and password credential.
Overview of the OAuth process

The following steps describe a workflow in the Tableau environment that calls the OAuth process.

1. You take an action that requires access to a cloud data source.
   
   For example, you open a workbook that’s published to Tableau Server.

2. Tableau directs you to the cloud data provider’s sign-in page. The information that is sent to the data provider identifies Tableau as the requesting site.

3. When you sign in to the data, the provider prompts you to confirm your authorization for Tableau Server to access the data.

4. Upon your confirmation, the data provider sends an access token back to Tableau Server.

5. Tableau Server presents your workbook and data to you.

The following workflows can use the OAuth process:
• Creating a workbook and connecting to the data source from Tableau Desktop or from Tableau Server.

• Publishing a data source from Tableau Desktop.

• Signing in to Tableau Server from an approved client, such as Tableau Mobile or Tableau Desktop.

Access tokens for data connections

You can embed credentials based on access tokens with data connections, to enable direct access after the initial authentication process. An access token is valid until a Tableau Server user deletes it, or the data provider revokes it.

It is possible to exceed the number of access tokens your data source provider allows. If that's the case, when a user creates a new token, the data provider uses length of time since last access to decide which token to invalidate to make room for the new one.

Access tokens for authentication from approved clients

By default, Tableau Server sites allow users to access their sites directly from approved Tableau clients, after users provide their credentials the first time they sign in. This type of authentication also uses OAuth access tokens to store the users' credentials securely.

For more information, see Disable Automatic Client Authentication

Configure the Server for OAuth Support

Instead of individual usernames and passwords, OAuth works through limited-purpose access tokens. Before you can obtain access tokens needed to create an OAuth connection in Tableau, you need to configure your server so that the data provider sending the token can recognize Tableau Server as a trusted destination. The following section describes how to prepare for setting up OAuth regardless of your data provider. The topics listed below it contain the steps for configuring your server for specific data providers.
Preparing for Configuring OAuth Support

Before you begin the configuration steps specific to your data provider, complete the following prerequisites:

- Obtain the fully qualified domain name of each Tableau Server node that will host views that connect to this data source. For example:
  
  https://sales.your_domain.com

  If you use Salesforce.com, you will need to provide an https address.

- Make sure at least one of your data-provider accounts is enabled for API access.
  
  For **Google** data types, you need access to the developers console on the **Google Cloud Platform**.

  For **Salesforce.com**, you need access to the **Force.com platform**.

  For **QuickBooks Online**, you need access to the **Intuit platform**.

Configure Settings for Your Data Provider

When you complete the OAuth-preparation steps, you can configure the appropriate settings with your data provider.

- Set up OAuth for Google
- Set up OAuth for Salesforce.com
- Set up OAuth for QuickBooks Online

Set up OAuth for Google

This topic describes how to set up your Google BigQuery, Google Sheets, and Google Analytics data sources for OAuth.

Complete these steps for each Tableau Server instance.
Note Before you complete these steps, make sure you have completed the pre-requisites described in Preparing for Configuring OAuth Support.

Set up OAuth by following these three procedures:

- Enable API access and create access token from Google.
- Configure OAuth on Tableau Server.
- Create and edit Google data source.

Obtain a Client ID and Enable Google APIs

Note These steps reflect the settings in the Google Cloud Platform console at the time of this writing. For more information, see Using OAuth 2.0 for Web Server Applications in the Google Developers Console Help.

1. Sign in to Google Cloud Platform, and then click Go to my console.
2. On the drop-down menu next to the Google Cloud Platform title, select Create project.
3. In the new project form that appears, complete the following:
   - Give the project a meaningful name that reflects the Tableau Server instance for which you’ll use this project.
   - Determine whether you want to change the project ID.

Note After you create the project, you will not be able to change the project
4. Open the new project, and navigate to **APIs Manager > Credentials**.

**Note:** You must generate credentials with the Google API Manager for Tableau Server. Do not attempt to use a Service Account, which generates a key, and is not supported.

5. Click the **OAuth consent screen** tab and then enter a meaningful name for **Product name** shown to users.

6. Click the **Credentials** tab, then click the **Create credentials** drop-down list, and then select **OAuth client ID**. Complete the following:

   - Select **Web Application**.

   - For **Authorized JavaScript Origins**, enter the local computer name of your Tableau Server.

   - For **Authorized Redirect URI**, replace the existing text with the Internet address for your server, and add the following text to the end of it: `auth/add_`
oauth_token. For example:

https://your_server_url.com/auth/add_oauth_token

7. Copy the Authorized Redirect URI, and paste it in a location that you can access from your Tableau Server computer.

8. Click Create.

9. Copy the following values that Google returns, and paste them in a location that you can access from your Tableau Server computer:
   
   - Client ID
   - Client secret

10. In APIs Manager > Dashboards, verify that BigQuery API, Google Drive API (to enable Google Sheets) or Analytics API is enabled. To enable APIs, click ENABLE API at the top of the page.

Configure Tableau Server for Google OAuth

Using the information you obtained by completing the steps in Obtain a Client ID and Enable Google APIs, configure your Tableau Server:

- On the Tableau Server computer, open the shell and run the following commands to specify the access token and URI:

  `tsm configuration set -k oauth.google.client_id -v <your_client_ID>`

  `tsm configuration set -k oauth.google.client_secret -v <your_client_secret>`

  `tsm configuration set -k oauth.google.redirect_uri -v <your_authorized_redirect_URI>`
The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

Create and edit Google data source

Next, you must publish the Google data sources to the server. See the Tableau Desktop topic, Google BigQuery.

After you've published the data sources, the final step is to edit the data source connection to use the embedded access token that you configured earlier. See Edit Connections on Tableau Server.

Managing access tokens

After you configure the server for OAuth, you can allow users to manage their own access tokens in their profile settings, or you can manage the tokens centrally. For more information, see Allow Saved Access Tokens.

Set up OAuth for Salesforce.com

This topic describes how to set up your Salesforce.com data sources for OAuth. Complete these steps for each Tableau Server instance.

**Note:** Before you complete these steps, make sure you have completed the prerequisites described in Preparing for Configuring OAuth Support.

Set up OAuth by following these two procedures:
Create a Connected App in Salesforce
Use the information you obtained to configure your server.

Create a Connected Salesforce App

1. Sign in to your Salesforce.com developer account, click your user name in the upper-right, and then select Setup.

2. In the left navigation column, under App Setup, select Create > Apps.

3. In the Connected Apps section, click New.

4. Complete the Basic Information, and in the API section, select Enable OAuth Settings.

5. In the new OAuth settings that appear, for Callback URL, type the fully qualified
domain name of your server, using the https protocol, and append the following text to the URL: auth/add_oauth_token.

For example:

https://www.your_server.com/auth/add_oauth_token

6. Move the following items from Available OAuth Scopes to Selected OAuth Scopes:

- Access and manage your data (api)
- Access your basic information (id)
- Perform requests on your behalf at any time (refresh_token)

7. Click Save.

After you save the app, Salesforce populates the API section with the following IDs that you will use to configure Tableau Server:

- Consumer Key
- Consumer Secret
- Callback URL
Configure Tableau Server for Salesforce.com OAuth

1. On the Tableau Server computer, open the bash shell and run the following commands:

   tsm configuration set -k oauth.salesforce.client_id -v <your_client_ID>

   tsm configuration set -k oauth.salesforce.client_secret -v <your_client_secret>

   tsm configuration set -k oauth.salesforce.redirect_uri -v <yourAuthorized_redirect_URI>

2. (Optional) To change the default login server, type the following command:

   tsm configuration set -k oauth.salesforce.server_base_url -v <URL>

3. Enter the following command to apply changes:

   tsm pending-changes apply

   The pending-changes apply command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the --ignore-prompt option, but this does not change the restart behavior. For more information, see tsm pending-changes apply.

Managing access tokens

After you configure the server for OAuth, you can allow users to manage their own access tokens in their profile settings, or you can manage the tokens centrally. For more
information, see Allow Saved Access Tokens.

Set up OAuth for QuickBooks Online

This topic describes how to set up your QuickBooks Online data sources for OAuth authentication. Complete these steps for each Tableau Server instance.

**Note:** Before you complete these steps, make sure you have completed the prerequisites described in Preparing for Configuring OAuth Support.

Setting up OAuth for QuickBooks Online consists of two tasks:

- Create a Connected App on the Intuit developer platform.
- Use the information you get as part of the Connected App to configure your server.

### Create a Connected Intuit App

1. Sign in to your Intuit developer account, and then click **My Apps**.

2. In the **Just start coding** section, click **Select APIs**.

3. Select **Accounting** and click **Create App**.

4. In the **Get your app ready for submission** section, click the link to get your production keys.

   **Important:** You must use production keys rather than development keys.

5. Copy the app token, OAuth consumer key, and OAuth consumer secret.
Configure Tableau Server for QuickBooks Online

- On the Tableau Server computer, open the bash shell and run the following commands:

  tsm configuration set -k oauth.quickbooks.oauth_callback_uri -v http://YOUR-SERVER/auth/add_oauth_token

  tsm configuration set -k oauth.quickbooks.consumer_key -v <your_consumer_key>

  tsm configuration set -k oauth.quickbooks.consumer_secret -v <your_consumer_secret>

  tsm pending-changes apply

  The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

Managing access tokens

If you run an extract refresh job for your QuickBooks Online data source, Tableau Server attempts to renew access tokens for you. To help ensure that your access tokens do not expire, run your extract refresh jobs more than once a month. Otherwise, the access tokens from QuickBooks Online expire and your extract refresh jobs fail. If your access tokens do expire, you can edit your saved credentials from the Settings page.

The saved credentials can be managed centrally or by your users. For more information, see Allow Saved Access Tokens.
Allow Saved Access Tokens

After you configure Tableau Server for OAuth, you can decide to allow users to manage their own OAuth credentials, or you want to manage them centrally. If you want users to manage their own, you need to enable user profile settings from the server.

**Note:** If you have not yet configured your server to enable OAuth data connections, see the related topics listed below.

1. Sign in to Tableau Server as a server administrator.

2. **Single-site:** Click **Settings > General**.
   
   **Multisite:** In the site menu, click **Manage All Sites** and then click **Settings > General**.

3. In the Saved Credentials section, select the following:
   
   - **Allow users to save passwords for data sources** (allows users to save their individual credentials with data sources).
   
   - **Allow users to save OAuth access tokens for data sources**

   ![Saved Credentials](image)

4. Click **Save**.
After you select these check boxes, users will see a **Manage Credentials** section in their profile settings, where they can add access tokens for OAuth data connections.

<table>
<thead>
<tr>
<th>Manage Credentials</th>
</tr>
</thead>
<tbody>
<tr>
<td>Salesforce</td>
</tr>
<tr>
<td>Google BigQuery</td>
</tr>
<tr>
<td>Google Analytics</td>
</tr>
<tr>
<td><a href="mailto:tableaonlineuser@gmail.com">tableaonlineuser@gmail.com</a></td>
</tr>
</tbody>
</table>

**Managing credentials centrally**

Server administrators alternatively can manage OAuth credentials centrally. This can work well, for example, if multiple users work from the same data, and you have a dedicated user account for your data provider.

To manage credentials centrally, you do the following:

- Clear the check boxes described in the preceding procedure.
- Edit connection information as data sources are published.

When you edit the connection, you embed credentials that use an OAuth access token instead of an individual’s user name and password.

When the settings for saving passwords and access tokens are not enabled, the Manage Credentials section is excluded from users’ profile settings.

Set up OAuth for QuickBooks Online
Configure SAP HANA SSO

You can configure Tableau Server to use SAML delegation to provide a single sign-on (SSO) experience for SAP HANA. This scenario is not dependent on SAML authentication to Tableau Server. You do not need to use SAML sign on with Tableau Server in order to use HANA SAML delegation. You can sign in to Tableau Server using whatever method you choose.

With SAML delegation for SAP HANA, Tableau Server functions as an identity provider (IdP).

Before you begin

Configuring SAML delegation with SAP HANA requires configuration on both Tableau Server and on SAP HANA. This topic provides configuration information about configuring Tableau Server. Before you configure Tableau Server, you must complete the following:

- Acquire a SAML certificate and key file for Tableau Server. The certificate file must be a PEM-encoded x509 certificate with the file extension .crt or .cert. This file is used by Tableau Server, and must also be installed on HANA. The private key must be a DER-encoded private key file that is not password protected, and that has the file extension .der. This file is only used by Tableau Server.
- Install the certificate in HANA.
- Install the latest version of SAP HANA driver (minimum version is 1.00.9) on Tableau Server.
- Configure network encryption from Tableau Server to SAP HANA (recommended).

For more information about generating the certificate/key pair, encrypting the SAML connection, and configuring SAP HANA, see How to Configure SAP HANA for SAML SSO with Tableau Server in the Tableau Community.

Configure Tableau Server SAML for SAP HANA

The following procedure describes how to configure SAML for SAP HANA on Tableau Server using tsm data-access set-saml-delegation. You can also configure SAML for SAP HANA using the sapHanaSettings Entity.
If you are running Tableau Server in a distributed deployment, run the following procedure on the initial node.

1. Place certificate files in a folder named `saml`. For example:

   ```
   /var/opt/saml
   ```

2. Run the following commands to specify the location of the certificate and key files:

   ```
   tsm data-access set-saml-delegation configure --cert-key <cert-key> --cert-file <cert-file>
   ```

   Where `<cert-key>` and `<cert-file>` are file paths to the private key and certificate file, respectively.

   For example,

   ```
   tsm data-access set-saml-delegation configure --cert-key /var/opt/saml/hana_pkey_pkcs8.der --cert-file /var/opt/saml/hana_cert.pem
   ```

   You can specify other options. For example, you can specify user name format and how credentials are normalized. See `tsm data-access set-saml-delegation`.

3. Run the following commands to enable delegation:

   ```
   tsm data-access set-saml-delegation enable
   ```

   ```
   tsm configuration set -k wgserver.sap_hana_sso.enabled -v true
   ```

   ```
   tsm configuration set -k wgserver.delegation.enabled -v true
   ```

4. When you have finished, run `tsm pending-changes apply`. 
The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

Enable Kerberos Service Account Access

You can configure Tableau Server to use a service account to access a database on behalf of users on Tableau Desktop. In this scenario, Tableau Server connects to databases with a service account (also referred to as a "RunAs service account"). Workbooks and data sources that use this service account are published as "Authentication: Server RunAs account" in Tableau Desktop.

Requirements

- MIT Kerberos is not supported.
- The RunAs service account must have read access to the target database.

Configuration process

This section provides an example of the process to enable Kerberos service account access. The scenario also includes example names to help describe the relationships between the configuration elements.

1. Create a domain user account to act as the RunAs service account. This account must have read access to the target database.

   In the example here, the RunAs service account is User principal named `tab-srv@example.com`.

2. Create a keytab file for the RunAs service account.

   For example, the following commands create a keytab (`tabsrv-runas.keytab`) using the `ktutil` tool:

   ```bash
   sudo ktutil
   ```
ktutil: addent -password -p tabsrv@example.com -k 2 -e <encryption scheme>

Encryption schemes for this command include RC4-HMAC, aes128-cts-hmac-sha1-96, and aes256-cts-hmac-sha1-96. Consult your IT team for the correct encryption scheme for your environment and data source.

ktutil: wkt tabsrv-runas.keytab

Tableau Server will use the RunAs service account and the associated keytab to authenticate and make a direct connection to the database.

3. Copy the keytab into the Tableau Server data directory and set proper ownership and permissions.

```bash
mkdir /var/opt/tableau/tableau_server/keytab
sudo cp -p tabsrv-runas.keytab /var/opt/tableau/tableau_server/keytab
sudo chown $USER /var/opt/tableau/tableau_server/keytab/tabsrv-runas.keytab
chgrp tableau /var/opt/tableau/tableau_server/keytab/tabsrv-runas.keytab
chmod g+r /var/opt/tableau/tableau_server/keytab/tabsrv-runas.keytab
```

4. Run the following TSM commands to enable RunAs access, set the RunAs service account, and associate the keytab file with the service account:

```bash
tsm configuration set -k features.RunAsAuthLinux -v true
tsm configuration set -k native_api.datasource_runas_principal -v tabsrv@example.com
tsm configuration set -k native_api.datasource_runas_keytab_path -v /var/opt/tableau/tableau_server/keytab/tabsrv-runas.keytab
```

5. Run the following TSM command apply the changes to Tableau Server:
The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

**Authorization**

*Authorization* refers to how and what users can access on Tableau Server after authentication has been verified. Authorization includes:

- What users are allowed to do with content hosted on Tableau Server, including projects, sites, workbooks, and views.
- What users are allowed to do with the data sources that are managed by Tableau Server.
- What tasks users are allowed to perform to administer Tableau Server, such as configuring server settings, running command line tools, creating sites, and other tasks.

Authorization for these actions is managed by Tableau Server and determined by a combination of the user’s site role and permissions associated with specific entities such as workbooks and data sources.

**Site roles**

Site roles define who is an administrator. Administrators can be assigned at the site or server level. For non-admins, site roles indicate the maximum level of access a user can have on a given site, subject to permissions set on content assets. For example, if one user is assigned the Viewer site role, and another the Creator site role.

For more information about site roles, see *Set Users’ Site Roles*. 
Permissions

Permissions determine whether a given user is allowed or denied to perform a specific action on a specific content asset.

As an administrator setting up Tableau Server, it’s important that you understand how permissions are evaluated. Understanding the Tableau permissions process will enable you to set up and configure permissions on sites, projects, and other assets so that you can control how content and data is shared, published, viewed, extracted, and imported.

Four important concepts to understand about permissions in Tableau are:

- **Permissions are asset-based.** Permissions are assigned to individual content assets (projects, data sources, workbooks) and are granted to users or groups.
- **Permissions are implicitly denied, and non-admin users must explicitly be allowed to access content.** The process by which Tableau Server determines the “allow” or “deny” permission is explained in detail in the topic, How Permissions are Evaluated.
- **Permissions inheritance exists only in locked projects and in workbooks with tabbed views.** When content permissions are locked to the top-level project, workbooks, views, and data sources in the entire project hierarchy will use the default permissions set at the top-level project. In workbooks saved with the option Show sheets as tabs, views inside those workbooks use the workbook permissions. For more information, see Content Permissions and Ownership.
- **In a project that is not locked, initial permissions are a one-time copy of the container item’s permissions.** A data source or workbook starts with the default permissions, but authorized users can subsequently edit permissions on those assets. For more information on default permissions and projects, see Set Project Default Permissions and Lock the Project.

Tableau Server provides a flexible permissions infrastructure that allows you to manage access to all content for countless scenarios. For more detailed information, see Content Permissions and Ownership.
Data access and external authorization

There are scenarios where Tableau Server and Desktop rely on external authorization to enable access to data. For example:

- Users connecting to external data sources might require authorization that is outside the scope of Tableau Server’s authority. If users publish an external data source, Tableau Server will manage access and capabilities of that data source. But if users embed an external data source in a workbook, it’s up to the user who publishes the workbook to determine how other users who open the workbook will authenticate with the underlying data that the workbook connects to.

- Running Tableau Server in an organization with Active Directory, where Tableau has been configured with a Run As user account, results in a dependency on Active Directory and NTFS for authorization. For example, if you configure Tableau Server to use the Run As account to impersonate users connecting to SQL, then object-level authorization is reliant on NTFS and Active Directory.

- How users authenticate and are authorized by specific database solutions can differ. As noted, Tableau Server can be configured to provide access authorization when a data source is configured, but some databases will authorize access according to their own authentication scheme.

Data Security

Tableau provides several ways for you to control which users can see which data. For data sources that connect to live databases, you can also control whether users are prompted to provide database credentials when they click a published view. The following three options work together to achieve different results:

- **Database login account**: When you create a data source that connects to a live database, you choose between authenticating to the database through Windows NT or through the database’s built-in security mechanism.

- **Authentication mode**: When you publish a data source or a workbook with a live database connection, you can choose an **Authentication mode**. Which modes are available depends on what you choose above.
- **User filters:** You can set filters in a workbook or data source that control which data a person sees in a published view, based on their Tableau Server login account.

The table below outlines some dependencies with the above options:

<table>
<thead>
<tr>
<th><strong>Database Connection Options</strong></th>
<th><strong>Data Security Questions</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Database login account uses...</td>
<td>Is database security possible per Tableau Server user?</td>
</tr>
<tr>
<td><strong>Active Directory credentials (Windows Authentication)</strong></td>
<td>Kerberos service account</td>
</tr>
<tr>
<td>Impersonate via server Kerberos service account</td>
<td>Yes</td>
</tr>
<tr>
<td>Viewer enters their credentials</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>User name and password</strong></td>
<td>Prompt user: Viewers are prompted for their database credentials when they click a view. Credentials can be saved.</td>
</tr>
<tr>
<td>Embedded credentials: The workbook or data source publisher can embed their database cre-</td>
<td>No</td>
</tr>
</tbody>
</table>

*Denotes no web caches shared among users.
<table>
<thead>
<tr>
<th>Database Connection Options</th>
<th>Data Security Questions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database login account uses...</td>
<td>Authentication mode</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>dentials.</td>
</tr>
<tr>
<td></td>
<td>Impersonate via embedded password: Database credentials with impersonate permission are embedded.</td>
</tr>
</tbody>
</table>

* Because it can create unexpected results, Tableau recommends that you not use this authentication mode with user filters.

User filters, the embedded credentials option and the impersonation modes have similar effects—when users click a view, they are not prompted for database credentials and they see only the data that pertains to them. However, user filters are applied in the workbook by authors, and the impersonation authentication modes rely on security policies defined by administrators in the database itself.

Some of the options described above require configuration steps that must happen during Tableau Server Setup or before you publish a workbook or data source. See the following topics for more information:

- Server Settings (General)

- Enable Kerberos Delegation
- OAuth Connections

- User Filters and Data Source Filters in the Tableau Help.

Related Topic

Manage Server Secrets

Tableau Server needs to store a number of secrets it uses to perform various functions, typically securing internal communication, communicating with other applications or the operating system, or providing secure communication with clients. In this context, the term secret may refer to a password, a token, or other string that is used to authenticate one entity to another.

There are two categories of secrets that are required to run Tableau Server. They differ according to how the secrets are generated:

- **Secrets that are generated by administrators.** These include credentials and associated secrets for the Run As User account and the SMTP credentials used by Tableau Server.

- **Secrets that are automatically generated by various processes in the system.** For example, a secret is required to protect communication between the Cluster Controller and ZooKeeper processes. And a number of different passwords are required for each service and programmatic user that communicates with Postgres.

Most secrets are encrypted while at rest. When a secret is needed, it is decrypted at run time.

This topic describes how secrets storage works and what you need to do to properly manage storage of secrets on Tableau Server.

Understanding how secrets storage works

During installation Tableau Server generates and stores a master key in a Java keystore. The master key is used to encrypt a configuration encryption key that is used across the
system.

Whenever a new secret is created or updated, the secret is encrypted with the configuration encryption key. The encrypted value is then stored with its corresponding configuration parameter in a YAML file on the server. Parameters that hold an encrypted value use the format, `ENC(<encrypted string>)`, where `<encrypted string>` is a Base64-encoded encrypted string.

At run time, when a given secret needs to be accessed, the encrypted values are read into memory and decrypted with the configuration encryption key.

Tableau Server encrypts secrets using 256-bit AES in GCM mode. The keys used for secure storage are different than the asset keys that are used to encrypt embedded database credentials before they are stored in the repository.

Who has access to the master key?

In a default installation, the Java key store for Tableau Server will be replicated into the `tabsvc/keystores` folder for each service on that node under `/var/opt/tableau/tableau_server/data/tabsvc/config`.

For example,

```
/var/opt/tableau/tableau_server-
data/tabsvc/config/tabadminagent_<version_number>/tabsvc/keystores/tableaulserver.jks.
```

If you use a custom install directory, then the keystore files will be found under

```
<install directory>/tableau_server/data/tabsvc/config/<service name_#.version_number>/tabsvc/keystores
```

By default, the following users and groups have access to this directory:

- root
- tableau (user)
- members of the 'tableau' group
Import and export configuration information

Tableau Services Manager introduces the capability to import and export configuration information using tsm configuration.

**Note:** This version of Tableau Server does not support restoring configuration information from a backup. Instead, we recommend using the export and import configuration commands to backup and restore configuration information.

While configuration secrets are encrypted when stored on disk internally, when the configuration is exported to a file, secrets are written into the file in plain text. It is up to the administrator to take measures to protect this file. There are a variety of options available:

- Write the file to an encrypted file system.
- Write the file to a directory that is restricted to specific users or groups by file system permissions.
- Encrypt the output file.

Securing secrets for import and export operations

This section describes how to PGP encrypt the backup output. With this method, you will create a named pipe and provide it as the file argument, then use that as input to gpg encrypt it. The advantage is the secrets are never written to disk in plain text. gpg must be available and a private key available. An example of this method is shown in the following section.

The example in this section describes one way of handing secrets to store them on a separate computer.

See the following external references for more information:

- File encryption on the command line
- mkfifo(1) - Linux man page

**Example: encrypt and export**

The following is an example of how to secure the file when exporting the configuration.
mkfifo -m 600 /tmp/secure1 && (gpg --symmetric --batch --yes --passphrase-file ~/.secrets/pgppassphrase.txt --cipher-algo AES256 --output encrypted.enc < /tmp/secure1 &) && tsm settings export -f /tmp/secure1 && rm /tmp/secure1

The details of this operation are:

- Create a named pipe with access limited by file permissions to rw for current user.

  mkfifo -m 600 /tmp/secure1

- Call gpg to encrypt the data sent to the named pipe, backgrounding it to a separate process. It will block waiting for data. The result will be a file containing the encrypted data.

  gpg --symmetric --batch --yes --passphrase-file ~/.secrets/pgppassphrase.txt --cipher-algo AES256 --output encrypted.enc < /tmp/secure1 &

- Call tsm to export the configuration, providing the named pipe as the file argument.

  tsm settings export -f /tmp/secure1

- Delete the named pipe.

  rm/tmp/secure1

The encrypted data is in the file "encrypted.enc."

Example: decrypt and import

The following is an example of how to decrypt and import the configuration.

mkfifo -m 600 /tmp/secret2 && (gpg --decrypt --batch --yes --passphrase-file ~/.secrets/pgppassphrase.txt encrypted.enc > /tmp/secret2 &) && tsm settings import -f /tmp/secret2 && rm /tmp/secret2
The details of this operation are:

- Create a named pipe with access limited by file permissions to rw for current user.
  
  ```
  mkfifo -m 600 /tmp/secure2
  ```

- Decrypt the configuration and send it to the named pipe. Background this to a separate process, it will block waiting to be read.
  
  ```
  gpg --decrypt --batch --yes --passphrase-file ~/.secret-s/pgppassphrase.txt encrypted.enc > /tmp/secret2 &
  ```

- Execute the tsm configuration import command, logging in as needed.
  
  ```
  tsm settings import -f /tmp/secret2
  ```

- Delete the named pipe.
  
  ```
  rm/tmp/secure1
  ```

The pending configuration contains the imported configuration.

Run tsm pending-changes apply to commit changes. The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see tsm pending-changes apply.

Cluster nodes

When adding a new node to your Tableau Server cluster, you will first need to generate the node configuration file (tsm topology). The node configuration file contains a copy of the master keystore file used for encrypting the configuration secrets.

**Important:** We strongly recommend that you take additional measures to secure the node configuration file when exporting a configuration file with secrets.
When installing and configuring Tableau Server on the new node, you will need to provide the node configuration file to the `initialize-tsm` command. You can use a similar technique as described above to decrypt the contents of the file that was previously encrypted and send it via a named pipe to the `initialize-tsm` command.

Secrets storage event logging

The following events related to secrets storage are logged:

- Generating new encryption keys
- Encryption key is rolled or changed
- Encrypting a new value in the configuration file

For more information about log files and where they are stored, see Work with Log Files.

Managing secrets

As a Tableau Server administrator the most important task related to secrets storage is to periodically update secrets. In some cases (server troubleshooting or auditing), you may need to retrieve a password.

For other operations, such as upgrading versions, backing up and restoring, or adding new nodes to a cluster—as noted above—Tableau Server manages secrets storage and related processes automatically.

Updating secrets

You should update secrets periodically, according to your company’s security policy.

To update the master key and automatically generated secrets, you will need to follow the steps described below. For the list of secrets and configuration key and corresponding values see the table below.

**Note:** The following procedure stops the server. Run this procedure during non-business hours.

**Step 1: Generate a new key**
Run `tsm security regenerate-internal-tokens` to generate a new master key that will be added to the master key store file. This command also prepares changes to the configuration information, such as generating new service passwords and internal SSL certs used to communicate with Postgres.

**Step 2: Copy the keystore file to other nodes**

If you are running Tableau Server in a multi-node cluster, you must manually copy the keystore file to each node in the cluster before you apply changes.

Use a secure process to transfer the master keystore file. Place the file in the `keystores` directory:

- **Default installation**: `/var/opt/tableau/tableau_server-/data/tabsvc/config/tabadminagent_0.<server_version>/tabsvc/keystores`
- **Custom installation**: `<install_directory>/tableau_server-/data/tabsvc/config/tabadminagent_0.<server_version>/tabsvc/keystores`

**Step 3: Apply changes**

Verify that you that the keystore file is on each node and then run `tsm pending-changes apply` on the node where you ran Step 1. The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

**Step 4: Start Tableau Server**

Run `tsm start` to restart Tableau Server.

**Retrieving passwords**

In some cases, you may need to retrieve a password for troubleshooting or other operations. For example, you may need the Postgres readonly user credentials that are generated and
encrypted by Tableau Server. In these cases, you can run a tsm command that will retrieve and decrypt the password for you.

To retrieve a password, open Command Prompt and issue a `tsm configuration get` command for one of the parameters listed in the table below.

For example, to retrieve a password for the readonly Postgres user, type the following command:

```
tsm configuration get -k pgsql.readonly_password
```

The command will return the password in clear text:

```
$ tsm configuration get pgsql.readonly_password
password
```

<table>
<thead>
<tr>
<th>Configuration Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>clustercontroller.zookeeper.password</code></td>
<td>Password for cluster controller to connect to zookeeper.</td>
</tr>
<tr>
<td><code>filestore.zookeeper.password</code></td>
<td>Password for filestore to connect to zookeeper.</td>
</tr>
<tr>
<td><code>jdbc.password</code></td>
<td>Password for the rails Postgres user.</td>
</tr>
<tr>
<td><code>oauth.google.client_secret</code></td>
<td>Client secret of the Google Cloud Platform account.</td>
</tr>
<tr>
<td><code>oauth.quickbooks.consumer_secret</code></td>
<td>Consumer secret of the Intuit developer account.</td>
</tr>
<tr>
<td><code>oauth.salesforce.client_secret</code></td>
<td>Client secret of the Salesforce developer account.</td>
</tr>
<tr>
<td><code>pgsql.adminpassword</code></td>
<td>Password for the tblwgadmin Postgres user.</td>
</tr>
</tbody>
</table>
**Note:** Although the configuration parameter is encrypted in Tableau's configuration files (tabsvc.yml, workgroup.yml), this password is stored in plain text in other files used by SAML and the Postgres recovery process.

<table>
<thead>
<tr>
<th>Environment Variable</th>

</tr>
<tr>
<td>vizqlserver.extsvc.password</td>
<td>Password for the service that supports R functionality in workbooks.</td>
</tr>
<tr>
<td>wgserver.domain.password</td>
<td>Password used to bind to Active Directory.</td>
</tr>
</tbody>
</table>

Network Security

There are three main network interfaces in Tableau Server:

- **Client to Tableau Server**: The client can be a web browser, Tableau Mobile, Tableau Desktop, or the tabcmd utility.

- **Tableau Server to your database(s)**: To refresh data extracts or handle live database connections, Tableau Server needs to communicate with your database(s).

- **Server component communication**: This applies to distributed deployments only.

Client to Tableau Server

A Tableau Server client can be a web browser, a device running Tableau Mobile, Tableau Desktop, or tabcmd commands. Communications between Tableau Server and its clients use standard HTTP requests and responses. We recommend configuring Tableau Server for HTTPS for all communications. When Tableau Server is configured for SSL, all content and communications between clients are encrypted using SSL, and the HTTPS protocol is used for requests and responses.

By default, passwords are communicated from browsers and tabcmd to Tableau Server using 1024-bit public/private key encryption. This level of encryption is not considered robust enough for secure communications. Additionally, this method, where a public key is sent to the recipient in the clear and without network layer authentication is susceptible to man-in-the-middle attacks.

To adequately secure network traffic from clients to Tableau Server, you must configure SSL with a certificate from a trusted certificate authority.

See Configure SSL for External HTTP Traffic to and from Tableau Server.
Client access from the Internet

We recommend a gateway proxy server to enable secure client access from the internet to your Tableau Server. We do not recommend running Tableau Server in a DMZ or otherwise outside your protected, internal network.

Configure a reverse proxy server, with SSL enabled, to handle all inbound traffic from the internet. In this scenario, the reverse proxy is the only external IP address (or range of addresses if multiple reverse proxies are load-balancing inbound requests) that Tableau Server will communicate with. Reverse proxies are transparent to requesting clients, thereby obfuscating Tableau Server network information and simplifying client configuration.

For configuration information, see Configuring Proxies for Tableau Server.

Clickjack Protection

By default, Tableau Server has *clickjack protection* enabled. This helps prevent certain types of attacks in which the attacker overlays a transparent version of a page on top of an innocuous-looking page in order to lure a user into clicking links or entering information. With clickjack protection enabled, Tableau Server imposes certain restrictions on embedding views.

For more information, see Clickjack Protection.

Tableau Server to your database

Tableau Server makes dynamic connections to databases to process result sets and refresh extracts. It uses native drivers to connect to databases whenever possible and relies on a generic ODBC adapter when native drivers are unavailable. All communications to the database are routed through these drivers. As such, configuring the driver to communicate on non-standard ports or provide transport encryption is part of the native driver installation. This type of configuration is transparent to Tableau.

When a user stores credentials for external data sources on Tableau Server, they are stored encrypted in Tableau Server’s internal database. When a process uses those credentials to query the external data source, the process retrieves the encrypted credentials from the internal database and decrypts them in process.
Tableau Server to the Internet

In some cases, where users connect to external data sources, such as the Tableau map servers, then Tableau Server will need to connect to the internet. We recommend that you run all components of Tableau inside your protected network. Therefore, connections to the internet may require that you configure Tableau Server to use a forward proxy.

Communication with the repository

You can configure Tableau Server to use Secure Sockets Layer (SSL) for encrypted communications on all traffic that is exchange with the Postgres repository to and from other server components. By default, SSL is disabled for communications between server components and the repository.

For more information, see tsm security repository-ssl enable

Server component communication in a cluster

There are two aspects to communication between Tableau Server components in a distributed server installation: trust and transmission. Each server in a Tableau cluster uses a stringent trust model to ensure that it is receiving valid requests from other servers in the cluster. Computers in the cluster running a gateway process accept requests from third parties (clients), unless they are fronted by a load balancer, in which case the load balancer receives the requests. Servers not running a gateway process only accept requests from other trusted members of the cluster. Trust is established by a whitelist of IP address, port, and protocol. If any of these are invalid, the request is ignored. All members of the cluster can communicate with each other.

When a user stores credentials for external data sources on Tableau Server, they are stored encrypted in Tableau Server’s internal database. When a process uses those credentials to query the external data source, the process retrieves the encrypted credentials from the internal database and decrypts them in process.
Clickjack Protection

Tableau Server includes protection against clickjack attacks. Clickjacking is a type of attack against web pages in which the attacker tries to lure users into clicking or entering content by displaying the page to attack in a transparent layer over an unrelated page. In the context of Tableau Server, an attacker might try to use a clickjack attack to capture user credentials or to get an authenticated user to change settings on your server. For more information about clickjack attacks, see Clickjacking on the Open Web Application Security Project website.

**Note:** Clickjack protection was available in previous versions of Tableau Server, but was disabled by default. New installations of Tableau Server 9.1 and later will always have clickjack protection on unless you explicitly disable it.

Effects of clickjack protection

When clickjack protection is enabled on Tableau Server, the behavior of pages loaded from Tableau Server changes in the following ways:

- **Tableau Server adds the X-Frame-Options: SAMEORIGIN header to certain responses from the server.** In the current versions of most browsers, this header prevents the content from being loaded into an `<iframe>` element, which helps prevent clickjacking attacks.

- **The top-level page from Tableau Server cannot be loaded in `<iframe>` elements.** This includes the sign-in page. One consequence is that you cannot host Tableau Server pages in an application that you create.

- **Only views can be embedded.**

- **If an embedded view requires data source credentials, a message is displayed in the `<iframe>` element with a link to open the view in a secure window where the user can safely enter credentials.** Users should always verify the address of the opened window before entering credentials.
Views can be loaded only if they include the `:embed=y` parameter in the query string, as in this example:

http://<server>/views/Sales/CommissionModel?:embed=y

**Note:** When clickjack protection is enabled, embedded views that use the URL copied from the browser address bar might not load. These view URLs usually contain the hash symbol (#) after the server name (for example, http://myserver/#/views/Sales/CommissionModel?:embed=y) are blocked when clickjack protection is enabled on Tableau Server.

Disabling clickjack protection

You should leave clickjack protection enabled unless it is affecting how your users work with Tableau Server. If you want to disable clickjack protection, use the following `tsm` commands:

1. `tsm configuration set -k wgserver.clickjack_defense.enabled -v false`
2. `tsm pending-changes apply`

The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

**Content Security Policy**

Tableau Server supports the Content Security Policy (CSP) standard. CSP is intended to be an additional layer of security against cross-site scripting and other malicious web-based attacks. CSP is implemented as a HTTP response header that allows you to specify where external resources, such as scripts and images, can be safely loaded from.
See the Mozilla website for more information about CSP.

Note: If your Tableau Server is configured to use SAML for user authentication, then do not enable CSP. Running CSP on Tableau Server with SAML is not supported.

Configure and enable CSP

CSP is configured and enabled using the tsm configuration set Options command. If you are running Tableau Server in a distributed deployment, run these commands on the initial node in the cluster. The configuration will be applied across the cluster after you run tsm pending-changes apply.

Step 1: Set default directives

Tableau Server includes the set of default directives in the table below.

To set a directive, use the following tsm syntax:

```
tsm configuration set -k content_security_policy.-directive.<directive_name> -v <value>
```

For example, to set the connect_src directive, run the following command:

```
tsm configuration set -k content_security_policy.-directive.connect_src -v 'http://example.com'
```

<table>
<thead>
<tr>
<th>Option</th>
<th>Default value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>content_security_policy.-directive.default_src</code></td>
<td>'none'</td>
<td>Serves as a fallback for the other fetch directives. Valid values for default_src.</td>
</tr>
<tr>
<td><code>content_security_policy.-directive.connect_src</code></td>
<td>*</td>
<td>Restricts the URLs which can be loaded using script</td>
</tr>
</tbody>
</table>
| content_security_policy.directive.script_src | * | Specifies valid sources for JavaScript.  
**Valid values for script_src.** |
| content_security_policy.directive.style_src | * ‘unsafe-inline’ | Specifies valid sources for stylesheets.  
**Valid values for style_src.** |
| content_security_policy.directive.img_src | * data: | Specifies valid sources of images and favicons.  
**Valid values for img_src.** |
| content_security_policy.directive.font_src | * data: | Specifies valid sources for fonts loaded using @font-face.  
**Valid values for font_src.** |
| content_security_policy.directive.frame_src | * data: | Specifies valid sources for nested browsing contexts loading using elements such as `<frame>` and `<iframe>`. |
| content_security_policy.-directive.object_src | data: | Specifies valid sources for the `<object>`, `<embed>`, and `<applet>` elements. Valid values for `object_src`. |
| content_security_policy.-directive.report_uri | /vizql/csp-report | Instructs the user agent to report attempts to violate the CSP. These violation reports consist of JSON documents sent via an HTTP POST request to the specified URI. Valid values for `report_uri`. |

Step 2: Add additional directives (optional)

The default directives included with Tableau Server are a subset of directives that are supported by CSP.

For a full list of supported CSP directives, go to https://developer.mozilla.org/en-US/docs/Web/HTTP/Headers/Content-Security-Policy.

You can add directives to the existing default set, by using adding the new directive in the `content_security_policy.directive` namespace. You must include the `--force-keys` parameter when adding new directives. The syntax is as follows:

```
tsm configuration set -k content_security_policy.-directive.<new_directive_name> -v <value> --force-keys
```
For example, to add the `worker-src` directive, run the following command:

```bash
tsm configuration set -k content_security_policy.directive.worker-src -v 'http://*.example.com' --force-keys
```

Step 3: Specify report-only directives (optional)

You can configure CPS to report some directives and to enforce others. When you set `content_security_policy.enforce_enabled` to true, then all directives are enforced (even if `content_security_policy.report_only_enable` is also set to true).

To specify directives as "report-only" and not enforced, add the directives to the `report_only_directive` namespace. You must include the `--force-keys` parameter when adding new directives. The syntax is as follows:

```bash
tsm configuration set -k content_security_policy.report_only_directive.<directive_name> -v <value> --force-keys
```

For example, to report only on the `script_src` directive, run the following command:

```bash
tsm configuration set -k content_security_policy.report_only_directive.script_src -v 'http://*.example.com' --force-keys
```

Step 4: Enable CSP on Tableau Server

After you have configured directives, enable CSP on Tableau Server.

The following options are used to enable enforcement or report only mode for the directives you have set.

<table>
<thead>
<tr>
<th>Option</th>
<th>Default value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>content_security_policy.enforce_enabled</code></td>
<td>false</td>
<td>Adds a CSP header to all requests so that any violation will be enforced by the browser.</td>
</tr>
</tbody>
</table>
content_security_policy.report_only_enabled | true | Adds a CSP header to all requests so that any violation will be recorded in our vizql-client logs, but will not be enforced by the browser.

To enable enforcement of the CSP directives that you’ve specified, run the following command

```
tsm configuration set -k content_security_policy.enforce_enabled -v true
```

**Step 5: Run tsm pending-changes apply**

When you are finished configuring CSP, run tsm pending-changes apply.

The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

**View CSP report**

To view CSP violations for a given viz, load the viz in a browser that includes developer tools. This example uses the Chrome browser.

1. Load a test viz with violations that is hosted on the Tableau Server deployment where you configured CSP.

2. Enter `CTRL+Shift+I` to open the developer tools in Chrome.

3. Click the **Network** tab.

4. In the **Filter** field, enter `csp-report`, and then click **Find All**.
If there are no violations then the search will not return any CSP reports.

If there are violations, click the Headers tab in the results pane and scroll to the bottom to view Request Payload.

SSL

SSL (Secure Sockets Layer) is a standard security technology that establishes an encrypted link between a web server and clients. To use SSL, you need to install an SSL certificate on Tableau Server.

You can configure Tableau Server to use SSL in the following ways:

- Use SSL for external HTTP traffic.
- Use mutual (two-way) SSL between clients (Tableau Desktop, web browsers, and tabcmd.exe) and Tableau Server.
- Use SSL for all HTTP traffic between internal server components and the repository.

If you are using mutual SSL, each client also needs a certificate.

**Note:** Tableau Server uses SSL for user authentication. SSL is not used to handle permissions and authorization to content (data sources and workbooks) hosted on Tableau Server.

Configure SSL for External HTTP Traffic to and from Tableau Server

You can configure Tableau Server to use Secure Sockets Layer (SSL) encrypted communications on all external HTTP traffic. Setting up SSL ensures that access to Tableau Server is secure and that sensitive information passed between the server and Tableau clients—such as Tableau Desktop, the REST API, and so on—is protected. Steps on how to configure the server for SSL are described this topic; however, you must first acquire a certificate from a trusted authority, and then import the certificate files into Tableau Server.

Mutual SSL authentication is not supported on Tableau Mobile.
In this article

SSL certificate requirements

Configuring SSL for a Cluster

  Use the TSM web interface

  Use the TSM CLI

Port redirection and logging

SSL certificate requirements

Acquire an Apache SSL certificate from a trusted authority (for example, Verisign, Thawte, Comodo, GoDaddy). You can also use an internal certificate issued by your company. Wild-card certificates, which allow you to use SSL with many host names within the same domain, are also supported.

When you acquire an SSL certificate for external communication to and from Tableau Server, follow these guidelines and requirements:

- If your organization issues certificates with a local PKI, or if you are using certificates that are not issued by a trusted certificate authority, you’ll need a certificate authority (CA) certificate file to identify the trusted CA.

  The CA certificate file must be a valid PEM-encoded X509 certificate with the extension .crt. If you have multiple trusted certificate authorities, you can copy and paste the entire contents of each CA certificate, including the "BEGIN CERTIFICATE" and "END CERTIFICATE" lines, into a new file, and then save the file as CAs.crt.

- Use a SHA-2 (256 or 512 bit) SSL certificate. Most browsers no longer connect to a server that presents an SHA-1 certificate.
In addition to the certificate file, you must also acquire a corresponding SSL certificate key file. The key file must be a valid RSA or DSA private key file (with the extension .key by convention).

You can choose to passphrase-protect the key file. The passphrase you enter during configuration will be encrypted while at rest. However, if you want to use the same certificate for SSL and SAML, you must use a key file that is not passphrase protected.

- **SSL certificate chain file**: A certificate chain file is required for Tableau Desktop on the Mac. The chain file is also required for the Tableau Mobile app if the certificate chain for Tableau Server is not trusted by the iOS or Android operating system on the mobile device. The chain file is a concatenation of all of the certificates that form the certificate chain for the server certificate. All certificates in the file must be x509 PEM-encoded and the file must have a .crt extension (not .pem).

- For multiple host names or sub-domains, Tableau Server supports wildcard certificates.

**Note:** If you plan to configure Tableau Server for single-sign on using SAML, see Using SSL certificate and key files for SAML in the SAML requirements to help determine whether to use the same certificate files for both SSL and SAML.

### Configuring SSL for a Cluster

You can configure a Tableau Server cluster to use SSL. If the initial node is the only one running the gateway process (which it does by default), you need to configure SSL only on that node, using the steps described in this topic.

### SSL with multiple gateways

A highly available Tableau Server cluster can include multiple gateways, fronted by a load balancer. If you are configuring this type of cluster for SSL, you have the following choices:
- Configure the load balancer for SSL: Traffic is encrypted from the client web browsers to the load balancer. Traffic from the load balancer to the Tableau Server gateway processes is not encrypted. No SSL configuration in Tableau Server is required by you. It’s all handled by the load balancer.

- Configure Tableau Server for SSL: Traffic is encrypted from the client web browsers to the load balancer, and from the load balancer to the Tableau Server gateway processes. For more information, continue to the following section.

Additional configuration information for Tableau Server cluster environments

When you want to use SSL on all Tableau Server nodes that run a gateway process, you complete the following steps.

1. Configure the external load balancer for SSL passthrough.

   Or if you want to use a port other than 443, you can configure the external load balancer to terminate the non-standard port from the client. In this scenario, you would then configure the load balancer to connect to Tableau Server over port 443. For assistance, refer to the documentation provided for the load balancer.

2. Make sure the SSL certificate is issued for the load balancer’s host name.

3. Configure the initial Tableau Server node for SSL.

4. If you are using mutual SSL, place the SSL CA certificate file in the same location on all computers that run a gateway process.

   You do not need to do any additional configuration on the subsequent nodes.

Example

Say you have a cluster that includes an initial Tableau Server node and three additional nodes, with gateway processes running on the initial, node2 and node3. In this situation, you
configure the initial Tableau Server for SSL, and then copy the same SSL certificate and key files to node2 and node3, to the same location as on the initial node.

Prepare the environment

When you get the certificate files from the CA, save them to a location accessible by Tableau Server, and note the names of the certificate .crt and .key files and the location where you save them. You’ll need to provide this information to Tableau Server when you enable SSL.

A common practice is to place a copy of the certificate files in a location that’s within the Tableau Server directory tree. For example:

/var/opt/tableau/tableau_server/data/ssl

Name the directory whatever is appropriate depending on whether you’ll use the certificate files only for SSL or also for configuring SAML authentication.

Note: If you think you might want to use the same certificate for SSL and SAML, see the Certificate and identity provider (IdP) requirements in the SAML Requirements topic.

Configure SSL on Tableau Server

Use the method you’re most comfortable with.

Use the TSM web interface

1. Open TSM in a browser:

   https://<tsm-computer-name>:8850. For more information, see Sign in to Tableau Services Manager Web UI.

2. On the Configuration tab, select Security > External SSL.

3. Under External web server SSL, select Enable SSL for server communication.

4. Upload the certificate and key files, and if required for your environment, upload the
chain file and enter the passphrase key:

<table>
<thead>
<tr>
<th>External web server SSL</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configure SSL for secure communication between Tableau Server and web clients. Learn more about external web server SSL.</td>
</tr>
<tr>
<td>Enable SSL for server communication</td>
</tr>
<tr>
<td>SSL certificate file (Required)</td>
</tr>
<tr>
<td>SSL certificate key file (Required)</td>
</tr>
<tr>
<td>SSL certificate key passphrase</td>
</tr>
<tr>
<td>SSL certificate chain file</td>
</tr>
</tbody>
</table>

If you are using SSL for server communication and want to configure SSL communication between Tableau Server and clients using certificates on both the server and clients, you must first enable mutual SSL. Click here to configure the mutual SSL authentication method.

5. Click **Save Pending Changes**.

6. Click **Apply Changes and Restart**.

**Use the TSM CLI**

After you have copied the certificate files to the local computer, run the following commands:

```
tsm security external-ssl enable --cert-file <path-to-file.crt> --key-file <path-to-file.key>
```

```
tsm pending-changes apply
```

See the command reference at `tsm security external-ssl enable` to determine whether you want to include additional options for `external-ssl enable`. Tableau has specific recommendations for the `--protocols` option.

The `external-ssl enable` command imports the information from the `.crt` and `.key` files. If you run this command on a node in a Tableau Server cluster, it also distributes the information to any other gateway node.

The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is
stopped, but in that case there is no restart. You can suppress the prompt using the --ignore-prompt option, but this does not change the restart behavior. For more information, see tsm pending-changes apply.

Port redirection and logging

After the server has been configured for SSL, it accepts requests to the non-SSL port (default is port 80) and automatically redirects to the SSL port 443.

Note: Tableau Server supports only port 443 as the secure port. It cannot run on a computer where another application is using port 443.

SSL errors are logged in the at the following location. Use this log to troubleshoot validation and encryption issues:

/var/opt/tableau/tableau_server-/data/tabsvc/logs/httpd/error.log

Add SSL port to the local firewall

If you are running a local firewall, you must add the SSL port to the firewall on Tableau Server. The example below describes how to configure the firewall running on RHEL/CentOS distributions. The example uses Firewalld, which is the default firewall on CentOS.

1. Start firewalld:

   ```
   sudo systemctl start firewalld
   ```

2. Add port 443 for SSL:

   ```
   sudo firewall-cmd --permanent --add-port=443/tcp
   ```

3. Reload the firewall and verify the settings:
sudo firewall-cmd --reload

Example: SSL Certificate - Generate a Key and CSR

**Important:** This example is intended to provide general guidance to IT professionals who are experienced with SSL requirements and configuration. The procedure described in this article is just one of many available methods you can use to generate the required files. The process described here should be treated as an example and not as a recommendation.

When you configure Tableau Server to use Secure Sockets Layer (SSL) encryption, this helps ensure that access to the server is secure and that data sent between Tableau Server and Tableau Desktop is protected.

**Looking for Tableau Server on Windows? See Example: SSL Certificate - Generate a Key and CSR.**

Tableau Server uses Apache, which includes OpenSSL. You can use the OpenSSL toolkit to generate a key file and Certificate Signing Request (CSR) which can then be used to obtain a signed SSL certificate.

**Steps to generate a key and CSR**

To configure Tableau Server to use SSL, you must have an SSL certificate. To obtain the SSL certificate, complete the steps:

1. Generate a key file.
2. Create a Certificate Signing Request (CSR).
3. Send the CSR to a certificate authority (CA) to obtain an SSL certificate.
4. Use the key and certificate to configure Tableau Server to use SSL.

You can find additional information on the SSL FAQ page on the Apache Software Foundation website.
Configure a certificate for multiple domain names

Tableau Server allows SSL for multiple domains. To set up this environment, you need to modify the OpenSSL configuration file, openssl.conf, and configure a Subject Alternative Name (SAN) certificate on Tableau Server. See For SAN certificates: modify the OpenSSL configuration file below.

Generate a key

Generate a key file that you will use to generate a certificate signing request.

1. Change to the Apache bin directory for Tableau Server:

   /opt/tableau/tableau_server/packages/apache.<version_code>/bin

2. Run the following command to create the key file:

   openssl genrsa -out <yourcertname>.key 4096

   **Note:** This command uses a 4096-bit length for the key. You should choose a bit length that is at least 2048 bits because communication encrypted with a shorter bit length is less secure. If a value is not provided, 512 bits is used.

Create a certificate signing request to send to a certificate authority

Use the key file you created in the procedure above to generate the certificate signing request (CSR). You send the CSR to a certificate authority (CA) to obtain a signed certificate.
Important: If you want to configure a SAN certificate to use SSL for multiple domains, first complete the steps in For SAN certificates: modify the OpenSSL configuration file below, and then return to here to generate a CSR.

1. Run the following command to create a certificate signing request (CSR) file:

   openssl req -new -key yourcertname.key -out yourcertname.csr -config ../conf/openssl.cnf

2. When prompted, enter the required information.

   Note: For Common Name, type the Tableau Server name. The Tableau Server name is the URL that will be used to reach the Tableau Server. For example, if you reach Tableau Server by typing tableau.example.com in the address bar of your browser, then tableau.example.com is the common name. If the common name does not resolve to the server name, errors will occur when a browser or Tableau Desktop tries to connect to Tableau Server.

Send the CSR to a certificate authority to obtain an SSL certificate

Send the CSR to a commercial certificate authority (CA) to request the digital certificate. For information, see the Wikipedia article Certificate authority and any related articles that help you decide which CA to use.

Use the key and certificate to configure Tableau Server

When you have both the key and the certificate from the CA, you can configure Tableau Server to use SSL. For the steps, see Configure External SSL.
For SAN certificates: modify the OpenSSL configuration file

In a standard installation of OpenSSL, some features are not enabled by default. To use SSL with multiple domain names, before you generate the CSR, complete these steps to modify the openssl.cnf file.

1. Navigate to the Apache conf folder for Tableau Server.

For example: /opt/tableau/tableau_server-
/packages/apache.<version_code>/conf

2. Open openssl.cnf in a text editor, and find the following line: req_extensions = v3_req

This line might be commented out with a hash sign (#) at the beginning of the line.

```plaintext
UTF8Strings
# so use this option with caution!
string_mask = nombstr

# req_extensions = v3_req # The extensions to add to a certificate request
[ req_distinguished_name ]
countryName = Country Name (2 letter code)
```

If the line is commented out, uncomment it by removing the # and space characters from the beginning of the line.

3. Move to the [ v3_req ] section of the file. The first few lines contain the following text:

```plaintext
# Extensions to add to a certificate request
basicConstraints = CA:FALSE
keyUsage = nonRepudiation, digitalSignature, keyEncipherment
```

After the keyUsage line, insert the following line:

```plaintext
subjectAltName = @alt_names
```
If you’re creating a self-signed SAN certificate, do the following to give the certificate permission to sign the certificate:

a. Add the cRLSign and keyCertSign to the keyUsage line so it looks like the following:
   `keyUsage = nonRepudiation, digitalSignature, keyEncipherment, cRLSign, keyCertSign`

b. After the keyUsage line, add the following line:
   `subjectAltName = @alt_names`

4. In the [alt_names] section, provide the domain names you want to use with SSL.

   DNS.1 = [domain1]
   DNS.2 = [domain2]
   DNS.3 = [etc]

The following image shows the results highlighted, with placeholder text that you would replace with your domain names.

```
[v3_req]
# Extensions to add to a certificate request

basicConstraints = CA:FALSE
keyUsage = nonRepudiation, digitalSignature, keyEncipherment
subjectAltName = @alt_names

[alt_names]
DNS.1 = domain1
DNS.2 = domain2
DNS.3 = etc
```

5. Save and close the file.

6. Complete the steps in Create a certificate signing request to send to a certificate authority section, above.
Configure SSL for Internal Postgres Communication

You can configure Tableau Server to use SSL (TLS) for encrypted communication between the Postgres repository and other server components. By default, communication that is internal to Tableau Server components is not encrypted.

While you enable support for internal SSL, you can also configure support for direct connections to the repository from Tableau clients, such as Tableau Desktop, Tableau Mobile, REST API, web browsers.

In this article
Configure Postgres SSL using your preferred method:
- Use the TSM web interface
- Use the TSM CLI

Use the TSM web interface

1. As a server administrator, open TSM in a browser:

   https://<tsm-computer-name>:8850

   For more information, see Sign in to Tableau Services Manager Web UI.

2. On the **Configuration** tab, select **Security > Repository SSL**.
3. Select one of the options for using repository SSL.

   - **Required for all connections**—uses SSL for internal Tableau Server communication, and requires SSL for Tableau clients that connect directly to the repository, including those using the **tableau** or **readonly** user.

   **Important:** If you select this option, you must also complete the steps in Configure Postgres SSL to Allow Direct Connections from Clients, to place the certificate files in the correct location on the client computers.

   - **Optional for user connections**—uses SSL for internal Tableau Server communication, and supports but does not require SSL for direct connections to the server from Tableau clients.

   - **Off for all connections (default)**—Internal server communication is not encrypted, and SSL is not required for direct connections from clients.

4. Click **OK**.

   The first two options generate the server’s certificate files, **server.crt** and **server.key**, and place them in the following location.
/var/opt/tableau/tableau_server/data/tabsvc/config/pgsql_<version>/security

Use this .crt file if you need to configure clients for direct connections.

Use the TSM CLI

To enable SSL for internal traffic among the server components, run the following commands:

```bash
  tsm security repository-ssl enable
  tsm pending-changes apply
```

What the command does

`repository-ssl enable` generates the server's certificate files, which it places in the following location:

```
/var/opt/tableau/tableau_server/data/tabsvc/config/pgsql_<version>/security
```

By default, this command sets Tableau Server to require SSL for traffic between the repository and other server components, as well as for direct connections from Tableau clients (including for connections through the `tableau` or `readonly` users).

To complete the configuration, you must also do the steps described in Configure Postgres SSL to Allow Direct Connections from Clients, to place the certificate files in the correct location on the client computers.

The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`. 

- 717 -
Option for repository-ssl enable

If you want to require SSL only for internal Tableau Server communication, and not for direct connections from client apps, use the following option with the repository-ssl enable command:

--internal-only

Cluster environments

If you run repository-ssl enable on a node in a cluster, it copies the required certificate file to the same location on each other node.

For more information about downloading the public certificate for direct connections, see Configure Postgres SSL to Allow Direct Connections from Clients.

Configure Postgres SSL to Allow Direct Connections from Clients

When Tableau Server is configured to use SSL for internal communication with the Postgres repository, you can also require SSL for Tableau clients that connect directly to the repository. Direct connections include those using the tableau user or the readonly user. Examples of Tableau clients include Tableau Desktop, Tableau Mobile, REST API, web browsers.

1. Run the following commands:

```
tsm security repository-ssl enable

 tsm pending-changes apply
```

This enables internal SSL support, generates new server certificate and key files, and requires all Tableau clients to use SSL to connect to the repository.

The pending-changes apply command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt
using the --ignore-prompt option, but this does not change the restart behavior.
For more information, see tsm pending-changes apply.

2. For each client computer that will connect directly to the repository, do the following:

   - Copy the server.crt file to the client computer. You can find this file in the following directory:

     ```
     /var/opt/tableau/tableau_server-
     /data/tabsvc/config/pgsql_<version_code>/security
     ```

     **Note:** Do not copy server.key to the client computer. This file should reside only on the server.

   - Import the certificate into the computer’s certificate store.

     For information, use the documentation from the operating system manufacturer.

See also

For additional repository-ssl commands and options, see tsm security.

Configure Mutual SSL Authentication

Using mutual SSL, you can provide users of Tableau Desktop and other approved Tableau clients a secure, direct-access experience to Tableau Server. With mutual SSL, when a client with a valid SSL certificate connects to Tableau Server, Tableau Server confirms the existence of the client certificate and authenticates the user, based on the user name in the client certificate. If the client does not have a valid SSL certificate, Tableau Server can refuse the connection. You can also configure Tableau Server to fall back to username/password authentication if mutual SSL fails.

Mutual SSL authentication is not supported on Tableau Mobile.
Use the TSM web interface

1. Configure SSL for External HTTP Traffic to and from Tableau Server.

2. Open TSM in a browser:

   https://<tsm-computer-name>:8850. For more information, see Sign in to Tableau Services Manager Web UI.

4. Under Authentication Method, select Mutual SSL in the drop-down menu.

5. Under Mutual SSL, select Use mutual SSL and automatic sign in with client certificates.

6. Click Select File and upload your certificate authority (CA) issued certificate to the server.

   This certificate must be a valid PEM-encoded x509 certificate with the extension .crt.

7. Enter remaining SSL configuration information for your organization.

   Username format: When Tableau Server is configured for mutual SSL, the server gets the user name from the client certificate, so it can establish a direct sign-in for the client user. The name that Tableau Server uses depends on how Tableau Server is configured for user authentication:

   - Local Authentication—Tableau Server uses the UPN (User Principal Name) from the certificate.
- Active Directory (AD)—Tableau Server uses LDAP (Lightweight Directory Access Protocol) to get the user name.

Alternatively, you can set Tableau Server to use the CN (Common Name) from the client certificate.

8. Click **Save Pending Changes** after you’ve entered your configuration information.

9. Click **Apply Changes and Restart**.

**Use the TSM CLI**

**1 Require SSL for external server communication**

To configure Tableau Server to use SSL for external communication between Tableau Server and web clients, run the `external-ssl enable` command as follows, providing the names for the server certificate’s .crt and .key files:

```bash
tsm security external-ssl enable --cert-file <file.crt> --key-file <file.key>
```
For --cert-file and --key-file, specify the location and file name where you saved the server’s CA-issued SSL certificate (.crt) and key (.key) files.

The above command assumes the you are signed in as a user that has the Server Administrator site role on Tableau Server. You can instead use the -u and -p parameters to specify an administrator user and password.

If the certificate key file requires a passphrase, include the --passphrase parameter and value.

2 Use mutual SSL

Add mutual authentication between the server and each client, and allow for Tableau client users to be authenticated directly after the first time they provide their credentials.

1. Run the following command:

   tsm authentication mutual-ssl configure --cert-file <file.crt>

   For --cert-file, specify the location and file name of the server’s CA certificate (.crt) file, as in the previous step for external SSL.

   See the remaining sections in this article for any additional options you might want to include with the mutual-ssl configure command.

2. Run the following commands to enable mutual SSL and apply the changes:

   tsm authentication mutual-ssl enable

   tsm pending-changes apply

   The pending-changes apply command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt
using the --ignore-prompt option, but this does not change the restart behavior. For more information, see tsm pending-changes apply.

Additional options for mutual SSL

You can use `mutual-ssl configure` to configure Tableau Server to support the following options.

For more information, see `tsm authentication mutual-ssl <commands>`.

Fallback authentication

When Tableau Server is configured for mutual SSL, authentication is automatic and a client must have a valid certificate. You can configure Tableau Server to allow a fallback option, to accept user name and password authentication.

`tsm authentication mutual-ssl configure -f true`

User name mapping

When Tableau Server is configured for mutual SSL, the server authenticates the user directly by getting the user name from their client certificate. The name that Tableau Server uses depends on how the server is configured for user authentication:

- **Local Authentication**—uses the UPN (User Principal Name) from the certificate.

- **Active Directory (AD)**—uses LDAP (Lightweight Directory Access Protocol) to get the user name.

You can override either of these defaults to set Tableau Server to use the common name.

`tsm authentication mutual-ssl configure -m cn`

For more information, see Mapping a Client Certificate to a User During Mutual Authentication
Certificate Revocation List (CRL)

You might need to specify a CRL if you suspect that a private key has been compromised, or if a certificate authority (CA) did not issue a certificate properly.

```
tsm authentication mutual-ssl configure -rf <revoke-file.pem>
```

Mapping a Client Certificate to a User During Mutual Authentication

When you use mutual (two-way) SSL authentication, the client presents its certificate to Tableau Server as part of the authentication process. Tableau Server then maps user information in the client certificate to a known user identity. The strategy that Tableau Server uses to perform client mapping depends on the content of your organization’s client certificates.

This topic discusses the ways information in a client certificate can map to a user identity and how to change the way Tableau Server performs that mapping. To understand how the mapping happens and whether you need to change it, you must know how client certificates are structured in your organization.

- User-name mapping options
- Change the certificate mapping
- Address user-name ambiguity in multi-domain organizations

User-name mapping options

Tableau Server uses one of the following approaches to map a client certificate to a user identity:

- **Active Directory.** If Tableau Server is configured to use Active Directory for user authentication, when Tableau Server receives a client certificate, it passes the certificate to Active Directory, which maps the certificate to an Active Directory identity. Any explicit user name information in the certificate is ignored.
**Note:** This approach requires client certificates to be published for the user accounts in Active Directory.

- **User principal name (UPN).** A client certificate can be configured to store the user name in the user principal name field. Tableau Server reads the UPN value and maps it to a user in Active Directory or to a local user.

- **Common name (CN).** A client certificate can be configured to store the user name in the common name field of the certificate. Tableau Server reads the CN value and maps it to a user in Active Directory or to a local user.

If you configure the server for Active Directory authentication and UPN or CN user-name mapping, put the user name in one of the following formats:

username, domain/username, or username@domain.

For example: asmith, example.org/asmith, or asmith@example.org.

If the server uses local authentication, the format of the name in the UPN or CN fields is not predetermined, but the name in the field must match a user name on the server.

Change the certificate mapping

You use the following command to map a client certificate to a user identity in Tableau Server:

```
  tsm authentication mutual-ssl configure -m <value>
```

Possible values are ldap for Active Directory mapping, upn for UPN mapping, or cn for CN mapping.

When you first install and configure Tableau Server, the server sets the default user-name mapping to match the server’s authentication type:
• If the server is configured to use Active Directory, it also uses Active Directory for mapping the certificate to the user identity.

• If the server is configured to use local authentication, the server gets the user-name value from the UPN field in the certificate.

If the default behavior for how Tableau Server maps a user name to an identity is not correct for your server configuration, run the following set of commands to change the mapping to use the CN value:

```plaintext
tsm authentication mutual-ssl configure -m cn
tsm pending-changes apply
```

The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

Address user-name mapping ambiguity in multi-domain organizations

Under some circumstances, the user name in a certificate’s UPN or CN field can be ambiguous. This ambiguity can lead to unexpected results when the user name is mapped to a user identity on the server.

For example, if Tableau Server is presented with a user name that does not include a domain, the server maps the user name to an identity using the default domain. This can cause an incorrect user-name mapping, potentially assigning a user a different user’s identity and permissions.

This can occur particularly in environments where the following conditions apply:

• Your organization supports multiple Active Directory domains.

• The server is configured to use Active Directory authentication.
• The server is configured to use UPN or CN mapping.

• Some users have the same user name but different domains. For example, asmith@example.org and asmith@example.com.

• The user name in the certificate’s UPN or CN fields does not include the domain as part of the user name—for example, it shows asmith.

To avoid incorrect user-name mapping, make sure the client certificates include fully qualified user names with the domain, using the format asmith@example.org or example.org/asmith.

tsm authentication mutual-ssl <commands>

How Mutual SSL Authentication Works

Mutual (or two-way) SSL authentication provides a combination of an encrypted data stream, mutual authentication of both server and client, and direct access convenience. To use mutual SSL with Tableau Server, you need the following:

• A trusted CA-issued SSL certificate for Tableau Server.

• A certificate on each client that will connect to Tableau Server.

• A Tableau Server configured to use mutual SSL.

Tableau Server and the client verify that each other has a valid certificate, and Tableau Server authenticates the user, based on the user name in the client certificate.

The following image shows a little more detail about the sequence of events that occurs with mutual SSL.
1. The user navigates to Tableau Server.

2. Tableau Server sends its SSL certificate to the client computer.

3. The client computer verifies the Tableau Server certificate.

4. The client computer sends its certificate to Tableau Server.

5. Tableau Server verifies the client certificate.

6. Tableau Server references the user name in the client certificate to authenticate the user.

System User, sudo Privileges, and systemd

This topic describes system user, systemd user service, and sudo privilege in the context of Tableau Server.

Privilege separation

Following standard security best practices, Tableau Server for Linux runs processes with the least privilege possible. During installation, the unprivileged user, tableau, is created in a server authorized group (tableau).

An example user entry in the /etc/passwd file is as follows:
All processes run as the unprivileged *tableau* user. This means that if one of the Tableau Server processes (such as a process displaying vizzes to users) were compromised in some fashion, it would only be able to impact Tableau Server, not the rest of the Linux system.

The *tableau* user is created by the Tableau Server initialization process. You can specify a different unprivileged user during installation. For more information about system users and groups, in the context of installation and LDAP configuration, see Identity Store.

*sudo* privileges

The first version (10.5) of Tableau Server on Linux relied on sudo privileges by updating the sudoers file. Updating the sudoers file conflicts with some system management configuration best practices and security policies. Therefore, the 2018.1 version (and later) of Tableau Server no longer creates or uses a privileged user (*tsmagent*). Nor does the current version of Tableau Server update or include a Tableau-specific sudoers file.

All privileged operations now occur during package and software installation.

*systemd* user service

In the 10.5 version of Tableau Server on Linux, sudo privileges were required to modify or restart the TSM services, which required systemctl commands. All TSM services were run from the normal system-wide systemd process (process ID 1, which runs all processes on the operating system). In this scheme, systemd process runs as root. Therefore, the 10.5 version of Tableau Server required sudo privileges.

With the current 2018.1 (and later) releases, we have removed the need for sudo privileges by making use of the systemd capability to run as a user service. The systemd user service runs as a normal user, so it does not need any special privileges once it has been enabled.

In normal use cases, you will not need to issue commands to systemd because TSM takes care of that. However, for troubleshooting scenarios, you may need to interact with the TSM services. As with the previous versions, you will issue the same systemctl commands for
these scenarios. However, commands should be run as the `tableau` user, and not as root. If you specified a different unprivileged system user during Tableau Server setup, then run the commands as that user.

Running systemctl commands

Use the following syntax example to issue request to systemd with the systemctl commands.

Start a session as the unprivileged user. The `-l` flag is critical to set environment variables properly.

```
sudo su -l tableau
```

Then issue commands. For example:

```
systemctl --user status tabadmincontroller_0
systemctl --user restart tabadmincontroller_0
```

**Security Hardening Checklist**

The following list provides recommendations for improving the security ("hardening") of your Tableau Server installation.

1. Update to the current version

We recommend that you always run the latest version of Tableau Server. Additionally, Tableau periodically publishes maintenance releases of Tableau Server that include fixes for known security vulnerabilities. (Information regarding known security vulnerabilities can be found on the Security Bulletins page.) We recommend that you review maintenance release notifications to determine whether you should install them.

To get the latest version or maintenance release of Tableau Server, visit the Customer Portal page.
2. Configure SSL/TLS with a valid, trusted certificate

Secure Sockets Layer (SSL/TLS) is essential for helping to protect the security of communications with Tableau Server. Configure Tableau Server with a valid, trusted certificate (not a self-signed certificate) so that Tableau Desktop, mobile devices, and web clients can connect to the server over a secured connection. For more information, see SSL.

3. Disable older versions of TLS

Tableau Server uses TLS to authenticate and encrypt many connections between components and with external clients. External clients, such as browsers, Tableau Desktop, Tableau Mobile connect to Tableau using TLS over HTTPS. Transport layer security (TLS) is an improved version of SSL. In fact, older versions of SSL (SSL v2 and SSL v3) are no longer considered to be adequately secure communication standards. As a result, Tableau Server does not allow external clients to use SSL v2 or SSL v3 protocols to connect. We recommend that you only allow external clients to connect to Tableau Server with TLS v1.2.

Specifically, we recommend that you disable TLS v1 and TLS v1.1 on Tableau Server. However, before you disable a specific version of TLS, verify that the browsers that your users connect to Tableau Server with support TLS v1.2. In some cases, you may need to preserve support for TLSv1.1.

The following tsm command enables TLS v1.2 (using the "all" parameter) and disables SSL v2, SSL v3, TLS v1, and TLS v1.1 (by prepending the minus [-] character to a given protocol).

```
 tsm configuration set -k ssl.protocols -v 'all -SSLv2 -SSLv3 -TLSv1 -TLSv1.1'
```

```
 tsm pending-changes apply
```

The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the ```
ignore-prompt option, but this does not change the restart behavior. For more information, see tsm pending-changes apply.

4. Disable Triple-DES cipher suite

The Triple-DES cipher suite is no longer considered adequate to encrypt sessions on the internet. Specifically, running Triple-DES ciphers leaves the Tableau Server vulnerable to information disclosure and denial of service attacks. You can learn more at the National Vulnerability Database webpage for CVE-2016-2183.

Triple-DES is enabled by default on the version of OpenSSL that is running on Tableau Server. However, other deprecated cipher suites (MD5 and RC4) are disabled. To add Triple-DES to the list of disabled ciphers, run the following commands. (The !aNULL parameter forces clients to use a legitimate cipher.)

```bash
tsm configuration set -k ssl.ciphersuite -v
'HIGH: MEDIUM: !aNULL: !MD5: !RC4: !3DES'

tsm pending-changes apply
```

5. Configure SSL encryption for internal traffic

Configure Tableau Server to use SSL to encrypt all traffic between the Postgres repository and other server components. By default, SSL is disabled for communications between server components and the repository. We recommend enabling internal SSL for all instances of Tableau Server, even single-server installations. Enabling internal SSL is especially important for multi-node deployments. See Configure SSL for Internal Postgres Communication

6. Enable firewall protection

Tableau Server was designed to operate inside a protected internal network.
**Important:** Do not run Tableau Server, or any components of Tableau Server on the internet or in a DMZ. Tableau Server must be run within the corporate network protected by an internet firewall. We recommend configuring a reverse proxy solution for internet clients that need to connect to Tableau Server. See Configuring Proxies for Tableau Server.

A local firewall should be enabled on the operating system to protect Tableau Server in single and multi-node deployments. In a distributed (multi-node) installation of Tableau Server, communication between nodes does not use secure communication. Therefore, you should enable firewalls on the computers that host Tableau Server. See Configure Local Firewall.

To prevent a passive attacker from observing communications between nodes, configure a segregated virtual LAN or other network layer security solution.

See Tableau Services Manager Ports to understand which ports and services Tableau Server requires.

7. Restrict access to the server computer and to important directories

Tableau Server configuration files and log files can contain information that is valuable to an attacker. Therefore, restrict physical access to the machine that is running Tableau Server. In addition, make sure that only authorized and trusted users have access to the Tableau Server files in the `/var/opt/tableau/tableau_server/` directory.

8. Generate fresh secrets and tokens

Any Tableau Server service that communicates with repository or the cache server must first authenticate with a secret token. The secret token is generated during Tableau Server setup. The encryption key that internal SSL uses to encrypt traffic to Postgres repository is also generated at during setup.
We recommend that after you install Tableau Server, you generate new encryption keys for your deployment.

These security assets can be regenerated with the `tsm security regenerate-internal-tokens` command.

Run the following commands:

```
    tsm security regenerate-internal-tokens
    tsm pending-changes apply
```

9. Disable services that you're not using

To minimize the attack surface of the Tableau Server, disable any connection points that are not needed.

REST API

The REST API interface is enabled by default. If no applications will make REST API calls to your installation of Tableau Server 9.3 (or later), disable it by using the following commands:

```
    tsm configuration set -k api.server.enabled -v false
    tsm pending-changes apply
```

**Important**: Tableau Prep uses REST API to access Tableau Server. If your organization uses Tableau Prep, do not disable REST API.

JMX Service

JMX is disabled by default. If it's enabled but you're not using it, you should disable it by using the following:

```
    tsm configuration set -k service.jmx_enabled -v false
    tsm pending-changes apply
```
10. Verify session lifetime configuration

By default, Tableau Server does not have an absolute session timeout. This means that client sessions can remain open indefinitely if the Tableau Server inactivity timeout is not exceeded. (The default inactivity timeout is 240 minutes.)

If your security policy requires it, you can set an absolute session timeout. Be sure to set your absolute session timeout in a range that allows the longest-running extract or publishing operations in your organization. Setting the session timeout too low may result in extract and publishing failures for long-running operations.

To set the session timeout run the following commands:

```bash
  tsm configuration set -k wgserver.session.apply_lifetime_limit -v true
  tsm configuration set -k wgserver.session.lifetime_limit -v value, where value is the number of minutes. The default is 1440, which is 24 hours.
  tsm configuration set -k wgserver.session.idle_limit -v value, where value is the number of minutes. The default is 240.
  tsm pending-changes apply
```

11. Configure a server safelist for file-based data sources

By default, Tableau Server allows authorized Tableau Server users to build workbooks that use files on the server as file-based data sources (such as spreadsheets). In this scenario, files are accessed by the `tableau` system account.

To prevent unwanted access to files, we recommend that you configure safelist (sometimes referred to as "whitelist") functionality. This lets you limit `tableau` account access to just the directory paths where you host data files.
1. On the computer running Tableau Server, identify the directories where you will host data source files.

   **Important** Make sure the file paths you specify in this procedure exist on the server. If the paths do not exist when the computer starts, Tableau Server will not start.

2. Run the following commands:

   ```
   tsm configuration set -k native_api.allowed_paths -v "path"
   
   tsm configuration set -k native_api.allowed_paths -v "/data-sources;/HR/data"
   
   tsm pending-changes apply
   ```

12. Enable HTTP Strict Transport Security for web browser clients

   HTTP Strict Transport Security (HSTS) is a policy configured on web application services, such as Tableau Server. When a conforming browser encounters a web application running HSTS, then all communications with the service must be over a secured (HTTPS) connection. HSTS is supported by major browsers.

   For more information about how HSTS works and the browsers that support it, see The Open Web Application Security Project web page, [HTTP Strict Transport Security Cheat Sheet](http://example.com).

   To enable HSTS, run the following commands on Tableau Server:

   ```
   tsm configuration set -k gateway.http.hsts -v true
   ```
By default, HSTS policy is set for one year (31536000 seconds). This time period specifies the amount of time in which the browser will access the server over HTTPS. You should consider setting a short max-age during initial roll-out of HSTS. To change this time period, run `tsm configuration set -k gateway.http.hsts_options -v max-age-e=<seconds>`. For example, to set HSTS policy time period to 30 days, enter `tsm configuration set -k gateway.http.hsts_options -v max-age=2592000`.

```
tsm pending-changes apply
```

13. Disable Guest access

Core-based licenses of Tableau Server include a Guest user option, which allows any user in your organization to see and interact with Tableau views embedded in web pages.

Guest user access is enabled by default on Tableau Servers deployed with core-based licensing.

Guest access allows users to see embedded views. The Guest user cannot browse the Tableau Server interface or see server interface elements in the view, such as user name, account settings, comments, and so on.

If your organization has deployed Tableau Server with core licensing and Guest access is not required, then disable Guest access.

You can disable Guest access at the server or site level.

You must be a server administrator to disable the Guest account at either the server or the site level.

**To disable Guest access at the server level:**

1. In the site menu, click **Manage All Sites** and then click **Settings > General**.

2. For **Guest Access**, clear the **Enable Guest account** check box.

3. Click **Save**.
To disable Guest access for a site:

1. In the site menu, select a site.
2. Click **Settings**, and on the Settings page, clear the **Enable Guest account** check box.

For more information, see Guest User.

### Change List

<table>

</table>

### Manage Licenses

#### Licensing Overview

Tableau Server term licenses are available with two different license metrics: user-based and core-based. Term licenses, also known as subscription licenses, allow you to use and update Tableau Server for a specified period of time.

Tableau offers multiple types of user-based term licenses that grant a range of capabilities at various price points, providing the flexibility for organizations to pay for the data analysis and data visualization capabilities that each type of user in their organization needs. To learn more, see **User-based licenses**.

#### License metric: user-based or core-based

Your license is defined by the metric that permits use of Tableau Server.
- A user-based license metric allows you to deploy Tableau Server on a single computer or on multiple computers in a cluster. Each user that accesses Tableau Server must be licensed. Administrators add users and license them.

- A core-based license metric imposes no constraints on the number of user accounts in Tableau Server. Instead, the license specifies the maximum number of computer cores on which you can run Tableau Server. You can install Tableau Server on a single computer or across multiple computers as a multi-node cluster, as long as the total number of cores in all the computers does not exceed the total number that the license allows.

  **Note:** Not all processes installed with Tableau Server impact the calculation of total number of cores used. A subset of processes are considered "licensed processes." Core licensing is calculated only on computers running licensed processes. If a computer has one or more licensed processes installed on it, the cores on that computer count toward the total cores used. For more information about licensed processes, see Licensed processes.

The topics in this section provide guidance about how to view and refresh Tableau licensing, as well as a topic that describes how to add user capacity on Tableau Server.

  **Note:** As a Tableau Server administrator, you may also be tasked with managing Tableau Desktop deployment and tracking license usage on client computers. If your organization will be using Desktop License reporting, you need to configure Tableau Server to support this. For details, see Configure Desktop License Reporting. For additional information on licensing and management tasks related to Tableau Desktop, see the Tableau Desktop Deployment Guide.
User-based licenses

Tableau offers user-based term licenses that grant a range of capabilities at various price points. Multiple types of user-based term licenses are available: Viewer, Explorer and Creator. The following capabilities are available to users with these licenses:

- **Viewer licenses** let users view and interact with workbooks in Tableau Server or Tableau Online. Viewer licenses also let users access Tableau Mobile, add comments to workbooks, download .png and .pdf versions of workbooks, download workbook summary data, create subscriptions for themselves, and receive data-driven alerts.

- **Explorer licenses** are equivalent to the user-based term licenses available in previous Tableau Server and Tableau Online releases, and include the capabilities provided with Viewer licenses. Depending on a user’s site role, a user with this license will have access to workbook authoring capabilities using a web browser, as well as a full set of collaboration features.

- **Creator licenses** grant a wide range of capabilities when using Tableau Server and Tableau Online, and also grant use of Tableau Desktop and Tableau Prep. Depending on a user’s site role, a user with a Creator license might have all of the capabilities available under the Explorer license, as well as the following capabilities when using Tableau Server and Tableau Online:
  - Create and publish new workbooks from a new data source.
  - Edit embedded data sources in the Data pane.
  - Create and publish new data connections.
  - Create new workbooks using Dashboard Starters (Tableau Online only).

**Note:** Tableau Server administrators will always use a Creator license, if available; additionally, activating a Creator license on Tableau Server causes all Tableau Server administrator accounts to require Creator licenses.

License keys provide administrators with a set of each type of license, which they can activate by assigning associated site roles to users. The first Creator or Explorer license that you add to Tableau Server activates Tableau Server, and will be used by a Server Administrator. Administrators can activate additional Creator, Explorer and Viewer licenses in Tableau Server or Tableau Online to increase licensed user capacity.
Tableau Server licenses and site roles after an upgrade

When upgraded to 2018.2, Tableau Server will display the new licensing information and site roles. Any users in the Read Only site role prior to the upgrade are reassigned to the Viewer site role.

To learn more about the site roles available with each type of user-based license, see Set Users’ Site Roles. To learn about pricing for each type of user-based license, see Tableau Pricing. To learn about troubleshooting issues with licensing, see Troubleshoot Licensing.

View Server Licenses

Server administrators can view the license and product key information for Tableau Server.

Viewing licenses from the Tableau Server web UI

How you navigate to the Licenses page in Tableau Server depends on whether you have a single site, or multiple sites.

- On a server with a single site, click Settings and Licenses:

- On a multi-site server, click Manage All Sites on the site menu, Settings, and Licenses:
Note: The Manage All Sites option only displays when you are signed in as a server administrator.

This page displays information for any licenses that have been activated on your server, including any user-based (term) or core-based licenses.

In this article

Use the TSM web interface

Use the TSM CLI

Use the TSM web interface

1. Open TSM in a browser:

   http://<tsm-computer-name>:8850

2. Click Configuration, and then click Licensing:

   The table displays the product key, expiration date, and expiration of maintenance.

   Note: The TSM Web UI provides a limited amount of licensing information. Use the TSM CLI or the Tableau Server Web UI to see additional licensing information, including the number of each type of user-based license (Creator, Explorer and Viewer).

Use the TSM CLI

1. Open a command prompt as administrator on the initial node (the node where TSM is
2. Run the following command:

   tsm licenses list

The output reflects whether Tableau Server uses a user-based license, a core-based license, or a combination of the two. The output of this command is formatted as follows:

<table>
<thead>
<tr>
<th>KE-</th>
<th>TYPE</th>
<th>CREAT-</th>
<th>EXPLOR-</th>
<th>VIEWE-</th>
<th>GUEST</th>
<th>LIC EXP</th>
<th>MAINT</th>
<th>VALI-</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;KE-</td>
<td>Term</td>
<td>Seat #</td>
<td>Seat #</td>
<td>true</td>
<td>mm/d-&lt;KE-</td>
<td>d/yy</td>
<td>mm/d-&lt;KE-</td>
<td>d/yy</td>
</tr>
<tr>
<td>Y&gt;</td>
<td>Core-</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

For example, a server with a core-based license and a second product key that grants user-based licenses might provide command output similar to the following:

<table>
<thead>
<tr>
<th>KE-</th>
<th>TYPE</th>
<th>CREAT-</th>
<th>EXPLOR-</th>
<th>VIEWER</th>
<th>GUEST</th>
<th>LIC EXP</th>
<th>MAINT</th>
<th>VALI-</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;KE-</td>
<td>Term</td>
<td>5</td>
<td>5</td>
<td>100</td>
<td>false</td>
<td>mm/d-&lt;KE-</td>
<td>d/yy</td>
<td>N/A</td>
</tr>
<tr>
<td>Y&gt;</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>32</td>
<td>Unlim-</td>
<td>Unlim-</td>
<td>true</td>
<td>N/A</td>
<td>mm/d-&lt;KE-</td>
<td>d/yy</td>
<td>true</td>
</tr>
<tr>
<td></td>
<td>Cor-</td>
<td>ited</td>
<td>ited</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>es</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Note: The license terms for Creator, Explorer and Viewer users are set according to the terms of the user-based license (term license), if present. So, a server with only a core-based license will have unlimited Explorer and Viewer users and guest access, but no Creator users. Adding a user-based license overrides these settings by providing a specific number of Creator, Explorer and Viewer users, and disabling guest access. To learn more, see Use user-based licenses on a server with core-based licensing.

Refresh Maintenance Date for the Product Key

If the maintenance date for your product key is not up-to-date, refresh the product key. Refreshing the product key will update the product key with the date that your current maintenance period expires and stops expiration messages you may have already received. If you believe that the latest displayed date is incorrect, contact Tableau Support.

Note: This topic describes how to refresh the maintenance date for Tableau Server. For information about refreshing the maintenance date on Tableau Desktop see Refreshing Tableau Desktop Product Key in the Tableau Knowledge Base.

In this article

Use the TSM web interface
Use the TSM CLI

Use the TSM web interface

1. Open TSM in a browser:

   http://<tsm-computer-name>:8850

2. Click Configuration and Licensing and click Refresh All:

![Web Interface Screenshot]

Use the TSM CLI

1. Open a command prompt as administrator on the initial node (the node where TSM is installed).

2. Run the following command:

   tsm licenses refresh
Add Capacity to Tableau Server

You may need to add capacity to your Tableau Server installation to allow you to increase the number of users (if you have a user-based license) or the number of cores (if you have a core-based license).

Tableau Software will provide you with a new product key that adds capacity to your existing Tableau Server installation. You need to activate this key and use it together with your existing product key(s) to get the combined capacity you are licensed for.

Follow the steps below to add a product key to Tableau Server.

**Note:** This process requires a restart of Tableau Server.

In this article

Use the TSM web interface

Use the TSM CLI

Use the TSM web interface

1. Open TSM in a browser:

   https://<tsm-computer-name>:8850

2. Click **Licensing** on the **Configuration** tab and click **Activate License**:
3. Enter or paste your new product key and click **Activate**:

4. Restart Tableau Server after registration is complete.

**Use the TSM CLI**

1. Copy the product key to your computer.

2. Run the following command:

   ```
   tsm licenses activate --license-key <license key>
   ```

3. Restart the server:
Automate Licensing Tasks

Use the tsm licenses category to automate licensing tasks.

C:\ProgramData\Tableau\Tableau Server\data\tabsvc\logs\

Troubleshoot Licensing

This topic includes instructions for troubleshooting issues related to Tableau Server licensing.

Handle an unlicensed server

Tableau offers two licensing models: user-based and core-based. To learn more about user-based and core-based licensing, see Licensing Overview.

User-based licensing requires each active user account to be covered by a license. User-based licenses have a defined capacity, or number of users that they allow. Each user is assigned a unique user name on the server and is required to identify themselves when connecting to the server.

Core-based licensing has no constraints on the number of user accounts in the system, but it does restrict the maximum number of processor cores that Tableau Server can use. You can install Tableau Server on one or more machines to create a cluster, with the restriction that the total number of cores in all the machines does not exceed the number of cores you have licensed and that all of the cores on a particular machine are covered by the license.

Unlicensed User-Based Server

The most common reason for a server that has user-based licensing to be unlicensed is an expired product key or an expired maintenance contract.
Unlicensed Core-Based Server

A core-based server can become unlicensed for a variety of reasons, such as when Tableau Server nodes running licensed processes cannot contact the Tableau Server node running the License Manager service. To learn more about licensed processes, see Tableau Server Processes.

When the server is unlicensed you may not be able to start or administer the server. You can, however, manage your licenses using the tsm licenses command.

Troubleshoot user-based licensing

This section provides information about resolving issues that can occur when adding the user-based Viewer, Explorer and Creator licenses to Tableau Server or Tableau Online, or when these licenses expire. The highest available license type is Creator, followed by Explorer, and finally Viewer. To learn more about user-based licensing, see Licensing Overview.

A user or administrator is unlicensed due to license expiration

To avoid having users unexpectedly become unlicensed or move to another site role, you should always do one of the following before the license that they are currently using expires:

- Renew and activate a replacement license. If a user occupies a Creator, Explorer or viewer license and their license expires, they will use another license of the same type, if available.
- Change the site role of those users to allow the use of a license that is not due to expire.

To learn how site roles can be changed to require a different license, see Set Users’ Site Roles.

The reassignment of users to new licenses is governed by the following logic:

- When a Server Administrator user occupies a Creator license and their license expires (with no replacement licenses available), they are reassigned to an Explorer license if
any Explorer licenses are available. This license reassignment occurs in order of most recent login. Server Administrators displace other users who might be currently using an Explorer license. If no Creator or Explorer licenses are available a Server Administrator becomes unlicensed.

- When a non-Server Administrator user occupies a Creator license and their license expires (with no replacement licenses available), they become unlicensed. To avoid having these users become unlicensed, change their site role prior to license expiration. This is especially important for users in the Site Administrator Creator site role, who must move to the Site Administrator Explorer site role before their Creator license expires to avoid losing Site Administrator capabilities.

- When a non-Server Administrator user occupies an Explorer or Viewer license and their license expires (with no replacement licenses available), they are upgraded to a higher license type, if licenses of that type are available. Specifically, the following occurs when a license expires:
  - Users who occupy an Explorer license will move to a Creator license, if available (with no change to site role).
  - Users who occupy a Viewer license will move to an Explorer license, if available. If no Explorer licenses are available, these users will move to a Creator license, if available (with no change to site role).
  - If no licenses are available at the higher license types, those users are moved to Unlicensed.

Users are reassigned to a new license as described above in order of most recent login, with lower license types reassigned first (first Viewer, then Explorer, and then Creator).

For example: Two users with a Viewer license, a user with the Creator license, and two Server Administrators with a Creator license all have their licenses expire. Four unexpired Explorer licenses are available for these users. In this situation, the following occurs in the order shown below:

1. The user with a Viewer license who logged in most recently is reassigned to an Explorer license.
2. The second user with a Viewer license is reassigned to an Explorer license.
3. The Server Administrator user with a Creator license who logged in most recently is reassigned to an Explorer license, and then the second Server Administrator with a
Creator license is reassigned to the remaining Explorer license.
4. The user with the Creator license becomes unlicensed.

Server Administrator site role is unchanged when using a Creator license

Server Administrators gain Creator capabilities if Creator licenses are available in Tableau Server, with no change to their site role name. All other Tableau Server and Tableau Online users gain Creator licenses only if assigned to a site role that includes Creator in its name.

Licenses are not immediately available

When you add a role-based license to Tableau Server, those licenses become available to all users when you restart Tableau Server. If you don’t restart Tableau Server, role-based licenses become available to all users within 24 hours.

A user with a Viewer license cannot open Tableau Server or Tableau Online workbooks from Tableau Desktop

A user with a Viewer license who also has a separate Tableau Desktop license will be unable to open workbooks on Tableau Server or Tableau Online using Tableau Desktop. To open workbooks such using Tableau Desktop, that user will need an Explorer or Creator license on Tableau Server or Tableau Online.

Migrate from Core-Based to User-Based Licensing

This guide tells you how to migrate Tableau Server from a core-based license metric (which counts the processor cores on which you have Tableau Server installed) to a user-based license metric (which counts named users). To learn more about licensing metrics, see Licensing Overview.

**Note:** As an alternative to migrating to user-based licensing, you can also continue using a core-based license and add user-based Viewer, Explorer and Creator licenses as-needed to provide users with the capabilities granted by these licenses. To learn more, see Use user-based licenses on a server with core-based licensing.
Prepare for migration to user-based licensing

Core-based licenses allow an unlimited number of users, including view-only guest accounts. Every user has a site role when they are added to Tableau Server, and these users and site roles persist when licensing is changed. Because user-based licenses limit the number of users, you should ensure that your new user-based licenses accommodate the number of users who are currently connecting to Tableau Server, including the users currently using guest accounts. If your new user-based licenses don’t accommodate the full number of users, some users will move to the **Unlicensed** site role. To learn more about site roles, see Set Users’ Site Roles.

To count the number of users in your Tableau Server installation, export a list of users to count them with a tool such as Microsoft Excel. To learn how to export a list of users, see Export a User List.

Migrate to user-based licensing

To migrate to user-based licensing you must stop Tableau Server, deactivate the core-based product key, activate the user-based product key(s), and then start Tableau Server. Because this process will result in a restart of Tableau Server and cause downtime for Tableau Server users, you should migrate licensing during a period of low usage.

1. **Stop Tableau Server:**

   Use the `tsm stop` command. To learn more, see: tsm stop.

2. **Deactivate the core-based product key:**

   Use the `tsm licenses deactivate` command with the core-based product key.

3. **Activate the user-based product key:**

   Use the `tsm licenses activate` command with the user-based product key.

4. **Start Tableau Server:**

   Use the tsm start command.
Use user-based licenses on a server with core-based licensing

The 2018.1 release of Tableau Server now lets you to add user-based licenses to Tableau Server installations with core-based licensing. If you upgrade a Tableau Server installation to 2018.1 without activating user-based licenses, Tableau Server will continue to operate as it did previously, with no changes to Tableau Server UI or permissions except that the legacy Viewer site role is renamed to Read Only.

The first Creator or Explorer license that you add to Tableau Server will be used by Server Administrator users. Administrators can activate additional Creator, Explorer and Viewer licenses in Tableau Server to increase licensed user capacity. Activating these user-based licenses gives you a combination of the capabilities granted by user-based Creator, Explorer and Viewer licenses and the capabilities granted by your core-based license. To learn more about the different types of user-based licenses, see User-based licenses.

Note: The unlimited number of users who have full access to Tableau Server under core-based licensing have equivalent capabilities to users with an Explorer license under user-based licensing.

For example, if a Tableau Server installation has a 16 core license that includes guest access, and you added 10 Creator licenses, that server would have the following capabilities:

- A limit of 16 processor cores on hardware that runs Tableau Server
- Guest access
- Unlimited Explorer licenses (from the unlimited user licenses that come with a core license)
- 10 Creator licenses

Example of completing a migration to core-based licensing

To extend the example above: If the core-based license was then deactivated, the following capabilities would be available:
- No limits on server hardware
- No guest access
- 10 Creator licenses

If you then added 50 Explorer licenses and 200 Viewer licenses, the following capabilities would be available:

- No limits on server hardware
- No guest access
- 10 Creator licenses
- 50 Explorer licenses
- 200 Viewer licenses

Add Users to Tableau Server

You can add users to Tableau Server one at a time or in batches. You can add them to the server as unlicensed users, and then add them to sites and assign site roles as you onboard them to Tableau Server. Or you can add users to sites and specify their site roles at the same time, at which point they are ready to sign in.

The steps below describe how to add an individual user and assign their site role. To add users in batches, you import them, providing Tableau Server with a CSV file that contains rows of users and their attributes. For information, see Import Users and CSV Import File Guidelines.

Considerations for Active Directory authentication

If your Tableau Server is configured for Active Directory authentication, before you add users, review User Management in Active Directory Deployments to understand how multiple domains, domain naming, NetBIOS, and Active Directory user name format influence Tableau user management.

**Note:** If you run Tableau Server on Linux, all external directory communication is configured and managed with a LDAP identity store. In the context of user and group
synchronization, Tableau Server configured with LDAP identity store is equivalent to Active Directory. Active Directory synchronization features in Tableau Server function seamlessly with properly configured LDAP directory solutions.

Adding users at the server level vs. the site level

In a single-site environment, server administrators can add users on the Users page.

After you add a site to Tableau Server, it becomes a multi-site server with a Server Users page (all server users from every site appear here) and a Site Users page. Only server administrators can access the Server Users page, and both site administrators and server administrators can access the Site Users page.
The **Server Users** page is the only place where you can assign users to multiple sites, delete users from the server, and if the server is using local authentication, reset user passwords.

---

### Add a user to the server

1. In the site menu, select **Manage All Sites > Users**, and then click **Add Users**.

To add a user to a site, you select the site and go to the **Users** page.
2. Do one of the following:

- If the server is configured for **local authentication**, click **New User**, and enter a user name. With local authentication, the best way to avoid user name collisions is to provide an email address for the user name. For example, *jsmith@example.com* instead of *jsmith*.

- If the server is configured for **Active Directory authentication**, click **Active Directory User**. If you are adding a user from the same Active Directory domain that Tableau Server runs on, the server domain will be assumed, and you can type the AD user name without the domain.

  **Note**: Do not enter the user’s full name; this can cause errors during the importing process.

3. If the server is using local authentication, provide the following:

- **Display Name**—Type a display name for the user (e.g., *John Smith*).

- **Password**—Type a password for the user.

- **Confirm password**—Retype the password.

- **Email**—This is optional and can be added at a later time in the user profile settings.
• **Selected users are Server Administrators**: Specify whether the user should be a server administrator.

• **Name (Site Membership) / Site Role**: If the user is not a server administrator, you can assign a user to zero or more sites, along with a site role for each site. You do not have to choose site membership and site role at this time. If you don’t specify site membership and site role for a new server user, the user will be added as a server user only, with a site role of Unlicensed. For details, see Set Users’ Site Roles.

4. Click **Create**.
Sign in to Tableau Server Admin Pages

This topic explains how to sign in to the Tableau Server as an administrator. Log onto the Tableau Server admin pages to create and edit sites, users, projects and other content-related tasks.

If you want to sign into Tableau Services Manager (TSM) to configure Tableau Server, see Sign in to Tableau Services Manager Web UI.

If you are running Tableau Desktop and want to sign in to Tableau Server to publish or access content and data sources, see Sign in to Tableau Server in Desktop.

If you want to change server settings such as processor, caching, authentication, distributed deployment, and other related configurations, see Sign in to Tableau Services Manager Web UI.

Here’s how to sign in to the Tableau Server admin pages:

1. Open your browser and enter the server URL. Here are some examples of what the URL might look like:

   http://localhost/ (if you're working directly on the server computer)

   http://MarketingServer/ (if you know the server's name)

   http://10.0.0.2/ (if you know the server's IP address)

   If the server is not using port 80, you need to include the port number in the URL, as in these examples:

   http://localhost:8000/

   http://MarketingServer:8080/

   http://10.0.0.2:8888/

   ... where 8000 or 8080 or 8888 is the port that you configured.
Tableau Server displays a page where you can enter a user name and password:

![Tableau Server login page]

2. Enter the credentials for the server administrator that you created when you finished installing Tableau Server.

You're then taken to the main page of the Default site, and you're ready to create users, sites, and manage content.

**Navigate Server Admin Pages**

As a server administrator, you can access all of the menus and pages in Tableau Server for server and site management. If your server is configured for multiple sites, the site menu is available for navigation. Click **Manage All Sites** in the site menu to access server administration pages.

The server administrator pages include server-wide settings that you will use to configure, monitor, and maintain Tableau Server.
Server Administrator Pages

In a single-site deployment, all server and site menus are available to you in the main menu. To create a site, click Settings > Add a Site.

On a multi-site server, when a site is selected, you will see these menus:

To access server administration pages, click the site menu, and then select Manage All Sites:

On a multi-site server, these are the server administration menus. The site menu text changes to All Sites to let you know you are managing server-wide settings.
To return to the site administration menus, click **All Sites**, and the select the site you want to manage.

Server administrators can:

- Monitor server status and activity.
- Generate log files.
- Add sites and edit site settings. Only server administrators can add sites to the server.
• Add users to the server, and assign users to sites.

• Add and manage site groups.

To manage site-related settings, you must first navigate to a specific site. Within each site, you can:

• Manage content and assign permissions.

• Manage schedules for extract refreshes and subscriptions.

• Monitor site activity and record workbook performance metrics.

• Manage storage space limits for content published by users.

• Allow web authoring.

• Enable revision history.

• Allow site administrators to add and remove users.

• Allow users to subscribe to workbooks and views, and allow content owners to subscribe others to workbooks and views.

• Enable offline snapshots for favorites (iOS only).

Sign in to Tableau Services Manager Web UI

This topic explains how to sign in to the Tableau Services Manager (TSM) web UI. The TSM web pages are used to configure Tableau Server settings such as user authentication, server processes, caching, and other server-related settings. You can also configure TSM from a command line shell. See tsm Command Line Reference.
The TSM web UI is not the same as the Tableau Server admin pages. Log on to the Tableau Server admin pages to create and edit sites, users, projects and other content-related tasks. See Sign in to Tableau Server Admin Pages.

If you are running Tableau Desktop and want to sign in to Tableau Server to publish or access content and data sources, see Sign in to Tableau Server in Desktop.

Requirements

- The account that you use to sign in to TSM must have administrative access to the local computer where Tableau Server is installed.

  Specifically, the account that you use to sign in to TSM must be a member of the `tsadmin` group that was created during initialization. To view the user accounts in the `tsadmin` group, run the following command in the Bash shell:

  `grep tsmadmin /etc/group`

  If the user account is not in the group, run the following command to add the user to the `tsadmin` group:

  `sudo usermod -G tsmadmin -a <username>`

- Specify an HTTPS protocol in the server URL. Tableau Server installs a self-signed certificate as part of the installation process. Therefore, the protocol must be specified as `https`.

- Specify the default port for TSM web UI (8850) in the URL.

- You must specify the hostname or IP address of the computer running TSM. If you have set up a load balancing or proxy solution in front of Tableau Server, do not specify the load balancer or proxy address.
Sign in to the TSM web UI

1. Open a browser and enter the Tableau Server URL, and append the dedicated TSM web UI port.

   Here are some examples of what the URL might look like:

   https://localhost:8850/ (if you're working directly on the server computer)

   https://MarketingServer:8850/ (if you know the server's name)

   https://10.0.0.2:8850/ (if you know the server's IP address)

2. In the sign-in page that appears, enter your administrator user name and password.

   **Note:** Tableau Server creates and configures a self-signed certificate during the installation process. This certificate is used to encrypt traffic to the TSM Web UI. Because it's a self-signed certificate, your browser will not trust it by default. Therefore, your browser will display a warning about the trustworthiness of the certificate.
Manage Sites

Sites Overview

The topics in this section describe the Tableau Server concept of a site and aspects of working with multiple sites. Topics include authentication type each site uses, and what to know about user licenses and administrator-level access to sites.
In this article

- What is a site
- Authentication and sign-in credentials
- The Default site
- Why or why not add sites
- Administrator-level access to sites
- Licensing and user limits
- See also

What is a site

You might be used to using the term site to mean “a collection of connected computers,” or perhaps as the short form of “website.” In Tableau-speak, we use site to mean a collection of users, groups, and content (workbooks, data sources) that’s walled off from any other groups and content on the same instance of Tableau Server. Another way to say this is that Tableau Server supports multi-tenancy by allowing server administrators to create sites on the server for multiple sets of users and content.

All server content is published, accessed, and managed on a per-site basis. Each site has its own URL and its own set of users (although each server user can be added to multiple sites). Each site’s content (projects, workbooks, and data sources) is completely segregated from content on other sites.

Authentication and sign-in credentials

By default, all sites on a server use the same identity store type. You configure these settings when you install Tableau Server. For information, Configure Initial Node Settings.

Users who have access to more than one site on the same Tableau Server instance use the same credentials for each site. For example, if Jane Smith has a user name of jsmith and a
password of *MyPassword* on Site A, she uses those same credentials on Site B. When she signs in to Tableau Server, she’ll be able to choose which site she wants to access.

**The Default site**

Tableau Server installs with a site named Default. If you maintain a single-site environment on Tableau Server, this becomes the site you work with, and on which your users share their Tableau analysis. If you add sites, Default becomes one of the sites you can select when you sign in to Tableau Server. Default differs from sites that you add to the system in the following ways:

- It can never be deleted but, just like sites that you add, it can be renamed.
- It stores the samples and data connections that ship with Tableau Server.
- The URL used for Default does not specify a site. For example, the URL for a view named Profits on a site named Sales is `http://localhost/#/site/sales/views/profits`. The URL for this same view on the Default site would be `http://localhost/#/views/profits`.

**Why or why not add sites**

On Tableau Server, users, projects, groups, data sources, and workbooks are managed per site. You can add users to multiple sites.

Each environment and its needs is unique. However, as a baseline, Tableau Zen Masters and Product Managers tend to recommend using sites for true multi-tenancy needs. In other words, create a new site only when you need to manage a unique set of users and their content completely separately from all other Tableau users and content.

**Examples for which it makes sense to use sites**

- You are a consultant who manages Tableau analysis for multiple clients, and you want to create a site for each client, to ensure that data from one client is not exposed to another.
- You want to allow Guest user access to a small and contained area of the server.
Examples for which projects can work better than sites

- A content-development process in which data sources and reports evolve from sandbox to production phases.

Migrating users and content from one site to another is a laborious process. Although you might have good reasons to use sites for this and similar processes, by creating sites, you as the site administrator compound your ongoing maintenance burden. For each configuration update you make to one site (for example creating new projects and setting permissions), you usually would need to duplicate the same work on each additional site.

- You want to separate areas of the server by functional area.

Among a group of Tableau users, it’s common that some users need to access content in multiple areas. Using sites would encourage publishing the same data sources and reports to multiple sites. This leads to data source proliferation and can negatively impact server performance. Using projects is a simpler way to work with this scenario.

For additional ideas, see the following resources:

- Why use projects in the topic User Projects to Manage Content Access.

- Discussions about sites on the Tableau Community forums. Here’s a link to get you started.

Administrator-level access to sites

Tableau Server includes three administrator-level site roles: Server Administrator, Site Administrator Creator, and Site Administrator Explorer.

The **Server Administrator** site role always takes the highest license available, and it allows full access to Tableau Server, including all content access. You can find more information about this role in Server Administrator Overview. Server administrators also create sites as needed. (Site administrators don’t have permissions to do this.)
A server administrator can assign one of the **Site Administrator** site roles to users to delegate creating and maintaining a specific site’s user and content framework. The content framework enables Tableau users to share, manage, and connect to data sources and workbooks.

- Assign **Site Administrator Creator** to administrators who also connect to data, and create and publish data sources or workbooks. This site role takes a **Creator** license.

- Assign **Site Administrator Explorer** if the user manages the content framework but doesn’t need to edit the content itself. This site role takes an **Explorer** license, and it allows viewing and interacting access.

By default, the Site Administrator site roles allow creating and managing the site’s users and groups, creating projects to organize content on the site, assigning permissions to allow users (groups) to access the content they need, scheduling extract refreshes, and a few other tasks.

A server administrator can deny site administrators’ user management tasks. For example, you might do this if you use the Site Administrator Creator role for the data experts. In other words, you want to allow these users to manage connections to underlying data, create and publish “single source of truth” data sources, create top-level projects, and organize content across projects without restriction; but not necessarily add and remove site users.

For each site the server administrator can also limit site administrator access, so that site administrators can manage groups and content, but not add or remove users or set users’ site roles.

In some organizations, the same person might be both a server administrator and site administrator for one or more sites. Even so, the tasks performed by a site administrator and a server administrator are distinct.

**Licensing and user limits**

You can add server users to multiple sites, and set their site roles and permissions on each site. A user who belongs to several sites does not need a license for each site. Each server
user needs only one license.

Server administrators can use the \textbf{Limit number of users} setting (select \texttt{Site <name> > Settings}) to specify a user limit for the site. Only licensed users are counted. For example, if a site has 90 licensed users (including administrators), 20 unlicensed users, the user count is 90.

\textbf{See also}

- For site administrator recommendations for how to set up users on a site, how to structure a site for publishers and other content users, how to give users permissions to share and manage their content, and so on, see the Manage Sites section.

- For information about how users can get their content to Tableau Server, see \textit{Publish Data Sources and Workbooks} in the Tableau user help.

\section*{Add or Update Sites}

Tableau Server comes with one site named Default. Server administrators can add sites to the server and modify any site’s settings.

\subsection*{Add a site}

1. Do one of the following:

   - If you’re adding a site to the server for the first time, select \texttt{Settings > Add a Site}, and then click \textbf{Add a Site}.
• If you’ve added sites before, in the site menu, click Manage All Sites, and then click New Site.

• If you’re editing an existing site, select it on the Sites page, and then select Edit Settings. Or, in a single-site deployment, click Settings, and then click the General tab.

2. Enter a Site name and Site ID for the site. (If you are editing the Default site, you cannot change the Site ID.)
**Note** The “#/site” portion of the URL (for example, http://localhost/#/site/sales) cannot be changed. In multi-site server environments, these segments appear in the URL for sites other than the Default site.

3. For **Storage**, select either **Server Limit** or **GB**, and enter the number of GB you want as a limit for storage space for published workbooks, extracts, and other data sources.

   **Storage**
   
   How much space is reserved for content published by users.
   
   - [ ] Server limit
   - [ ] **GB**

If you set a server limit and the site exceeds it, publishers will be prevented from uploading new content until the site is under the limit again. Server administrators can track where the site is relative to its limit using the **Max Storage** and **Storage Used** columns on the Sites page.
4. Select whether only server administrators can add and remove users and change their site roles, or whether you want to allow site administrators to manage users on this site.

If you are allowing site administrators to manage users, specify how many users they can add to the site by selecting one of the following:

- **Server limit**: For a server with user-based licensing, the limit is the number of available server seat licenses. For a server with core-based licensing, there is no limit. For more information, see View Server Licenses and Troubleshoot Licensing.

- **<number of> users**: Allows a site administrator to add users up to a limit you specify. See Work with Sites for information on licensing and user limits.

5. Select **Allow users to use web authoring** if you want to enable browser-based authoring for site content.

When web authoring is disabled, users cannot edit published workbooks from the server web environment. To update a workbook published to the server, a Tableau Desktop user must re-publish it. For more information, see Set a Site’s Web Authoring Access.

6. Enable comments so users can share a conversation about data views, including
snapshot images to highlight discoveries. For more information, see Comment on Views in Tableau user Help.

7. Enable data-driven alerts to let users automatically receive emails when data reaches key thresholds. For more information, see Send Data-Driven Alerts in Tableau user Help.

8. Select Allow users to subscribe to workbooks and views to let site users subscribe to views and receive regular emails of them. Select Allow content owners to subscribe other users to workbooks and views to let administrators, project leaders, and content owners set up subscriptions for other users. These options are visible only if you have configured subscription settings.

9. Under Email Settings, you can enter a custom From Address for alerts and subscriptions. While the email address you enter should use valid syntax (such as bizdev@myco.com or noreply@sales), Tableau Server does not require it to correspond to a real email account. (Some SMTP servers may require an actual address, however).

If you want a standard email footer to appear, select Custom footer, and enter the text you want to display above Tableau Server links in email messages.

The email footer will look similar to the following:
10. Enable offline favorites for Tableau Mobile to let mobile users access cached snapshots of views.

11. Select **Record workbook performance metrics** to permit your site users to collect metrics on how workbooks perform, such as how quickly they load.

To initiate recording, users must add a parameter to the workbook’s URL. For more information, see **Create a Performance Recording**.

12. Click **Create** or **Save**.

**Note:** After you add your first site to Tableau Server, the site menu becomes available. When you select **All Sites** and click **Users**, the **Server Users** page appears, showing all users. When you select a specific site and click **Users**, the **Site Users** page appears. To add users to the server or specific sites, see **Manage Users and Groups**.

### Export or Import a Site

You can provision a new Tableau Server site by importing (migrating) information from another site. You do this by exporting the existing site’s (**source** site) information to a file. Then you complete steps to verify and import that information to the **target** site.

**In this article**

**Before you export**
Site migration options

What information is or isn’t preserved in a site export

Prepare the source and target sites

Tips for importing to a target with fewer users or schedules than the source site

### Steps to migrate a site

1. Export a site
2. Generate the import mapping files
3. Verify that site settings are mapped correctly
4. Import the correctly mapped files to the target site

### Site migration options

You can migrate a site in any of these ways:

- To another site on the same Tableau Server instance.
- To a site on a separate Tableau Server instance.
- From Tableau Online to your Tableau Server deployment.

Many of the tips listed in Prepare the source and target sites apply to the Tableau Online-to-Tableau Server migration. However, become familiar with What information is or isn’t preserved in a site export.

**Note:** After you prepare your Tableau Online site for export, contact your Tableau representative. Tableau will complete the export steps, and your rep-
representative will send you the export files, which you can then import to your site on Tableau Server.

- From Tableau Server on Windows to Tableau Server on Linux or vice-versa (or cross-platform Tableau Online-to-Tableau Server site migration).

What information is or isn’t preserved in a site export

The export file you create preserves workbooks, projects, data sources, and users. This includes permissions set on content, user favorites lists, site quota, and other site settings.

Users’ custom views are preserved; however, depending on the type of site migration, custom view URLs might change in a way that breaks users’ bookmarks to their views. For example, migrating from Tableau Online to a self-managed Tableau Server will change the host name and invalidate bookmarks.

In addition:

- When you export a site on Tableau Server to import to another Tableau Server site, subscription and extract refreshes schedules are preserved.

- When you export a Tableau Online site to import to Tableau Server, only the default schedules are preserved.

  On Tableau Online, users can create their own custom subscription schedules. These schedules currently are only supported on Tableau Server version 2018.2 if the administrator has followed the steps provided in Enable Custom Schedules for Subscriptions.

Usage data, which appears in the site’s administrative views, is not preserved. For example, view and data source counts, user actions, and performance data.

In addition, OAuth access tokens embedded in data connections are reset. For those data sources, you will need to edit the connections and re-authenticate to the underlying data.
Prepare the source and target sites

Before you export a site, complete the following checklist to prepare both environments. Some of these instructions depend on whether both sites are on the same server instance or on separate ones.

- **Verify version compatibility**
  To import a site successfully, the source and target sites must be in the same product version family. For example, 2018.2 through 2018.2.x. You cannot import a site that is outside the target site’s version family. For example, 2018.1 to 2018.2. For version information, see the Tableau Release Notes.

- **Identify node**
  The `tsm sites` commands will use your local file store to hold the export and import data. If you are running a multinode Tableau cluster, then you must run the `tsm sites` commands on a Tableau Server that is running the Data Engine process. For information about the Data Engine process and the processes that require it, see Tableau Server Processes.

- **Delete stale content items**
  Make sure the source site contains only what you want to import to the new site. Delete unused workbooks, data sources, or projects.

- **Remove obsolete users**
  Confirm that all server users are licensed, and remove accounts that are no longer in use. You can’t remove users during the import process, so if the two sites are on the same server instance, all users you export from the source site are imported to the target site.

- **Create or identify the target site**
  You must import a site file to a site that already exists on the target Tableau Server instance. Because the import process removes anything from the target site that is not included in the import file, we recommend that you import to an empty site. For more information, see Add or Edit Sites.

**Notes**
• If the target site is not empty, workbooks and data sources with names that are identical on both target and source sites are replaced. This can be verified by the time stamp.

• If your source site has workbooks that use published data sources, the data connections in these workbooks continue to refer to the source site name. To maintain those connections without having to republish the workbooks, make sure the target and source site names match.

• Locate site IDs
The tsm command you use to export or import a site requires a parameter that takes the site ID. You can get the site ID from the URL when you’re signed in to the site from a web browser.

If only one site exists on the server, that site is named Default. When you’re signed in to the Default site, the browser URL looks something like this:

https://server-name/#/projects

In the URL, the absence of the /site parameter indicates that it’s the Default site. The site ID for the Default site is "Default" without the quotation marks.

On a multi-site Tableau Server deployment, the browser URL includes #/site/ followed by the site ID. The following URL would appear if you navigate to the Views page on a site whose site ID is finance:

https://localhost/#/site/finance/views

• Check user authentication
You can export from and import to sites that do not use the same user authentication method, but you will need to modify the mapping files used for the import. This step is built into the import process and described in 3. Verify that site settings are mapped correctly.
• **Create users on the target server if necessary**

The site import process assigns users to the target site. If the source site is on Tableau Online or on a Tableau Server instance other than the target site, you must create users on the target server before you can perform the import. If the two sites are on the same Tableau Server instance, the target site has access to the existing users, and you can skip this step.

User names are stored differently in Tableau Online, so when you export a Tableau Online site, you must edit the user-specific mapping file as part of the verification steps.

• **Configure the target server to deliver subscriptions**

Subscriptions are imported, but you must configure the server to deliver them.

For more information, see Set Up a Server for Subscriptions.

• **Check schedules**

The Schedules page lists the existing schedules for extract refreshes and subscriptions.

For migrations from one Tableau Server site to another, refreshes and subscriptions assigned to default schedules on the source site are mapped to the same schedules on the target site.

If the source site has schedules that do not exist on the target site, and the target site is on another Tableau Server instance, you must create the schedules on the target site that you
want the source schedules to map to. You can edit the mapping files to make sure this is done as you expect.

For migrations from Tableau Online to Tableau Server, custom subscription schedules that users create are not mapped. Before you contact Tableau to request your site export, remove these custom schedules.

To remove them, go to Tasks > Subscriptions, and select the check boxes for the custom subscriptions. Then, on the Actions menu, select Unsubscribe.

Tips for importing to a target with fewer users or schedules than the source site

When a target site has fewer users or schedules than the source site, many-to-one importing is not supported. How you can address this depends on whether the source and target sites are on the same Tableau Server instance.

Note: Subscription schedule information in this section does not apply to Tableau Online-to-Tableau Server site migration.

You can take any of the following approaches that apply to your situation:

- Remove extra users or schedules from the source site before you export.

  This is the preferred option if the two sites are on the same server instance.
• Add missing users or schedules to the target site before beginning the import.
  
  This is required if the target site is on another server instance.

• Add the missing users or schedules to the target site in the middle of the import process and manually update the mapping files.
  
  This is an option only if the sites are on the same instance.

• Manually map the users or schedules to different users and schedules in the target site during the import process.
  
  This is required if a user name differs between servers—for example, the exported user named adavis@company.com is defined on the target site as davisa.

1. Export a site

On the Tableau Server machine, type the following command:

```bash
tsm sites export --site-id <source-siteID> --file <filename>
```

Tableau Server must be running when you use the export command. During the export process, Tableau Server locks the site you’re exporting.

For example, to export a site with site ID weather-data to the file export-file.zip, type the following:

```bash
tsm sites export --site-id weather-data --file export-file
```

By default, Tableau Server saves <export-file>.zip to /var/opt/tableau/tableau_server/data/tabsvc/files/siteexports. For more information, see tsm File Paths.

2. Generate the import mapping files

To generate import files for the target site, you need the .zip file you created when you completed the steps in 1. Export a site.
1. On the Tableau Server machine, copy the exported .zip file to the directory Tableau
   Server expects to find the files for importing. For example:

   /var/opt/tableau/tableau_server-
   /data/tabsvc/files/siteimports

2. Run the following command (Tableau Server must be running):

   tsm sites import --site-id <target-siteID> --file <export-
   file.zip>

   This command generates a set of .csv files that show how source site settings will
   map to the target site. In the steps described in the next section of this article, you con-
   firm these mappings and adjust them where needed.

   By default these .csv files are generated to a mappings directory created under
   siteimports. For example:

   /var/opt/tableau/tableau_server-
   /data/tabsvc/files/siteimports/working/import_<id>_<date-
   time>/mappings

   For more information, see tsm File Paths.

3. Verify that site settings are mapped correctly

   The .csv files you generated in the previous section describe how the source site’s resources
   will be assigned to the target site when the import is complete. Items in the files that Tableau
   Server was unable to map, and that you need to edit, are indicated by a series of question
   marks (???). Before you can complete the import process, you must replace the question
   marks with valid assignments on the target site.

   **Important:** Some requirements apply to mapping users, schedules, and published con-
   tent resources, particularly when the source and target sites are on separate Tableau
Server instances. For more information, see Prepare the source and target sites earlier in this article.

To verify mapping files

1. Navigate to the directory that contains the .csv map files generated by the `tsm sites import` command. By default:

```
/var/opt/tableau/tableau_server-
data/tabsvc/files/siteimports/working/import_<id>_<date-time>/mappings
```

2. Use your preferred text editor to open one of the .csv files in the `mappings` directory, and do the following.

   a. Confirm that the mappings are correct.

   b. If an entry shows a series of question marks (???) , replace them with a valid value.

      For descriptions of the settings in each of these files, use the tables in Mapping file content reference later in this article.

   c. Save the changes and preserve the CSV file formatting.

Repeat this process for the remaining .csv files.

4. Import the correctly mapped files to the target site

After you verify the site mappings in the .csv files, you can import the settings to the new site to complete the migration process.

1. Run the following command:

```
  tsm sites import-verified --import-job-dir <import-id-directory> --site-id <target-siteID>
```
For example:

tsm sites import-verified --import-job-dir /var/-
opt/tableau/tableau_server-
data/tabsvc/files/siteimports/working/import_ff00_2018010222014457
--site-id new-site

2. When the success message appears, sign in to the new site and confirm that everything was imported as you expected.

**Note:** The `tsm sites import` and `tsm sites export` commands can leave a site in a locked state if an error occurs. To unlock a site, use the `tsm sites unlock` command.

**Mapping file content reference**

The following tables list the columns in each of the mapping files created when you run the `tsm site import` command.

CSV file name: mappingsDomainMapperForGroups

<table>
<thead>
<tr>
<th>Column title</th>
<th>Can it be edited?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source_name</td>
<td>No</td>
<td>A user group name on the source site.</td>
</tr>
<tr>
<td>source_domain_name</td>
<td>No</td>
<td>The user authentication type on the source site: either local (for local authentication) or a domain name (for Active Directory).</td>
</tr>
<tr>
<td>target_domain_name</td>
<td>Yes*</td>
<td>The user authentication type on the target site: either local for local authentication, or a domain name (such as example.com or</td>
</tr>
</tbody>
</table>
example.lan) for Active Directory.

*For the All Users group, keep the target\_domain\_name value set to local, even if your target server is configured for Active Directory user authentication. The All Users group is a special default user group that must exist on every Tableau Server.

CSV file name: mappingsScheduleMapper

<table>
<thead>
<tr>
<th>Column title</th>
<th>Can it be edited?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source_name</td>
<td>No</td>
<td>The names of custom and default extract or subscription schedules on the source site.</td>
</tr>
<tr>
<td>source_scheduled_action_type</td>
<td>No</td>
<td>The type of schedule, either Refresh Extract, for extract refreshes, or Subscriptions, for subscription deliveries on the source site.</td>
</tr>
<tr>
<td>target_name</td>
<td>Yes</td>
<td>The names of custom schedules on the target site. You can edit this value. For example, if the schedule is named Friday Update on the source site you can rename it Friday Refresh on the target site.</td>
</tr>
<tr>
<td>target_scheduled_action_type</td>
<td>No*</td>
<td>The type of schedule, either Refresh Extract, for extract refreshes, or Subscriptions, for subscription deliveries on the target site.</td>
</tr>
</tbody>
</table>

*In the rare case that you see question
marks (???) in this column, replace them with either **Refresh Extract** or **Subscriptions**, to match the entry you see under **source_scheduled_action_type**.

CSV file name: mappingsSiteMapper

<table>
<thead>
<tr>
<th>Column title</th>
<th>Can it be edited?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source_url_namespace</td>
<td>No</td>
<td>The site ID of the source site.</td>
</tr>
<tr>
<td>target_url_namespace</td>
<td>No</td>
<td>The site ID of the target site.</td>
</tr>
</tbody>
</table>

CSV file name: mappingsSystemUserNameMapper

<table>
<thead>
<tr>
<th>Column title</th>
<th>Can it be edited?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source_name</td>
<td>No</td>
<td>The user name attribute of a user on the source site.</td>
</tr>
<tr>
<td>source_domain_name</td>
<td>No</td>
<td>The user authentication type on the source site: <strong>local</strong>, for local authentication, a domain name (such as example.com) for Active Directory, or <strong>external</strong> (for a Tableau Online site).</td>
</tr>
<tr>
<td>target_name</td>
<td>Yes</td>
<td>The user name attribute for users who will be assigned to the target site upon import.</td>
</tr>
</tbody>
</table>

Confirm that all the user names in the list exist on the target server, and replace question marks (???) with user names that exist on the target server.
You cannot create user names by adding rows to the CSV file. Similarly, you cannot remove user names by deleting rows.

You can edit a user name in the `target_name` column to be different from its source user name, as long as the user already exists on the target server with that name.

For example, a user can have a `source_name` value of `agarcia@company.com` and a `target_name` value of `ashleygarcia@company.com`.

You can map a user on the source site to only one user name on the target site.

<table>
<thead>
<tr>
<th>target_domain_name</th>
<th>Yes</th>
</tr>
</thead>
<tbody>
<tr>
<td>The user authentication type on the target site: either <code>local</code>, for Local Authentication, or a domain name (such as example.com) for Active Directory.</td>
<td></td>
</tr>
</tbody>
</table>

CSV file name: MappingsScheduleRecurrenceMapperWithAutoCreation

This file does not require updates.

**Delete Sites**

Server administrators can delete sites that have been added to Tableau Server. Deleting a site also removes workbooks and data sources that were published to the site, as well as users. If a user belongs to additional sites, they will not be removed. To permanently delete a user, go to the Server Users page.
1. On the site menu, click **Manage All Sites**, and then click **Sites**.

2. Select the site you want to remove, and click **Delete**.

3. Click **Delete** in the confirmation dialog box that appears.

**Site Availability**

A site can become suspended or locked due to a site import failure, or because a server administrator chooses to suspend the site for a period of time.

When a site is suspended, only the server administrator can activate the site to make it available again.

**Note:** If a site becomes locked and you cannot access the Sites page through the Server interface, use the tsm sites unlock command to change the state to active.
To activate or suspend a site

1. In the site menu, click Manage All Sites, and then click Sites.

2. Select the site, and then select Actions > Activate or Suspend.

Allow Users to Save Revision History

Revision history enables your users to see how workbooks and data sources (content resources) have changed over time. Each time someone saves (publishes) a content resource, Tableau Server creates a new version, which becomes the current version. It makes the previous version the most recent revision in the revision history list. Revision history gives users confidence to experiment with their content, knowing that their older versions are available.

Notes

- This information applies to Tableau Server, and is for server administrators who want to allow publishers to work with revisions.
On Tableau Online, workbook revision history (and not data source revision history) is enabled on all sites. Users can save up to 10 revisions.

For information about working with the content revisions themselves, including potential issues, see Work with Content Revisions in the User/Analyst section of the Tableau help.

Permissions users need to work with revision history

To access revision history, a user must have a site role of Creator or Explorer (Can Publish), plus the following permissions, depending on the content type:

- Project: View and Save
- Workbooks in the project: View, Save, and Download Workbook/Save As
- Data sources in the project: View, Save, and Download Data Source

Enable revision history and set the number of revisions allowed

Revision history is set at the site level, and is enabled by default, with a limit of 25 revisions for each content resource.

1. Sign in to a site as a Server Administrator, and click Settings.
2. Under Revision History, select Save a history of revisions, and enter the maximum number of revisions you want to allow for each content resource.
3. Click Save.

When you lower the number of revisions, the most recent revisions are saved. For example, if you set the limit to 15, the 15 most recent versions of the workbook or data source are saved.

Note: A content resource's revision history list might not show the changes to the limit until a background cleanup process runs on the server.
Clear all revisions

Server administrators can delete all previous revisions of published workbooks and data sources from a site. The most recent version of each published workbook and data source is always retained.

1. Sign in to a site as a Server Administrator, and click Settings.
2. Under Revision History, click Clear Revision History.
3. Click Save.

Security for previewing and restoring workbooks

When users select Restore or Preview for workbook revisions, user passwords are exchanged between the user’s browser and the server. Tableau Server encrypts these passwords using public/private key encryption. To ensure these public keys are provided by Tableau Server, you must configure the server to use SSL (https). For more information, see SSL.

Potential revision history issues in the User/Analyst section of the Tableau help.

Customize a Site

You can customize how a site on Tableau Server looks to personalize it for your company or group. You can perform these customizations:

- Change the server name that appears in the browser tab, tooltips, and messages.
- Change the logos that appear in the web environment.

  For more information, see tsm customize.
- Set the language used for the web environment and the locale used for views. See
Language and Locale for Tableau Server.

- Install custom fonts on Tableau Server and client computers that connect to Tableau Server. See Use Custom Fonts in Tableau Server.

Administrators and project leaders can also add images for projects in thumbnail view.

Language and Locale for Tableau Server

Tableau Server is localized into several languages. Server language and locale settings impact how this affects users. The **Language** setting controls user interface (UI) items such as menus and messages. The **Locale** setting controls items in views such as number formatting and currency.

Administrators can configure language and locale on a server-wide basis and individual users can configure their own settings (search for "Your Account Settings" in the Tableau Server Help). If a user configures their own language and locale, their settings override the server settings.

Supported Languages

Tableau Server is localized into several languages. See the "Internationalization" section of the [Tableau Server Technical Specification](#) page for more information.

Default Settings

The default language for Tableau Server is determined during Setup. If the host computer is configured for a language Tableau Server supports, Tableau Server installs with that language as its default. If computer is configured for a language that is not supported, Tableau Server installs with English as its default language.

How Language and Locale are Determined

Another influence on which language and locale display when a user clicks a view is the user’s web browser. If a server user has not specified a **Language** setting on their User Account page, and their web browser is set to a language that Tableau Server supports, the browser’s language will be used—even if Tableau Server itself is set to a different language.
Here’s an example: Assume that Tableau Server has a system-wide setting of English as the Language for all users. Server user Claude does not have a language specified on his Tableau Server User Account page. Claude’s browser uses German (Germany) for its language/locale.

When Claude signs in to Tableau Server, the server UI displays in German and when he clicks a view, the view uses the Germany locale for numbers and currency. If Claude had set his user account Language and Locale to French (France), the UI and view would have been displayed in French. His user account setting supersedes those of his web browser, and both of those have precedence over the Tableau Server system-wide setting.

Another setting to be aware of is the Locale setting in Tableau Desktop (File > Workbook Locale). This setting determines the locale of the data in the view, such as which currency is listed or how numbers are formatted. By default, Locale in Tableau Desktop is set to Automatic. However, an author can override that by selecting a specific locale. Using the above example, if the author of View A set Locale to Greek (Greece), certain aspects of the data in View A would display using the Greek (Greece) locale.

Tableau Server uses these settings, in this order of precedence, to determine language and locale:

1. Workbook locale (set in Tableau Desktop)
2. Tableau Server User Account language/locale settings
3. Web browser language/locale
4. Tableau Server Maintenance page language/locale settings
5. Host computer’s language/locale settings

Use Custom Fonts in Tableau Server

You can use custom fonts with Tableau Server. When you do this the safest way to guarantee that users have the experience you intend is to keep the following in mind:
• The fonts need to be installed on the computer where Tableau Server is running.

• The fonts need to be installed on any client computers that will connect to Tableau Server. You need to have the fonts installed locally in order for your browser to properly display them.

• As a best practice, use "web safe" fonts that are installed by default on all major browsers. This increases the likelihood that the fonts will display properly on client machines.

• Different browsers render the same fonts differently, so even when a client browser has the custom font installed, it may look different when viewed in different browsers. This can be especially noticeable with comments or titles where specific spacing is used for an intentional effect.

Note: For more information about installing fonts on Linux, refer to your Linux distribution's documentation and support.

Extract Refresh Schedules

Tableau Desktop authors and data stewards can create and publish extracts. Extracts are copies or subsets of the original data. Because extracts are imported into the data engine, workbooks that connect to extracts generally perform faster than those that connect to live data. Extracts can also increase functionality.

Before refreshing extracts

When an extract refresh is performed on extracts created in Tableau 10.4 and earlier (that is, a .tde extract), the extract is upgraded to .hyper extract automatically. While there are many benefits of upgrading to a .hyper extract, you will be unable to open the extract with previous versions of Tableau Desktop. For more information, see Extract Upgrade to .hyper Format.
Setting up refresh schedules

As a server administrator, you can enable scheduling for extract refresh tasks, and then create, change, and reassign schedules. General scheduling options you change on the server are available as part of the publishing process when a Tableau Desktop user publishes an extract.

Schedules that you create have the following options:

**Priority**

The priority determines the order in which refresh tasks are run, where 0 is the highest priority and 100 is the lowest priority. The priority is set to 50 by default.

**Execution mode**

The execution mode indicates to the Tableau Server backgrounder processes whether to run refreshes in parallel or serially. Schedules that run in parallel use all available backgrounder processes, even if the schedule contains only one refresh task. Serial schedules run on only one backgrounder process.

By default, the execution mode is set to parallel, so that refresh tasks finish as quickly as possible. You might want to set the execution mode to serial (and set a lower priority) if you have a very large schedule that prevents other schedules from running.

**Frequency**

You can set the frequency to hourly, daily, weekly, or monthly.

For information, see Create or Modify a Schedule.

**Refreshing extracts manually**

In the Tableau Server web environment, both server and site administrators can run extract refreshes on-demand on the Schedules page:

- Select the schedule and click **Actions > Run Now**.
You can also refresh extracts from the command line using the tabcmd refreshextracts command. For more information, see tabcmd Commands.

Refreshing extracts from Tableau Desktop

Tableau Desktop users can refresh extracts they publish and own. They can do this the following ways:

- **At publish time:** When an author publishes a workbook or data source that uses an extract, that author can add it to server refresh schedule. The refresh can be a full or an incremental refresh.

  Incremental refreshes reference a column in the extract that has a data type of date, date/time, or integer; such as a timestamp. Tableau uses this column to identify new rows that need to be added to the extract. For more information, see Refreshing Extracts and Schedule Extract Refreshes as You Publish a Workbook in the Tableau Help.

- **User interface:** In Tableau Desktop, you can use the Refresh from Source, Add Data From File, and Add Data From Data Source commands to upload an addition to or refresh an extract on Tableau Server. A user might want to do this if Tableau Server doesn’t have sufficient credentials to access the underlying data. For more information, see Updating Extracts on Tableau Server in the Tableau Help.

- **Data Extract command line utility:** The Data Extract command line utility installs with Tableau Desktop. You can use it to append to or refresh a published extract. For more information, see Tableau Data Extract Command Line Utility in the Tableau Help.

Enable Extract Refresh Scheduling and Failure Notification

Automate Refresh Tasks
Enable Extract Refresh Scheduling and Failure Notification

Before your publishers can schedule extract refreshes, you must enable scheduling on the server.

While you’re enabling scheduling, you can decide whether also to enable sending email to owners of data sources or workbooks that are refreshed when those extract refreshes do not complete successfully. You can read more about these emails below. When you enable refresh failure notification, the owners of the content that has scheduled refreshes can opt out individually by changing their account settings.

1. Sign in as a server administrator, and select Settings.

2. On the General page, do the following:

   • Under Refresh Failure Notifications, select Send email to data source and workbook owners when scheduled refreshes fail.

     To clarify, if a scheduled refresh for a particular data source fails, the email goes only to the owner of that data source, not to owners of workbooks that connect to that data source.

   • Under Embedded Credentials, select both options to let publishers embed credentials and schedule extract refreshes. (Automatic refresh schedules require embedded credentials so Tableau Server can directly access data.)

   Note: On a multi-site server, failure notifications are a site setting, and embedded credentials are a server setting.

Managing schedules from the server

In your organization it might be more appropriate to manage embedded credentials and refresh schedules centrally from the server. If you do that, you might clear the check boxes in
the Embedded Credentials section described in the steps above, so that Tableau Desktop publishers do not see schedule options during publishing.

Managing schedules centrally enables you to distribute extract refresh and subscription tasks, so you can run them when most people are offline. It also enables you to oversee which credentials are embedded in connections.

For more guidelines for managing schedules and refreshes on the server, see Provide access to data sources and Keep data fresh in Everybody’s Install Guide.

How refresh failure emails work

The email notification for a failed extract refresh lists the extract name and location on the server, gives the time of last successful refresh, the number of consecutive times the refresh has failed, and suggests the reason for the failure and possible solution.

After five consecutive failures, the refresh schedule is suspended until you or the data owner takes an action to address the cause of the failure, such as updating database credentials or a path to the original data file.

How the last successful refresh date is determined

The last successful refresh date and time are shown when that last refresh occurred within a number of days. By default it is 14 days, and this value is set in wgserv-er.alerts.observed_days. If the number of days since the last successful refresh exceeds the number specified in this setting, the message in the email shows “not in the last N days.”

Create or Modify a Schedule

The Schedules page shows a list of schedules, including their name, type, what they’re for (scope), number of tasks, behavior (concurrent or serial processing), and when they are scheduled to run.
Note: If you enable custom schedules for subscriptions on one or more sites, users will control schedules for their subscriptions on those sites. To learn more, see Enable Custom Schedules for Subscriptions.

To create a new schedule

1. In a site, click Schedules.

2. Click New Schedule.

3. Specify a descriptive Name for the schedule. For example, End of week.

4. Select a Task type the schedule will handle—either refreshing extracts or delivering subscriptions.
5. Optionally you can define a **Default Priority** from 1 to 100, where 1 is the highest priority. This is the priority that will be assigned to the tasks by default. If two tasks are pending in the queue, the one with the higher priority runs first.

6. Choose whether a schedule will run in parallel or serially. Schedules that run in parallel run on all available backgrounder processes so that they can complete faster.

7. Finish defining the schedule. You can define an hourly, daily, weekly, or monthly schedule.
8. Click **Create**.

To modify an existing schedule

1. Navigate to the Schedules page.

2. Select an existing schedule, click the Actions drop-down arrow, and then select **Edit Settings**.
3. Finish editing the schedule, and click **Save**.

Manage Refresh Tasks

Extract Refresh Schedules

**Enable Custom Schedules for Subscriptions**

Custom schedules for subscriptions allow users to receive email messages on a schedule that they define, rather than using a fixed schedule defined by a server administrator. Custom schedules for subscriptions have been available to users of Tableau Online since March 2017, and these schedules can now be enabled on a per-site basis in Tableau Server version 2018.2. Enabling custom schedules for subscriptions is a permanent change on any sites where you make this change. Any sites where you don’t enable custom schedules remain on fixed schedules defined by a server administrator.

**Enable custom schedules**

Before you can enable custom schedules on one or more sites, you must first enable custom schedules on Tableau Server, and then enable custom schedules on one or more sites on
that server. To learn more about enabling subscriptions on Tableau Server, see Set Up a Server for Subscriptions.

Step 1: Enable custom schedules on Tableau Server

From a command prompt with Tableau administrator permissions, run the following commands:

```bash
tsm configuration set -k features.SelfServiceSchedules -v true
tsm pending-changes apply
```

This operation will restart Tableau Server.

Step 2: Enable custom schedules on a site

1. Log in to Tableau Server as a server administrator using a web browser:

   https://<hostname>/#/login

2. Browse to the Site Settings page for a site, and then enable custom schedules:

   1. Click All Sites, and then choose one of the sites from the drop-down list.
   2. Click Settings.
   3. On the General tab, under Subscriptions, select the following checkbox: Permanently convert from fixed schedules created by administrators to custom schedules created by users. (You can't undo this).
   4. Click Save.

When custom schedules are enabled on a site, all fixed schedules with a subscription are converted to an equivalent custom schedule.

How Scheduled Server Tasks are Prioritized

When processing scheduled extract refreshes and subscriptions, Tableau Server prioritizes background tasks in this order:

1. Any task already in process is completed first.

2. Any task that you initiate manually using Run now starts when the next backgrounder
process becomes available.

3. Tasks with the highest priority (the lowest number) start next, independent of how long they have been in the queue.

For example, a task with a priority of 20 will run before a task with a priority of 50, even if the second task has been waiting longer. To change task priority, see Create or Modify a Schedule.

4. Tasks with the same priority are executed in the order they were added to the queue. The first task added to the queue starts first; then the second task starts.

5. When multiple tasks with the same priority are scheduled to run at the same time, they start in the order they were created or enabled. Tasks scheduled for the same time are executed by job type with the fastest category of jobs starting first: subscriptions, then incremental extracts, then full extracts.

The following limitations also impact scheduled tasks:

- The number of concurrent tasks is limited to the number of backgrounder processes you have configured for Tableau Server.
- Separate refreshes for the same extract cannot run at the same time.
- Tasks associated with a schedule that is set to run serially run one at a time.

Configure Workbook Performance after a Scheduled Refresh

To improve the load times for workbooks, Tableau Server caches the results of queries included in workbooks. For most workbooks, query results are computed and cached when they are first viewed by a user on Tableau Server. However, for workbooks that connect to data extracts, Tableau Server can recompute query results when the corresponding extract refresh tasks run. This reduces the load time for these workbooks when they are first viewed, so this option is turned on by default for workbooks that have been viewed recently.
Determine the performance impact

Although this option reduces the initial load time for workbooks, recomputing query results also increases the load on Tableau Server. If your Tableau Server installation is already performance-constrained, you might want to turn this option off or lower the threshold for workbook caching.

Here are some possible reasons why you might want to turn this option off or lower the threshold:

- The Background Tasks for Non Extracts administrative view displays many long-running jobs in the **Warming up external query cache on data change** category.
- The Background Task Delay administrative view displays long delays.
- CPU and memory consumption for the backgrounder processes is consistently high.

However, note that this is only one of the options that impacts the performance of background tasks. For more information about performance, see Performance.

Turn off workbook caching for the server

To decrease the load on Tableau Server, you can turn off workbook caching after a scheduled refresh at the server-level. If you turn this option off, Tableau Server caches query results for workbooks the first time the workbooks are viewed.

Use the following tsm configuration set option to turn off workbook caching after a scheduled refresh:

```
backgrounder.externalquerycachewarmup.enabled
```

For more information on how to use and apply tsm set options, see tsm configuration set Options.
Turn off workbook caching for a site

You can also turn off workbook caching after a scheduled refresh for an individual site. For example, you might do this if there is one site in particular that contains many slow workbooks which increase load on the server.

1. Select the site for which you want to turn off workbook caching in the sites drop-down.
2. Click Settings.
3. In the Workbook Performance after a Scheduled Refresh section, clear the check box.

**Note:** Although this option is available in the settings for an individual site, you must have server administrator permissions to view it.

Configure the workbook caching threshold

Tableau Server only recomputes query results for workbooks that both have scheduled refresh tasks and have been viewed recently.

You can increase or decrease the number of workbooks that are cached after a scheduled refresh with the following tsm configuration set option:

```
backgrounder.externalquerycachewarmup.view_threshold
```

By default, the threshold is set to 2.0. The threshold is equal to the number of views that a workbook has received in the past seven days divided by the number of refreshes scheduled in the next seven days. (If a workbook has not been viewed in the past seven days, it is unlikely that it will be viewed soon, so Tableau Server does not spend resources recomputing queries for the workbook.)
Ensure Access to Subscriptions and Data-Driven Alerts

To ensure that users see the Subscribe and Alert buttons in the Tableau Server toolbar and can receive related emails, do the following:

- **Ensure that users have an email address in Tableau Server**: Users can update their email address on their account settings page.

- **Embed database credentials or don't require them**: To email data in a view, Tableau Server needs to access the data without user involvement. This can be accomplished by using a workbook with embedded database credentials, a Tableau Server data source, or data that doesn't require credentials (such as a file that's included with the workbook at publish time).

- **Ensure that users can access needed workbooks and views**: Access to content on the server is controlled by the View permission. To receive images of content in email messages, users also need the Download Image/PDF permission. For more information, see View or Edit Permissions.

- **Avoid trusted authentication for embedded views**: If you use restricted tickets (the default) to render an embedded view, the Subscribe and Alert buttons don’t appear.

Set Up a Server for Subscriptions

When users subscribe to a workbook or view, a snapshot of the view is email to them on scheduled basis, so they can see the latest updates without having to sign into Tableau Server. Administrators, project leaders with appropriate site roles, and content owners have the option to subscribe other users to workbooks and views. For more information, see **Subscribe to Views**.

**Note:** To create and receive subscriptions, users need access to related databases and views. See this list of requirements for details.
In this article

- Configure the server to send subscription emails
- Enable subscriptions in a site
- Test subscriptions in a site
- Manage all user subscriptions

Configure the server to send subscription emails

1. Configure SMTP Setup
2. Configure Server Event Notification

Enable subscriptions in a site

As an administrator, you decide which sites allow subscriptions.

1. At the top of the browser window, click **Settings**.
2. Select **Allow users to subscribe to workbooks and views**.
3. Optionally, select **Allow content owners to subscribe other users to workbooks and sheets**, or enter an email "From" address and message footer.

   A site's "From" address and message footer are also used in emails for data-driven alerts.
4. Click **Save**.

To specify the subscription schedules available to users, see **Create or Modify a Schedule**.
Test subscriptions in a site

1. **Subscribe to a view.**

2. At the top the browser window, click **Schedules.**

3. Select the schedule you chose for the subscription, and then click **Actions > Run Now.**

   A snapshot of the view should be emailed to you within 10 minutes. If you experience an issue, see Troubleshoot Subscriptions.

Manage all user subscriptions

1. At the top the browser window, click **Tasks,** and then click **Subscriptions.**

   All user subscriptions for the current site appear, including information like subscriber name, view name, and delivery schedule.

2. Select any subscription you want to update. From the **Actions** menu, select **Change Schedule, Change Subject, Change Empty View Mode,** or **Unsubscribe.**
(The empty-view option sends subscription emails only when data exists in a view. It's a good choice for high-priority alerts.)

Project-level administration to learn which site roles allow full Project Leader capabilities.

Set Up a Server for Data-Driven Alerts

When data reaches important thresholds for your business, data-driven alerts automatically send email notifications to key people users specify. As a Tableau Server administrator, you set up data-driven alerts much like you do subscriptions. For information about how users create and manage these alerts, see Send Data-Driven Alerts in Tableau User Help.

**Note:** To create and receive data-driven alerts, users need access to related databases and views. See this list of requirements for details. If alerts are enabled for a site, any user on that site can create them.

In this article

- Configure email for data-driven alerts
- Manage all data-driven alerts in a site
- Disable data-driven alerts for a site
- Control how often the server checks data-driven alerts
- Track the server's alert-checking process
- Identify and fix failing alerts
Configure email for data-driven alerts

1. Complete the steps in Configure SMTP Setup so the server can send email.

2. While viewing a site, click **Settings** at the top of the browser window.

3. Under Email Settings, enter a site-specific "From" address or message footer.

   A site's "From" address and message footer are also used in emails for subscriptions.

4. Click **Save**.

Manage all data-driven alerts in a site

1. At the top the browser window, click **Tasks**, and then click **Alerts**.

2. Select any alerts you want to update.

3. From the **Actions** menu, do any of the following:

   - Add or remove yourself as a recipient.
   - Edit alerts to change data thresholds, delivery schedules, and the full list of recipients.
   - Change alert ownership to different users, or delete alerts.

Disable data-driven alerts for a site

Data-driven alerts are supported for all sites by default, but administrators can disable them for specific ones.

1. While viewing a site, click **Settings** at the top of the browser window.

2. Under Data-Driven Alerts, uncheck **Let users create alerts and receive alert emails**.

3. Click **Save**.
Tip: To entirely disable data-driven alerts at the server level, change the `tsm configuration set` option, "features.AlertOnThresholdCondition", to false.

Control how often the server checks data-driven alerts

By default, Tableau Server checks every 60 minutes to confirm whether data conditions for alerts are true. If you notice performance impacts, you can customize this time interval with the `tsm configuration set` option, "dataAlerts.checkIntervalInMinutes".

Regardless of the `dataAlerts.checkIntervalInMinutes` setting, the server also checks alerts whenever extracts in the related workbook are refreshed. To check an alert more frequently than the setting specifies, change the extract-refresh schedule.

Track the server’s alert-checking process

In the Background Tasks for Non Extracts view, you can track the server’s alert-checking process by looking for these tasks:

- Find Data Alerts to Check

- Check If Data Alert Condition Is True

The "Find" task limits "Check" tasks to alerts that can currently send related emails. For example, if a user has chosen an email frequency of "Daily at most", after the alert condition becomes true, the server waits 24 hours before checking the alert again.

Each "Check" task uses one server backgrounder process, loading the related view to evaluate the alert condition. If all users see the same version of a view, it loads only once. But if users have applied filters to a view, or the data they see is limited by user-level security, the view loads once for each recipient.

Identify and fix failing alerts

As an administrator, you can proactively identify failing alerts that users may be unaware of. To check:
1. Select Status in your site menu
2. Select Background tasks for non-extracts
3. From the Task drop-down menu, select Check if Data Alert is True
4. In the far right, click on Error to see a list of failing alerts
5. Hover over the red failure icon to display a tooltip with alert details

To determine the alert owner, look for the alert ID number in the data_alerts table of the Tableau Server Repository. (In the alert management area of a site, you can also look for the alert name following the number, but be aware that multiple different alerts may use the same name.)

**Note:** Starting in Tableau Server 2018.1, alert owners will be automatically notified when an alerts fails ten times. Administrators can customize when alert owners receive notifications. Administrators can configure Users will not be notified for alerts that failed prior to upgrading to Tableau Server 2018.1.

<table>
<thead>
<tr>
<th>Check data alert</th>
</tr>
</thead>
<tbody>
<tr>
<td>Task ID: <strong>1157751</strong></td>

</tr>
</tbody>
</table>

Data Alert Id: 169 - Stock Summary - ‘AVG(Price)’ is above 100
Evaluated for 0 recipients out of 1
Evaluated true for 0 recipients
Failing alerts are often caused by content changes on Tableau Server. Encourage users to recreate alerts if changes like the following occur:

- A workbook, view, or data field is removed or renamed.
- Database credentials embedded in workbooks expire. (Alerts require workbooks to use either embedded credentials, or none at all.)
- A data source becomes inaccessible.

**Tip:** To automatically get emailed when alerts fail, follow the steps in Collect Data with the Tableau Server Repository, and connect to the "background_jobs" table. From that table, create a custom view that includes the "Check If Data Alert Condition Is True" job name and its finish code. Then set up a data-driven alert to email you whenever a finish code equals 1 (failure).

**Administrative Views**

The Status page contains an embedded Tableau workbook with various administrative views. These views help you to monitor different types of server or site activity.

- Shows server and site activity for Tableau Server.
- Shows site activity for Tableau Online.

**Note:** You must install PostgreSQL drivers before you can see Administrative views. For more information, see Database Drivers.

**Navigating to administrative views**

To see administrative views, click **Status**. Site administrators can see administrative views for their site. Administrators of multiple sites can see views for the current site.
On a multi-site server, server administrators can see views for the entire server. Click the site menu, and then click **Manage All Sites** to access the server menus.

To see views for individual sites on a multi-site server, click the site menu, select the site name, and then click **Status**.

### Pre-built Administrative Views

Administrative views are powerful monitoring tools that can help you optimize Tableau Server and better understand how your users are interacting with Tableau content. The administrative views listed to the right are included with Tableau Server. Click on the link for a view to learn more about how to interpret and act on the information the view provides.

To create your own administrative view, see Create Custom Administrative Views.

### Performance of Views

**Note:** This view is only available to server administrators. For information about how to navigate to administrative views, see Administrative Views.

The Performance of Views administrative view displays how long it takes for views to load and how many sessions are running at a time on the server.
You can compare spikes in the number of sessions with spikes in slow load times to identify the times of day when high user traffic is slowing down the server. You can also look at the individual views by load time to understand which views take the longest to load.

Some views might take a long time to load regardless of when they are viewed. You can identify which workbooks need to be optimized with the Stats for Load Times administrative view. Some simple ways to optimize workbooks includes the following:

- Display less information in each view.
- Break up views.
- Reduce the number of filters.
- Use data extracts.
Traffic to Views

The Traffic to Views view gives you the ability to see how much of your user traffic goes to views.

You can filter what information is displayed and the time frame it comes from by selecting the view, the workbook, and the time range. Server administrators can specify the site.

Two time lines at the top of the view show you how views are being used over a time range you specify (the default is the last 7 days):

- **What is the Total View Count by Day**—This shows total view count by day, based on the filters you set. Hover your mouse pointer over a point on the line to see the count of views. Select the point to update the other sections of the view based on your selection.

- **What is the Total View Count by Time**—This shows the view count by time of day. The filters and any selection impact this graph.
Two bar graphs at the bottom of the view show results that are filtered by the **Min View Count** filter at the top of the view. These show you the views that are most often accessed, and the users who most frequently access views. Only those views and users with counts greater than or equal to the minimum view count value are displayed:

- **What Views are Seen the Most**—This is a list of the most visited views. Like the other sections of the view, the information is limited by filters and any selection you make.
- **Who Accesses Views Most Often**—This shows the users who most often access the views and is limited by filters and any selection you make.

**Traffic to Data Sources**

The Traffic to Data Sources view gives you the ability to see usage of data sources on your Tableau Server installation. This can help you determine which data sources are most heavily used and those that are less often used. You can filter the information you see by selecting the data source, the action taken on that data source, and the time range. Server administrators can specify the site.

A time line at the top of the view shows you how data sources are being used over a time range you specify (the default is the last 7 days):

- **What is the Total Data Source Usage by Day**—This shows total data source usage by day, based on the filters you set. Hover your mouse pointer over a point on
the line to see the count. Select the point to update the other sections of the view based on your selection.

Two bar graphs at the bottom of the view show results that are filtered by the Min Interactions filter at the top of the view. These show you which data sources are most used, and who uses data sources most often. Only those data sources and users with interaction counts greater than or equal to the minimum interactions value are displayed:

- **What Data Sources are Used Most**—This is a list of the most used data sources. Like the other sections of the view, the information is limited by filters and any selection you make.
- **Who Uses Data Sources Most Often**—This shows the users who most often use the data sources. This is impacted by filters and any selection you make.

**Actions by All Users**

The Actions by All Users view gives you insight into how your Tableau Server installation is being used. You can filter the view by actions and by time range. Server administrators can filter by site. The Total Users count shows the number of users who have performed an action. This value is not affected by any filtering. The Active user count shows the number of active users who have performed one of the selected actions.
Up to three separate groups of time lines show you how users are using Tableau Server over a time range you specify (the default is the last 7 days). If no actions are selected for a particular group, that group does not display. Possible groups are:

- **Access & Interactions**—This shows you sign in (log on) activity, view access and data source use.
- **Publish & Download**—This shows publishing and downloading of workbooks and data sources.
- **Subscriptions**—This shows counts of subscription email sent for workbooks and views.

Use the legend at the bottom to view a subset of the displayed actions. Click a single action to highlight the line for the action, or **Ctrl + Click** on multiple actions to highlight more than one. To clear the selection and display all the selected actions, click on any action in the legend.
Actions by Specific User

The Actions by Specific User view gives you insight into how individual users are working in your Tableau Server installation. You can filter the view by user name, actions, and time range. Server administrators on multi-site installations can filter by site.

Up to three separate groups of time lines show you how a selected user is using Tableau Server over a time range you specify (the default is the last 7 days). If no actions are selected for a particular group, or if no actions were taken, that group does not display. Possible groups are:

- **Access & Interactions**—This shows you sign in (log on) activity, view access and data source use.
- **Publish & Download**—This shows publishing and downloading of workbooks and data sources.
- **Subscriptions**—This shows counts of subscription email sent for workbooks and views.
A bar graph at the bottom of the view shows which items the selected user is using.

Use the legend at the bottom to view a subset of the displayed actions. Click a single action to highlight the line for the action, or Ctrl + Click on multiple actions to highlight more than one. To clear the selection and display all the selected actions, click on any action in the legend.

**Actions by Recent Users**

The Actions by Recent Users view shows you which signed-in users have been active on Tableau Server over the past 24 hours. This can be useful if you need to perform some maintenance activity and want to know how many and which users this will affect, and what they are doing on Tableau Server.

The view **Active, Recently Active**, and **Idle** users that are currently signed in to Tableau Server. For this view, an active user is one who took an action in the last 5 minutes, a recently active user is one who last took an action within 30 minutes, and an idle user is one who last took an action more than 30 minutes ago. The actions are displayed in the lower section of the view.
Select a user to see only the actions that user performed recently. Hover over an action to see details of the action.

Background Tasks for Extracts

The Background Tasks for Extracts view displays extract-specific tasks that run on the server.

Understand this view

To better understand this pre-built administrative view, make note of the following:
The table, What Extracts Ran on this Server, lists the extracts that ran in the time period specified in Timeline.

You can click Success or Error to filter the table based on status.

You can also click a specific task to update the How Much Time did Extracts Take graph for the selected task.

The table, How Many Extracts Succeeded or Failed, updates for the status (success or failure) of the task, but the count of extracts that succeeded or failed does not change.

Status

Tasks can have one of two statuses: successful or error.

<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>✗</td>
<td>Error—Server was unable to complete the task.</td>
</tr>
<tr>
<td>🌟</td>
<td>Success—Server completed the task.</td>
</tr>
</tbody>
</table>

See details about a task

For details on a task, hover over its icon.

Background Tasks for Non Extracts

The Background Tasks for Non Extracts view displays tasks that the server runs that are not related to refreshing extracts. For example, edited OAuth connections, subscription
notifications, and so on.

A table lists the tasks that ran in the time range specified. Click Success or Error to filter the table based on status. Select a specific task in the How Many Tasks Succeeded or Failed on this Site table to update the What Background Tasks Ran on this Site graph for the selected task.

Tasks can have a status of successful or error.

<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>⚠</td>
<td>Error—Server was unable to complete the task.</td>
</tr>
<tr>
<td>⚫</td>
<td>Success—Server completed the task.</td>
</tr>
</tbody>
</table>

For details on a task, hover over its icon.
Background Task Delay

**Note:** This view is only available to server administrators. For information about how to navigate to administrative views, see Administrative Views.

The Background Task Delay view displays the delay for extract refresh tasks and for subscription tasks—that is, the amount of time between when they are scheduled to run and when they actually run. You can use the view to help you identify places you can improve server performance by distributing your task schedules and by optimizing tasks.

Here are possible reasons for the delays, and ways that you might reduce the delays:

- Many tasks are scheduled for the same time. In the example view, tasks that show long delays are clustered at the same time every day, which creates spikes in the wait
time. Note that you can set the **Timeline** filter to a single day to view task delays by hour and identify the hours of the day which have many tasks scheduled at the same time. A solution to this issue can be to distribute the tasks to off-peak hours to reduce load on the server.

- Specific tasks take a long time to run and are preventing other tasks from running. For example, there might be an extract refresh job that is connecting to a slow data source or that is processing a large amount of data. Use the **Background Tasks for Extracts** administrative view to identify which extract refresh tasks are running slowly. You can then optimize the extract refresh task by filtering the data, aggregating the data, or creating multiple data sources for individual tables in a data source.

- Other server processes are running at the same time and are consuming server resources and slowing down performance. Monitor the CPU and memory usage of server processes to see which processes are consuming the most resources and then adjust the configuration of processes on your server.

**Stats for Load Times**

The Stats for Load Times view shows you which views are the most expensive in terms of server performance. You can filter by view and time range. Server administrators can filter by site. You can also limit the view based on load time in seconds, using the sliding Load Time filter. Load times are for the server. Depending on your client browser and networking, actual load time may vary slightly.

The **Average Load Times** graph shows average load times for views based on the filters you set. Hover over a point to see details. Select a point on the line to update the rest of the view for the selection:
The **Exact Load Times** view shows exact time to load the listed views. A vertical line shows the average load time for each view. Select a mark to see details of a specific instance of the view loading:

**Stats for Space Usage**

The Stats for Space Usage view can help you identify which workbooks and data sources are taking up the most disk space on the server. Disk space usage is displayed by user, pro-
object, and by the size of the workbook or data source and is rounded down to the nearest number:

Use the **Min Size** filter to control which data sources and workbooks are displayed, based on the amount of space they take up.

Three bar graphs give you information about space usage on your Tableau Server:

- **What Users Use the Most Space**—This shows the users who own data sources and workbooks that are taking up the most space. Click a user name to filter the next two graphs for that user. Click the data source bar or the workbook bar for a user to filter the next two graphs for that type of object for that user. Click the selected user or bar to clear the selection.

- **What Projects Use the Most Space**—This shows the projects with the data sources and workbooks that are using the most space. If a user or object type is selected in the What Users Use the Most Space graph, this displays information specific to the selection.
• **What Workbooks and Data Sources Use the Most Space**—This shows the workbooks and data sources that are taking the most space. The bars are color-coded based on the length of time since the last refresh.

Move your cursor over any bar to display usage details:

![What Users Use the Most Space?](image)

Click on a bar to select it and update the other areas of the view based on that selection.

**Server Disk Space**

**Note:** This view is only available to server administrators. For information about how to navigate to administrative views, see Administrative Views.

Use the Server Disk Space view to see how much disk space is in use on the computer or computers that run Tableau Server, where disk space refers only to the partition where Tableau Server is installed. You can also use this view to identify sudden changes in disk space usage.

For a distributed installation, the view displays information about each computer in the cluster.
The Server Disk Space view includes two graphs:

- **What is the most recent disk space usage?**—This graph shows disk space usage for the last 30 days both in gigabytes and as a percentage. Disk space refers only to the partition where Tableau Server is installed.
- **How has free disk space trended in the last month?**—This graph shows changes to disk space usage over the last month. Rest your pointer on a line to view the exact amount of free disk space for a point in time.

When Tableau Server is low on disk space, you can remove files to free space.

**Tip:** You can have Tableau Server notification you when free disk space falls below a threshold that you specify. For more information, see Configure Server Event Notification.
Desktop License Usage

**Note:** This view is only available to server administrators. For information about how to navigate to administrative views, see Administrative Views.

The Desktop License Usage view lets server administrators see usage data for Tableau Desktop licenses in your organization. This can help you manage licenses efficiently and determine if you need more or fewer licenses. This view can help you answer the following questions:

- Who is using a Tableau Desktop license in my enterprise?
- Have any licenses been shared or transferred?
- Is any license being used on a computer where it should not be?
- Does a specific user use their license?
- What types of licenses are being used in my enterprise?
- Do I need to convert any trial licenses?

**Note:** To get data about licenses, each copy of Tableau Desktop version 10.0 or later needs to be configured to send data to Tableau Server. This configuration can be done at installation time, using scripting or third-party software to install and configure Tableau, or after installation, by modifying the registry or property list file. For more information, see Configure Desktop License Reporting.

In order to view license data, Desktop License Reporting must be enabled on Tableau Server. See Enable and configure Desktop license reporting.

**Filters**

- **Product Keys.** Type a string to filter the dashboard to only those licenses that include
the string anywhere in the product key. For example, to see only licenses that begin with TDTD, type TDTD and press Return to filter the view. Click the X after the string to reset the filter.

- **Action.** Use this filter to control what the dashboard displays, based on the action taken. Actions are **Activate, Use, and Return** (deactivate). If the **Use** action is not selected, nothing is displayed in the top bar graph.

- **Department.** Use this filter to control what departments the dashboard displays licenses for. The filter is populated based on the **Department** values specified when Tableau Desktop is registered.

- **Select time duration in days.** Use this slider to specify the time length in days that the dashboard displays information for. The default value is 183 days.

When you hover over the filter card in the first three filters, a drop-down icon appears. Click the icon to specify whether the view should include data that matches the filter (the default) or exclude data that matches the filter:

![Filter Options](image)

**Who has used Tableau in the last <nn> days?**

This area of the dashboard shows a bar graph of three types of Tableau Desktop licenses (Perpetual, Trial, and Term) and the number of users who have used each license type during the specified time period. Hover over a license type segment to see an explanation of the license type. Click a segment to filter the rest of the dashboard for only that license type. This action filters both the tables that show licenses that have been used and those that have not been. For example, to see a list of term licenses that have been used during the time period, click the Term bar. The "used" and "not been used" lists are filtered to just show term licenses.
A table of detailed information shows under the bar graph. For each row in the table, action icons display on the right, above a timeline that shows you when the action last took place.

To see a list of the underlying data in a format that allows you to select and copy values like email or product key, click a row in the list of licenses and click the View Data icon:

![Checkmark and X icons]  

Keep only | Exclude

The data displays in summary form. Click **Full data** to see all the data. From this view you can select and copy individual values, or download the data as a text file.

**What licenses have not been used in the last <nn> days**

This area of the dashboard shows a list of licenses that have not been used during the specified time period. A timeline shows the last use date. Hovering over a last use mark gives you information including the registered user of the copy of Tableau.

**Desktop License Expiration**

**Note:** This view is only available to server administrators. For information about how to navigate to administrative views, see Administrative Views.

The Desktop License Expiration view gives server administrators information about which Tableau Desktop licenses in your organization have expired or need maintenance renewal. This can help you manage licenses efficiently. This view can help you answer the following questions:

- What trial or term licenses have expired?
- What perpetual licenses have expired maintenance?
- What perpetual licenses have maintenance renewals coming up?
Note: In order to get data about licenses, each copy of Tableau Desktop version 10.0 or later needs to be configured to send data to Tableau Server. This configuration can be done at installation time, using scripting or third-party software to install and configure Tableau. For more information, see Configure Desktop License Reporting.

In order to view license data, Desktop License Reporting must be enabled on Tableau Server. See Enable and configure Desktop license reporting.

Filters:

- **Product Keys**—Type a string to filter the dashboard to only those licenses that include the string. For example, to only see licenses that begin with TDTD, type TDTD and press return to filter the view. Click the "x" after the string to reset the filter.

- **Department**—Use this filter to control what department(s) the dashboard displays licenses for. The filter is populated based on the Department values used when registering copies of Tableau Desktop.

- **Time Duration**—Use this filter to control the length of time for which the dashboard displays information.

The view includes the following tables, which are affected by the filters you set at the top of the view:

- **What keys have expired maintenance**—This table shows the product keys for which maintenance has expired, with a vertical line indicating the point at which the six month window for renewing maintenance closes. If maintenance for a key is expired for more than six months you need to purchase a new key in order to qualify for support or upgrades.

- **What trial and term licenses have expired**—This shows the trial or term product keys that have expired.
• **What is the maintenance schedule for my keys**—This shows the keys and their maintenance status.

Create Custom Administrative Views

In addition to the pre-built administrative views available on the Maintenance page on the Server, you can use Tableau Desktop to query and build your own analyses of server activity. To do this, you can connect to and query views in the Tableau Server repository using one of two built-in users: the "tableau" or "readonly" user.

To connect to the Tableau Server repository, see Collect Data with the Tableau Server Repository.

• The **tableau** user—The tableau user has access to special views and a subset of tables in repository database. These views and tables are provided so that administrators can create custom administrative views. Tableau makes an effort to limit changes to these tables and views so that custom views built with them do not break.

• The **readonly** user—The readonly user has access to a large number of the repository tables, providing more data about server usage. Administrators can use these to create custom administrative views too, but many of the tables are intended primarily to support the functioning of Tableau Server and may be changed or removed without warning. This means that views created from these tables can break when the database structure is changed.

For examples of custom administrative views, see the Tableau Community.

Before you can connect using one of the built-in users, you must enable access to the Tableau Server database. After doing this you can use Tableau Desktop to connect to and query the database as the tableau user or the readonly user.

The `tsm configuration set option auditing.enabled` controls whether Tableau Server collects historical user activity and other information in the repository. It is enabled by default. Be aware that collecting historical events impacts the size of Tableau Server's
backup file (.tsbak).

- All hist_tables are controlled by the tsm configuration set option wgserver.audit_history_expiration_days, which controls how many days of event history are kept in the repository and has default value of 183 days.

- The _http_requests table is cleaned of all data older than 7 days when you run tsm maintenance cleanup. For more information, see Remove Unneeded Files.

- The _background_tasks table is cleaned automatically and keeps data for the last 30 days.

- All other tables with names that begin with a "_" prefix contain current data.

## Performance

### Tableau Server Performance Overview

When you take the time to understand the performance of Tableau Server, you make it easier to serve your users by improving the efficiency of Tableau Server. Although every server environment is unique, and there are many variables that can impact performance, the general steps that you take to understand and act on performance data in Tableau Server are the same.

- **Notifications.** Configure email notifications for important server events. For example, you can receive notifications when server processes become unavailable and when the server is running out of disk space.

- **Monitoring.** Collect and analyze data about Tableau Server to understand how well the server is performing.

- **Tuning.** Make adjustments to tasks, process configurations, and more to improve the performance of Tableau Server.
• **Troubleshooting.** Identify bottlenecks in resources, workbooks, and more to improve the performance of Tableau Server.

**General Performance Guidelines**

**Hardware and Software**

**Add more cores and memory:** Regardless of whether you’re running Tableau Server on one computer or several, the general rule is that more CPU cores and more RAM will give you better performance. Make sure you meet the Tableau Server recommended hardware and software requirements.

If you are running Tableau Server in a virtual environment, use your VM host’s best practices for vCPU allocation in relation to the number of physical CPU cores on the VM host.

**Configuration**

**Schedule refreshes for off-peak hours:** Backup tasks tend to stall other background tasks until the backup is completed. Use the Background Tasks for Extracts administrative view to see your refresh and backup task schedules. Your refresh tasks should be scheduled for off-peak hours that don’t overlap with your backup window.

**Look at caching:** Caching helps Tableau Server respond to client requests quickly, especially for views that connect to live databases. Use the tsm data-access caching list command to confirm the caching frequency is set to low (this is the default).

**Consider changing two session memory settings:**

- **VizQL session timeout limit:** The default VizQL session timeout limit is 30 minutes. Even if a VizQL session is idle, it is still consuming memory and CPU cycles. If you can make do with a lower limit, use tsm configuration set Options to change the `vizqlserver.session.expiry.timeout` setting.

- **VizQL clear session:** By default, VizQL sessions are kept in memory even when a user navigates away from a view. This reduces the need to rebuild views but
consumes more session memory. To free up memory, you can end sessions when users leave views by changing the value of the `vizqlserver.clear_session_on_unload` setting to true. (Regardless of this setting, sessions for the Tableau Mobile app are always kept in memory, improving mobile performance.)

Assess your process configuration: Tableau Server is divided into six different components called server processes. While their default configuration is designed to work for a broad range of scenarios, you can also reconfigure them to achieve different performance goals. Specifically, you can control on which computers the processes run and how many are run. See Performance Tuning Examples for general guidelines for one-, two-, and three-node deployments.

Server Resource Manager (SRM)

The Server Resource Manager (SRM) monitors the system resources each Tableau process is using as well as tracking the total usage of Tableau Server on the system. If either a specific process or the product as a whole takes up too much system resources, SRM can notify the processes to free the resources or restart those processes.

The thresholds that determine when SRM will notify or restart a process are set in the SRM configuration options. The Tableau development team has set the default settings based on internal testing and don’t recommend you change these settings directly.

If you are seeing excessive system resource usage, we recommend that you contact Tableau Support to help determine if these configuration options need to be modified to solve the problem or issue that you are seeing.

Performance Monitoring Overview

When you monitor a server, you collect and analyze data that signals whether the server is performing badly or running into problems. For example, if you notice that your server is using 100% of its processing capacity for long periods of time, you know that there’s a problem.
The data that you need to collect and analyze can be broken down into the following broad categories:

- Resource usage data—how Tableau Server uses hardware resources like diskspace, memory, and processors.

- Session and load time data—how users interact with Tableau Server, including how long it takes for views to load and how many concurrent users there are.

- Background task data—how Tableau Server runs tasks that are not directly tied to a user action. For example, background tasks include extract refresh tasks, subscription tasks, and more.

Some of this data, including load time data and extract refresh data, is already accessible from the administrative views that are built into Tableau Server. However, to collect resource usage data you need to use external performance monitoring tools. To collect additional load time data and background task data, you can connect to the Tableau Server repository.

For more information on the built-in administrative views, see Administrative Views.

**Note:** To use the sample workbook and to publish views to Tableau Server, you must have Tableau Desktop.

### Collect Data with the Tableau Server Repository

The Tableau Server repository is a PostgreSQL database that stores data about all user interactions, extract refreshes, and more. You can enable access to the repository and use the data in it to help analyze and understand Tableau Server performance.

Looking for Tableau Server on Windows? See [Collect Data with the Tableau Server Repository](#).
After you enable access to the Tableau Server repository, you can create views with data from the repository. The views that you create with this data are sometimes called custom administrative views. In addition to being used for performance monitoring, custom admin views can be used for tracking user activity, workbook activity, and more. For more information on the type of data that you can use for these views, see Create Custom Administrative Views. Alternatively, if you are only interested in performance data, you can use the preselected database tables in the sample performance workbook.

Enable access to the Tableau Server repository

You can use Tableau Desktop to connect to and query the Tableau Server repository using two built-in users. The user named tableau has access to several database views you can use as part of building your own analyses of Tableau Server activity. The user named readonly has access to additional database tables that you can use to create views for even more in-depth analysis and this is the user we recommend you use.

Before you can connect to the repository, you need to enable access for the readonly user to the database. Use the tsm data-access repository-access enable command to enable repository access. When you enable repository access, you also create a password for the readonly user. You will use this password to access to the repository. You may also need to have port 8060 opened so you can connect to the database.

1. Enable repository access and create a readonly user password:

    tsm data-access repository-access enable --repository-user-name readonly --repository-password <PASSWORD>

This command will restart Tableau Server.

**Note:** If you later decide that you want to disable remote access to the Tableau Server repository, use the tsm data-access repository-access disable command. The command disables external access to the repository. This
will not disable access from localhost. For more information, see tsm data-access repository-access disable.

Connect to the Tableau Server repository

This section describes how to connect to a custom set of tables from Tableau Server repository.

1. In Tableau Desktop select **Data > Connect to Data**, and then select **PostgreSQL** as the database to connect to.

   **Note**: You might need to install the PostgreSQL database drivers. You can download drivers from [www.tableau.com/support/drivers](http://www.tableau.com/support/drivers).

2. In the PostgreSQL connection dialog box, enter the name or URL for Tableau Server in the **Server** box. If you have a distributed server installation, enter the name or IP address of the node where the repository is hosted.

   Connect using the port you have set up for the `pgsql.port`, which is 8060 by default.

3. Specify **workgroup** as the database to connect to.

4. Connect using the user and the password you specified.

5. Click **Connect**.
6. Select one or more tables to connect to.

   The tableau user has access to all of the tables that start with an underscore or with hist_. For example, you can connect to _background_tasks and _data-sources. The hist_ tables include information about server users that isn’t currently presented in the Actions by Specific User view. The readonly user has access to additional tables that can be used to query other information about server usage.

7. Click **Go to Worksheet**.
Performance Tuning

This section describes how to use the performance data that you collect to identify ways to improve the performance of Tableau Server. Because no two server environments are identical, we can’t provide hard and fast rules for tuning server performance. However, you can draw conclusions about performance from patterns in the data that you collected.

For example, are there recurring spikes? Do any of the patterns that you notice in the administrative views correspond to similar patterns in a monitoring tool? Observing patterns like this can guide you in testing and incremental tuning.

Most performance tuning for Tableau Server boils down to these general approaches:

- Optimize for user traffic. This tunes the server to respond to user requests and to display views quickly.

- Optimize for extracts. This tunes the server to refresh extracts for published data sources. You might want to optimize for extract refreshes if your organization has a lot of data and the data needs to be as up to date as possible.

Rendering views and refreshing extracts generate the most load on the server, so you should optimize for the task that your organization is most interested in.

Optimize for User Traffic

You can optimize for traffic if you have many active Tableau Server users and few published data sources that need extract refreshes.

- When to optimize for user traffic

- Ways to optimize for user traffic
When to optimize for user traffic

Slow load times for views

Use the Requests and Sessions dashboard of the sample performance workbook to analyze how long views take to load.

If multiple views take longer than 10 seconds to load, and if the slow load times correspond to a large number of sessions, that can indicate that user traffic is slowing down the server.

However, if a particular view takes a long time to load regardless of when it is viewed, it’s a sign that the workbook for the view needs to be optimized. You can identify which workbooks need to be optimized with the Stats for Load Times administrative view. Some simple ways of optimizing workbooks includes displaying less information in each view or breaking up views, reducing the number of filters, and using data extracts.

High resource usage corresponding to user traffic

If your server displays high CPU and memory usage during peak traffic hours, you should optimize for user traffic. To determine peak traffic hours and analyze how many concurrent users are on your server, use the Users and Actions dashboard. In addition, you can use
the Traffic to Views administrative view to see how much user traffic involves accessing views (as opposed to performing administrative functions, publishing, or other tasks).

If you click a point in the **Number of Users** view, the dashboard displays the users that were active at the time and the number of user actions that those users performed. By default, the only user actions displayed are user views, but you can use the **Action Types** filter to display additional user actions.

Make a note of the times of day when there are many concurrent users and views so that you can compare this to resource usage. As a rule of thumb, the number of users should correspond to a high number of user actions. However, the view in this example displays an artificially high number of actions for a single user as part of a load generation test. As an example, you can compare the high number of views at 12 AM on June 28th with the resource usage in the dashboard illustrated later.

Use the **CPU Usage** dashboard to display the percent of total CPU usage and the percent of CPU usage for each process. In the following example, note the large spike in total CPU usage and in the VizQL server process at 12 AM on June 28th. Because the VizQL server process loads and render views, the VizQL server process is often the first process to show strain under high user traffic.
Note: The percent of CPU usage for individual processes may add up to more than 100 percent. This is because processor utilization for individual processes is measured for a given processor core. By contrast, the total CPU usage is measured for all processor cores.

Use the Memory Usage dashboard to display the percent of total memory usage and the average memory usage in gigabytes. As a general rule, memory usage increases steadily with user traffic. Here again the VizQL server process is the first to show strain under high traffic.
Ways to optimize for user traffic

When high user traffic corresponds to high resource usage as it does in the example shown previously, you should optimize for user traffic.

Adjust the number of VizQL server processes

The most effective way of optimizing for user traffic is to adjust the number of VizQL server processes. Add one VizQL server process at a time and measure the effect with more performance monitoring. Because VizQL server processes can consume a lot of CPU and memory, adding too many processes can slow down the server instead. If you see consistently high memory usage, try to reduce the number of VizQL server processes to reduce the amount of memory reserved.

For more information about configuring processes, see Configure Nodes.

Adjust the number of other processes

Although the most effective way of improving performance for user traffic is to adjust the number of VizQL server processes, you can also tune other processes that support the VizQL server process or that prevent the VizQL server process from accessing resources.
For example, the VizQL server process makes frequent requests to the cache server process, so you might also want to increase the number of cache server processes. On the other hand, the Backgrounder processes might contend for CPU resources with the VizQL server process. As a result, if you do not need to run frequent extract refreshes, you might reduce the number of processes for the backgrounder. If you do need additional instances of the backgrounder, and if you’re running Tableau Server on a cluster, you can move the Backgrounder process to a dedicated node.

Adjust the VizQL session timeout limit

In the example shown previously, the amount of memory used by the VizQL server process increases with user traffic, and it remains reserved by Tableau Server for some time after the traffic finished. This is because the VizQL server process reserves memory for each session for a specified amount of time. If the VizQL server process uses a high percentage of the available memory, try reducing the timeout for each session to make memory available more quickly.

To do this, use the `tsm configuration set` command to reduce the `vizqlserver.session.expiry.timeout` setting. The default is 30 minutes.

Refresh the cache less often

If your users do not always need the most up-to-date data, you can optimize for user traffic by configuring Tableau Server to cache and reuse data as much as possible.

To do this, use the `tsm data-access caching list` command to confirm the refresh frequency. The default is `Low`. Use the `tsm data-access caching set` command to change the refresh frequency.

Assess view responsiveness

When a user opens a view, the components of the view are first retrieved and interpreted, then displayed in the user’s web browser. For most views, the display rendering phase occurs in the user’s web browser and in most cases, this yields the fastest results and highest level of interactive responsiveness. Handling most interactions in the client web browser reduces bandwidth and eliminates round-trip request latencies. If a view is very
complex, Tableau Server handles the rendering phase on the server instead of in the client web browser, because that generally results in the best performance. If you find that views aren’t as responsive as you’d like, you can test and change the threshold that causes views to be rendered by the server instead of in the client web browser. For more information, see About Client-Side Rendering.

About Client-Side Rendering

When you navigate to a view in Tableau Server, the processing required to display the view (the rendering) can either be performed by your client web browser or by Tableau Server depending on the complexity of the view. The complexity of the view is determined by the number of marks, rows, columns, and more. If a view is less complex, then it is faster for your web browser to render the view than it is to send a request to Tableau Server. If a view is more complex, then it is faster to send a request to Tableau Server and take advantage of the server’s computing power.

As a server administrator, you can configure when client-side rendering happens both for web browsers on your computer and web browsers on mobile devices by adjusting the complexity threshold.

Requirements

- **Supported browsers**: Client-side rendering is supported in Internet Explorer version 9.0 or higher, Firefox, Chrome, and Safari. All of these web browsers include the HTML 5 `<canvas>` element, which is used by client-side rendering.

- **Polygons and the page history feature**: If a view uses the polygon mark type or the page history feature, server-side rendering is performed, even if client-side rendering is otherwise enabled.

Configure the complexity threshold for computers and mobile devices

Because computers have more processing power than mobile devices, Tableau Server performs more client-side rendering in your computer’s web browser than in your mobile device’s web browser. You can adjust how much client-side rendering happens for computers and mobile devices with the complexity thresholds. You might want to adjust the
complexity thresholds if you notice that views display slowly on mobile devices. Alternatively, you might want to increase the thresholds to reduce the number of requests to Tableau Server.

By default, the complexity threshold for computer web browsers is 100. To adjust the complexity threshold for computer web browsers, use the following command:

```
 tsm configuration set -k vizqlserver.browser.render_threshold -v [new value]
```

By default, the complexity threshold for web browsers on mobile devices is 60. To adjust the complexity threshold for web browsers on mobile devices, use the following command:

```
 tsm configuration set -k vizqlserver.browser.render_threshold_mobile -v [new value]
```

For example, to change the mobile threshold to 40, you might enter the following command:

```
 tsm configuration set -k vizqlserver.browser.render_threshold_mobile -v 40
```

For more information on how to use tsm option set, see tsm configuration set Options.

Disable client-side rendering

Client-side rendering is enabled by default and is recommended to improve the performance of views. However, you might want to disable client-side rendering temporarily for testing or if your server is being accessed primarily by computers or mobile devices with very little processing power.

Use the following command to disable client-side rendering:

```
 tsm configuration set -k vizqlserver.browser.render -v false
```

For more information on how to use tsm option set, see tsm configuration set Options.
Testing with the URL Parameter

To test server-side rendering on a session basis, type `?:render=false` at the end of the view's URL. For example:

http://localhost/views/Supplies/MyView?:render=false

If client-side rendering is disabled on Tableau Server, enter `?:render=true` to enable it for the session:

http://localhost/views/Supplies/MyView?:render=true

You can also test particular complexity thresholds on individual views to see if it’s appropriate to adjust the server-wide threshold for your server and network conditions. For example, you may find that lower complexity (such as 80) or higher complexity (such as 120) tipping points result in more responsiveness to user interactions. To test a threshold, you can keep the server’s default configuration (client-side-rendering enabled) and enter the test threshold number at the end of the view’s URL. For example:

http://localhost/views/Supplies/MyView?:render=80

Optimize for Extracts

Try to optimize for extracts if the extract schedules correspond to high resource usage or if extracts take a long time to finish.

- When to optimize for extracts
- Ways to optimize for extracts

When to optimize for extracts

High CPU usage corresponds to extract schedules

Use the **Background Jobs** dashboard of the sample performance workbook to view the number of background jobs run by Tableau Server, including extract refresh jobs. The dashboard also displays how long background jobs are delayed—that is, the amount of time between when a background job is scheduled and when it actually runs. If you see long
delays at particular times of the day or if many jobs are running at the same time, try distributing the job schedules across different times of the day to reduce the load on the server.

Also compare the times when there are many background jobs or long delays with the CPU usage of the server. Use the CPU Usage dashboard to display the percent of total CPU usage and the percent of CPU usage for each process. Because the backgrounder process runs background jobs, it is the first process to show strain when there are many extract refresh jobs or when there are slow extract refresh jobs. Note that the CPU usage of the backgrounder process periodically but briefly reaches 100 percent. This indicates that there are intensive refresh jobs on a recurring schedule.

Note: The percent of CPU usage for individual processes may add up to more than 100 percent because processor utilization for individual processes is measured for a given processor core. By contrast, the total CPU usage is measured for all processor cores.
Extracts fail or run slowly

Use the Background Tasks for Extracts administrative view to determine how many extracts fail and how long extracts take to complete. Frequent failures can indicate a problem with a particular data source.
Ways to optimize for extracts

When high CPU usage corresponds to extract refresh schedules like it does in the example shown previously, you should optimize for extracts.

Adjust the extract refresh schedule

Use the **Background Jobs** dashboard of the sample performance workbook to identify optimal times for running extracts. In addition to running extracts in off-peak hours, you can distribute extract refreshes to minimize concurrent server load. If extract refreshes continue to cause problems, reduce the frequency of extract refreshes as much as possible in these ways:

- Schedule extracts for times when the server isn’t busy.
- Reduce the frequency of refreshes.
Speed up specific extracts

Use the Background Tasks for Extracts administrative view to identify failing extracts and long-running extracts.

- Reduce the size of extracts. You can help improve server performance by keeping the extract’s data set short, through filtering or aggregating, and narrow, by hiding unused fields. To make these changes, use the Tableau Desktop options **Hide All Unused Fields** and **Aggregate data for visible dimensions**. For more information, see Creating an Extract in the Tableau Help.

For general tips on building well-performing workbooks, search for “performance” in the Tableau Help. To see how workbooks perform after they’ve been published to Tableau Server, you can create a performance recording. For more information, see Create a Performance Recording.

- Use incremental refresh jobs. Incremental refresh jobs append new rows to an existing extract instead of creating the extract from scratch. This type of extract refresh runs quickly because it processes only the data that has been added since the last time the extract refresh job ran. However, it does not account for data that has been updated rather than appended to a data source. As a result, if you run incremental refresh jobs, you should still occasionally run full refresh jobs. For example, you might run a full refresh job once or twice a week for a data source instead of every day.

Configure the execution mode for extract refreshes

When you create extract refresh schedules, ensure that they run in parallel execution mode. When you run a schedule in parallel, it runs on all available back grounder processes, even if the schedule contains only one refresh task. When you run a schedule serially, it only runs on one backgrounder process. By default, the execution mode is set to parallel so that refresh tasks finish as quickly as possible.

However, in some circumstances, it can make sense to set the execution mode to serial. For example, you might set the execution mode to serial if a very large job is preventing other schedules from running because it uses all available backgrounder processes.
Increase the number of backgrounder processes

A single background process can consume 100 percent of a single CPU core for certain tasks. As a result, the total number of instances you should run depends on the computer’s available cores. If you have Tableau Server installed in a cluster and you run backgrounder processes on a separate node, a good rule of thumb is to set the number of backgrounder process to between half the number of cores and the full number of cores of the computer running the backgrounder processes.

For more information about configuring processes, see Configure Nodes.

Isolate processes

If you have Tableau Server installed in a cluster, you see the largest benefit from moving the backgrounder processes to a separate node to avoid resource contention. This is because the backgrounder process is very CPU-intensive and running it on the same node where other CPU-intensive processes are running can slow down the server. For example, both the VizQL server process and the data engine process can be CPU-intensive.

When to Add Nodes and Reconfigure

Tableau Server can scale up and out as your needs and requirements evolve. Here are some guidelines to help you figure out whether it’s time to add more nodes to your system, reconfigure the server, or both:

- **More than 100 concurrent users**: If your deployment is user-intensive (>100 simultaneous viewers), it’s important to have enough VizQL processes—but not so many that they exceed your hardware’s capacity to handle them. Also, enabling the Tableau Server Guest User account can increase the number of potential simultaneous viewers beyond the user list you may think you have. The administrative view can help you gauge this. For more information, see Actions by Specific User.

- **Heavy use of extracts**: Extracts can consume a lot of memory and CPU resources. There’s no one measurement that qualifies a site as extract-intensive. Having just a few, extremely large extracts could put your site in this category, as would having very
many small extracts. Extract heavy sites benefit from isolating the Backgrounder process on its own machine.

- **Frequent extract refreshes**: Refreshing an extract is a CPU-intensive task. Sites where extracts are frequently refreshed (for example, several times a day) are often helped by more emphasis on the background process, which handles refresh tasks. Use the Background Tasks for Extracts administrative view to see your current refresh rate.

- **Downtime potential**: If your server system is considered mission critical and requires a high level of availability, you can configure it so there’s redundancy for the server processes that handle extracts, the repository, and the gateway.

**Performance Tuning Examples**

Performance tuning examples have been expanded and moved to separate topics. For more information, see Performance Tuning.

For recommended baseline configurations that serve as starting point for installations with one, two, and three nodes, see Recommended Baseline Configurations.

**Performance Recording**

This section describes how to create performance recordings and use the results to improve workbook performance. With performance recordings, you can view how long workbook events take. For example, you can see how long it takes to connect to a data source, run a query, render data, and more.

**Create a Performance Recording**

The Performance Recording feature in Tableau records performance information about key events as you interact with a workbook. You can then view performance metrics in a workbook that Tableau creates to analyze and troubleshoot different events that are known to affect performance:
- Query execution
- Geocoding
- Connections to data sources
- Layout computations
- Extract generation
- Blending data
- Server blending (Tableau Server only)

Tableau support may ask that you create a performance workbook as they work with you to diagnose performance issues.

Looking for Tableau Server on Windows? See Create a Performance Recording.

Enable Performance Recording for a Site

By default, performance recording is not enabled for a site. A server administrator can enable performance recording site by site.

1. Navigate to the site for which you want to enable performance recording.

2. Click **Settings:**

3. Under Workbook Performance Metrics, select **Record workbook performance metrics.**

4. Click **Save.**
Start a Performance Recording for a View

1. Open the view for which you want to record performance.

   When you open a view, Tableau Server appends ":iid=<n>" after the URL. This is a session ID. For example:

   http://10.32.139.22/#/views/Coffee_Sales2013/USSalesMarginsByAreaCode?:iid=1

2. Type :record_performance=yes & at the end of the view URL, immediately before the session ID. For example:

   http://10.32.139.22/#/views/Coffee_Sales2013/USSalesMarginsByAreaCode?:record_performance=yes & :iid=1

3. Click the Refresh button in the toolbar.

4. Load the view.

   A visual confirmation that performance recording has started is the Performance option in the view toolbar:

View a Performance Recording

1. Click Performance to open a performance workbook. This is an up-to-the-minute snapshot of performance data. You can continue taking additional snapshots as you continue working with the view; the performance data is cumulative.
2. Move to a different page or remove :record_performance=yes from the URL to stop recording.

Interpret a Performance Recording

A performance recording workbook is a Tableau dashboard that contains three views: **Timeline, Events**, and **Query**.

For information on how to create a performance recording in Tableau Server, see Create a Performance Recording.

Timeline

The uppermost view in a performance recording dashboard shows the events that occurred during recording, arranged chronologically from left to right. The bottom axis shows elapsed time since Tableau started, in seconds.

In the Timeline view, the **Workbook, Dashboard, and Worksheet** columns identify the context for events. The **Event** column identifies the nature of the event, and the final column shows each event’s duration and how it compares chronologically to other recorded events:

![Timeline view of a performance recording workbook](image)

Events

The middle view in a performance recording workbook shows the events, sorted by duration (greatest to least). Events with longer durations can help you identify where to look first if you want to speed up your workbook.
Different colors indicate different types of events. The range of events that can be recorded is:

- **Computing layouts**
  
  If layouts are taking too long, consider simplifying your workbook.

- **Connecting to data source**
  
  Slow connections could be due to network issues or issues with the database server.

- **Executing query**
  
  - For live connections, if queries are taking too long, it could be because the underlying data structure isn't optimized for Tableau. Consult your database server's documentation. As an alternative, consider using an extract to speed performance.
  
  - For extracts, if queries are taking too long, review your use of filters. If you have a lot of filters, would a context filter make more sense? If you have a dashboard that uses filters, consider using action filters, which can help with performance.

- **Generating extract**
  
  To speed up extract generation, consider only importing some data from the original data source. For example, you can filter on specific data fields, or create a sample based on a specified number of rows or percentage of the data.

- **Geocoding**
To speed up geocoding performance, try using less data or filtering out data.

- Blending data

To speed up data blending, try using less data or filtering out data.

- Server rendering

You can speed up server rendering by running additional VizQL Server processes on additional machines.

Query

If you click on an Executing Query event in either the Timeline or Events section of a performance recording dashboard, the text for that query is displayed in the Query section.

If you are connected to a published data source, the query text is displayed in XML. If you are connected to the data source directly, the query is displayed in SQL like shown below:

```
FROM "StateSynonyms"
INNER JOIN "State" ON ("State"."ID" = "StateSynonyms"."ParentID") AND ("State"."MapCode" = "StateSynonyms"."MapCode"
```

If it makes sense, you can use the query text to work with your database team on optimizing at the database level. Sometimes the query is truncated and you'll need to look in the Tableau log to find the full query. Most database servers can give you advice about how to optimize a query by adding indexes or other techniques. See your database server documentation for details.

Sometimes for efficiency, Tableau combines multiple queries into a single query against the data. In this case, you may see an Executing Query event for the Null worksheet and zero queries being executed for your named worksheets.
Performance Resources

This topic describes external resources that you can use to monitor and tune performance.

Disclaimer: This topic includes information about third-party and community supported products. Please note that while we make every effort to keep references to third-party and community content accurate, the information we provide here might change without notice. For the most up-to-date information, please consult the documentation for products referenced here. To learn more about community supported tools, see Support levels for IT and developer tools.

- **TabJolt.** A load generation tool that you can use to understand how Tableau Server responds to user interactions over time. Use TabJolt to establish a baseline for server performance and test deployments before pushing them to production environments.

- **Replayer.** A tool that can replay log-based real user traffic from a Tableau Server against any other server or configuration. It replays Tableau Server single- or multi-user sessions. Here are some ways that Replay can be used:
  
  - Playback specific Tableau Server sessions, and filter the session based upon start time or RequestID.
  
  - Use it to simulate load conditions so that you can test how to scale and balance your Tableau Server installations.
  
  - Perform regression testing by running and comparing end-to-end user scenarios for Tableau Server upgrades.
  
  - Capture and report HTTP exceptions that occur in a single-user session.
  
  - Replay a defect, so that you can troubleshoot and verify that it is fixed.

- **Scout.** An exploratory tool that captures performance metrics across any workbooks
on both Tableau Desktop and Tableau Server Here are some ways that Scout can be used:

- Find slow workbooks on Server.
- Validate performance improvements or regressions after making server configuration or topology changes.
- Validate that workbooks and dashboards are loading properly after upgrading to new Tableau Server.
- Validate that workbooks are still working properly after data source changes.

- **TabMon.** A monitoring tool that uses Windows Performance Monitor and Java Management Extensions to record performance data about Tableau Server to a PostGreSQL database.

- **Microsoft System Center.** A set of server management products for monitoring, configuration, automation, and more.

- **HP Sitescope.** An agentless application monitoring tool.

- **Zabbix.** An open-source, real-time monitoring tool.

- **Splunk.** A tool for monitoring and analyzing machine data, including logs.

- **Graylog.** An open-source log management tool.

### About Client-Side Rendering

When you navigate to a view in Tableau Server, the processing required to display the view (the rendering) can either be performed by your client web browser or by Tableau Server depending on the complexity of the view. The complexity of the view is determined by the number of marks, rows, columns, and more. If a view is less complex, then it is faster for your web browser to render the view than it is to send a request to Tableau Server. If a view is more complex, then it is faster to send a request to Tableau Server and take advantage of the server’s computing power.
As a server administrator, you can configure when client-side rendering happens both for web browsers on your computer and web browsers on mobile devices by adjusting the complexity threshold.

Requirements

- **Supported browsers**: Client-side rendering is supported in Internet Explorer version 9.0 or higher, Firefox, Chrome, and Safari. All of these web browsers include the HTML 5 `<canvas>` element, which is used by client-side rendering.

- **Polygons and the page history feature**: If a view uses the polygon mark type or the page history feature, server-side rendering is performed, even if client-side rendering is otherwise enabled.

Configure the complexity threshold for computers and mobile devices

Because computers have more processing power than mobile devices, Tableau Server performs more client-side rendering in your computer's web browser than in your mobile device's web browser. You can adjust how much client-side rendering happens for computers and mobile devices with the complexity thresholds. You might want to adjust the complexity thresholds if you notice that views display slowly on mobile devices. Alternatively, you might want to increase the thresholds to reduce the number of requests to Tableau Server.

By default, the complexity threshold for computer web browsers is 100. To adjust the complexity threshold for computer web browsers, use the following command:

```bash
tsm configuration set -k vizqlserver.browser.render_threshold -v [new value]
```

By default, the complexity threshold for web browsers on mobile devices is 60. To adjust the complexity threshold for web browsers on mobile devices, use the following command:

```bash
tsm configuration set -k vizqlserver.browser.render_threshold_mobile -v [new value]
```

For example, to change the mobile threshold to 40, you might enter the following command:
tsm configuration set -k vizqlserver.browser.render_threshold_mobile -v 40

For more information on how to use tsm option set, see tsm configuration set Options.

Disable client-side rendering

Client-side rendering is enabled by default and is recommended to improve the performance of views. However, you might want to disable client-side rendering temporarily for testing or if your server is being accessed primarily by computers or mobile devices with very little processing power.

Use the following command to disable client-side rendering:

```
$tspm configuration set -k vizqlserver.browser.render -v false
```

For more information on how to use tsm option set, see tsm configuration set Options.

Testing with the URL Parameter

To test server-side rendering on a session basis, type `?render=false` at the end of the view’s URL. For example:

```
http://localhost/views/Supplies/MyView?render=false
```

If client-side rendering is disabled on Tableau Server, enter `?render=true` to enable it for the session:

```
http://localhost/views/Supplies/MyView?render=true
```

You can also test particular complexity thresholds on individual views to see if it’s appropriate to adjust the server-wide threshold for your server and network conditions. For example, you may find that lower complexity (such as 80) or higher complexity (such as 120) tipping points result in more responsiveness to user interactions. To test a threshold, you can keep the server’s default configuration (client-side-rendering enabled) and enter the test threshold number at the end of the view’s URL. For example:

```
http://localhost/views/Supplies/MyView?render=80
```
Monitoring Tableau Server

Configure SMTP Setup

Tableau Server can email server administrators about system failures, and email server users about subscribed views and data-driven alerts. First, however, you need to configure the SMTP server that Tableau Server uses to send email. After configuring SMTP, complete the steps to configure notifications (Configure Server Event Notification), then when you start or restart the server, it will trigger an email notification, which confirms that you have set up notifications correctly.

Configuring SMTP requires that you restart Tableau Server services.

In this article

Use the TSM web interface
Use the TSM CLI

Use the TSM web interface

1. Open TSM in a browser:

   https://<tsm-computer-name>:8850. For more information, see Sign in to Tableau Services Manager Web UI.

2. Click Notifications on the Configuration tab and click Email Server.

3. Enter the SMTP configuration information for your organization:
4. Click **Save Pending Changes** after you've entered your configuration information.

5. Click **Apply Changes and Restart**.

Use the TSM CLI

For the initial configuration of SMTP, we recommend that you use the configuration file template below to create a .json file. You can also set any single configuration key listed below with the syntax described in tsm configuration set.

1. Copy the following json template to a file. Fill in the key values with your SMTP configuration. See the reference section that follows for more information about SMTP key options.

```json
{
    "configKeys": {
        "svcmonitor.notification.smtp.server": "SMTP server url",
```
"svcmonitor.notification.smtp.send_account": "SMTP user name",
"svcmonitor.notification.smtp.port": 25,
"svcmonitor.notification.smtp.password": "SMTP server password",
"svcmonitor.notification.smtp.ssl_enabled": false,
"svcmonitor.notification.smtp.from_address": "From email address",
"svcmonitor.notification.smtp.target_addresses": "To email address1,address2",
"svcmonitor.notification.smtp.canonical_url": "Tableau Server URL"
}

2. Run the `tsm settings import -f file.json` to pass the json file with the appropriate values to Tableau Services Manager to configure Tableau Server for SMTP. Tableau Services Manager will validate the entity values.

3. Run the `tsm pending-changes apply` command to apply the changes. See `tsm pending-changes apply`.

Configuration file reference

This table lists all of the options that can be used to configure SMTP.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>

</tbody>
</table>
Configure Server Event Notification

You can configure the following server notifications on the following events:

- Content updates
  - Extract failures
  - Subscription views for users
- Server health monitoring
  - Server status changes
  - License reporting
- Drive space
  - Recording usage history
  - Email alerts when space crosses or remains below pre-configured thresholds

Note: You need to configure SMTP before you can configure subscriptions or notifications. For more information, see Configure SMTP Setup.

Content updates

You can set notifications for extract failures. You can also enable notifications for user subscriptions.

When users subscribe to a workbook or view, a snapshot of the view is email to them on scheduled basis, so they can see the latest updates without having to sign into Tableau Server.

After you have enabled subscriptions in this procedure, you can configure subscriptions in each site. See Set Up a Server for Subscriptions.
Server health monitoring

Server status changes and license reporting.

Server status changes

Tableau Server sends an email when the data engine, repository, or gateway server processes stop or restart, or when the initial Tableau Server node stops or restarts. If you are running a single-server installation (all processes on the same machine), health alerts are only sent when Tableau Server is up. No "down" alerts are sent. If you are running a distributed installation that’s configured for failover, a DOWN alert means that the active repository or a data engine instance has failed and the subsequent UP alert means that the passive instance (repository) or second instance (data engine) of that process has taken over.

License reporting

License reporting is generated at Tableau Desktop and sent to Tableau Server.

Drive space

Enable notifications for remaining drive space on your Tableau Server.

Remaining space thresholds

You can configure Tableau Server to send email alerts when disk space usage on any node crosses a threshold, or remains below the threshold.

There are two thresholds you must set. Thresholds are expressed in percentage of disk space remaining.

You can set a warning threshold and a critical threshold. The critical threshold must be less than the warning threshold.

Setting email interval

Specify how often, in minutes, warning and critical alerts should be sent. The default value is 60 minutes.
Recording usage history

When you configure Tableau Server to record disk space usage, information about free disk space is saved in the repository and you can view the usage history using the Administrative Views.

In this article

- Use the TSM web interface
- Use the TSM CLI

Use the TSM web interface

1. Open TSM in a browser:

   https://<tsm-computer-name>:8850. For more information, see Sign in to Tableau Services Manager Web UI.

2. Click **Notifications** on the **Configuration** tab and click **Events**.

3. Configure notification settings for your organization:
4. Click **Save Pending Changes** after you've entered your configuration information.

5. Click **Apply Changes and Restart**.

**Use the TSM CLI**

The various notification values described above can be set individually with the tsm configuration set command. Alternatively, you can construct a json file and pass all configuration values in one operation. Both methods are described in this section.

Set notification values individually

The following table shows the key/value pairs that map to the notification events described earlier in this topic. Use the tsm configuration set command with the following syntax to set a single key/value pair:
For example, to enable extract failure notifications, run the following command:

tsm configuration set -k backgrounder.send_email_on_refresh_failure -v true

<table>
<thead>
<tr>
<th>Notification option</th>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Extract failures</td>
<td>backgrounder.send_email_on_refresh_failure</td>
<td>true</td>
</tr>
<tr>
<td>Enable subscription views for user</td>
<td>subscriptions.enabled</td>
<td>true</td>
</tr>
<tr>
<td>Server status changes</td>
<td>svcmonitor.notification.smtp.enabled</td>
<td>true</td>
</tr>
<tr>
<td>License reporting</td>
<td>features.DesktopReporting</td>
<td>true</td>
</tr>
<tr>
<td>Remaining space thresholds: enable email notifications</td>
<td>storage.monitoring.email_enabled</td>
<td>true</td>
</tr>
<tr>
<td>Remaining space thresholds: warning percentage</td>
<td>storage.monitoring.warning_percent</td>
<td>integer value, for example, 20</td>
</tr>
<tr>
<td>Remaining space thresholds: critical percentage</td>
<td>storage.monitoring.critical_percent</td>
<td>integer value, for example, 15</td>
</tr>
</tbody>
</table>
Set email interval

<table>
<thead>
<tr>
<th>Set email interval</th>
<th>storage.monitoring.email_interval_min</th>
<th>integer value, in minutes, for example, 25</th>
</tr>
</thead>
</table>

Record usage history

| Record usage history | storage.monitoring.record_history_enabled | true|false |
|----------------------|------------------------------------------|----------------------------------------|

After you are done setting values, you must run the following command:

```
tsm pending-changes apply
```

The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

Set all notification values with a single json file

To make all notifications settings with a single configuration, you can pass a json file.

Copy and edit the following template to create a file for your configuration.

```
{
    "configKeys": {
        "backgrounder.send_email_on_refresh_failure": true,
        "subscriptions.enabled": true,
        "svcmonitor.notification.smtp.enabled": true,
        "features.DesktopReporting": true,
        "storage.monitoring.email_enabled": true,
        "storage.monitoring.warning_percent": 20,
        "storage.monitoring.critical_percent": 15,
        "storage.monitoring.email_interval_min": 25,
        "storage.monitoring.record_history_enabled": true
    }
}
```

After you have saved the file, pass it with the following command:
tsm settings import -f <path-to-file.json>

To apply changes, run the following command:

```bash
tsm pending-changes apply
```

The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

## Maintenance

### Backup and Restore

A Tableau Server administrator should perform regular database maintenance, monitor disk usage on the server, clean up unnecessary files to free up space on the server, and back up Tableau Server and its data. Taking these steps can help ensure that Tableau Server runs with maximum efficiency.

You can use the Tableau Services Manager (TSM) command line tool to back up and restore your Tableau data. Tableau data includes Tableau Server’s own PostgreSQL database, which stores workbook and user metadata, data extract files, and server configuration data. Tableau Server log files capture activity and can help you diagnose problems. Logs are written to folders on the server and you can archive and remove them to save disk space.

You can use the `tsm maintenance restore` command to restore Tableau Server backups created using `tabadmin backup` and `tsm maintenance backup`. Database backups made in other ways, and virtual machine snapshots are not valid sources for restoring Tableau Server.
Platform compatibility

You can use a backup created with Tableau Server on Linux to restore Tableau Server on Windows version 2018.2 and later.

You cannot use a backup created with Tableau Server on Linux to restore earlier versions of Tableau Server on Windows (version 2018.1 and earlier).

You can use a backup created with Tableau Server on Windows (version 2018.2 and earlier) to restore Tableau Server on Linux. For more information about restoring a Windows backup on Tableau Server on Linux, see Migrate Tableau Server from Windows to Linux.

Backup Disk Space Usage

You must have adequate disk space for database backup and restore processes to run successfully. In addition to the amount of space needed for the backup file, you need temporary disk space roughly 10 times the size of the backup file (so if your backup is 4 GB, you should have about 40 GB of temporary disk space available). Similarly you will need adequate temporary disk space for restoring from a backup.

When calculating disk space, be aware that background tasks for cleaning up old extracts are temporarily paused. This means that, for the duration of the backup, extract refreshes will leave extra files in place, adding to disk space usage. If your backup takes a long time, or if your organization uses many extracts that are regularly updated, this can result in a significant amount of temporary disk space usage. These old files will be removed after the backup is complete.

Best Practices for Backing Up Tableau Server

There are several ways you can maximize backup efficiency. Your environment can impact how effective each of these is, so test with your data to see what works best.
• Locating the repository (pgsql) and the File Store on the same node as the Administration Controller can reduce the length of time it takes to back up Tableau Server. The Administration Controller is usually on the initial node, unless you have had an initial node failure and had to move the controller to another node. When the repository is co-located with the controller it eliminates or greatly reduces the need to compress and transfer data between nodes during the backup process. This is also true with the File Store, especially if your organization uses extracts heavily.

• Use the **--skip-compression** option when backing up Tableau Server. This creates the backup without using compression, and results in a larger backup file but can reduce the amount of time it takes for the backup to complete. For more information, see tsm maintenance backup.

**Perform a Full Backup and Restore of Tableau Server**

You can use the following steps to back up your Tableau Server deployment. Specifically, these steps describe how to recover a clone of a server from a collection of backup data and assets.

**Note:** The backup process can take a long time to run. Since no other jobs can be run while backup is running, we recommend that you run backup during non-business hours.

In this article

- Backup data types
- Backup assets that require a manual process
- Backing up Tableau Server for recovery
- Restoring core Tableau Server functionality
- Restore other functionality
Backup data types

There are two types of backup data that Tableau Server can generate. We recommend performing regular backups of each type in case you must restore a server in a recovery scenario:

- Repository data: Tableau Server data consists of the Tableau PostgreSQL database or repository, which contains workbook and user metadata, data extract files, and site configuration data. When you use TSM to create a backup, all of this data is saved in a single file with a .tsbak extension. This data is backed up with the `tsm maintenance backup` command.

- Configuration and Topology data: includes most of the server configuration information required to fully recover a server. SMTP, alerting, authentication, are all examples of configuration data that are exportable for backup. Topology data defines how your Tableau Server processes are configured in both single-server and multiple node deployments. Configuration and topology data is backed up with the `tsm settings export` command.

**Note:** You can change the file path used by the `tsm maintenance backup` command from the default value. For more information, see `tsm File Paths`.

Backup assets that require a manual process

Some configuration data is not included in the `tsm settings export` command and must therefore be documented and restored manually. The following configuration data is excluded from the `tsm settings export` operation. Your backup maintenance process should include documenting the following Tableau Server configuration data:

- System user accounts. Tableau Server setup creates an unprivileged user account, `tableau`. This account is used to access Tableau Server resources. This account can be changed during setup. If you have not changed this account, then you do not need to document it.
- TSM group membership. There are two groups created by Tableau Server:
  `tableau` and `tsmadmin`. If you configured alternative groups when you installed
  Tableau Server, then you'll need to document the group names.

  In all cases you should document the user accounts that are in these groups. To view
  membership in a group, run the following command `grep <group_name> /etc/-
  group`.

- Coordination Service deployment configuration. If you are running a multinode
  cluster, document which nodes are running the Coordination Services process. To
  view process configuration on your nodes, run `tsm topology list-nodes -v`.

- Customization settings. If your organization uses custom header or sign-in logos for
  Tableau Server web pages, you should include a copy of those assets with your back
  up portfolio. See `tsm customize`.

- Authentication assets. Most certificate files, key files, keytab files or other authen-
  tication-related assets are not backed up by TSM. The exception are the public cer-
  tificate and private key for the PostgreSQL database and certificate and key for the
  gateway process.

  However, all other authentication-related assets are not backed up. For example, if
  you have enabled access to the PostgreSQL database with the `tsm data-access
  repository-access enable` command, be sure to document the name/password pairs
  for each account you've configured. These credentials are not backed up.

- LDAP assets. Keytab files, configuration files, and or other LDAP-related assets are
  not backed up by TSM.

  Internal server secrets and repository passwords are crypto-related configurations that are
  not exported. However, you do not need to document configuration values. New secrets will
  be created as part of the restoration process when you initialize the new instance.
Backing up Tableau Server for recovery

Tableau Server includes commands that you run to generate backup data for Tableau Server.

**Note:** When backing up Tableau Server on Linux, the unprivileged user must have write access to the network share where the backup files are written. Otherwise, backup will fail.

1. **Backup topology and configuration data.** Both of these data sets are included when you run the `tsm settings export` command. The data is exported as a json file. Specify the name and location of the json file by running the following command:

```
 tsm settings export -f <filename>.json
```

**Note:** Because the backup contains secrets, we recommend that you encrypt the backup and store it in a secure place. For more information about Tableau Server secrets, see Manage Server Secrets.

2. **Back up repository data.** Repository data is backed up with the `tsm maintenance backup` command. Specify the name and location of the backup file by running the following command:

```
 tsm maintenance backup -f <filename>.tsbak -d
```

By default, the backup file is written here:

```
/var/opt/tableau/tableau_server-
data/tabsvc/files/backups/<filename>.tsbak
```
For more information about where back up files are written, see tsm File Paths. For more information about backing up the repository data, see Back up Tableau Server data for more information.

Restoring core Tableau Server functionality

The procedure below uses the assets from the previous two sections to rebuild a Tableau Server in a recovery scenario.

**Note:** If you need to restore only the repository on an otherwise functional Tableau Server, see Restore from a backup. If you are running a distributed deployment, and your initial node has failed, see Recover from an Initial Node Failure.

Topology and configuration backup data must be from Tableau Server on Linux. You cannot restore configuration data from a backup file that was generated on Tableau Server on Windows. To restore a backup made from Tableau Server on Windows to Tableau Server on Linux, see Migrate Tableau Server from Windows to Linux.

You must have the following assets ready:

- **Topology and configuration data:** This is the json file that is generated by the `tsm settings export` command.

- **Repository backup file:** This is the file with a .tsbak extension that is generated by the `tsm maintenance backup` command.

- **Backup assets:** These assets include the list of documented configurations as noted in the previous section.

**To restore a standalone Tableau Server**

1. On the computer where you want to restore Tableau Server, Install and Initialize
TSM. If your organization used non-default system user accounts, as described in an early section of this topic, then you must specify the users during this step.

2. Activate and Register Tableau Server.

3. (Optional). On the initial node, Configure Local Firewall.

4. Import topology and configuration data. Copy the topology and configuration json backup file to the computer. Import the json file by running the following command:

   tsm settings import -f <filename>.json

5. Set identity store type.
   
   - For local identity store, run the following command:

     tsm configuration set -k "wgserver.authenticate" -v "local"

   - For any type of LDAP directory identity store, run the following command:

     tsm configuration set -k "wgserver.authenticate" -v "activedirectory"

   LDAP directory will require authentication-related files (keytab file, Kerberos config file, and/or SSL certificates). Copy these files to the appropriate directories as part of this step. See identityStore Entity.

6. Restore repository data. See Restore from a backup.

7. (Optional). Repopulate TSM group membership. Add users to groups with this command:

   sudo usermod -G <group_name> -a <username>

To restore a Tableau Server cluster
1. On the initial node, Install and Initialize TSM. If your organization used non-default system user accounts, as described in an early section of this topic, then you must specify the users during this step.

2. On the initial node, Activate and Register Tableau Server.

3. (Optional). On the initial node, Configure Local Firewall.

4. On the initial node, set identity store type.
   - For local identity store, run the following command:
     
     tsm configuration set -k "wgserver.authenticate" -v "local"

   - For any type of LDAP directory identity store, run the following command:
     
     tsm configuration set -k "wgserver.authenticate" -v "activedirectory"

   LDAP directory will require authentication-related files (keytab file, Kerberos config file, and/or SSL certificates). Copy these files to the appropriate directories as part of this step. See identityStore Entity.

5. On the initial node, Deploy a Coordination Service Ensemble. The ensemble configuration must match your previous configuration.

6. On the initial node, restore repository data. See Restore from a backup.

7. On the initial node, run tsm topology nodes get-bootstrap-file --file <path\file>.json.

8. Copy the bootstrap.json file to all additional nodes in the cluster.

9. On each additional node in the cluster:
a. Install the Tableau Server package.

b. Navigate to the scripts directory.

c. Initiate communication between initial node and the additional node:

   sudo ./initialize-tsm -b <path-to-bootstrap>.json -u <admin-user-on-first-node> --accepteula

10. On the initial node, run tsm topology list-nodes -v and ensure that the node names have not changed from exported topology settings. If they have, topology settings should be manually updated with new names, or the processes should be manually configured.

11. On the initial node, run tsm settings import -f <filename>.json --topology-only to import topology settings if not configuring manually.

12. (Optional). On the initial node, finalize setup, verify LDAP (optional), and initialize Tableau Server. See Configure Initial Node Settings.

13. (Optional). On the initial node, run tsm pending-changes apply

14. On the initial node, run tsm restart

15. On the initial node, repopulate TSM group membership. Add users to groups with this command:

   sudo usermod -G <group_name> -a <username>

Restore other functionality

If the previous server was configured with the following features, then you will need to re-enable and reconfigure them on the restored server:

- Authentication solutions: OpenID, external SSL, and trusted authentication. See Authentication.

- Site customizations: See tsm customize.
• Enable access to PostgreSQL repository: See tsm data-access repository-access enable.

Back up Tableau Server data

Regularly backing up Tableau Server is an important step in proper administration and maintenance of your server. You can use the tsm maintenance restore command to restore Tableau Server backups created using tabadmin backup and tsm maintenance backup. Database backups made in other ways, and virtual machine snapshots are not valid sources for restoring Tableau Server, so it is critical that you have an up-to-date backup.

Tableau Server data consists of the Tableau PostgreSQL database or repository, which contains workbook and user metadata, data extract files, and configuration data. When you use TSM to create a backup, all of this data is saved in a single file with a .tsbak extension. If you are running a multi-node installation of Tableau Server data from all the nodes is backed up.

With multi-node installations, you should also be aware that the speed of a backup can depend on the location of certain processes. For details, see Best Practices for Backing Up Tableau Server.

The frequency of your backups depends on your environment, including how much use your server gets and how much and frequently the content and users change. Any changes or updates that happen after your backup will be lost if there is a system failure and you need to restore Tableau Server. The more activity there is, the more often you need to back the server up.

In addition to regular backups, you should always create a backup before upgrading to a new version of Tableau Server.
To help protect against data loss, after you create the backup, you should store the .tsbak file on a computer that is not a part of your Tableau Server installation.

In this topic

- Backup and Disk Space Usage
- Create a backup using the TSM command line interface (CLI)
- Create a pre-upgrade backup
- Script the backup process

Backup and Disk Space Usage

You must have adequate disk space for database backup and restore processes to run successfully. In addition to the amount of space needed for the backup file, you need temporary disk space roughly 10 times the size of the backup file (so if your backup is 4 GB, you should have about 40 GB of temporary disk space available). Similarly you will need adequate temporary disk space for restoring from a backup.

When calculating disk space, be aware that background tasks for cleaning up old extracts are temporarily paused. This means that, for the duration of the backup, extract refreshes will leave extra files in place, adding to disk space usage. If your backup takes a long time, or if your organization uses many extracts that are regularly updated, this can result in a significant amount of temporary disk space usage. These old files will be removed after the backup is complete.

Create a backup using the TSM command line interface (CLI)

Use the `tsm maintenance backup` command to create a backup of the data managed by Tableau Server. This data includes the Tableau PostgreSQL database (the repository) which contains workbook and user metadata, and extract files. To back up server configuration data, use the `tsm settings` command. When you use the `tsm maintenance backup` command, the current date is appended to the backup file:

```
tsm maintenance backup -f <backup_file> -d
```
Note: When backing up Tableau Server on Linux, the unprivileged user must have write access to the network share where the backup files are written. Otherwise, backup will fail.

For more information, see tsm maintenance backup.

Create a pre-upgrade backup

You should always create a backup before upgrading Tableau Server. You can create a backup while Tableau Server is running and minimize the amount of time the server is unavailable during upgrade. The process for creating a pre-upgrade backup is the same as for creating regular backups, with one additional consideration for distributed installations.

Note: Uninstall Tableau Server from any nodes that you are not including in your new installation to avoid conflicts between the older nodes and the new installation.

Script the backup process

If you back up often, you might want to create a script that performs the backup and related tasks for you. These tasks include:

- Clean up files and folders before running the backup.
- Running the backup itself.
- Copying the backup file to a separate computer for safekeeping.

This section discusses tsm commands you can use together to perform a backup and related tasks.

For additional information about scripting TSM commands, see the Tableau Community Forums.
Remove log files and clear temporary folders

You can clean old Tableau Server log file and temporary files to reduce the time it takes to create a backup, and to ensure the backup file is as small as possible.

To clean log files older than a few days, run the following command:

tsm maintenance cleanup

Run the backup

**Note:** When backing up Tableau Server on Linux, the unprivileged user must have write access to the network share where the backup files are written. Otherwise, backup will fail.

To create the backup, use the `tsm maintenance backup` command:

```
 tsm maintenance backup --file <backup_file> --append-date
```

Note the following about the command:

- Add `--append-date` to the command to include the date in the backup file name.
- By default the backup file is created in `/var/opt/tableau/tableau_server-<version>/data/tabsvc/files/backup/`. For more information, see `tsm maintenance backup`.

Copy the backup file to another computer

As a best practice, after the backup is created, copy the backup file to another location that is separate from Tableau Server.

**Restore from a backup**

Use the `tsm maintenance restore` command to restore your Tableau Server data.

You might do this if you had a system failure and need to restore your data, if you need to
switch back to a previous version of Tableau Server (for example, if there is a problem with an upgrade), or if you are moving Tableau Server to new hardware. You can use the \texttt{tsm maintenance restore} command to restore Tableau Server backups created using \texttt{tabadmin backup} and \texttt{tsm maintenance backup}. Database backups made in other ways, and virtual machine snapshots are not valid sources for restoring Tableau Server.

When you use \texttt{tsm maintenance restore} to restore your Tableau data, the contents of the PostgreSQL database, and data extracts are overwritten with the content in the backup file (.tsbak). If you are running a distributed installation of Tableau Server, perform the restore on the initial node or wherever the TSM Controller is running.

You can only restore from a backup that has the same type of identity store as the running server. For example, a backup from a server using local authentication can be restored to a Tableau Server initialized with local authentication, but a backup from a server using Active Directory authentication cannot be restored to a server initialized with local authentication.

**Restore Tableau Server from a backup file**

**Note:** This operation includes steps that you may need to perform using the TSM command line.

1. (Optional) Copy the .tsbak file to the default file location.

**Note:** If you are restoring a backup that was copied into the backups folder, ensure that the Run As service account, which can be found in TSM Web UI under Security, has at least Read access to the backup file. Otherwise, the restore process may not be able to unzip the backup file and the restore will fail.

2. Stop the server. At a command prompt, type:
tsm stop

3. Restore from a backup file. At a command prompt, type:

   tsm maintenance restore --file <file_name>

   In the above line, replace <file_name> with the name of the backup file you want to restore from.

   **Note:** If you encounter errors when trying to restore from backup, see Troubleshoot Tableau Server on Linux.

4. Restart the server:

   tsm start

   When you restore a .tsbak file, Tableau Server automatically creates a copy of its current data folder, names it tabsvc.bak-*, and places it in /var/opt/tableau/tableau_server/data. This folder is an emergency backup of Tableau Server that Tableau Support may be able to use in case something goes wrong during backup restoration.

   When the restore is complete and you have verified that Tableau Server is running correctly with all the expected data, it's safe to remove any tabsvc.bak-* folders from /var/-opt/tableau/tableau_server/data to free additional disk space. In Tableau Server clusters, tabsvc.bak-* folders are created on each machine running Tableau Server

   **Important:** Only remove the tabsvc.bak-* folders. Do not remove the tabsvc folder, which is also located under /var/opt/tableau/tableau_server/data. It contains necessary Tableau Server data.
Server Maintenance

As an administrator, you will want to check the status of the server, analyze and monitor the activity on the server, manage scheduled tasks, or perform certain maintenance activities such as clearing saved data connection passwords. In addition, there are several settings that you may want to specify to customize the user experience for people using the server. You can do some of these tasks from the General page of the Status page and others from the Settings page.

View Server Process Status

There are two locations in Tableau Server or Tableau Services Manager (TSM) where administrators can view the state of Tableau processes. You may be able to access one or both of these locations, depending on how your account and server are set up. Most of the process status information that displays is duplicated on both Status pages. This article explains each page, and identifies what is unique for each one.

- The Tableau Services Manager (TSM) status page is accessible in TSM and can be viewed by TSM administrators. You must be able to log into TSM to see this page. For information about signing into TSM, see Sign in to Tableau Services Manager Web UI.

- The Tableau Server status page appears in the Tableau Server web UI and is accessible by Tableau Server administrators. This page includes Tableau Server processes, along with links to troubleshooting documentation if a process is not running as expected. If you hover your mouse pointer over the status indicator for a process, a tooltip shows the node name and the port the process is running on. The Tableau Server status page does not show TSM processes. For information about signing into Tableau Server as an administrator, see Sign in to Tableau Server Admin Pages.

Tableau Services Manager (TSM) Status page

The TSM Status page shows you the state of server processes, including TSM Controller and License Server. These two processes do not display on the Tableau Server Status page.
Possible status indicators are listed at the bottom of the table:

<table>
<thead>
<tr>
<th>Active</th>
<th>Busy</th>
<th>Error</th>
<th>Stopped</th>
</tr>
</thead>
</table>

<table>

</table>
Tableau Server Status page

Possible status indicators are listed at the bottom of the table:

- **Active**—The process is functioning as intended. See File Store in Troubleshoot Server Processes for details on possible active states.
- **Busy**—The process is completing some task. See File Store and Repository in Troubleshoot Server Processes for more information.
- Passive—The repository is in passive mode
- Unlicensed—The process is unlicensed.
- Down—The process is down. The implications of this differ depending on the process.
- Status unavailable—Tableau Server is unable to determine the status of the process.

If there is additional information, a message displays below the status icon and links to appropriate documentation:

![Ready for removal](image)

For more information about troubleshooting process status, see Troubleshoot Server Processes.

Access Status Remotely

**Note:** The information in this article refers to the Tableau Server status page. For information about the Tableau Server status page and the TSM status page, see View Server Process Status.

You must be a Tableau Server administrator to see the Server Status page, but you can grant remote access to other computers to allow access to a machine-readable (XML) version of the Status table by non-admin users and by computers other than the initial Tableau Server node. One reason you might do this is as part of a remote monitoring process.

To grant remote access to Tableau Server status:

1. Open a command prompt as an administrator and type the following:

   ```bash
   tsm configuration set -k wgserver.systeminfo.allow_referer_ips -v <ip address>
   ```

   In the above command, `<ip address>` is the IPv4 address of the computer for
which you want to enable remote access to the Tableau Server status XML.

For example:

```bash
tsm configuration set -k wgserver.systeminfo.allow_referrer_ips -v 10.32.139.31
```

If you are enabling remote access for more than one computer, use commas to separate each IP address.

```bash
tsm configuration set -k wgserver.systeminfo.allow_referrer_ips -v 10.32.139.31,10.32.139.35
```

2. Commit the configuration change:

```bash
tsm pending-changes apply
```

The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

Now, users of computers with the IP addresses that have been added can view Tableau process status by entering the URL `http://<server>/admin/systeminfo.xml` in a browser or from a command line (for example, `curl http://jsmith/admin/systeminfo.xml`).

For details on the XML that is returned, see Get Process Status as XML.

Get Process Status as XML

To get a machine-readable version of the server process status, that is, a version of the status formatted in XML, use the following URL:

`http://my_tableau_server/admin/systeminfo.xml`

You must be signed in to Tableau Server to view the machine-readable process status, or have enabled remote access.
The server returns a status report similar to the following:

```xml
<systeminfo xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <machines>
    <machine name="my_tableau_server">
      <repository worker="my_tableau_server:8060" status="Active" preferred="false"/>
      <dataengine worker="my_tableau_server:27042" status="Active"/>
      <applicationserver worker="my_tableau_server:8600" status="Active"/>
      <apiserver worker="my_tableau_server:8000" status="Active"/>
      <vizqlserver worker="my_tableau_server:9100" status="Active"/>
      <dataserver worker="my_tableau_server:9700" status="Active"/>
      <backgrounder worker="my_tableau_server:8250" status="Active"/>
      <gateway worker="my_tableau_server:80" status="Active"/>
      <searchandbrowse worker="my_tableau_server:11000" status="Active"/>
      <cacheserver worker="my_tableau_server:6379" status="Active"/>
      <filestore worker="my_tableau_server:9345" status="Active" pendingTransfers="0" failedTransfers="0" syncTimestamp="2015-02-27T20:30:48.564Z"/>
      <clustercontroller worker="my_tableau_server:12012" status="Active"/>
      <coordination worker="my_tableau_server:12000" status="Active"/>
    </machine>
  </machines>
</systeminfo>
```
Status values in the XML

- `<process> worker` - The name of the node running the process and the port the process is using.

- `status` - The status of the process on the node. Possible values are: Active, Passive, Unlicensed, Busy, Down, ReadOnly, ActiveSyncing, StatusNotAvailable, StatusNotAvailableSyncing, NotAvailable, DecommissionedReadOnly, DecomisioningReadOnly, and DecommissionFailedReadOnly

- `pendingTransfers` - A count of the workbook or data source extracts the node needs to get to be fully synced. These represent items that were published to this file store node, and items that were published to other file store nodes and need to be copied to this node.

- `failedTransfers` - A count of the workbooks or data sources that did not transfer successfully to this file store node during the last automated job. The automated job normally runs about every 15 to 30 minutes, but may take longer when transferring a large number of extracts or large extracts.

Failed transfers do not necessarily indicate a problem with Tableau Server. The recurring automated job will normally transfer files that failed during the previous sync. Reasons for failed file transfers are listed in the logs.

- `syncTimestamp` - The time in UTC of the last automated job that ran and synchronized files.
Troubleshoot Server Processes

**Note:** The information in this article refers to the Tableau Server status page. For information about the Tableau Server status page and the TSM status page, see View Server Process Status.

When Tableau Server is functioning properly, processes will show as Active, Busy or Passive (Repository). If there is additional information, a message appears below the status icon:

![Status Icon](image)

**Ready for removal**

Possible status indicators are:

- ![Status Icon](image)
- ![Status Icon](image)
- ![Status Icon](image)
- ![Status Icon](image)
- ![Status Icon](image)

The following sections provide troubleshooting recommendations for status messages that you may see.

**Cluster Controller**

This message will only display if you have more than two nodes.

**Status: Down; Message: "Node degraded"**

One or more of the following are true:

- Repository on the node is stopped.
- Node cannot respond to failover elsewhere on the cluster.
- If Tableau Server is configured for high availability and this is the active repository, fail-over to the second repository occurs.
- No status available for repository or file store on this node.
No action is necessary unless the cluster controller is regularly down or is down for an extended period of time.

If that occurs, take the following actions, in order, until the problem is resolved:

1. Check disk space. If disk space is limited, save the log files (use `tsm maintenance ziplogs`) in case you need them for Support, then remove unnecessary files.
2. Restart Tableau Server.
3. If Cluster Controller continues to show as down, save the log files (`tsm maintenance ziplogs`) and contact Support.

File Store

File Store status only reflects the state of the file store when the page was loaded.

An active status (✔️) with no message indicates that no extracts were being synchronized when the page was loaded. It is possible that the recurring "catch-all" job is running and synchronizing extracts.

Status: Busy; Message: "Synchronizing"

"Synchronizing," usually indicates that extracts were being synchronized across file store nodes when the page was loaded.

However, the "synchronizing" message is also returned following installation (both single-node and multi-node). After Tableau initializes the status should disappear within 15 or 20 minutes.

Status: Down; "Data Extracts unavailable"

On a single-node installation: "Data Extracts unavailable" indicates that existing extracts may be available but publish/refresh will fail. On multi-node installations, this message indicates that extract synchronization will fail for this node.

No action is necessary unless the file store is regularly down or is down for an extended period of time.
If that occurs, take the following actions, in order, until the problem is resolved:

1. Check disk space. If disk space is limited, save the log files (use `tsm maintenance ziplogs`) in case you need them for Support, then remove unnecessary files.
2. Restart Tableau Server.
3. If Cluster Controller continues to show as down, save the log files (`tsm maintenance ziplogs`) and contact Support.

⚠️ **Status: Busy; "Decommissioning"**

This message indicates that this File Store is in read-only mode and that any unique files on this node are being replicated to other file store nodes.

To remove this node, wait until the status message changes to "Ready for removal".

✅ **Status: Active; "Ready for removal"**

This message indicates that the File store is in read-only mode.

You can safely stop (`tsm stop`) the cluster and remove File Store processes, or remove entire node.

✅ **Status: Active; "Decommission failed"**

This message indicates that the File store is in read-only mode, and that at least one unique file failed to replicate to another file store node.

To resolve a failed decommissioning:

1. Run the `tsm topology filestore decommission` command again.
2. Check disk space on other file store nodes. Decommissioning will fail if another file store node does not have enough space to store all the extracts.
3. Check the `tsm.log` file on the initial node and additional nodes for errors.
4. Stop Tableau Server (`tsm stop`) and then try running the `tsm topology filestore decommission` command again.
5. Put the file store node back into read/write mode (`tsm topology filestore recommission`), collect logs, and then contact Support.
6. With Support: copy and merge extracts directory from this file store node to the same directory on another file store node.

Repository

蹚Status: Busy; Message: "Setting up"

The "Setting up" message indicates one or more of the following states:

- Passive repository is being synchronized with active repository.
- Repository is not ready to handle failover.
- Repository may have gotten more than two minutes behind active repository and is being setup again (this is faster than waiting for a sync).
- Failover occurred and this former active repository is rejoining the cluster.

Wait until the repository status message changes to "Passive".

If this message does not appear, or if it is taking a long time:

1. Check disk space and free space if possible.
2. Check cluster controller logs for errors.
3. Restart node.

蹚Status: Busy; Message: "Synchronizing"

Repository is synchronizing, for example after a failover.

蹚Status: Down; Message: n/a

When the Repository shows a status of down and there is no message, then the Repository is in one of the following states:

- If the installation is configured for high availability, failover of the repository occurred.
- Processes are restarting with updated database connection configurations after failover.
- If another active repository is not available, Tableau Server is down.

Take these actions in order until a step resolves the problem:
1. Wait several minutes for cluster controller to attempt to restart.
2. Restart Tableau Server (*tsm restart*).
3. Check disk space. If disk space is limited, save the log files (use *tsm maintenance ziplogs*) in case you need them for Support, then remove unnecessary files.
4. Restart Tableau Server.
5. If repository continues to show as down, save the log files (*tsm maintenance ziplogs*) and contact Support.

**Status: Passive; Message: n/a**

A passive status with no message indicates that the node is working as intended and that it is ready for failover if needed.

VizQL Server

**Status: Unlicensed; Message: n/a**

For information about unlicensed status for a VizQL Server process, see Handle an Unlicensed VizQL Server Process.

**Clear Saved Data Connection Passwords**

As the administrator, if you enable users to save data source passwords, server users can save data source passwords across multiple visits and browsers so they are no prompted for their credentials each time they connect to a data source.

You can reset the data source passwords for all Tableau Server users. Doing this forces them to sign in to the data sources the next time they visit a view that requires database authentication. Server users can also clear their saved data connection passwords on an individual basis using their User Preferences page.
To clear saved data connection passwords for all server users:

1. In a site, click **Settings > General**.

2. Under Saved Credentials, click **Clear All Saved Credentials**.

Synchronize All Active Directory Groups on the Server

As a server administrator, you can synchronize all Active Directory groups on a regular schedule or on-demand on the **General** tab of the **Settings** page for the server.

**Note:** If you run Tableau Server on Linux, all external directory communication is configured and managed with a LDAP identity store. In the context of user and group synchronization, Tableau Server configured with LDAP identity store is equivalent to Active Directory. Active Directory synchronization features in Tableau Server function seamlessly with properly configured LDAP directory solutions.
The Last synchronized time indicates the time that synchronization most recently began.

Synchronize Active Directory groups on a schedule

1. **Single-site**: Click Settings > General.

   **Multisite**: In the site menu, click Manage All Sites and then click Settings > General.

2. Scroll down the page to Active Directory Synchronization, and then select Synchronize Active Directory groups on a regular schedule.
3. Select the frequency and time of synchronization.

4. Click **Save**.

Synchronize all Active Directory groups on demand

At any time, you can synchronize Active Directory groups with Tableau Server to ensure that new users and changes in Active Directory are reflected in all Active Directory groups on Tableau Server.

1. **Single-site**: Click **Settings > General**.

   **Multisite**: In the site menu, click **Manage All Sites**, and then click **Settings > General**.
2. Under **Active Directory Synchronization**, click **Synchronize All Groups**.

View synchronization activity

You can view the results of synchronization jobs in the **Background Tasks for Non Extracts** administrative view. **Queue Active Directory Groups Sync** is the task that queues and indicates the number of **Sync Active Directory Group** tasks to be run.

1. **Single-site**: Click **Status**.

   **Multisite**: In the site menu, click **Manage All Sites** and then click **Status**.

2. Click the **Background Tasks for Non Extracts** link.

3. Set the **Task** filter to include **Queue Active Directory Groups Sync** and **Sync Active Directory Group**.

You can quickly navigate to this administrative view by clicking the **View synchronization activity** link in the **Settings** page for the server.

Set the minimum site role for users in an Active Directory group

In the **Groups - Details** page, you can set the minimum site role for group users to be applied during Active Directory synchronization.
This setting does not run synchronization; instead, it sets the minimum site role to applied to the group every time synchronization runs. The result is that when you synchronize Active Directory groups, new users are added to the site with the minimum site role. If a user already exists, the minimum site role is applied if it gives the user more access in a site. If you don’t set a minimum site role, new users are added as **Unlicensed** by default.

**Note:** A user’s site role can be promoted but never demoted based on the minimum site role setting. If a user already has the ability to publish, that ability will always be maintained. For more information on minimum site role, see Site roles and Active Directory import and synchronization.

1. In a site, click **Groups**.

2. On the Groups page, select a group.

   Click **Actions > Minimum Site Role**.

3. Select the minimum site role, and then click **Change Site Role**.
What happens when users are removed in the source Active Directory?

Users cannot be automatically removed from the Tableau Server through an Active Directory sync operation. Users that are disabled, deleted, or removed from groups in Active Directory remain on Tableau Server so that administrators can audit and reassign the user's content before removing the user's account completely. For more information, see Sync behavior when removing users from Active Directory.

Set the Default Start Page for All Users

By default, Tableau Server installs with the Views page as the default start page for all users. As the administrator, you can change this to another page that all users have access to, such as the Workbooks page. Individual users will be able to override your setting (search for "Access Your Profile and Account Settings" in the Tableau Server Help for details).

To set the default start page for all users

1. Navigate to the page you want to be the default page.
2. Click your name on the upper right corner of the page.
3. Select Make This the Start Page for All Users.

Disable Automatic Client Authentication

After Tableau Desktop clients first successfully sign in to Tableau Server, they are automatically authenticated in the future. Client sessions are managed by OAuth access and
refresh tokens.

By default, all client tokens reset after a year. If a client token has not been used in 14 days, then it will expire. You can change these values by setting the `refresh_token.-absolute_expiry_in_seconds` and `refresh_token.idle_expiry_in_seconds` options. See tsm configuration set Options.

As a Tableau Server administrator can also disable automatic authentication.

To immediately disconnect all clients from Tableau Server and require users to sign in every time they connect:

1. In the site menu, click Manage All Sites, and then click Settings > General.
2. Under Connected Clients, clear the option Allow clients to automatically connect to Tableau Server.
3. Click Save.

Remove Unneeded Files

As a best practice, you should monitor space usage on your server. If you need to make more space available, you can use the `tsm maintenance cleanup` command to remove Tableau Server log files, temporary files, and rows from the `http_requests` table of the Tableau Server PostgreSQL database.

You should run the `tsm maintenance cleanup` command regularly.

Server Settings (General)

The following settings are available on the General page in Server - Settings.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Embedded Credentials - Allow publishers to embed data source credentials in a workbook</td>
<td>Allows publishers to attach passwords to published workbooks that will automatically authenticate web users to connect to data sources.</td>
</tr>
</tbody>
</table>
The passwords are attached to workbooks and are only accessible on server. That is, when the workbook is opened in Tableau Desktop, users will still need to enter a user name and password to connect to the data source. When this setting is turned off, all existing embedded passwords are saved but are not used for authentication. If you turn the setting back on, users don't have to re-embed the passwords.

<table>
<thead>
<tr>
<th>Embedded Credentials - Allow publishers to schedule data extract refreshes</th>
<th>Allows publishers to assign workbooks to schedules. This option is only available if <strong>Allow publishers to embed data source credentials in a workbook</strong> is enabled. When this setting is enabled, publishers will see scheduling options in the Publish dialog box.</th>
</tr>
</thead>
</table>
| Saved Credentials - Allow users to save passwords for data sources | Allows users to choose "Remember my password" and save data source passwords across multiple visits, browsers, and devices. (By default, users can choose to "Remember my password until I sign out," which lets them save their password only for a single browser session.)

As an administrator, you can **clear all saved passwords** at any time. In addition, users can clear their own saved passwords. |
<p>| Saved Credentials - Allow users to save OAuth access tokens for data sources | Allows users to store access tokens with their user preferences. Access tokens are provided by cloud data sources that support OAuth connections, and they are used instead of user names and passwords to grant access to the data. |</p>
<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Connected Devices - Allow devices to automatically connect to Tableau Server</strong></td>
<td>Controls whether mobile users must sign in and provide their credentials every time they connect to Tableau Server, or if users can connect with their devices to Tableau Server without providing credentials after they authenticate their device successfully the first time. For more information, see Disable Automatic Client Authentication.</td>
</tr>
<tr>
<td><strong>Guest Access - Enable Guest account</strong></td>
<td>Allows users to view and interact with embedded views without having to sign in to a Tableau Server account. Permission can be assigned to the Guest User account to control the interactivity allowed for each view. This option is only available if you have a core-based server license.</td>
</tr>
<tr>
<td><strong>Default Start Page</strong></td>
<td>Takes you to the server’s current default start page for all users. For more information on how to change the default start page, see Set the Default Start Page for All Users. Individual users will be able to override this setting (search for &quot;Access Your Profile and Account Settings&quot; in the Tableau Server Help for details).</td>
</tr>
<tr>
<td><strong>Language and Locale</strong></td>
<td>Controls the language used for the server user interface and the locale used for views. Individual users can override this setting on their Account Settings page. Also, web browser settings are evaluated first to determine which language and locale should be used. For more information, see Language and Locale for Tableau Server.</td>
</tr>
<tr>
<td><strong>Active Directory Synchronization - Synchronize Active Directory</strong></td>
<td>Controls the synchronization of all Active Directory groups in Tableau Server based on a</td>
</tr>
<tr>
<td><strong>groups on a regular schedule</strong></td>
<td>schedule that you specify after you select the option <strong>Synchronize Active Directory groups on a regular schedule</strong>. For more information, see Synchronize All Active Directory Groups on the Server.</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| **Recommendations Trainer**  | Suggests server content, such as data sources and tables, to Tableau Desktop users. Content suggestions are based on popularity of the content or on content frequently used by other users who are similar to the current user. Scheduling options control how often the server checks for new content and new usage information to keep the recommendations up to date. New content includes new and updated data sources. New usage information includes information such as "Laura Rodriguez used the Food Catering data source" and "Henry Wilson used the Monthly Sales data source."
If you notice any impact on server performance, schedule this process to occur at a time when the server load is low. To track performance impact, look for the "Recommendations Trainer" task in the Background Tasks for Non Extracts view.
If you want to disable Recommendations, change the tsm configuration set Options option, "recommendations.enabled", to false. |
| **Reset to Default Settings** | Returns any server settings that have been changed since setup to their original state. |
Stop or Restart the Tableau Server Computer

As a best practice, you should always stop Tableau Server before you stop or restart the computer it is running on. This is true whether you are running Tableau on virtual machines (VMs), or on dedicated hardware. You should never turn off a computer without first stopping Tableau Server. Shutting down the computer while Tableau is running can cause problems restarting Tableau Server, and may result in unexpected results.

To be safe, follow these steps, whether you have a scripted process to shut down your systems, or manually shut down your computers:

1. Stop Tableau Server.

   You can do this either from the command line, using the `tsm stop` command, or from the TSM Web UI, by clicking **Tableau Server is running**, and selecting **Stop Tableau Server**.

   **Note:** Some TSM processes will continue to run, even after you stop Tableau Server. This is normal, and you can go ahead and stop your computer. The running services are designed to shut themselves off when the computer is stopped.

2. Once Tableau is stopped, stop your computer.

3. When you are ready, restart your computer. This might be after you have completed planned maintenance, or after leaving the computer off for some extended period of down time.

   You can do this either from the command line, using the `tsm start` command, or from the TSM Web UI, by clicking **Tableau Server is stopped**, and selecting **Start Tableau Server**.
TSM will start automatically when the computer starts, so you can run tsm commands even though Tableau Server is stopped.

**tsm Command Line Reference**

The topics in this section include reference content for Tableau Services Manager (TSM) command line interface (CLI) to support Tableau Server.

TSM is used to manage installation and configuration of Tableau Server. To learn more about TSM, see Tableau Services Manager Overview.

You can automate the installation and configuration tasks supported by the TSM CLI using the TSM API. To learn more about the prerelease (Alpha) TSM API, see Tableau Services Manager API.

Looking for tsm commands for Tableau Server on Windows? See tsm Commands.

**Using the tsm CLI**

You can run tsm commands on the initial node (the node where TSM is installed), or on any additional node in the cluster.

To run tsm commands, you need to open a command prompt.

1. Open a command prompt as administrator on a node in the cluster.

2. Run the command you want. If you are running the command from a node other than the initial node, include the `-s` option to specify the URL of the initial node by name (not IP address), and include the TSM port, 8850.

To see the version of TSM and Tableau Server from the initial node:

```
tsm version
```
To see the version of TSM and Tableau Server from an additional node:

```bash
tsm version -s https://<initial_node_name>:8850
```

For example:

```bash
tsm version -s https://myTableauHost:8850
```

**Viewing help content in the shell**

To view minimal help content from a command line, use the `tsm help category`.

**Synopsis**

```bash
tsm help [category] [command]
```

**Commands**

```bash
tsm help
```

Help for all tsm commands

```bash
tsm help <category>
```

Show help for a specific command category. For example, `tsm help authentication`.

```bash
tsm help <category> <command>
```

Show help for a specific command. For example, `tsm help authentication open-id`.

```bash
tsm help command
```

List all top-level commands or categories.

**Categories**
You can use the `tsm authentication` commands to enable, disable, and configure user authentication options for Tableau Server.

- sspi
- kerberos
- list
- mutual-ssl
- openid
- saml
- sitesaml
- trusted

### tsm authentication sspi <commands>

This command will only work on Tableau Server on Windows. If you attempt to enable SSPI on Tableau Server on Linux, an error will be returned.

Enable or disable automatic sign-in using Microsoft SSPI.

If you use Active Directory for authentication, you can optionally enable automatic logon, which uses Microsoft SSPI to automatically sign in your users based on their Windows username and password. This creates an experience similar to single sign-on (SSO). Do not enable SSPI if you plan to configure Tableau Server for SAML, trusted authentication, or for a proxy server.

**Synopsis**

```
  tsm authentication sspi enable [global options]

  tsm authentication sspi disable [global options]
```
tsm authentication kerberos <commands>

Enable, disable, and configure Kerberos user authentication on Tableau Server. See Configure Kerberos.

Synopsis

tsm authentication kerberos enable [global options]
tsm authentication kerberos disable [global options]
tsm authentication kerberos configure --keytab-file <keytab_file.keytab> [global options]

Options for kerberos configure

-k, --keytab-file <keytab_file.keytab>

Required.

Specifies the service.keytab file used for requests to the KDC.

tsm authentication list

List the server’s existing authentication-related configuration settings.

Synopsis

tsm authentication list [--verbose][global options]

Options

-v, --verbose

Optional.

Show all configured parameters.
tsm authentication mutual-ssl <commands>

Enable, disable, and configure mutual SSL for user authentication on Tableau Server. To learn more about mutual SSL, see Configure Mutual SSL Authentication.

Before you enable mutual SSL, you must enable and configure SSL for external communication. For information, see Configure SSL for External HTTP Traffic to and from Tableau Server.

Synopsis

tsm authentication mutual-ssl enable [global options]

tsm authentication mutual-ssl disable [global options]

tsm authentication mutual-ssl configure [options]
[global options]

Options

-cf, --ca-cert <certificate-file.crt>

Optional.

Specifies the location and file name for the certificate file. The file must be a valid, trusted certificate from a Certificate Authority (for example, Verisign).

-fb, --fallback-to-basic <true | false>

Optional.

Specifies whether Tableau Server should accept user name and password for authentication if SSL authentication fails.

Default value is false, to indicate that when configured for mutual SSL, Tableau Server does not allow a connection when SSL authentication fails.

-m, --user-name-mapping <upn | ldap | cn>
Optional.

Specifies the user name syntax (UPN, LDAP or CN) to retrieve from identity store or directory. The syntax must match the format for Subject or Subject Alternative Name on the user certificate.

-rf, --revocation-file <revoke-file.pem>

Optional.

Specifies the location and file name for the certificate revocation list file. This file can be a .pem or .der file.

**tsm authentication openid <commands>**

Enable, disable, and configure OpenID Connect (OIDC) user authentication on Tableau Server.

**Synopsis**

tsm authentication openid enable [global options]
tsm authentication openid disable [global options]
tsm authentication openid configure [options] [global options]
tsm authentication openid map-claims [options] [global options]
tsm authentication openid get-redirect-url [global options]

**Options for openid configure**

-a, --client-authentication <string>

Optional.

Specifies custom client authentication method for OpenID Connect.
To configure Tableau Server to use the Salesforce IdP, set this value to `client_secret_post`.

- `cs`, `--client-secret <string>`
  - Optional.
  - Specifies the provider client secret. This is a token that is used by Tableau to verify the authenticity of the response from the IdP. This value is a secret and should be kept securely.

- `cu`, `--config-url <CONFIG-URL>`
  - Optional.
  - Specifies the provider configuration URL. The default value is constructed based on the name of the server (gateway.public.host), and the gateway port, if any (gateway.public.port). In addition, by default the protocol is set to `https://` if SSL is enabled for the server.

- `mf`, `--config-file <config-file.json>`
  - Optional.
  - Specifies the local path to the static OIDC discovery JSON document.

- `i`, `--client-id <CLIENT-ID>`
  - Optional.
  - Specifies the provider client ID that your IdP has assigned to your application.

- `id`, `--ignore-domain <true | false>`
  - Optional. Default: `false`
  - Set this to `true` if the following are true:
- You are using email addresses as usernames in Tableau Server
- You have provisioned users in the IdP with multiple domain names
- You want to ignore the domain name portion of the email claim from the IdP

Before you proceed, review the user names that will be used as a result of setting this option to true. User name conflicts may occur. In the case of a user name conflict, the risk of information disclosure is high. See Requirements for Using OpenID Connect.

- **-if, --iframed-idp-enabled <true | false>**
  
  Optional. Default: false
  
  Specifies if IdP is allowed inside of an iFrame. The IdP must disable clickjack protection to allow iFrame presentation.

- **-ij, --ignore-jwk <true | false>**
  
  Optional. Default: false
  
  Set this to true if your IdP does not support JWK validation. In this case, we recommend authenticating communication with your IdP using mutual TLS or another network layer security protocol.

- **-r, --return-url <return-url>**
  
  The URL of your server. This is typically the public name of your server, such as "http://example.tableau.com".

- **-sn, --custom-scope-name <string>**
  
  Optional.
  
  Specifies a custom scope user-related value that you can use to query the IdP. See Requirements for Using OpenID Connect.
Options for openid map-claims

Use these options to change the default OIDC claims Tableau Server will use when communicating with your IdP. See Requirements for Using OpenID Connect.

-i, --id <string>

Optional. Default: sub

Change this value if your IdP does not use the sub claim to uniquely identify users in the ID token. The IdP claim that you specify should contain a single, unique string.

-un, --user-name <string>

Optional. Default: email

Change this value to the IdP claim that your organization will use to match user names as stored in Tableau Server.

**tsm authentication saml <commands>**

Configure Tableau Server to support single-sign on using the SAML 2.0 standard, enable or disable SAML for a site, map assertion attribute names between Tableau Server and the identity provider (IdP).

**Available commands**

- `tsm authentication saml configure [options] [global options]`
- `tsm authentication saml disable [options] [global options]`
- `tsm authentication saml enable [options] [global options]`
- `tsm authentication saml export-metadata [options] [global options]`
- `tsm authentication saml map-assertions [options]`
tsm authentication saml configure

Configure the SAML settings for the server. Specify the SAML certificate and metadata files, provide additional required information, set additional options.

If you are configuring SAML for the first time or have previously disabled it, you must run this command with tsm authentication saml enable. For more information, see Configure Server-Wide SAML.

Synopsis

`tsm authentication saml configure [options] [global options]`

Options

- `e, --idp-entity-id <id>`
  
  Required for initial SAML configuration; otherwise optional. IdP entity ID value.
  
  Typically this is the same as the Tableau Server return URL (specified in the `--idp-return-url` parameter). The entity ID that you enter is used as a base for generating site-specific entity IDs. For example, if you enter the following:

  `http://tableau-server`

  A site configured for SAML might display the following entity ID:

  `http://tableau-server/samlservice/public/sp/metadata?alias=48957410-9396-430a-967c-75bdb6e002a0`

  To find a site’s entity ID, go to the site’s Settings page, and select the Authentication tab. When SAML is enabled, the entity ID is shown under the first step for configuring site-specific SAML, exporting metadata.

- `r, --idp-return-url <idp-return-url>`
  
  Required for initial SAML configuration; otherwise optional. The SAML return URL configured in the IdP. This is typically the Tableau Server external URL; for example,
https://tableau-server.

**Notes**

- http://localhost does not work for an external server.
- Adding a trailing slash to the URL (https://tableau-server/) is not supported.

```
-i, --idp-metadata <idp-metadata.xml>
```

Required for initial SAML configuration; otherwise optional. Provide the location and name of the XML metadata file you exported from the IdP’s settings.

For example, `/var/opt/tableau/tableau_server/data/saml/<metadata-file.xml>`

```
-cf, --cert-file <certificate.crt>
```

Required for initial SAML configuration; otherwise optional. The location and file name for the x509 certificate file for SAML. For requirements for the certificate file, see SAML Requirements.

For example, `/var/opt/tableau/tableau_server/data/saml/<file.crt>`

```
-kf, --key-file <certificate.key>
```

Required for initial SAML configuration; otherwise optional. Location and name of the key file that goes along with certificate.

For example, `/var/opt/tableau/tableau_server/data/saml/<file.key>`

```
-a, --max-auth-age <max-auth-age>
```

Optional. Default value is 7200 (30 mins).

The maximum number of seconds allowed between a user’s authentication and processing of the AuthNResponse message.
-d, --desktop-access <enable | disable>

Optional. Default value is enable.

Use SAML to sign in to the server from Tableau Desktop. If single sign-on from Tableau client applications does not work with your IdP, you can set this to disable.

-m, --mobile-access <enable | disable>

Optional. Default value is enable.

Allow using SAML to sign in from older versions of Tableau Mobile app. Devices running Tableau Mobile app version 19.225.1731 and higher ignore this option. To disable devices running Tableau Mobile app version 19.225.1731 and higher, disable SAML as a client login option on Tableau Server.

-so, --signout <enable | disable>

Optional. Enabled by default.

Enable or disable SAML sign out for Tableau Server.

-su, --signout-url <url>

Optional. Enter the URL to redirect to after users sign out of the server. By default this is the Tableau Server sign-in page. You can specify an absolute or a relative URL.

Example

tsm authentication saml enable and saml disable

Enable or disable server-wide SAML authentication. In this context, all sites and users that you enable for SAML go through a single identity provider.

Synopsis

tsm authentication saml enable [global options]
tsm authentication saml disable [global options]

tsm authentication saml export-metadata

Export the Tableau Server .xml metadata file that you will use to configure the SAML IdP.

Synopsis

tsm authentication saml export-metadata [options]
[global options]

Options

-f, --file [/path/to/file.xml]

Optional.

Specifies the location and file name in which the metadata will be written. If you don’t include this option, export-metadata saves the file to the current directory, and names it samlmetadata.xml.

-o, --overwrite

Optional.

Overwrites an existing file of the same name specified in -f, or of the default name if -f is not included. If a file specified in -f exists, and -o is not included, the command does not overwrite the existing file.
tsm authentication saml map-assertions

Maps attributes between the IdP and Tableau Server. Provide the name that the IdP uses for the attribute specified in each argument.

Synopsis

tsm authentication saml map-assertions --user-name <user-name> [global options]

Options

-r, --user-name <user-name-attribute>

Optional. The attribute in which the IdP stores the user name. On Tableau Server this is the display name.

-e, --email <email-name-attribute>

Optional. The name of the attribute in which the IdP stores email addresses.

-o, --domain <domain-name-attribute>

Optional. The attribute in which the IdP stores the domain name.

Example for saml map-assertions

tsm authentication saml map-assertions --email=Email --user-name=DisplayName

tsml authentication sitesaml enable and sitesaml disable

Set the server to allow or disallow SAML authentication at the site level. Enabling site-specific SAML gives you access to the Settings > Authentication tab in the Tableau Server
web UI. The **Authentication** tab contains the site-specific SAML configuration settings.

Use the `sitesaml enable` command with `saml configure` if you haven’t yet configured the server to allow site-specific SAML. For more information, see [Configure Site-Specific SAML](#).

**Synopsis**

```bash
tsm authentication sitesaml enable [global options]
tsm authentication sitesaml disable [global options]

```

**tsm authentication trusted <commands>**

Configure trusted authentication (trusted tickets) for user authentication on Tableau Server.

**Synopsis**

```bash
tsm authentication trusted configure [options] [global options]
```

**Options**

```bash
-th,  --hosts <string>
```

*Optional.*

Specifies the trusted host names (or IPv4 addresses) of the web servers that will be hosting pages with Tableau content.

For multiple values, enter the names in a comma-separated list where each value is encapsulated in double-quotes.

For example:

```bash
tsm authentication trusted configure -th "192.168.1.101", "192.168.1.102", "192.168.1.103"
```

or
tsm authentication trusted configure -th "webserv1", "webserv2", "webserv3"

-t, --token-length <integer>

Optional.

Determines the number of characters in each trusted ticket. The default setting of 24 characters provides 144 bits of randomness. The value can be set to any integer between 9 and 255, inclusive.

Global options

-h, --help

Optional.

Show the command help.

-p, --password <password>

Required, along with -u or --username if no session is active.

Specify the password for the user specified in -u or --username.

If the password includes spaces, enclose it in quotes:

--password 'my password'

-s, --server <url_to_tsm>

Optional.

Use the specified address for Tableau Services Manager. The URL must start with https, include port 8850, and use the server name not the IP address, for example https://mytableauhost:8850. If no server is specified, https://<localhost | dnsname>:8850 is assumed.
-u, --username <user>

Required if no session is active, along with -p or --password.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

**tsm configuration**

You can use the `tsm configuration` commands to get, set, and update configuration values.

For specific configuration keys you can set, see tsm configuration set Options.

- get
- set

**tsm configuration get**

View the current server configuration and topology.

**Synopsis**

`tsm configuration get --key <config.key> [global options]`

**Option**

- `-k, --key`

  Required.

  Get the current value of the specified configuration key.

**tsm configuration set**

Set or import server configuration or topology.
Quotes around the `<config.key>` and the `<config_value>` are optional unless there are spaces, in which case you must use quotes around the key or value.

**Note:** After setting a configuration key value you must apply the pending configuration changes using `tsm pending-changes apply`. Until you do, the new value will not be used by Tableau or show up in the results of a `tsm configuration get` command. You can view pending changes using `tsm pending-changes list`. For more information, see `tsm pending-changes`.

**Synopsis**

```
tsm configuration set --key <config.key> --value <config_value>  
[global options]
```

**Options**

- **-k, --key <config.key>**
  
  Required.
  
  Configuration key.

- **-v, --value <config_value>**
  
  Required.
  
  Configuration value.

- **-d**

  Optional.

  Reset the configuration value to its default.

- **-frc, --force-keys**
Optional.

Force a key to be added to configuration even if it did not previously exist.

Global options

-h, --help

Optional.

Show the command help.

-p, --password <password>

Required, along with -u or --username if no session is active.

Specify the password for the user specified in -u or --username.

If the password includes spaces, enclose it in quotes:

--password 'my password'

-s, --server <url_to_tsm>

Optional.

Use the specified address for Tableau Services Manager. The URL must start with https, include port 8850, and use the server name not the IP address, for example https://mytableauhost:8850. If no server is specified, https://<localhost | dnsname>:8850 is assumed.

-u, --username <user>

Required if no session is active, along with -p or --password.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.
tsm configuration set Options

You can use the following configuration options with the `tsm configuration set` command.

Essential syntax is:

```
  tsm configuration set -k <config.key> -v <config_value>
```

After setting a configuration key value you must apply the pending configuration changes using `tsm pending-changes apply`. Until you do, the new value will not be used by Tableau or show up in the results of a `tsm configuration get` command. You can view pending changes using `tsm pending-changes list`. For more information, see `tsm pending-changes`.

To reset a configuration key back to its default value, use the `-d` option:

```
  tsm configuration set -k <config.key> -d
```

**Note:** Configuration keys are case-sensitive.

Options

api.server.enabled

  **Default value:** true

  Allows access to the Tableau Server REST API. By default, this functionality is enabled.

auditing.enabled

  **Default value:** true
Allows access to the PostgreSQL (Tableau Server's own database) historical auditing tables.

`backgrounder.externalquerycachewarmup.enabled`

Default value: `true`

Controls the caching of workbook query results after scheduled extract refresh tasks.

`backgrounder.externalquerycachewarmup.view_threshold`

Default value: `2.0`

The threshold for caching workbook query results after scheduled extract refresh tasks. The threshold is equal to the number of views that a workbook has received in the past seven days divided by the number of refreshes scheduled in the next seven days.

`backgrounder.extra_timeout_in_seconds`

Default value: `1800`

The number of seconds beyond the setting in `backgrounder.querylimit` before a background task is canceled. This setting makes sure that tasks do not hold up subsequent jobs if they are stalled. The setting applies to processes listed in `backgrounder.timeout_tasks`.

`backgrounder.failure_threshold_for_run_prevention`

Default value: `5`

The number of consecutive failures of a subscription or extract job before that job is suspended. Suspending continuously failing jobs helps preserve backgrounder resources for other jobs. To disable suspension of failing background tasks, set this to `-1`.

`backgrounder.querylimit`
Default value: 7200

Longest allowable time, in seconds, for completing a single extract refresh task or subscription task. 7200 seconds = 2 hours.

**Note:** If a background task reaches this time limit, it may continue to run for an additional several minutes while being canceled.

`backgrounder.send_email_on_refresh_failure`

Default value: `true`

Controls whether extract refresh alerts are enabled for all sites on the server. By default alerts are enabled. To disable extract refresh alerts for all sites on a server, set this to `false`.

Extract alerts can be enabled or disabled on a site basis by site administrators in site settings, or at the user level in user settings.

`backgrounder.sort_jobs_by_run_time_history_observable_hours`

Default value: `-1`

Controls the time window used when determining duration of the last full extract job.

Tableau Server can sort full extract refresh jobs so they are executed based on the duration of their "last run," executing the fastest full extract refresh jobs first.

The "last run" duration of a particular job is determined from a random sample of a single instance of the full extract refresh job in last `<n>` hours. Full extract jobs are then prioritized to run in order from shortest to longest based on their "last" run duration. By default this is sorting is disabled (-1). If enabling this, the suggested value is 36 (hours).

`backgrounder.sort_jobs_by_type_schedule_boundary_heuristics_milliseconds`

Default value: 60000
Controls the time window that identifies backgrounder jobs which are determined to have the same scheduled start time.

The backgrounder process orders work that is scheduled at the same time to be executed by job type, running the fastest category of jobs first: Subscriptions, then Incremental Extracts, then Full Extracts.

Jobs are batched to determine which jobs are scheduled at the “same time”. A value 60,000 milliseconds (the default) indicates jobs for schedules starting within a 1 minute window should be classified in the same batch and so are ordered by type within that batch.

backgrounder.subscription_image_caching

Default value: true

Controls whether backgrounder will cache images that are generated for subscriptions. Cached images do not have to be regenerated each time so caching improves subscription performance. By default image caching is enabled. To disable image caching for all sites on a server, set this to false.

backgrounder.timeout_tasks

Default value: refresh_extracts, increment_extracts, subscription_notify, single_subscription_notify

The list of tasks that can be canceled if they run longer than the combined values in backgrounder.querylimit and backgrounder.extra_timeout_in_seconds. The list of tasks is delimited with commas. The default list represents all the possible values for this setting.

clustercontroller.zk_session_timeout_ms

Default value: 300000
The length of time, in milliseconds, that Cluster Controller will wait for the Coordination Service (ZooKeeper), before determining that failover is required.

dataAlerts.checkIntervalInMinutes

Default value: 60

The frequency, in minutes, at which Tableau Server checks to determine if data-alert conditions are true.

(The server also checks whenever extracts related to data alerts are refreshed.)

dataAlerts.retryFailedAlertsAfterCheckInterval

Default value: true

Determines how often Tableau Server rechecks failing data alerts. When set to true, the server rechecks failing alerts at the frequency defined by dataAlerts.checkIntervalInMinutes. When set to false, the server rechecks failing alerts every five minutes, more quickly notifying alert recipients if data conditions have changed, but reducing server performance.

(The server also checks whenever extracts related to data alerts are refreshed.)

DataServerRefreshMetadataPerSession

Default value: false

Determines whether Tableau Server will make additional queries to get updated schema data for a published data source when there have been changes in the underlying schema structure. This is disabled by default for performance reasons, and there is a delay in the display of schema changes. If you want changes in the schema of a live published data source to be reflected quickly, or if you see errors (for example, "An error occurred while communicating with the data source: Invalid column name. Statement could not be prepared.") set this to true. When set to true, Tableau Server makes additional queries to update the schema.
features.AlertOnThresholdCondition

Default value: true

Controls whether data-drive alerts data-driven alerts are enabled for users on the server.

features.DesktopReporting

Default value: false

Controls whether Desktop License Reporting is enabled on the server. When set to false (the default), no Administrative Views related to desktop licenses are available. Set this to true to enable license reporting and make license usage and expiration Administrative Views visible on the Server Status page.

features.PasswordReset

Default value: false

Applies only to servers that use local authentication. Set to true to let users reset their passwords with a "Forgot password" option on the sign-in page.

gateway.http.cachecontrol.updated

Default value: false

The Cache-Control HTTP header specifies whether the client browser should cache content sent from Tableau Server. To disable caching of Tableau Server data on the client, set this option to true.

gateway.http.hsts

Default value: false
The HTTP Strict Transport Security (HSTS) header forces browsers to use HTTPS on the domain where it is enabled.

gateway.http.hsts_options

Default value: "max-age=31536000"

By default, HSTS policy is set for one year (31536000 seconds). This time period specifies the amount of time in which the browser will access the server over HTTPS.

gateway.http.request_size_limit

Default value: 16380

The maximum size (bytes) of header content that is allowed to pass through the Apache gateway on HTTP requests. Headers that exceed the value set on this option will result in browser errors, such as HTTP Error 413 (Request Entity Too Large) or authentication failures.

A low value for gateway.http.request_size_limit can result in authentication errors. Single sign-on solutions that integrate with Active Directory (SAML and Kerberos) often require large authentication tokens in HTTP headers. Be sure to test HTTP authentication scenarios before deploying into production.

We recommend setting tomcat.http.maxrequestsize option to the same value that you set for this option.

gateway.http.x_content_type_nosniff

Default value: true

The X-Content-Type-Options response HTTP header specifies that the MIME type in the Content-Type header should not be changed by the browser. In some cases, where MIME type is not specified, a browser may attempt to determine the MIME type by evaluating the characteristics of the payload. The browser will then display the content accordingly. This process is referred to as "sniffing." Misinterpreting the MIME
type can lead to security vulnerabilities. The X-Content-Type-Options HTTP header is set to 'nosniff' by default with this option.

gateway.http.x_xss_protection

Default value: true

The HTTP X-XSS-Protection response header is sent to the browser to enable cross-site scripting (XSS) protection. The X-XSS-Protection response header overrides configurations in cases where users have disabled XSS protection in the browser. The X-XSS-Protection response header is enabled by default with this option.

gateway.public.host

Default value: <hostname>

The name (URL) of the server, used for external access to Tableau Server. If Tableau Server is configured to work with a proxy server or external load balancer, it is the name entered in a browser address bar to reach Tableau Server. For example, if Tableau Server is reached by entering tableau.example.com, the name for gateway.public.host is tableau.example.com.

gateway.public.port

Default value: 80 (443 if SSL)

Applies to proxy server environments only. The external port the proxy server listens on.

gateway.slow_post_protection.enabled

Default value: false

Enabling this can provide some help in protecting against slow POST (Denial-of-Service) attacks by timing out POST requests that transfer data at extremely slow rates.
**Note:** This will not eliminate the threat of such attacks, and could have the unintended impact of terminating slow connections.

`gateway.timeout`

Default value: 1800

Longest amount of time, in seconds, that the gateway will wait for certain events before failing a request (1800 seconds = 30 minutes).

`gateway.trusted`

Default value: IP address of proxy server machine

Applies to proxy server environments only. The IP address(es) or host name(s) of the proxy server.

`gateway.trusted_hosts`

Default value: Alternate names of proxy server

Applies to proxy server environments only. Any alternate host name(s) for the proxy server.

`hyper.file_partition_size_limit`

Default value: 0

When set to 0, the size is set to unlimited and will use all the disk space that is available.

This option is used to set the disk space limit for a query that spools to disk. If your disk space usage by the spool.<id>.tmp file is higher than where you need it to be for your environment, it means that queries are spooling and taking up disk space. Use this option to limit the amount of disk space that any one query can use. The spool.<id>.tmp file can be found in the temp folder of the user account running Tableau Server. You can specify this value in K(KB), M(MB), G(GB), or T(TB) units.
For example, you can specify the size limit as 100G when you want to limit the disk space usage to 100 GB.

For more information about spooling see the Memory and CPU Usage section in Tableau Server Data Engine.

**hyper.global_file_partition_size_limit**

Default value: 0

When set to 0, the size is set to unlimited and will use all the disk space that is available.

This option is used to set the disk space limit for all queries that spool to disk. If your disk space usage by the spool.<id>.tmp file is higher than where you need it to be for your environment, it means that queries are spooling and taking up disk space. The spool.<id>.tmp file can be found in the temp folder of the user account running Tableau Server. Use this option to limit the amount of disk space in sum total that all queries use when spooling to disk. You can specify this value in K(KB), M(MB), G (GB), or T(TB) units. For example, you can specify the size limit as 100G when you want to limit the disk space usage to 100 GB. Tableau recommends that you start with this configuration when fine tuning your spooling limits.

For more information about spooling see the Memory and CPU Usage section in Tableau Server Data Engine.

**hyper.log_queries**

Default value: true

When set to true, query information is logged.

By default query information is logged. If however you find that the log files are too large for the amount of disk space available, you can set it to false to disable logging query information. Tableau recommends leaving this configuration set to true.

**hyper.log_query_cpu**
Default value: false

Use this setting to log how much time each query takes and the CPU usage.

**hyper.log_timing**

Default value: false

This setting is useful to find out more information about the queries, like compilation and parsing times. By default this setting is disabled. You can turn this by setting the value to true to collect more details about your queries. Note, however that this will increase the size of your data engine log files (\logs\hyper).

**hyper.log_troublesome_query_plans**

Default value: true

When set to true, logs query plans of query that are identified as problematic. Queries that are either canceled, running slower than 10 seconds, or if the queries are spooling to disk fall into this category. The information in the logs can be useful to troubleshoot problematic queries. You can change the setting to false if you are concerned about the size of the logs.

**hyper.num_job_worker_threads**

Default value: 75%

Use this option to specify maximum number of queries that can be run simultaneously. By default, the num_job_worker_thread = 75% of the logical cores. The values can be specified as an actual number or a percentage of the total logical cores on the machine. Use the following symptoms to determine when to make changes:

- Sustained 100% CPU consumption for 30 minutes or more.
- The CPU consumption is primarily by Data Engine. You can use the TOP com-
mand to display the process and resource consumption to find out if Data
Engine is responsible for the high CPU usage.

If the CPU load is caused by a large number of simple queries, try reducing the num-
ber or percentage of the total cores on the machine. Note, however, that the number
should not be set higher than the number of cores available on the machine. Also, it
must never be set lower than half of the total number of cores on production systems
as it may result in very slow performance of workbooks and extract creation.

hyper.num_task_worker_threads

Default value: 75%

Use this option to specify the maximum number of cores that a single query can be par-
allelized across. Use the following symptoms to determine when to make changes:

- Sustained CPU consumption for 30 minutes or more.

- The CPU consumption is primarily by Data Engine. You can use the TOP com-
mand to display the process and resource consumption to find out if Data
Engine is responsible for the high CPU usage.

If the CPU usage is caused by a few large or complex queries indicated by individual
workbooks (that use extracts) taking a long time to load vs. general overall slow work-
book performance, try reducing the number of num_task_worker_threads.

hyper.use_spooling_fallback

Default value: true

When set to true, it allows spooling to disk when querying extracts exceeds set RAM
usage (80% of installed RAM).

Tableau recommends that you use the default setting. You can turn this off by setting
the value to false if you are concerned about disk usage. If you turn this setting off,
queries that use more than 80% of installed RAM will be canceled.
For more information about spooling see the Memory and CPU Usage section in Tableau Server Data Engine.

install.firewall.allowedprograms.manage

Default value: true

Controls whether Tableau Server can add firewall rules. When set to true (the default), Tableau Server will add new firewall rules to allow its processes to make connections through Windows Firewall. Change this to false if you want to manage all firewall rules yourself and do not want Tableau Server to add new rules.

java.heap.size

Default value: 128m

Size of heap for Tomcat (repository and solr). This generally does not need to change except on advice from Tableau.

monitoring.dataengine.connection_timeout

Default value: 30000

The length of time, in milliseconds, that Cluster Controller will wait for the data engine, before determining that a connection timeout occurred. The default is 30,000 milliseconds (30 seconds).

native_api.connection.limit.<connection class>

Set parallel query limit for the specified data source (connection class). This overrides the global limit for the data source.

native_api.connection.globallimit

Default value: 16
Global limit for parallel queries. Default is 16 except for Amazon Redshift which has a default of 8.

native_api.ProtocolTransitionLegacyFormat

Default value: false

Use the legacy name format for constrained delegation.

The name format was changed in version 10.1 to allow cross-domain protocol transition (S4U). If this causes problems with existing configurations and you don't need cross-domain protocol transition, configure Tableau Server to use the old behavior by setting this to true.

native_api.unc_mountpoints

Default value: none

Specifies UNC and FQDN path for shared Windows directories that are accessed by Tableau Server on Linux. Each path must also be referenced in a corresponding auto.-cifs file. Separate each path by a semicolon, for example:

'//files-rv01/development;/mnt/filesrv01/development;//filesrv01.example.lan/development;/mnt/filesrv01/development'

Subsequent updates to the native_api.unc_mountpoints value will overwrite the existing value. Therefore, each time you add a Windows share, you must include all shares in the updated value.

For more information, see the Community wiki topic, Connecting to a Windows Shared Directory.

pgsql.port

Default value: 8060
Port that PostgreSQL listens on.

pgsql.preferred_host

Specifies the computer name of the node with the preferred repository installed. This value is used if the `--preferred` or `-r` option is specified with the `tsm topology failover-repository command`.

Example:

```
 tsm configuration set -k pgsql.preferred_host -v "<host_name>"
```

**Note:** The `host_name` is case-sensitive and must match the node name shown in the output of `tsm status -v`.

pgsql.verify_restore.port

Default value: 8061

Port used to verify the integrity of the PostgreSQL database. See `tsm maintenance backup` for more information.

recommendations.enabled

Default value: `true`

Suggests server content, such as data sources and tables, to Tableau Desktop users. Content suggestions are based on popularity of the content or on content frequently used by other users who are similar to the current user.

refresh_token.absolute_expiry_in_seconds

Default value: 31536000
Specifies the number of seconds for absolute expiry of OAuth refresh and access tokens. The OAuth tokens are used by clients for authentication to Tableau Server after initial sign-in. To remove limits set to -1. To disable OAuth tokens, see Disable Automatic Client Authentication.

refresh_token.idle_expiry_in_seconds

Default value: 1209600

Specifies the number of seconds when idle OAuth tokens will expire. The OAuth tokens are used by clients for authentication to Tableau Server after initial sign-in. To remove limits set to -1.

refresh_token.max_count_per_user

Default value: 24

Specifies the maximum number of refresh tokens that can be issued for each user. If user sessions are expiring more quickly than you expect, either increase this value or set it to -1 to entirely remove token limits.

rsync.timeout

Default value: 600

Longest allowable time, in seconds, for completing file synchronization (600 seconds = 10 minutes). File synchronization occurs as part of configuring high availability, or moving the data engine and repository processes.

schedules.display_schedule_description_as_name

Default value: false

Controls whether a schedule name displays when creating a subscription or extract refresh (the default), or the "schedule frequency description" name describing the
time and frequency of the schedule displays. To configure Tableau Server to display timezone-sensitive names for schedules, set this value to `true`

When true, the "schedule frequency description" is also displayed after the schedule name on the schedule list page.

`schedules.display_schedules_in_client_timezone`

**Default value:** `true`

Shows the "schedule frequency description" in the timezone of the user when true (uses the client browser timezone to calculate the "schedule frequency description").

`service.jmx_enabled`

**Default value:** `false`

Setting to `true` enables JMX ports for optional monitoring and troubleshooting.

`service.max_procs`

**Default value:** `<number>`

Maximum number of server processes.

`service.port_remapping.enabled`

**Default value:** `true`

Determines whether or not Tableau Server will attempt to dynamically remap ports when the default or configured ports are unavailable. Setting to `false` disables dynamic port remapping.

`session.ipsticky`

**Default value:** `false`
Makes client sessions valid only for the IP address that was used to sign in. If a request is made from an IP address different from that associated with the session token, the session token is considered invalid.

In certain circumstances—for example, when Tableau Server is being accessed by computers with known and static IP addresses—this setting can yield improved security.

**Note:** Consider carefully whether this setting will help your server security. This setting requires that the client have a unique IP address and an IP address that stays the same for the duration of the session. For example, different users who are behind a proxy might look like they have the same IP address (namely, the IP address of the proxy); in that case, one user might have access to another user’s session. In other circumstances, users might have a dynamic IP address, and their address might change during the course of the session. If so, the user has to sign in again.

---

**sheet_image.enabled**

**Default value:** `true`

Controls whether you can get images for views with the REST API. For more information, see [REST API Reference](#).

**solr.rebuild_index_timeout**

**Default value:** `3600`

When Tableau Server is upgraded or when a `.tsbak` file is restored, the background task rebuilds the search index. This setting controls the timeout setting for that task (3600 seconds = 60 minutes).

**subscriptions.enabled**

**Default value:** `false`
Controls whether subscriptions are configurable system-wide. See Set Up a Server for Subscriptions.

subscriptions.timeout

Default value: 1800

Longest allowable time, in seconds, for a single view in a workbook subscription task to be rendered before the task times out. This value applies separately to each view in the workbook, so the total length of time to render all the views in a workbook (the full subscription task) may exceed this timeout value. 1800 seconds = 30 minutes.

tomcat.http.maxrequestsize

Default value: 16380

The maximum size (bytes) of header content that is allowed to pass through the Apache gateway on HTTP requests. Headers that exceed the value set on this option will result in browser errors, such as HTTP Error 413 (Request Entity Too Large) or authentication failures.

A low value for tomcat.http.maxrequestsize may result in authentication errors. Single sign-on solutions that integrate with Active Directory (SAML and Kerberos) often require large authentication tokens in HTTP headers. Be sure to test HTTP authentication scenarios before deploying into production.

We recommend setting gateway.http.request_size_limit option to the same value that you set for this option.

tomcat.https.port

Default value: 8443

SSL port for Tomcat (unused).

tomcat.server.port

Default value: 8085
Port that tomcat listens on for shutdown messages.

vizportal.adsync.update_system_user

Default value: false

Specifies whether email addresses and display names of users are changed (even when changed in Active Directory) when an Active Directory group is synchronized in Tableau Server. To ensure that user email addresses and display names are updated during synchronization, set vizportal.adsync.update_system_user to true, and then restart the server.

vizportal.commenting.delete_enabled

Default value: true

When set to true, lets users delete comments on views. You can delete a comment if you created it, are the content owner, a project leader with an appropriate site role, or are an administrator. To learn which site roles are required for full project leader access, see Project-level administration.

vizportal.csv_user_mgmt.index_site_users

Default value: true

Specifies whether indexing of site users is done user by user when importing or deleting users with a CSV file. When set to true (the default) indexing is done as each user is added or deleted. To delay the indexing of the site users until after the entire CSV file has been processed, set this to false.

vizportal.log.level

Default value: info

The logging level for vizportal Java components. Logs are written to /var/opt/tableau/tableau_server/data/tabsvc/logs/vizportal/*.log.
Set to debug for more information. Using the debug setting can significantly impact performance, so you should only use this setting when directed to do so by Tableau Support.

vizportal.openid.client_authentication

Specifies custom client authentication method for OpenID Connect. To configure Tableau Server to use the Salesforce IdP, set this value to client_secret_post.

vizportal.rest_api.cors.allow_origin

Specifies the origins (sites) that are allowed access to the REST API endpoints on Tableau Server when vizportal.rest_api.cors.enabled is set to true. You can specify more than one origin by separating each entry with a comma (,).

If vizportal.rest_api.cors.enabled is false, the origins listed by this option are ignored. For more information, see Enabling CORS on Tableau Server.

Note: You can use an asterisk (*) as a wild card to match all sites. This is not recommended as it allows access from any origin that has access to the server and can present a security risk. Do not use an asterisk (*) unless you fully understand the implications and risks for your site.

vizportal.rest_api.cors.enabled

Default value: false

Controls whether Tableau Server allows Cross Origin Resource Sharing (CORS). When set to true, the server allows web browsers to access the Tableau REST API endpoints. You can use this option and the REST API to create custom portals.
default, this functionality is not enabled. To specify which origins (sites) have access, use the `vizportal.rest_api.cors.allow_origin` option. Only the origins specified with this option are allowed to make requests to the Tableau Server REST API. For more information, see Enabling CORS on Tableau Server.

`vizportal.rest_api.view_image.max_age`

Default value: 720

The amount of time, in minutes, to cache images that are generated by the Query View Image method of the REST API. For more information, see the REST API Reference in the REST API help.

`vizqlserver.allow_insecure_scripts`

Default value: false

Allows a workbook to be published to the server from Tableau Desktop, and to be opened from the server, even if the workbook contains SQL or R expressions that are potentially unsafe (for example, a SQL expression that could potentially allow SQL injection). When this setting is false (the default), publishing a workbook or opening it from the server results in an error message, and the workbook is blocked. You should set this value to true only if you want to use workbooks that contain SQL or R expressions that have been detected as potentially unsafe, and only if the workbooks come from a safe source and you have verified that they do not contain an unsafe expression.

`vizqlserver.browser.render`

Default value: true

Views under the threshold set by `vizqlserver.browser.render_threshold` or `vizqlserver.browser.render_threshold_mobile` are rendered by the client web browser instead of by the server. See About Client-Side Rendering for details.

`vizqlserver.browser.render_threshold`
Default value: 100

The default value represents a high level of complexity for a view displayed on a PC. Complexity factors include number of marks, headers, reference lines, and annotations. Views that exceed this level of complexity are rendered by the server instead of in the PC's web browser.

**vizqlserver.browser.render_threshold_mobile**

Default value: 60

The default value represents a high level of complexity for a view displayed on a tablet. Complexity factors include number of marks, headers, reference lines, and annotations. Views that exceed this level of complexity are rendered by the server instead of in the tablet's web browser.

**vizqlserver.clear_session_on_unload**

Default value: false

Determines whether or not VizQL sessions are kept in memory when a user navigates away from a view or closes their browser. The default value (false) keeps sessions in memory. To close VizQL sessions on leaving a view or closing a browser, set this to true.

**vizqlserver.extsvc.connect_timeout_ms**

Default value: 1000

Extends the timeout value, in milliseconds, for connections to Microsoft’s RServer. Raise the value of this setting if Tableau is timing out before the server can respond.

**vizqlserver.extsvc.host**

Specifies an external service host.
Note: In versions of Tableau before version 10.1, this setting was named vizqlserver.rserve.host. Be sure to use this earlier setting name if your Tableau version is older than version 10.1.

This setting, and the other vizqlserver.extsvc settings, support external service functionality in workbooks—in particular, R servers and Python servers.

R is an open source software programming language and a software environment for statistical computing and graphics. In Tableau Desktop, you can use a set of four functions to pass R expressions to an Rserve server and obtain a result. If you upload a workbook that uses any of these functions, you should configure Tableau Server for an Rserve connection, by configuring this option and the three following. Otherwise, any worksheets that use R functionality will be unavailable.

See Pass Expressions to External Services in the Tableau Help for further details.

vizqlserver.extsvc.password

Specifies an external service password. This setting supports R and Python functionality in workbooks. Not all Rserve hosts require a username and password.

Note: In versions of Tableau before version 10.1, this setting was named vizqlserver.rserve.password. Be sure to use this earlier setting name if your Tableau version is older than version 10.1.

vizqlserver.extsvc.port

Default value: 6311

Specifies an external service port. This setting supports R and Python functionality in workbooks.
**Note:** In versions of Tableau before version 10.1, this setting was named `vizqlserver.rserve.port`. Be sure to use this earlier setting name if your Tableau version is older than version 10.1.

`vizqlserver.extsvc.username`

Specifies an external service username. This setting supports R and Python functionality in workbooks. Not all Rserve hosts require a username and password.

**Note:** In versions of Tableau before version 10.1, this setting was named `vizqlserver.rserve.username`. Be sure to use this earlier setting name if your Tableau version is older than version 10.1.

`vizqlserver.geosearch_cache_size`

Default value: 5

Sets the maximum number of different geographic search locale/language data sets that can be loaded into server memory at the same time. When the server receives a geographic search request for locale/language data set that is not in memory, it will load the set into memory. If loading the data set will exceed the specified limit, the least recently used locale/language data set is cleared from memory so the requested one can be loaded. The minimum value is 1. Each cache takes approximately 60 MB in memory (so if you set this to 10, the memory usage would be 600 MB (60 * 10)).

`vizqlserver.initialsql.disabled`

Default value: false

Specify whether to ignore initial SQL statements for all data sources. Set this to true to ignore initial SQL:
tsm configuration set -k vizqlserver.initialsql.disabled -v true

vizqlserver.log.level

Default value: info

The logging level for vizportal Java components. Logs are written to /var/opt/tableau/tableau_server/data/tabsvc/logs/vizportal/*.log.

Set to debug for more information. Using the debug setting can significantly impact performance, so you should only use it when directed to do so by Tableau Support.

vizqlserver.port

Default value: 9100

Base port for the VizQL servers.

vizqlserver.protect_sessions

Default value: true

When set to true, prevents VizQL sessions from being reused after the original user signs out.

vizqlserver.querylimit

Default value: 1800

Longest allowable time for updating a view, in seconds.

vizqlserver.session.expiry.minimum

Default value: 5
Number of minutes of idle time after which a VizQL session is eligible to be discarded if the VizQL process starts to run out of memory.

`vizqlserver.session.expiry.timeout`

Default value: 30

Number of minutes of idle time after which a VizQL session is discarded.

`vizqlserver.showdownload`

Default value: true

Controls the display of the **Tableau Workbook** option of the Download menu in views. When set to false, the Tableau Workbook option is unavailable.

`vizqlserver.showshare`

Default value: true

Controls the display of Share options in views. To hide these options, set to false.

**Note:** Users can override the server default by setting the "showShareOptions" JavaScript or URL parameter.

`vizqlserver.url_scheme_whitelist`

Specifies one or more URL schemes to whitelist when using URL actions on views and dashboards. The schemes http, https, gopher, mailto, news, sms, tel, tsc, and tsl are whitelisted by default. This command can contain multiple comma and space-separated values, as in this example:

```
tsm configuration set vizqlserver.url_scheme_whitelist scheme1, scheme2
```
The values you specify overwrite previous settings. Therefore, you must include the full list of schemes in the `set` command. (You cannot amend the list of schemes by running the `set` command repeatedly.)

```plaintext
webdataconnector.refresh.enabled

Deprecated. Use `tsm data-access web-data-connectors allow` instead.

Determines whether extract refreshes for web data connectors (WDCs) are enabled in Tableau Server. To disable refresh for all WDCs, set the value for this key to `false`, as shown below:

```bash
tsm configuration set --key webdataconnector.refresh.enabled --value false
```

To learn more, see [Web Data Connectors in Tableau Server](#).

```plaintext
webdataconnector.whitelist.fixed

Deprecated. Use `tsm data-access web-data-connectors add` instead.

Specifies one or more web data connectors (WDCs) that can be used by to access data connections that are accessible over HTTP or HTTPS. This command is formatted as JSON data on a single line, with all double-quotes (") escaped using a back-slash (\).

For example to add a San Francisco Film Locations WDC to the safe list:

```bash
tsm configuration set --key webdataconnector.whitelist.fixed --value "'{"https://tableau.data.world:443": {"properties": {"secondary_whitelist": ["(https://data.world/).*/"] }}}'"'
```

To learn more, see [Web Data Connectors in Tableau Server](#).

```plaintext
webdataconnector.enabled

Deprecated. Use `tsm data-access web-data-connectors allow` instead.
```
Default value: true

When set to true, you can use tsm commands to manage web data connectors on the server.

webdataconnector.whitelist.mode

Default value: mixed

Determines how Tableau Server can run web data connectors. Supported modes are:

- fixed. Users can run connectors that are on a safe list (whitelist) of URLs.
- insecure. Users can run any connector.

**Important:** Use the insecure option only for development and testing. Because connectors run custom code, running connectors that have not been vetted can pose a security threat.

wgserver.audit_history_expiration_days

Default value: 183

Specifies the number of days after which historical events records are removed from the PostgreSQL database (the Tableau Server database).

wgserver.change_owner.enabled

Default value: true

Controls whether the ownership of a workbook, data source or project can be changed. Other options include false and adminonly.

wgserver.clickjack_defense.enabled

Default value: true
When set to `true`, helps prevent a malicious person from "clickjacking" a Tableau Server user. In a clickjack attack, the target page is displayed transparently over a second page, and the attacker gets the user to click or enter information in the target page while the user thinks he or she is interacting with the second page.

For more information, see Clickjack Protection.

`wgserver.domain.ldap.domain_custom_ports`

**Default value:** `null`

Allows you to map child domains and their LDAP ports. Domain and port are separated by a colon (`:`) and each domain:port pair is separated by a comma (`,`) using this format: `FQDN1:port,FQDN2:port`

**Example:**
```
```

`wgserver.extended_trusted_ip_checking`

**Default value:** `false`

Enforces IP client matching for trusted ticket requests.

`wgserver.restrict_options_method`

**Default value:** `true`

Controls whether Tableau Server accepts HTTP OPTIONS requests. If this option is set to `true`, the server returns HTTP 405 (Method Not Allowed) for HTTP OPTIONS requests.

`wgserver.saml.idpattribute.username`

Specifies the name of the attribute in which your SAML IdP stores user names. By default, this is set to `username`. If the attribute name that your IdP uses contains
spaces, enclose it in quotation marks. For more information, see Configure Server-
Wide SAML or Configure Site-Specific SAML.

wgserver.saml.iframed_idp.enabled

Default value: false

Default of false means that when users select the sign-in button on an embedded
view, the IdP’s sign-in form opens in a pop-up window.

When you set it to true, and a server SAML user who is already signed in navigates to
a web page with an embedded view, the user will not need to sign in to see the view.

You can set this to true only if the IdP supports signing in within an iframe. The iframe
option is less secure than using a pop-up, so not all IdPs support it. If the IdP sign-in
page implements clickjack protection, as most do, the sign-in page cannot display in
an iframe, and the user cannot sign in.

If your IdP does support signing in via an iframe, you might need to enable it explicitly.
However, even if you can use this option, it disables Tableau Server clickjack pro-
tection for SAML, so it still presents a security risk.

wgserver.saml.maxassertiontime

Default value: 3000

Specifies the maximum number of seconds, from creation, that a SAML assertion is usable.

wgserver.saml.responseskew

Default value: 180

Sets the maximum number of seconds difference between Tableau Server time and
the time of the assertion creation (based on the IdP server time) that still allows the
message to be processed.
wgserver.session.apply_lifetime_limit

Default value: false

Controls whether there is a session lifetime for server sessions. Set this to true to configure a server session lifetime.

wgserver.session.idle_limit

Default value: 240

The number of minutes of idle time before a sign-in to the web application times out.

wgserver.session.lifetime_limit

Default value: 1440

The number of minutes a server session lasts if a session lifetime is set. The default is 1440 minutes (24 hours). If wgserver.session.apply_lifetime_limit is false (the default) this is ignored.

wgserver.unrestricted_ticket

Default value: false

Specifies whether to extend access to server resources for users authenticated by trusted tickets. Default behavior allows users to access views only. Setting this to true allows users with valid trusted tickets to access server resources (projects, workbooks, and so on) as if they had signed in using their credentials.

workerX.gateway.port

Default value: 80 (443 if SSL)
External port that Apache listens on for workerX (where a “worker” is the term used for subsequent server nodes in the cluster). worker0.gateway.port is Tableau Server’s external port. In a distributed environment, worker0 is the initial Tableau Server node.

workerX.vizqlserver.procs

Default value: <number>

Number of VizQL servers.

zookeeper.config.snapCount

Specifies the number of transactions necessary to cause the Coordination Service to create a snapshot of the logs. By default this value is 100,000 transactions. If your Coordination Service is not writing enough transactions to result in snapshots, the automatic cleanup of snapshots older than five days will not take place, and you may lose disk space to the transaction logs. By default transaction logs and snapshots are created in the Tableau data directory.

tsm customize

You can use the tsm customize command to customize the look and feel of the Tableau Server client browser experience.
A - The Tableau logo for the browser window tab cannot be changed.

B - The server name can be changed using the --server-name option.

C - The header logo can be changed using the --header-logo option.

The image files you use should be in GIF, JPEG, or PNG format.

The header logo image can be up to 160 by 160 pixels, but not smaller than 32 by 32 pixels. For best results use an image that is 125 by 35 pixels. If the image is larger than 160 by 160 pixels, it will be clipped.

You can also add a logo to the user sign in page for Tableau Server.

The sign in logo image can be a maximum of 3000 by 3000 pixels.

The background colors on the header and sign in page are not the same. Your logo might look different depending on where it appears in the server interface.

Synopsis

tsm customize [options] [global options]
Options

--header-logo <path-to-logo>
Optional.
Specify a path to the image file that will be displayed in the header only.

--logo <path-to-logo>
Optional.
Path to a single image file that will display for both the header and the sign-in window.

--restore-defaults
Optional.
Reset all customization options to default install state.

--server-name <server_name>
Optional.
Server name that appears in the browser tab, tooltips, and messages.

--signin-logo <path-to-logo>
Optional.
Specify a path to the image file that will be displayed for sign-in window only.

Global options

-h, --help
Optional.
Show the command help.

-p, --password <password>

Required, along with -u or --username if no session is active.

Specify the password for the user specified in -u or --username.

If the password includes spaces, enclose it in quotes:

--password 'my password'

-s, --server <url_to_tsm>

Optional.

Use the specified address for Tableau Services Manager. The URL must start with https, include port 8850, and use the server name not the IP address, for example https://mytableauhost:8850. If no server is specified, https://<localhost | dnsname>:8850 is assumed.

-u, --username <user>

Required if no session is active, along with -p or --password.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

tsm data-access

You can use the tsm data-access commands to configure data caching, enable or disable data repository access, enable SAML for single sign-on, and configure settings for Web Data Connectors (WDCs).

- data-access caching set
- data-access caching list
tsm data-access caching set

Sets data connection caching settings. To learn more about data connection caching settings, see Configure Data Cache.

Synopsis

tsm data-access caching set [options] [global options]

Options

-r, --refresh-frequency

Optional.

Sets the frequency to refresh cached data with a new query to the underlying data source. You can specify a number to define the maximum number of minutes that data should be cached. You can also specify low to cache and reuse data for as long as possible, or always (equivalent to 0) to refresh data each time that a page is loaded. If this option is not specified, it defaults to low.

Global options

-h, --help

Optional.
Show the command help.

-p, --password <password>

Required, along with -u or --username if no session is active.

Specify the password for the user specified in -u or --username.

If the password includes spaces, enclose it in quotes:

--password 'my password'

-s, --server <url_to_tsm>

Optional.

Use the specified address for Tableau Services Manager. The URL must start with https, include port 8850, and use the server name not the IP address, for example https://mytableauhost:8850. If no server is specified, https://<localhost | dnsname>:8850 is assumed.

-u, --username <user>

Required if no session is active, along with -p or --password.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

tsm data-access caching list

Displays data connection caching settings. To learn more about data connection caching settings, see Configure Data Cache.

Synopsis

tsm data-access caching list [global options]
Global options

-h, --help

Optional.
Show the command help.

-p, --password <password>

Required, along with -u or --username if no session is active.
Specify the password for the user specified in -u or --username.
If the password includes spaces, enclose it in quotes:
--password 'my password'

-s, --server <url_to_tsm>

Optional.
Use the specified address for Tableau Services Manager. The URL must start with https, include port 8850, and use the server name not the IP address, for example https://mytableauhost:8850. If no server is specified, https://<localhost | dnsname>:8850 is assumed.

-u, --username <user>

Required if no session is active, along with -p or --password.
Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

tsm data-access repository-access disable

Disable external access to the Tableau PostgreSQL database for the default remote user. This will not disable access from localhost.
Synopsis

tsm data-access repository-access disable [options]
[global options]

Options

--repository-username <username>

  Required.

  The username, either tableau or readonly, with access to the data repository.

--request-timeout <timeout in seconds>

  Optional.

  Wait the specified amount of time for the command to finish. Default value is 1800 (30 minutes).

-r, --restart

  Optional.

  Suppress the prompt for restart and restart Tableau Server.

Global options

-h, --help

  Optional.

  Show the command help.

-p, --password <password>

  Required, along with -u or --username if no session is active.
Specify the password for the user specified in -u or --username.

If the password includes spaces, enclose it in quotes:

--password 'my password'

-s, --server <url_to_tsm>

Optional.

Use the specified address for Tableau Services Manager. The URL must start with https, include port 8850, and use the server name not the IP address, for example https://mytableauhost:8850. If no server is specified, https://<localhost | dnsname>:8850 is assumed.

-u, --username <user>

Required if no session is active, along with -p or --password.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

tsmt data-access repository-access enable

Enables access to the Tableau PostgreSQL database.

By default, PostgreSQL traffic uses port 8060 (TCP). If you are running a local firewall, be sure to allow traffic for this port. To change the PostgreSQL port, see Ports that are not dynamically mapped.

Synopsis

tsmt data-access repository-access enable [options] [global options]

Options

--repository-password <password>
Required.
Sets (or changes) the password to access the data repository for the specified username.

--repository-username <username>

Required.
The username, either tableau or readonly, with access to the data repository.

--request-timeout <timeout in seconds>
Optional.
Wait the specified amount of time for the command to finish. Default value is 1800 (30 minutes).

--ignore-prompt
Optional.
Suppress the prompt for restart and restart Tableau Server.

Global options

-h, --help
Optional.
Show the command help.

-p, --password <password>
Required, along with -u or --username if no session is active.
Specify the password for the user specified in -u or --username.
If the password includes spaces, enclose it in quotes:
--password 'my password'

-s, --server <url_to_tsm>

Optional.

Use the specified address for Tableau Services Manager. The URL must start with https, include port 8850, and use the server name not the IP address, for example https://mytableauhost:8850. If no server is specified, https://<localhost | dnsname>:8850 is assumed.

-u, --username <user>

Required if no session is active, along with -p or --password.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

tsm data-access repository-access list

Lists users who have access to the Tableau PostgreSQL database.

Synopsis

tsm data-access repository-access list [global options]

Global options

-h, --help

Optional.

Show the command help.

-p, --password <password>

Required, along with -u or --username if no session is active.

Specify the password for the user specified in -u or --username.
If the password includes spaces, enclose it in quotes:

```
--password 'my password'
```

-s, --server <url_to_tsm>

Optional.

Use the specified address for Tableau Services Manager. The URL must start with https, include port 8850, and use the server name not the IP address, for example https://mytableauhost:8850. If no server is specified, https://<localhost | dnsname>:8850 is assumed.

-u, --username <user>

Required if no session is active, along with -p or --password.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

tsm data-access set-saml-delegation

Setup single sign-on for SAML SAP HANA so that Tableau Server functions as an Identity Provider (IdP) that provides single sign-on for users making SAP HANA data connections.

Synopsis

tsm data-access set-saml-delegation [options] [global options]

Options

- kf, --cert-key <cert-key>

Optional.

The SAML certificate key file.

-cf, --cert-file <file-path>
Optional.

The location of the SAML certificate file.

-uf, --username-format <username-format>

Optional.

Username format using valid format keys.

-e, --enabled <enabled>

Optional.

Enables SAML for single sign-on.

-uc, --username-case <username-case>

Optional.

Username case using valid case keys.

Global options

-h, --help

Optional.

Show the command help.

-p, --password <password>

Required, along with -u or --username if no session is active.

Specify the password for the user specified in -u or --username.

If the password includes spaces, enclose it in quotes:

--password 'my password'
-s, --server <url_to_tsm>

Optional.

Use the specified address for Tableau Services Manager. The URL must start with 
https, include port 8850, and use the server name not the IP address, for example
https://mytableauhost:8850. If no server is specified,
https://<localhost | dnsname>:8850 is assumed.

-u, --username <user>

Required if no session is active, along with -p or --password.

Specify a user account. If you do not include this option, the command is run using cre-
dentials you signed in with.

tsm data-access web-data-connectors add

Add a web data connector (WDC) to the WDC safe list ("whitelist").

Synopsis

tsm data-access web-data-connectors add [options]
[global options]

Options

-n, --name <name>

Required.

The name for the WDC that will be displayed in the Tableau Server Data Sources
page. This name must be enclosed in single quotes (') or double quotes (").

-sec, --secondary <secondary-URL-1>, <secondary-URL-2>

Optional.
A comma-delimited list of URLs that indicates which domains the connector can make requests to or receive data from. To add a domain to this secondary safe list, use a wildcard character (*), as follows: https://www.example.com/*

--url <URL>

Required.

The URL for the WDC (formatted as <scheme>:<host>:<port>/<path>, for example https://www.tableau.com:80/example/). For many WDCs, the <port> value is 443 or 80, but you can check the value for your connector by looking at the data source details on Tableau Server or Tableau Online.

Global options

-h, --help

Optional.

Show the command help.

-p, --password <password>

Required, along with -u or --username if no session is active.

Specify the password for the user specified in -u or --username.

If the password includes spaces, enclose it in quotes:

--password 'my password'

-s, --server <url_to_tsm>

Optional.

Use the specified address for Tableau Services Manager. The URL must start with https, include port 8850, and use the server name not the IP address, for example

-u, --username <user>

Required if no session is active, along with -p or --password.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

tsm data-access web-data-connectors allow

Enable or disable WDC refreshes. Also, enable or disable the use of WDCs on Tableau Server.

Synopsis

tsm data-access web-data-connectors allow [options]
[global options]

Options

-r, --refreshes <refreshes-allowed>

Optional.

Set to false to disallow WDC refreshes. Defaults to true.

-t, --type <WDC-allowed>

Optional.

Set to none to disallow the use of WDCs on Tableau Server (and omit WDCs from backups). Defaults to all, which allows the use of WDCs.

Global options

-h, --help
Optional.

Show the command help.

-p, --password <password>

Required, along with -u or --username if no session is active.

Specify the password for the user specified in -u or --username.

If the password includes spaces, enclose it in quotes:

--password 'my password'

-s, --server <url_to_tsm>

Optional.

Use the specified address for Tableau Services Manager. The URL must start with https, include port 8850, and use the server name not the IP address, for example https://mytableauhost:8850. If no server is specified, https://<localhost | dnsname>:8850 is assumed.

-u, --username <user>

Required if no session is active, along with -p or --password.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

**tsm data-access web-data-connectors delete**

Delete a specified WDC, or all WDCs, from the Tableau Server safe list ("whitelist").

**Synopsis**

```
tsm data-access web-data-connectors delete [options]
[global options]
```
Options

--all

Optional.
This option will delete all WDCs.

--url <URL>

Optional.
The URL for the WDC to delete.

Global options

-h, --help

Optional.
Show the command help.

-p, --password <password>

Required, along with -u or --username if no session is active.
Specify the password for the user specified in -u or --username.
If the password includes spaces, enclose it in quotes:

--password 'my password'

-s, --server <url_to_tsm>

Optional.
Use the specified address for Tableau Services Manager. The URL must start with https, include port 8850, and use the server name not the IP address, for example

-u, --username <user>

Required if no session is active, along with -p or --password.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

tsm data-access web-data-connectors list

List all WDCs currently on the safe list ("whitelist").

Synopsis

tsm data-access web-data-connectors list [options]
       [global options]

Options

Global options

-h, --help

Optional.

Show the command help.

-p, --password <password>

Required, along with -u or --username if no session is active.

Specify the password for the user specified in -u or --username.

If the password includes spaces, enclose it in quotes:

--password 'my password'
-s, --server <url_to_tsm>

Optional.

Use the specified address for Tableau Services Manager. The URL must start with https, include port 8850, and use the server name not the IP address, for example https://mytableauhost:8850. If no server is specified, https://<localhost | dnsname>:8850 is assumed.

-u, --username <user>

Required if no session is active, along with -p or --password.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

tsm initialize

You can use the tsm initialize command to initialize Tableau Server.

Note: You must apply or discard pending changes before running tsm initialize or the initialize will fail. Apply pending changes using the tsm pending-changes apply command. Discard any pending changes you do not want to apply using tsm pending-changes discard.

Synopsis

tsm initialize [options] [global options]

Options

-r, --start-server

Optional. Leave the server running after initialization is complete.
Global options

-h, --help

Optional.
Show the command help.

-p, --password <password>

Required, along with -u or --username if no session is active.
Specify the password for the user specified in -u or --username.
If the password includes spaces, enclose it in quotes:
--password 'my password'

-s, --server <url_to_tsm>

Optional.
Use the specified address for Tableau Services Manager. The URL must start with https, include port 8850, and use the server name not the IP address, for example https://mytableauhost:8850. If no server is specified, https://<localhost | dnsname>:8850 is assumed.

-u, --username <user>

Required if no session is active, along with -p or --password.
Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

tsm jobs

You can use the tsm jobs commands to list, reconnect to, and cancel jobs.
tsm jobs cancel

Cancel a job on the server. Any job can be canceled before it starts running (when queued), but only backup and cleanup jobs can be canceled when they are already running.

Synopsis

tsm jobs cancel --id <jobID> [global options]

Options

-i, --id <jobID>

Required.

Id of the job to cancel.

tsm jobs list

List asynchronous jobs on the server.

Synopsis

tsm jobs list [--status <status>] [global options]

Options

-t, --status <status>

Optional.

Filter for jobs that match the given status.
Reconnect to an asynchronous job to display its progress. If no job id is specified, it reconnects to the latest job.

Synopsis

tsm jobs reconnect [--id <jobID>] [global options]

Options

-i, --id <jobID>

Optional.

Specifies the id of the job that should be reconnected.

Global options

-h, --help

Optional.

Show the command help.

-p, --password <password>

Required, along with -u or --username if no session is active.

Specify the password for the user specified in -u or --username.

If the password includes spaces, enclose it in quotes:

--password 'my password'

-s, --server <url_to_tsm>

Optional.
Use the specified address for Tableau Services Manager. The URL must start with https, include port 8850, and use the server name not the IP address, for example https://mytableauhost:8850. If no server is specified, https://<localhost | dnsname>:8850 is assumed.

-u, --username <user>

Required if no session is active, along with -p or --password.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

tsm licenses

You can use the tsm licenses commands to manage server license tasks like activating or deactivating a Tableau Server product key on- or off-line, and getting associated files for offline activation or deactivation.

- activate
- deactivate
- get-offline-activation-file
- get-offline-deactivation-file
- list
- refresh

tsm licenses activate

Activates a Tableau Server product key.

Synopsis

tsm licenses activate --license-key <product-key>
[global options]
Options

-\texttt{f, \textquote{license-file}} <\texttt{file.tlf}>

  Required if doing offline activation.

  Specifies the license file (<\texttt{file}.tlf) used for offline activation.

-\texttt{k, \textquote{license-key}} <\texttt{product-key}>

  Required if activating a valid product key.

  Specifies the product key to use for online activation.

-\texttt{t, \textquote{trial}}

  Required if activating a trial license.

  Activate a trial license.

\texttt{tsm licenses deactivate}

Deactivates a Tableau Server product key either online or offline.

Synopsis

\texttt{tsm licenses deactivate \textquote{license-key}} <\texttt{product-key}>

[global options]

Options

-\texttt{f, \textquote{license-file}} <\texttt{return_file.tlr}>

  Required if doing offline deactivation.

  Specifies the license file (<\texttt{file}.tlf) used for offline deactivation.

-\texttt{k, \textquote{license-key}} <\texttt{product-key}>
Required if deactivating a product key.

Specifies the product key to use for online deactivation.

tsm licenses get-offline-activation-file

Generate an offline activate file to use for activating Tableau Server offline. To learn more, see Activate Tableau Server Offline.

Synopsis

tsm licenses get-offline-activation-file --license-key <product-key> --output-dir <path> [global options]

Options

- `-k, --license-key <product-key>`
  Required.
  Specifies the product key to use for offline activation.

- `-o, --output-dir <path>`
  Required.
  The location where the offline activation file should be saved. This location must exist.

tsm licenses get-offline-deactivation-file

Generate an offline deactivation file to use for deactivating Tableau Server offline. To learn more, see Deactivate Tableau Server Offline.

Synopsis

tsm licenses get-offline-deactivation-file --license-key <product-key> --output-dir <path> [global options]
Options

-k, --license-key <product-key>

  Required.

  Specifies the product key to use for offline deactivation.

-o, --output-dir <path>

  Required.

  The existing location where the offline deactivation file should be saved.

tsrm licenses list

List licenses on Tableau Server. The output reflects whether Tableau Server uses a user-based license, a core-based license, or a combination of the two. This command provides license keys, license expiration dates, maintenance expiration dates, and quotas for each type of user-based license. To learn more, see View Server Licenses.

Synopsis

  tsm licenses list [global options]

tsrm licenses refresh

Update the maintenance expiration date of all product keys on Tableau Server.

Synopsis

  tsm licenses refresh [global options]

Global options

-h, --help
Optional.

Show the command help.

-p, --password <password>

Required, along with -u or --username if no session is active.

Specify the password for the user specified in -u or --username.

If the password includes spaces, enclose it in quotes:

--password 'my password'

-s, --server <url_to_tsm>

Optional.

Use the specified address for Tableau Services Manager. The URL must start with https, include port 8850, and use the server name not the IP address, for example https://mytableauhost:8850. If no server is specified, https://<localhost | dnsname>:8850 is assumed.

-u, --username <user>

Required if no session is active, along with -p or --password.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

tsm login

Use the tsm login command to log in to Tableau Services Manager. You need to authenticate to TSM before running any TSM command.

Synopsis

tsm login [global options]
Global options

-h, --help

Optional.
Show the command help.

-p, --password <password>

Required, along with -u or --username if no session is active.
Specify the password for the user specified in -u or --username.
If the password includes spaces, enclose it in quotes:
--password 'my password'

-s, --server <url_to_tsm>

Optional.
Use the specified address for Tableau Services Manager. The URL must start with https, include port 8850, and use the server name not the IP address, for example https://mytableauhost:8850. If no server is specified, https://<localhost | dnsname>:8850 is assumed.

-u, --username <user>

Required if no session is active, along with -p or --password.
Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

tsm logout

You can use the tsm logout command to log out of Tableau Server.
Synopsis

```bash
tsm logout [global options]
```

Global options

```bash
-h, --help
```

Optional.

Show the command help.

```bash
-p, --password <password>
```

Required, along with `-u` or `--username` if no session is active.

Specify the password for the user specified in `-u` or `--username`.

If the password includes spaces, enclose it in quotes:

```bash
--password 'my password'
```

```bash
-s, --server <url_to_tsm>
```

Optional.

Use the specified address for Tableau Services Manager. The URL must start with `https`, include port 8850, and use the server name not the IP address, for example `https://mytableauhost:8850`. If no server is specified, `https://<localhost | dnsname>:8850` is assumed.

```bash
-u, --username <user>
```

Required if no session is active, along with `-p` or `--password`.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.
You can use the `tsm maintenance` commands to manage server maintenance tasks like creating regular backups or restoring Tableau Server from a previously created backup.

- backup
- cleanup
- reindex-search
- restore
- send-logs
- validate-resources
- ziplogs

**tsm maintenance backup**

Creates a backup of the data managed by Tableau Server. This data includes the Tableau PostgreSQL database (the repository) which contains workbook and user metadata, and extract (.tde or .hyper) files. This data does not include configuration data. See Perform a Full Backup and Restore of Tableau Server.

Locating the repository (pgsql) and the File Store on the same node as the Administration Controller can reduce the length of time it takes to back up Tableau Server. The Administration Controller is usually on the initial node, unless you have had an initial node failure and had to move the controller to another node.

When the repository is co-located with the controller it eliminates or greatly reduces the need to compress and transfer data between nodes during the backup process. This is also true with the File Store, especially if your organization uses extracts heavily.

**Synopsis**

```
    tsm maintenance backup --file <backup_file> [options]
    [global options]
```
Options

-d, --append-date

Optional.

Append the current date to the backup file name.

-f, --file <backup_file>

Required.

Write the backup to the specified file. An extension of .tsbak is automatically used. The file is written to the directory defined in the TSM basefilepath.backuprestore variable. By default:

/var/opt/tableau/tableau_server/data/tabsvc/files/backups/

For more information about file paths and how to change them, see tsm File Paths.

-i, --description <string>

Optional.

Include the specified description of the backup file.

--skip-compression

Optional.

Create a backup without using compression. This results in a larger backup file but can reduce the amount of time it takes to complete the backup. If using this in a multi-node installation, we strongly recommend you have a File Store instance configured on your initial node.

-k, --skip-verification

Optional.
Do not verify the integrity of the database backup.

```
--override-disk-space-check
```

Optional.

Attempt to create a backup even when there is a low disk space warning.

```
-po, --pg-only
```

Optional.

Generates only the repository backup.

```
--request-timeout <timeout in seconds>
```

Optional.

Wait the specified amount of time for the command to finish. Default value is 1800 (30 minutes).

Examples

This example creates a backup called `ts_backup-<yyyymmdd>.tsbak` in the `/var/-opt/tableau/tableau_server/data/tabsvc/files/backups/` directory:

```
tsm maintenance backup -f ts_backup -d
```

**tsm maintenance cleanup**

Deletes old log files and temporary files.

If you are running Tableau Server on a distributed deployment, run this command on the node that is running the Administration Controller (also referred to as the *TSM Controller*) process. By default, the controller is on the initial node in the cluster.

The purpose of this command is to create free space on the Tableau deployment by deleting old files. Therefore, running this command when the server is started will remove the
majority of old content for this scenario. To remove current log files, then you must stop the server before running this command.

**Note:** This command was added in Tableau Server version 10.5.1 and some options were added in version 2018.1.

Synopsis

```
tsm maintenance cleanup [options] [global options]
```

Options

-a, --all

Optional.

Perform all cleanup operations with default retention values. Equivalent to running the `cleanup` command with the following options: `-l -t -r -q`.

`--http-requests-table-retention <# of days>`

Optional.

Delete http requests table entries older than this number of days. (Default: 7 days)

-l, --log-files

Optional.

Delete log files that are older than the retention-period. Files in the subdirectories under `data/tabsvc/logs` will be deleted.

`--log-files-retention <# of days>`

Optional.
Default: 1 (24 hours)
Delete logs older than this number of days. This command does not apply to temporary files.

-q, --http-requests-table
Optional.
Delete old http_requests table entries.

-r, --redis-cache
Optional.
Clear the Redis cache.

--request-timeout <timeout in seconds>
Optional.
Wait the specified amount of time for the command to finish. Default value is 1800 (30 minutes).

-t, --temp-files
Optional.
Delete all files and subdirectories in the following directories:

- /var/opt/tableau/tableau_server/data/tabsvc/temp: Only directories that are storing files for expired (not running) sessions are deleted.
- /var/opt/tableau/tableau_server/data/tabsvc/httpd/temp
- /var/opt/tableau/tableau_server/temp

-v, --verbose
Optional.
Show details of what was cleaned.

Examples

This example cleans up all log files older than 2 days old:

```bash
tsmp maintenance cleanup -l --log-files-retention 2
```

**tsm maintenance reindex-search**

Use the reindex-search command to rebuild the search index.

**Synopsis**

```bash
tsmp maintenance reindex-search [global options]
```

**Option**

```bash
--request-timeout <timeout in seconds>
```

Optional.

Wait the specified amount of time for the command to finish. Default value is 1800 (30 minutes).

**tsm maintenance restore**

Restore Tableau Server using the specified backup file. Restoring a backup file does not restore any configuration data. See Perform a Full Backup and Restore of Tableau Server.

You can only restore from a backup that has the same type of identity store as the running server. For example, a backup from a server using local authentication can be restored to a Tableau Server initialized with local authentication, but a backup from a server using Active Directory authentication cannot be restored to a server initialized with local authentication.
Synopsis

```
tsm maintenance restore --file <file_name> [--restart-server]
[global options]
```

Options

- **-ak, --asset-key-file <file_name>**

  Optional. Specify this option only if you are restoring from assets that were created by tabadmin on Tableau Server (versions 2018.1 and earlier).

  Name of asset key file to restore from. The asset key file is created by the `tabadmin assetkeys` command. The file must be in the predefined backup/restore location on the server.

- **-f, --file <file_name>**

  Required.

  Specifies the backup file to restore from.

  The `restore` command expects a backup file in the directory defined in the TSM basefilepath.backuprestore variable. By default:

  
  ```
  /var/opt/tableau/tableau_server/data/tabsvc/files/backups/
  ```

  For more information about file paths and how to change them, see tsm File Paths.

- **-k, --skip-identity-store-verification**

  Optional. Specify this option only if you are restoring from a backup file that was created by tabadmin on Tableau Server (versions 2018.1 and earlier).

  Skip identity store verification. Specify this option if you are restoring a backup file that was created with the `tabadmin backup --no-config` command.

- **-po, --pg-only**
Optional.

Restores only the repository.

-r, --restart-server

Optional.

Restart the server after the restore.

--request-timeout <timeout in seconds>

Optional.

Wait the specified amount of time for the command to finish. Default value is 1800 (30 minutes).

--request-timeout <timeout in seconds>

Optional.

Wait the specified amount of time for the command to finish. Default value is 1800 (30 minutes).

tsm maintenance send-logs

Upload the specified file to Tableau and associate it with a support case.

Synopsis

tsm maintenance send-logs --case <case_number> --email <contact_email> --file <path/to/file> [global options]

Options

-c,--case <case_number>

Required.
Support case number.

-e, --email <contact_email>

Required.
Contact email.

-f, --file <path/to/file>

Required.
Specifies the location and name of the log file archive to send.

--request-timeout <timeout in seconds>

Optional.
Wait the specified amount of time for the command to finish. Default value is 1800 (30 minutes).

**tsm maintenance validate-resources**

Validate workbooks and data sources for a site.

**Synopsis**

```
 tsm maintenance validate-resources --site-id <site ID> 
 [global options]
```

**Options**

-id, --site-id <site ID>

Required.

ID for the site whose resources you are validating.

-r, --repair
Optional.

Repair invalid resources.

--request-timeout <timeout in seconds>

Optional.

Wait the specified amount of time for the command to finish. Default value is 1800 (30 minutes).

tsm maintenance ziplogs

Use the ziplogs command to create an archive of Tableau Server log files.

Note: If you cannot run the ziplogs command successfully, you can manually zip the Tableau Server logs. For more information, see Manually gather logs.

Synopsis

tsm maintenance ziplogs [options] [global options]

Options

-a, --all

Optional.

Include all files except PostgreSQL data.

-d, --with-postgresql-data

Optional.
Include the PostgreSQL data folder if Tableau Server is stopped or PostgreSQL dump files if Tableau Server is running.

-f, --file <name>

Optional.

Specify a name for the zipped archive file. If no name is provided the archive is created as logs.zip. The file is written to the directory defined in the TSM basefilepath.log_archive variable. By default:

/var/opt/tableau/tableau_server/data/tabsvc/files/log-archives/

For more information about file paths and how to change them, see tsm File Paths.

-i, --description <string>

Optional.

Include the specified description of the archive file.

-l, --with-latest-dump

Optional.

Include latest dumps.

-m, --minimumdate <date>

Optional.

Earliest date of log files to be included. If not specified, a maximum of two days of log files are included. Format of date should be "mm/dd/yyyy".

-o, --overwrite

Optional.
For an overwrite of an existing ziplog file. If a file by the same name already exists and this option is not used, the ziplogs command will fail.

By default the file is written to:

/var/opt/tableau/tableau_server/data/tabsvc/files/log-archives/

For more information about file paths and how to change them, see tsm File Paths.

--request-timeout <timeout in seconds>

Optional.

Wait the specified amount of time for the command to finish. Default value is 1800 (30 minutes).

-t, --with-netstat-info

Optional.

Include netstat information.

Global options

-h, --help

Optional.

Show the command help.

-p, --password <password>

Required, along with -u or --username if no session is active.

Specify the password for the user specified in -u or --username.

If the password includes spaces, enclose it in quotes:
--password 'my password'

-s, --server <url_to_tsm>

Optional.

Use the specified address for Tableau Services Manager. The URL must start with https, include port 8850, and use the server name not the IP address, for example https://mytableauhost:8850. If no server is specified, https://<localhost | dnsname>:8850 is assumed.

-u, --username <user>

Required if no session is active, along with -p or --password.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

**tsm pending-changes**

You can use the `tsm pending-changes` commands to apply, discard, or view pending configuration and topology changes to Tableau Server.

- apply
- discard
- list

**tsm pending-changes apply**

You can use the `tsm pending-changes apply` command to apply pending configuration and topology changes to Tableau Server.
A prompt warns you that the command will restart Tableau Server. If Tableau Server is currently running it is restarted, and if it is stopped it is left in a stopped state with no restart. You can suppress the prompt using the \(-r\) option, but this does not change the restart behavior.

**Synopsis**

`tsm pending-changes apply [global options]`

**Options**

\-iw, \(--ignore-warnings\)

Optional.

Ignore warning level constraints.

\--ignore-prompt

Optional.

Suppress the prompt for restart. This only suppresses the prompt. The restart behavior is unchanged.

\--request-timeout \(<\text{timeout in seconds}>\)

Optional.

Wait the specified amount of time for the command to finish. Default value is 1800 (30 minutes).

**tsm pending-changes discard**

You can use the `tsm pending-changes discard` command to discard pending configuration and topology changes to Tableau Server.

**Synopsis**

`tsm pending-changes discard [options] [global options]`
Options

---config-only

Optional.

Discard only pending configuration changes.

---topology-only

Optional.

Discard only pending topology changes.

tsm pending-changes list

You can list pending configuration and topology changes to Tableau Server.

Synopsis

tsm pending-changes list [options] [global options]

Options

---config-only

Optional.

List only pending configuration changes.

---topology-only

Optional.

List only pending topology changes.

Global options

-h, --help
Optional.

Show the command help.

-p, --password <password>

Required, along with -u or --username if no session is active.

Specify the password for the user specified in -u or --username.

If the password includes spaces, enclose it in quotes:

--password 'my password'

-s, --server <url_to_tsm>

Optional.

Use the specified address for Tableau Services Manager. The URL must start with https, include port 8850, and use the server name not the IP address, for example https://mytableauhost:8850. If no server is specified, https://<localhost | dnsname>:8850 is assumed.

-u, --username <user>

Required if no session is active, along with -p or --password.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

tsm register

You can use the tsm register command to register Tableau Server. This command lets you either display the registration file template (using the --template option) or provide the path to a completed registration file (using the --file option). You must use one of these two options when calling the tsm register command.
Synopsis

`tsm register --template | --file <registration-filename>`

[global options]

Options

`--file <registration-filename>`

  Required.

  Path to the file that contains the registration data.

`--template`

  Required.

  Display registration file template.

Global options

`-h, --help`

  Optional.

  Show the command help.

`-p, --password <password>`

  Required, along with `-u` or `--username` if no session is active.

  Specify the password for the user specified in `-u` or `--username`.

  If the password includes spaces, enclose it in quotes:

    `--password 'my password'`

`-s, --server <url_to_tsm>`

  Optional.
Use the specified address for Tableau Services Manager. The URL must start with https, include port 8850, and use the server name not the IP address, for example https://mytableauhost:8850. If no server is specified, https://<localhost | dnsname>:8850 is assumed.

-\u007bu, --username <user>

Required if no session is active, along with -p or --password.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

**tsm reset**

Use the tsm reset command to clear the initial admin user so that you can enter a new one. After you run tsm reset you must rerun the tabcmd initialuser command to create a new initial admin. The new name cannot be the same username as the previous admin user.

**Note:** This command was added in Tableau Server version 2018.1.

**Synopsis**

```plaintext
tsm reset[option] [global options]
```

**Option**

-\u007dd, --delete-all-sessions

Optional.

Delete all active user sessions when the server is reset.

```plaintext
--request-timeout <timeout in seconds>
```

Optional.
Wait the specified amount of time for the command to finish. Default value is 1800 (30 minutes).

Global options

-h, --help
Optional.
Show the command help.

-p, --password <password>
Required, along with -u or --username if no session is active.
Specify the password for the user specified in -u or --username.
If the password includes spaces, enclose it in quotes:
--password 'my password'

-s, --server <url_to_tsm>
Optional.
Use the specified address for Tableau Services Manager. The URL must start with https, include port 8850, and use the server name not the IP address, for example https://mytableauhost:8850. If no server is specified, https://<localhost | dnsname>:8850 is assumed.

-u, --username <user>
Required if no session is active, along with -p or --password.
Specify a user account. If you do not include this option, the command is run using credentials you signed in with.
tsm restart

You can use the tsm restart command to restart Tableau Server.

Synopsis

```
  tsm restart [global options]
```

Option

```
--request-timeout <timeout in seconds>
  Optional.
  Wait the specified amount of time for the command to finish. Default value is 1800 (30 minutes).
```

Global options

```
-h, --help
  Optional.
  Show the command help.

-p, --password <password>
  Required, along with -u or --username if no session is active.
  Specify the password for the user specified in -u or --username.
  If the password includes spaces, enclose it in quotes:
  --password 'my password'
```

```
-s, --server <url_to_tsm>
  Optional.
```
Use the specified address for Tableau Services Manager. The URL must start with https, include port 8850, and use the server name not the IP address, for example https://mytableauhost:8850. If no server is specified, https://<localhost | dnsname>:8850 is assumed.

-u, --username <user>

Required if no session is active, along with -p or --password.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

tsm security

Use the tsm security commands to configure Tableau Server support for external (gateway) SSL or repository (Postgres) SSL. Repository SSL configuration includes the option to enable SSL over direct connections from Tableau clients—including Tableau Desktop, Tableau Mobile, and web browsers—to the repository.

- tsm security external-ssl enable
- tsm security external-ssl disable
- tsm security external-ssl list
- tsm security regenerate-internal-tokens
- tsm security repository-ssl enable
- tsm security repository-ssl disable
- tsm security repository-ssl get-certificate-file
- tsm security repository-ssl list
- tsm security validate-asset-keys

Prerequisites

Before you configure SSL, you must acquire certificates, and then copy them to the computer that runs the Tableau Server gateway process. Additional preparation is required for
enabling direct connections from clients. To learn more, see the following articles:

Configure SSL for External HTTP Traffic to and from Tableau Server

Configure SSL for Internal Postgres Communication

**Note:** For information about mutual (two-way) SSL, see Configure Mutual SSL Authentication and `tsm authentication mutual-ssl` commands.

tsm security external-ssl enable

Enable and specify certificate and key files for SSL over external HTTP communication.

**Synopsis**

```
tsm security external-ssl enable --cert-file <file.crt> --key-file <file.key> [options] [global options]
```

**Options**

`--cert-file <file.crt>`

Required. Specify the name of a valid PEM-encoded x509 certificate with the extension .crt.

`--key-file <file.key>`

Required. Specify a valid RSA or DSA private key file, with the extension .key by convention.

`--chain-file <chainfile.crt>`

Specify the certificate chain file (.crt)
A certificate chain file is required for Tableau Desktop on the Mac. In some cases, a certificate chain file may be required for Tableau Mobile.

Some certificate providers issue two certificates for Apache. The second certificate is a chain file, which is a concatenation of all the certificates that form the certificate chain for the server certificate.

All certificates in the file must be x509 PEM-encoded and the file must have a .crt extension (not .pem).

```
--passphrase
```

Optional. Passphrase for the certificate file. The passphrase you enter will be encrypted while at rest.

**Note:** If you create a certificate key file with a passphrase, you cannot reuse the SSL certificate key for SAML.

```
--protocols <list protocols>
```

Optional. List the Transport Layer Security (TLS) protocol versions you want to allow or disallow.

TLS is an improved version of SSL. Tableau Server uses TLS to authenticate and encrypt connections. Accepted values include protocol versions supported by Apache. To disallow a protocol, prepend the protocol version with a minus (-) character.

**Default setting:** "all, -SSLv2, -SSLv3"

This default explicitly does not allow clients to use SSL v2 or SSL v3 protocols to connect to Tableau Server. However, we recommend that you also disallow TLS v1 and TLS v1.1.

Before you deny a specific version of TLS, verify that the browsers from which your users connect to Tableau Server support TLS v1.2. You might need to preserve support for TLSv1.1 until browsers are updated.
If you do not need to support TLS v1 or v1.1, use the following command to allow TLS v1.2 (using the value all), and explicitly deny SSL v2, SSL v3, TLS v1, and TLS v1.1.

```
$ tsm security external-ssl enable --cert-file file.crt --key-file file.key --protocols "all -SSLv2 -SSLv3 -TLSv1 -TLSv1.1"
```

tsm security external-ssl disable

Removes the server’s existing SSL configuration settings and stops encrypting traffic between external clients and the server.

Synopsis

```
$ tsm security external-ssl disable [global options]
```

tsm security external-ssl list

Displays a list of settings related to the configuration of gateway external SSL. The list includes the names of the certificate files in use, but not their location.

Synopsis

```
$ tsm security external-ssl list [global options]
```

tsm security regenerate-internal-tokens

Stops the server, regenerates a new tokens, keys, and secrets. Also creates new security tokens that Tableau Server uses internally. Then starts the server.

The security tokens include the passwords used by Tableau Server to access the repository, and the certificates used to validate internal SSL connections between Tableau Server components and the repository.

Synopsis

```
$ tsm security regenerate-internal-tokens [options]
[global options]
```
Options

-r, --restart

Optional.

Suppress the prompt that notifies you that running regenerate-internal-tokens will stop Tableau Server and then start it after regenerating the key and tokens.

--request-timeout <timeout in seconds>

Optional.

Wait the specified amount of time for the command to finish. Default value is 1800 (30 minutes).

Regenerate tokens and apply changes on a single server

- Run the following commands:

  tsm security regenerate-internal-tokens
  tsm pending-changes apply

  Like the regenerate-internal-tokens command, the pending-changes-apply command displays a prompt to let you know it will restart Tableau Server if the server is running. You can use the -r option with this command as well. Although pending-changes-apply generally does not start the server if it is stopped, the regenerate-internal-tokens always stops and starts the server as part of its process.

Regenerate tokens and apply changes in a Tableau Server cluster

1. Run the following commands:

  tsm security regenerate-internal-tokens
  tsm pending-changes apply
Like the `regenerate-internal-tokens` command, the `pending-changes-apply` command displays a prompt to let you know it will restart Tableau Server if the server is running. You can use the `-r` option with this command as well. Although `pending-changes-apply` generally does not start the server if it is stopped, the `regenerate-internal-tokens` always stops and starts the server as part of its process.

2. Stop the server, and then use a secure process to copy the master key to each node in the cluster:
   
   a. Run the following command:

   ```
   tsm stop
   ```

   b. Use a secure process to copy the file `tableauserver.jks` to the `keystores` directory on each node. The default location is as follows:

   ```
   /var/opt/tableau/tableau_server-/data/tabsvc/config/tabadminagent_0.<server_version>/tabsvc/keystores
   ```

   3. Run the following command to start the server:

   ```
   tsm start
   ```

**tsm security repository-ssl enable**

Enables SSL and generates the server’s `.crt` and `.key` files used for encrypted traffic between the Postgres repository and other server components. Enabling this also gives you the option to enable SSL over direct connections from Tableau clients to the server.

**Synopsis**

```
 tsm security repository-ssl enable [options] [global options]
```
Options

-i, --internal-only

Optional. When set to --internal-only, Tableau Server uses SSL between the repository and other server components, and it supports but does not require SSL for direct connections through `tableau` or `readonly` users.

If this option is not set, Tableau Server requires SSL for traffic between the repository and other server components, as well as for direct connections from Tableau clients (for connections through the `tableau` or `readonly` users).

When you specify this option, you must also complete the steps described in Configure Postgres SSL to Allow Direct Connections from Clients.

tsm security repository-ssl disable

Stop encrypting traffic between the repository and other server components, and stop support for direct connections from Tableau clients.

Synopsis

tsm security repository-ssl disable [global-options]

tsm security repository-ssl get-certificate-file

Get the public certificate file used for SSL communication with the Tableau repository. SSL must be enabled for repository communication before you can retrieve a certificate. The certificate file is distributed automatically to internal clients of the repository in the Tableau Server cluster. To enable remote clients to connect over SSL to the repository, you must copy the public certificate file to each client.

Synopsis

tsm security repository-ssl get-certificate-file [global-options]
Options

-f, --file

Required.

Full path and file name (with .cert extension) where the certificate file should be saved. If a duplicate file exists it will be overwritten.

tsm security repository-ssl list

Returns the existing repository (Postgres) SSL configuration.

Synopsis

tsm security repository-ssl list [global-options]

tsm security validate-asset-keys

Confirms whether the asset keys in use are valid and present.

Synopsis

tsm security validate-asset-keys [global options]

Global options

-h, --help

Optional.

Show the command help.

-p, --password <password>

Required, along with -u or --username if no session is active.

Specify the password for the user specified in -u or --username.
If the password includes spaces, enclose it in quotes:

```
--password 'my password'
```

```
-s, --server <url_to_tsm>
```

Optional.

Use the specified address for Tableau Services Manager. The URL must start with https, include port 8850, and use the server name not the IP address, for example https://mytableauhost:8850. If no server is specified, https://<localhost | dnsname>:8850 is assumed.

```
-u, --username <user>
```

Required if no session is active, along with -p or --password.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

**tsm settings**

You can use the **tsm settings** commands to set and update configuration values.

- export
- import

**Important:** The server configuration file referenced in this topic includes a copy of the master keystore file used for encrypting configuration secrets. We strongly recommend that you take additional measures to secure the node configuration file, using mechanisms as described in Securing secrets for import and export operations.

**tsm settings export**

Export the current server configuration and topology to a file.
Synopsis

```
tsm settings export --output-config-file <path/to/output_file.json> [global options]
```

Options

```
-f, --output-config-file <file>
```

**Required.**

Specifies the location and name of the file created by this operation.

**tsm settings import**

Import server configuration or topology.

Synopsis

```
tsm settings import --import-config-file <path/to/import_file.json> [global options]
```

Options

```
-f, --import-config-file <FILE>
```

**Required.**

Path to input file.

```
--config-only
```

**Optional.**

```
--topology-only
```

**Optional.**
-frc, --force-keys

Optional.

Force a key to be added to configuration even if it did not previously exist.

Global options

-h, --help

Optional.

Show the command help.

-p, --password <password>

Required, along with -u or --username if no session is active.

Specify the password for the user specified in -u or --username.

If the password includes spaces, enclose it in quotes:

--password 'my password'

-s, --server <url_to_tsm>

Optional.

Use the specified address for Tableau Services Manager. The URL must start with https, include port 8850, and use the server name not the IP address, for example https://mytableauhost:8850. If no server is specified, https://<localhost | dnsname>:8850 is assumed.

-u, --username <user>

Required if no session is active, along with -p or --password.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.
You can use the `tsm sites` commands to export an existing site for import to a new site (also referred to as site migration), and to import the new site. An `unlock` command is available in case an error leaves a site locked.

The `tsm sites` commands will use your local file store to hold the export and import data. If you are running a multinode Tableau cluster, then you must run the `tsm sites` commands on a Tableau Server that is running the Data Engine process. For information about the Data Engine process and the processes that require it, see Tableau Server Processes.

For comprehensive steps for migrating a site, see Export or Import a Site.

- export
- import
- import-verified
- unlock

**tsm sites export**

Export a specified Tableau Server site to a .zip file. You can export a site to archive its settings at a specific point in time, or to complete the first step of a site migration process.

*Note:* The `tsm sites import` and `tsm sites export` commands can leave a site in a locked state if an error occurs. To unlock a site, use the `tsm sites unlock` command.

**Synopsis**

```
  tsm sites export --site-id <source-siteID> --file <export-file> [options] [global options]
```
Options

-f, --file <export-file>

Required.

Specify the name of the file to which Tableau Server saves all of the site’s information.

This file is generated to the directory defined in the TSM basefilepath.site_export.exports variable. By default:

/var/opt/tableau/tableau_server/data/tabsvc/files/siteexports

For more information about file paths and how to change them, see tsm File Paths.

-id, --site-id <source-siteID>

Required.

The site ID for the site you are exporting. You can get the site ID from the URL when you’re signed in to the site from a web browser. For information about locating the site ID, see Prepare the source and target sites.

-ow, --overwrite

Optional.

Overwrite an export file of the same name that already exists.

--request-timeout <timeout in seconds>

Optional.

Wait the specified amount of time for the command to finish. Default value is 1800 (30 minutes).
tsm sites import

This command uses the .zip file you created using tsm sites export to generate a set of .csv files that show how the exported source site settings will map to the new target site.

By default, the .zip file is generated and saved to the siteexports directory at:

/var/opt/tableau/tableau_server/data/tabsvc/files/siteexports

Before you use this command, you must copy the .zip file to the directory in which Tableau will expect it. This location is defined in the TSM basefilepath.site_import.-exports variable. By default, the import directory is:

/var/opt/tableau/tableau_server/data/tabsvc/files/siteimports

For more information about file paths and how to change them, see tsm File Paths.

Note: The tsm sites import and tsm sites export commands can leave a site in a locked state if an error occurs. To unlock a site, use the tsm sites unlock command.

Synopsis

    tsm sites import --file <export-file.zip> --site-id <target-siteID> [options] [global options]

Options

-f,--file <export-file.zip>

Required.

Name of the .zip file created by the tsm sites export process, and which you must copy to the import directory. By default:

/var/opt/tableau/tableau_server/data/tabsvc/files/siteimports
-id,--site-id <target-siteID>

Required.
The site ID for the new site you are importing to (the target site). For information about locating the site ID, see Prepare the source and target sites.

-c,--continue-on-ignorable-errors

Optional.
Continue site import if errors occur which can be ignored. These errors can indicate issues with the import of a specific workbook or data source.

-k,--no-verify

Optional.
Skip verification of mapping files.

-m, --override-schedule-mapper <mapping-file.csv>

Optional.
Schedule mapping file to override the normal mapping by name.

--request-timeout <timeout in seconds>

Optional.
Wait the specified amount of time for the command to finish. Default value is 1800 (30 minutes).

tsm sites import-verified

Specify the directory that contains an exported site’s .csv mapping files, to import to a new site. This is the final step of a site migration process.
Synopsis

`tsm sites import-verified --import-job-dir <importjob-directory> --site-id <target-siteID> [options] [global options]`

Options

- `-id,--site-id <target-siteID>`
  
  Required.
  
  The site ID for the new site you are importing to (the target site). For information about locating the site ID, see Prepare the source and target sites.

- `-w, --import-job-dir <importjob-directory>`
  
  Required.
  
  The parent of the mappings directory that contains the .csv files from the exported (source) site. The name of this parent directory includes the import id and date and time. For example:

  `/var/opt/tableau/tableau_server-/data/tabsvc/files/siteimports/working/import_ff00_20180102022014457`

- `--request-timeout <timeout in seconds>`
  
  Optional.
  
  Wait the specified amount of time for the command to finish. Default value is 1800 (30 minutes).

`tsm sites unlock`

Use this command to unlock a site.
Options

-id, --site-id <target-siteID>

Required.

The site ID for the site you are unlocking. For information about locating the site ID, see Prepare the source and target sites.

-d, --desired-state <state to leave unlocked site in>

Optional.

The state the site should be left in after it is unlocked. Options are "active" and "suspended". The default is "active" if not specified.

For example:

```
tsm sites unlock -id mysite -d suspended
```

--request-timeout <timeout in seconds>

Optional.

Wait the specified amount of time for the command to finish. Default value is 1800 (30 minutes).

Global options

-h, --help

Optional.

Show the command help.

-p, --password <password>

Required, along with -u or --username if no session is active.
Specify the password for the user specified in -u or --username.

If the password includes spaces, enclose it in quotes:

--password 'my password'

-s, --server <url_to_tsm>

Optional.

Use the specified address for Tableau Services Manager. The URL must start with https, include port 8850, and use the server name not the IP address, for example https://mytableauhost:8850. If no server is specified, https://<localhost | dnsname>:8850 is assumed.

-u, --username <user>

Required if no session is active, along with -p or --password.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

tsm start

You can use the tsm start command to start Tableau Server.

Synopsis

tsm start [option][global options]

Option

--request-timeout <timeout in seconds>

Optional.

Wait the specified amount of time for the command to finish. Default value is 1800 (30 minutes).
Global options

-h, --help

Optional.
Show the command help.

-p, --password <password>

Required, along with -u or --username if no session is active.
Specify the password for the user specified in -u or --username.
If the password includes spaces, enclose it in quotes:

--password 'my password'

-s, --server <url_to_tsm>

Optional.
Use the specified address for Tableau Services Manager. The URL must start with https, include port 8850, and use the server name not the IP address, for example https://mytableauhost:8850. If no server is specified, https://<localhost | dnsname>:8850 is assumed.

-u, --username <user>

Required if no session is active, along with -p or --password.
Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

**tsm status**

You can use the **tsm status** command to display the status of Tableau Server.
Synopsis

```
tsm status [global options]
```

Options

```
-v, --verbose
```

Optional.

Display status for every node in the Tableau Server cluster.

**tsm status** will return one of four potential statuses for a Tableau Server node:

- **RUNNING:** The node is running without error statuses for any service.
- **DEGRADED:** A primary service - such as the repository - is in an error state.
- **ERROR:** One or more services is in an error state.
- **STOPPED:** The node is stopped.

When running **tsm status** with the **--verbose** option, TSM will return a status for each individual service. There are four status messages:

- **is running:** The service is running.
- **status is unavailable:** The status is not returned - such as when processes are starting up.
- **is in an error state:** The process is running, but returning errors. This status indicates the process failed to install properly, or has not been configured.
- **is stopped:** The process is stopped.

Global options

```
-h, --help
```

Optional.
Show the command help.

-p, --password <password>

Required, along with -u or --username if no session is active.

Specify the password for the user specified in -u or --username.

If the password includes spaces, enclose it in quotes:

--password 'my password'

-s, --server <url_to_tsm>

Optional.

Use the specified address for Tableau Services Manager. The URL must start with https, include port 8850, and use the server name not the IP address, for example https://mytableauhost:8850. If no server is specified, https://<localhost | dnsname>:8850 is assumed.

-u, --username <user>

Required if no session is active, along with -p or --password.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

**tsm stop**

You can use the *tsm stop* command to stop Tableau Server.

**Synopsis**

tsm stop [option] [global options]
Option

--request-timeout <timeout in seconds>

Optional.
Wait the specified amount of time for the command to finish. Default value is 1800 (30 minutes).

Global options

-h, --help

Optional.
Show the command help.

-p, --password <password>

Required, along with -u or --username if no session is active.
Specify the password for the user specified in -u or --username.
If the password includes spaces, enclose it in quotes:
--password 'my password'

-s, --server <url_to_tsm>

Optional.
Use the specified address for Tableau Services Manager. The URL must start with https, include port 8850, and use the server name not the IP address, for example https://mytableauhost:8850. If no server is specified, https://<localhost | dnsname>:8850 is assumed.

-u, --username <user>

Required if no session is active, along with -p or --password.
Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

**tsm topology**

You can use the `tsm topology` commands to prepare File Store nodes for safe removal or to put them back into read-write mode. You can also initiate a repository failover, get a list of nodes or ports, get the bootstrap configuration file required to add additional nodes to your cluster, and remove nodes.

- cleanup-coordination-service
- deploy-coordination-service
- failover-repository
- filestore
  - decommission
  - recommission
- list-nodes
- list-ports
- nodes
  - get-bootstrap-file
- remove-nodes
- set-ports
- set-process
- toggle-coordination-service

**tsm topology cleanup-coordination-service**

Use the `tsm topology cleanup-coordination-service` command to remove the non-production Tableau Server Coordination Service ensemble after you deploy a new ensemble. This command removes the old Coordination Service instances on all nodes in the non-production Coordination Service ensemble and is required after you deploy a new
Coordination Service ensemble. To learn more about Coordination Service ensembles, see Deploy a Coordination Service Ensemble.

Synopsis

tsm topology cleanup-coordination-service [option] [global options]

Option

--request-timeout <timeout in seconds>

Optional.

Wait the specified amount of time for the command to finish. Default value is 2700 (45 minutes).

tsm topology deploy-coordination-service

You can use the tsm topology deploy-coordination-service command to deploy the Tableau Server Coordination Service. This command deploys a Coordination Service ensemble, which is a set of Coordination Service instances that run on specified nodes in your server cluster. To learn more about Coordination Service ensembles, including how many nodes in your cluster should have a Coordination Service instance, see Deploy a Coordination Service Ensemble.

Synopsis

tsm topology deploy-coordination-service --nodes <nodeID,nodeID,...> [option] [global-options]

Options

-n, --nodes <nodeID,nodeID,...>

Required.
Node IDs of nodes to include in the new Coordination Service ensemble, separated by commas. You can specify 1, 3, or 5 Coordination Service nodes, depending on the total number of nodes in your cluster. For more information, see The Coordination Service Quorum.

--request-timeout <timeout in seconds>

Optional.

Wait the specified amount of time for the command to finish. Default value is 2700 (45 minutes).

tsm topology failover-repository

You can use the `tsm topology failover-repository` to manually initiate a repository failover from the current active repository to the second, passive repository.

The `tsm topology failover-repository` command is persistent. The failover repository remains the active repository until you issue the command again, or, if Tableau Server is configured for it, until automatic failover occurs. If you have a preferred active repository configured, use the `--preferred` option to switch back to that repository. For more information about configuring a preferred active repository, see Tableau Server Repository. If Tableau Server is configured for high availability, failover of the repository is automatic when necessary. Use the failover-repository command to manually fail over the repository.

Synopsis

tsm topology failover-repository --preferred | --target <node_id> [global options]

Options

-r, --preferred

Required if -t or --target is not used.
Use the configured preferred node as the target for repository failover. This requires that the configuration value `pgsql.preferred_host` already be set.

`--request-timeout <timeout in seconds>`

Optional.

Wait the specified amount of time for the command to finish. Default value is 1800 (30 minutes).

`-t, --target <node_id>`

Required if `-r` or `--preferred` is not used.

The node id of the target node onto which failover will occur. Find the node id by using the `tsm topology list-nodes` command.

**tsm topology filestore decommission**

You must use the `tsm topology filestore decommission` command to prepare a file store node or nodes for safe removal. This command puts the specified nodes into read-only mode and ensures there is no unique content on the specified nodes.

If decommissioning results in a single file store node, you must use the `--override` option or the decommission will fail.

**Synopsis**

`tsm topology filestore decommission --nodes <nodeID,nodeID,...> [options] [global options]`

**Options**

`-n, --nodes <nodeID,nodeID,...>`

Required.
List of one or more nodes to decommission, specified by node ID and separated by commas.

--delete-filestore

Optional.

Forces the removal of the file store, even if it has not been decommissioned. You should only use this option if the node the file store is on is in a error state and decommissioning cannot be done. Any unique files on the node will be permanently deleted.

-o, --override

Optional.

Overrides warnings or failures that would normally occur if removing the target File Store node would reduce the number of remaining file store nodes to one.

--request-timeout <timeout in seconds>

Optional.

Wait the specified amount of time for the command to finish. Default value is 1800 (30 minutes).

**tsm topology filestore recommission**

Use the `tsm topology filestore recommission` command to revert any decommissioned nodes back to read-write mode.

**Synopsis**

`tsm topology filestore recommission --nodes <nodeID,nodeID,...> [global options]`
Options

-n, --nodes <nodeID,nodeID,...>

Required.

List of one or more nodes to recommission, specified by node ID and separated by commas.

tsm topology nodes get-bootstrap-file

You can use the tsm topology nodes get-bootstrap-file command to get the bootstrap file that is required to add a new node to the cluster.

Important: The bootstrap file contains a copy of the master keystore file used for encrypting the configuration secrets. We strongly recommend that you take additional measures to secure the bootstrap file using mechanisms as described in Securing secrets for import and export operations.

Synopsis

tsm topology nodes get-bootstrap-file --file <path\file>.json
[global options]

Options

-f, --file <file>

Required.

Full path and file name where the configuration file will be saved. If a duplicate file exists it will be overwritten.
tsm topology list-nodes

Display the nodes in the cluster and (optionally) the services on each node.

Synopsis

tsm topology list-nodes [options] [global options]

Options

-v, --verbose

Optional.

Shows the services on each node.

tsmtopology list-ports

Display the ports in the cluster.

Synopsis

tsm topology list-ports [options] [global options]

Options

--node-name <nodeID>

Optional.

Specify the node to list ports for.

--service-name

Optional.

Specify the service to list ports for.
tsm topology remove-nodes

Remove nodes from the cluster.

To complete removal of a node, you also must run the `tsm pending-changes apply` command. Some scenarios require that you move or redeploy processes before removing nodes. See Remove a Node.

If you remove a node and want to re-add it to the cluster, you need to first run the obliterate script to clean Tableau off it, then reinstall the node using the normal process for adding a new node. For more information, see Remove Tableau Server from Your Computer and Install and Configure Additional Nodes.

**Note:** To remove a node from a cluster it must have been configured with a process at some point in the past. If you are removing a node on which you've not configured any processes, then you must add a process on it, run `tsm pending-changes apply`, and then remove the node.

**Synopsis**

```
tsm topology remove-nodes --nodes <nodeID,nodeID,...>  
[global options]
```

**Options**

```
-n, --nodes <nodeID,nodeID,...>  
```

Required.

Specify the node or nodes to remove. If specifying multiple nodes, separate node IDs with a comma.
tsm topology set-ports

Set the ports for a service instance.

Synopsis

tsm topology set-ports --node-name <nodeID> --port-name <port_name> --port-value <port_value> [options] [global options]

Options

-i, --instance <instance_id>

Optional.

Specifies the instance id of the service. Defaults to 0 (zero) if not specified.

-n, --node-name <nodeID>

Required.

Specifies the node ID of the node.

-pn, --port-name <port_name>

Required.

The name of the port to be set, in this format: service_name:port_type. If no port type is specified, the primary port is assumed.

-pv, --port-value <port_value>

Required.

The port to set.

-r, --restart

Optional.
Suppress the prompt for restart and restart Tableau Server when necessary.

tsm topology set-process

Set the number of instances of a process on a node. If a node already has the specified process, the number is updated to match the specified count.

You can only set one process at a time. If you specify more than one process, any process after the first one will be silently ignored.

**Note:** For a complete list of process names, see Tableau Server Processes.

**Synopsis**

```
tsm topology set-process --count <process_count> --node <nodeID> --process <process_name> [global options]
```

**Options**

- `-c, --count <process_count>`
  
  Required.
  
  The process count (number of instances) to set.

- `-n, --node <nodeID>`
  
  Required.
  
  Specifies the node ID of the node on which to set the process.

- `-pr, --process <process_name>`
  
  Required.
The name of the process to be set.

tsm topology toggle-coordination-service

You can use the `tsm topology toggle-coordination-service` command to switch between coordination service ensembles. To learn more about Coordination Service ensembles, see Deploy a Coordination Service Ensemble.

Synopsis

```
tsm topology toggle-coordination-service [option]  
[global options]
```

Option

```
--request-timeout <timeout in seconds>
```

Optional.

Wait the specified amount of time for the command to finish. Default value is 1800 (30 minutes).

Global options

```
-h, --help
```

Optional.

Show the command help.

```
-p, --password <password>
```

Required, along with `-u` or `--username` if no session is active.

Specify the password for the user specified in `-u` or `--username`.

If the password includes spaces, enclose it in quotes:
--password 'my password'

-s, --server <url_to_tsm>

Optional.

Use the specified address for Tableau Services Manager. The URL must start with https, include port 8850, and use the server name not the IP address, for example https://mytableauhost:8850. If no server is specified, https://<localhost | dnsname>:8850 is assumed.

-u, --username <user>

Required if no session is active, along with -p or --password.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

tsm user-identity-store

You can use the tsm user-identity-store commands to configure the identity store for Tableau Server. You can also connect to and authenticate with Active Directory and LDAP directory services.

- get-group-mappings
- get-user-mappings
- list
- set-connection
- set-group-mappings
- set-user-mappings
- verify-group-mappings
- verify-user-mappings

tsm user-identity-store get-group-mappings [options]

Displays identity store group mappings.
Synopsis

tsm user-identity-store get-group-mappings [global options]

tsm user-identity-store get-user-mappings [options]

Displays identity store user mappings.

Synopsis

tsm user-identity-store get-user-mappings [global options]

tsm user-identity-store list [options]

Lists user-identity configuration.

Synopsis

tsm user-identity-store list [options] [global options]

Options

-v, --verbose

Optional.

Lists all configuration parameters.

tsm user-identity-store set-connection [options]

Sets identity store connection parameters.

Synopsis

tsm user-identity-store set-connection --kerbkeytab <kerb-keytab> [options] [global options]

Options

-b,--bind <username and password | Kerberos>
Optional.
Set LDAP bind type.

-d, --domain <domain>
Optional.
Domain name.

-hn, --hostname <hostname>
Optional.
Hostname value.

-kc, --kerbconfig <kerbconfig>
Optional.
Kerberos configuration file path.

-kp, --kerbprincipal <kerbprincipal>
Optional.
Kerberos Principal.

-kt, --kerbkeytab <kerbkeytab>
Required.
Kerberos keytab file path.

-l, --port <port>
Optional.
Set LDAP Port value.

- lp, --ldappassword <ldappassword>

Optional.

LDAP Password.

- lu, --ldapusername <ldapusername>

Optional.

Set LDAP Username value.

- n, --nickname <nickname>

Optional.

NetBIOS name (nickname).

tsm user-identity-store set-group-mappings [options]

Sets identity store group mappings and configures LDAP directories that implement an arbitrary or custom schema.

Synopsis

tsm user-identity-store set-group-mappings [options]
[global options]

Options

- b, --basefilter <groupbasefilter>

Optional.

Set group BaseFilter value.

- cn, --classnames <group_classnames>
Optional.

Override default user classname values (contains "group" string) with the values you set here. You can provide multiple classnames separated by commas.

-d, --description <description>

Optional.

Group description.

-e, --groupemail <groupemail>

Optional.

Group email value.

-m, --member <member>

Optional.

Set the group members.

-n, --groupname <groupname>

Optional.

Name of the group.

tsm user-identity-store set-user-mappings [options]

Sets identity store user mappings and configures LDAP directories that implement an arbitrary or custom schema.

Synopsis

tsm user-identity-store set-user-mappings --certificate <certificate> [options] [global options]
Options

- **c, --certificate <certificate>**
  Optional.
  Users' certificate file location.

- **cn, --classnames <user_classnames>**
  Optional.
  Override default user classname values ("user" and "inetOrgPerson") with the values you set here. You can provide multiple classnames separated by commas.

- **dn, --displayname <displayname>**
  Optional.
  Display name of the user.

- **e, --email <email>**
  Optional.
  Users' email address.

- **jp, --jpegphoto <jpegfile>**
  Optional.
  Users' jpeg image location.

- **m, --memberof <groupname>**
  Optional.
  Group that the user is a member of.
-t, --thumbnail <thumbnail>
  Optional.
  Users' thumbnail location.

-ub, --basefilter <userbasefilter>
  Optional.
  Users' BaseFilter.

-uu, --ldapusername <ldapusername>
  Optional.
  User name.

tsm user-identity-store verify-group-mappings [options]
Validates configuration for LDAP group mapping.

Synopsis

tsm user-identity-store verify-group-mappings --verify <group_name> [global options]

Options

-v, --verify <group_name>
  Optional.
  Name of group to search for.

tsm user-identity-store verify-user-mappings [options]
Validates configuration for LDAP user mapping.
Synopsis

```
  tsm user-identity-store verify-user-mappings --verify <user_name> [global options]
```

Options

- `-v, --verify <user_name>`
  
  Optional.

  Name of user to search for.

Global options

- `-h, --help`
  
  Optional.

  Show the command help.

- `-p, --password <password>`
  
  Required, along with `-u` or `--username` if no session is active.

  Specify the password for the user specified in `-u` or `--username`.

  If the password includes spaces, enclose it in quotes:

  ```
  --password 'my password'
  ```

- `-s, --server <url_to_tsm>`
  
  Optional.

  Use the specified address for Tableau Services Manager. The URL must start with `https`, include port 8850, and use the server name not the IP address, for example `https://mytableauhost:8850`. If no server is specified, default value is assumed.
-u, --username <user>

Required if no session is active, along with -p or --password.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

**tsm version**

You can use the `tsm version` command to get the version of Tableau Server.

**Synopsis**

tsm version [global options]

**Global options**

-h, --help

Optional.

Show the command help.

-p, --password <password>

Required, along with -u or --username if no session is active.

Specify the password for the user specified in -u or --username.

If the password includes spaces, enclose it in quotes:

--password 'my password'

-s, --server <url_to_tsm>

Optional.

Use the specified address for Tableau Services Manager. The URL must start with https, include port 8850, and use the server name not the IP address, for example

-u, --username <user>

Required if no session is active, along with -p or --password.

Specify a user account. If you do not include this option, the command is run using credentials you signed in with.

tsm File Paths

Certain tsm commands read files from or write files to default locations. These default locations are determined by basefilepath variables defined for each command. You can use tsm to view the current value of the variables, and to change the locations.

Default locations for files

During the tsm maintenance backup, restore, send-logs, and ziplogs processes, and the tsm sites export and sites import processes, Tableau Server uses default locations for the files created or used by these commands.

By default:

- tsm maintenance commands:
  - backup—The backup .tsbak file is generated in:

    /var/opt/tableau/tableau_server-/data/tabsvc/files/backups

  - restore—The restore process restores a backup file from:
/var/opt/tableau/tableau_server-/data/tabsvc/files/backups

- send-logs—The send-logs sends the logs file from:
/var/opt/tableau/tableau_server-/data/tabsvc/files/backups

- ziplogs—The ziplogs file is generated in:
/var/opt/tableau/tableau_server/data/tabsvc/files/log-archives

- tsm sites

  - export—The export .zip file is generated to the following directory:
  /var/opt/tableau/tableau_server-/data/tabsvc/files/siteexports

  - import—During the import process, Tableau Server looks for files in:
  /var/opt/tableau/tableau_server-/data/tabsvc/files/siteimports

Get the current file location

You can see the current file location for a specific command using tsm configuration get:

- For tsm maintenance commands:
  
  - backup, restore, and send-logs:

    tsm configuration get -k basefilepath.backuprestore
- ziplogs:

  tsm configuration get -k basefilepath.log_archive

- For tsm sites commands:

  - export

    tsm configuration get -k basefilepath.site_export.-exports

  - import

    tsm configuration get -k basefilepath.site_import.-exports

**Change the current file location**

You can change the expected file locations using the `tsm configuration set` command to update the `basefilepath` variables.

Changing a `basefilepath` variable does not move existing files from the original directory to the new directory. If you want existing backup, restore, log files, or site export or import files to reside in the new directory you specify, you must move them manually. You are responsible for creating the new location and for setting the correct permissions to allow `tsm` access to any files that will be placed there, and to the directory structure containing those files. For more information about permissions and `tsm`, see Files and Permissions in TSM.

- For tsm maintenance commands:

  - To change the backup, restore, or send-logs directory, run the following command:

    tsm configuration set -k basefilepath.backuprestore -v "/new/directory/path"
To change the ziplogs directory:

```bash
tsm configuration set -k basefilepath.log_archive -v "/new/directory/path"
```

For tsm sites commands:

- To change the sites export directory:

```bash
tsm configuration set -k basefilepath.site_export.exports -v "/new/directory/path"
```

- To change the sites import directory:

```bash
tsm configuration set -k basefilepath.site_import.exports -v "/new/directory/path"
```

After you change a default file location you need to do the following:

1. Apply pending changes:

   ```bash
tsm pending-changes apply
   ```

2. Stop Tableau Server:

   ```bash
tsm stop
   ```

3. Restart the TSM Controller (as tableau system account):

   ```bash
   sudo su -l tableau -c "systemctl --user restart tabadmincontroller_0.service"
   ```

4. Wait several minutes for the controller to restart. You can confirm the controller has restarted with this command:

   ```bash
tsm status -v
   ```
When you can run that command and the Tableau Server Administration Controller is listed as 'running' the controller has restarted.

5. Start Tableau Server:

   

tsm start

Migrate from Tabadmin to the TSM CLI

The Tableau Services Manager (TSM) command-line interface (CLI) replaces the tabadmin CLI in Tableau Server on Linux, and in Tableau Server on Windows version 2018.2. This page maps tabadmin commands to TSM commands to help you to migrate to the TSM CLI.

To learn more about the TSM CLI, see tsm Command Line Reference.

Tabadmin commands with a corresponding TSM CLI command

The following table shows which tabadmin commands correspond to commands available in the TSM CLI.

<table>
<thead>
<tr>
<th>Command Description</th>
<th>Tabadmin Command(s)</th>
<th>Comparable TSM CLI Command</th>
</tr>

<tr>
<td>Reset the password for a Tableau Server account</td>
<td>tabadmin passwd</td>
<td>If your server uses local authentication, you can use the Tableau Server REST API Update User method to reset the password for a user account.</td>
</tr>
<tr>
<td>Reset binding between Tableau Server user ID and Open ID Connect identity provider</td>
<td>tabadmin reset_openid_sub</td>
<td></td>
</tr>
<tr>
<td>Determine whether your environment meets the minimum requirements to run Tableau Server</td>
<td>tabadmin validate</td>
<td></td>
</tr>
<tr>
<td>Verify that a backup of the Tableau Server repository will restore successfully</td>
<td>tabadmin verify_database</td>
<td>The tsm maintenance backup command automatically verifies that a backup will restore correctly unless you use the --skip-verification parameter.</td>
</tr>
<tr>
<td>Prepare VizQL processes for fast load times</td>
<td>tabadmin warmup</td>
<td>The tabadmin warmup command is no longer necessary, as Tableau Server is now optimized</td>
</tr>
</tbody>
</table>
after a Tableau Server restart to automatically provide fast load times after a server restart.

Entity Definitions and Templates

Configuration File Example

This article provides an example of a complete JSON configuration file, with gatewaySettings and identityStore entities specified. In addition, a configuration key sets the gateway timeout to 900 seconds.

Your configuration file will look different depending on the options you need to set.

You might set multiple .json configuration files during installation. To set the values for each file in Tableau Server, you run the following command, once for each configuration file:

```
tsm settings import -f path-to-file.json
```

After you set the configuration files, run tsm pending-changes apply to apply the changes from all of the .json files you’ve set.

```json
{
    "configEntities": {
        "gatewaySettings": {
            "_type": "gatewaySettingsType",
            "port": 80,
            "firewallOpeningEnabled": true,
            "sslRedirectEnabled": true,
            "publicHost": "localhost",
            "publicPort": 80
        }
    }
}
```
"identityStore": {  
  "_type": "identityStoreType",  
  "type": "local",  
  "domain": "example.lan",  
  "nickname": "EXAMPLE"
}

"configKeys": {
  "gateway.timeout": "900"
}

Entities vs keys

As shown in the example above, there are two classes of configuration parameters: configEntities and configKeys.

configEntities

Certain types of configuration are done through entity sets that map to specific scenarios, such as the identity store and gateway configurations. When you pass a set of configEntities with the tsm settings import -f path-to-file.json command, TSM validates the configuration. If values passed are invalid, TSM will provide an error. This enables you to make changes during the configuration process, rather than experience a configuration failure at initialization or run time.

Entities can be set only by including a configEntities block in a .json file.

Important: All files that are referenced in configEntities must be located on the local computer. Do not specify UNC paths.

configKeys
Entities cover only a small portion of the configuration values that can be set. Hundreds of keys correspond to parameters stored in .yml files. Tableau Server uses these parameters to store all of the configuration information for all services.

You can set individual keys with the tsm configuration command. But during deployment, setting them along with other configuration scenarios in JSON files, as shown above, is more convenient.

Unlike configEntities, configKeys are not validated.

**Note:** We do not recommend setting parameters that are not documented in tsm configuration set Options.

gatewaySettings Entity

You must configure the gateway settings for the Tableau Server computer.

Use the configuration file template below to create a json file. After you have filled in the options with the appropriate values, pass the json file and apply settings with the following commands:

```
tsm settings import -f /path/to/file.json

tsm pending-changes apply
```

The pending-changes apply command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the --ignore-prompt option, but this does not change the restart behavior. For more information, see tsm pending-changes apply.

Gateway settings

The gateway settings in the template below specify the HTTP settings for Tableau Server. We recommend using SSL/TLS. Tableau Server is hard-coded to use port 443 for
SSL/TLS. Therefore, if you enable SSL, you do not need to update the gatewaySettings entity.

Configuration template

Use this template to configure the gateway settings.

All entity options are case sensitive.

For more explanation about configuration files, entities, and keys see Configuration File Example.

```
{
   "configEntities": {
      "gatewaySettings": {
         "_type": "gatewaySettingsType",
         "port": 80,
         "sslRedirectEnabled": true,
         "publicHost": "localhost",
         "publicPort": 80
      }
   }
}
```

Configuration file reference

This table includes all of the options that can be included with the "gatewaySettings" entity set.

_**_type_

Required.

Value: "gatewaySettingsType"

Do not change.

_port_

Specifies HTTP port. Default is port 80.

sslRedirectEnabled

Options: true or false.

publicHost

Specifies host name for http/s service.

publicPort

The externally facing port that clients use to access the gateway process on Tableau Server over HTTP/HTTPS. This value defaults to 80, which is the same as the default for the gateway port itself. However, if there is a proxy or a NAT between gateway and an external client, the public port used by the proxy can be different from the internal port the gateway uses. See Configuring Proxies for Tableau Server.

trustedIPs

Specifies trusted IP addresses that communicate with Tableau Server. Trusted IP addresses include upstream proxy servers and servers that are used for trusted authentication with Tableau Server. See Configuring Proxies for Tableau Server and Add Trusted IP Addresses or Host Names to Tableau Server.

If you are running Tableau Server in a cluster then all other nodes of the cluster will automatically be included in the corresponding configuration file that this entity updates. Therefore, if you specify a new value for trustedIPs, then you must include the IP addresses for the other nodes in the value.

trustedHosts

Specifies trusted IP addresses that communicate with Tableau Server. Typically, this value contains a list of upstream proxy servers. The values in trustedHosts are used to determine client request targets.
If you are running Tableau Server in a cluster then all other nodes of the cluster will automatically be included in the corresponding configuration file that this entity updates. Therefore, if you specify a new value for trustedIPs, then you must include the IP addresses for the other nodes in the value.

The hostname may be entered as a name or an IP address. Format is hostname:port, for example, proxy_server1:80. In the case where a given proxy server has multiple name forms (proxy_server1, proxy_server1.example.com, etc), each name must be entered in the hostname:port format. Enter multiple hostname:port pairs in a comma-separated list.

identityStore Entity

Tableau Server requires an identity store to store user and group information. Review Authentication and Identity Store topics before configuring the identity store for the first time. After you have installed the identity store on Tableau Server, you cannot change it without reinstalling the server.

All entity options are case sensitive.

Before you begin

Review the following information:

- If you plan to enable OpenID Connect then you must configure the local identity store.

- If you will not be using the local identity store, then you will be using some version of LDAP. In this case, work with your directory/LDAP administrator to configure Tableau Server for your LDAP schema and bind requirements.

- Tableau Server configuration is optimized for Active Directory. If you are installing into Active Directory, we recommend configuring the identity store with TSM web interface. Alternatively, if you are configuring with TSM CLI, use the LDAP - Active Directory template in this topic to configure identity store.

- LDAP bind is independent of user authentication. For example, you can configure
Tableau Server to use simple bind to authenticate to the LDAP directory and then configure Tableau Server to authenticate users with Kerberos after installation.

- Do not connect to LDAP with simple bind over a unsecured connection. We recommend LDAPS for simple bind. See LDAP over SSL.

- To use Kerberos authentication for the Tableau Server service, then you'll need a keytab file for GSSAPI bind, as described in the sections below. See also, Understanding Keytab Requirements. In the context of Kerberos, GSSAPI bind is all you need during the base installation of Tableau Server. After you install the server, you can then configure Kerberos for user authentication and Kerberos delegation to data sources.

- In this topic, we make the distinction between LDAP (the protocol for connecting to directory services) and an LDAP server (an implementation of a directory service). For example, slapd is an LDAP server that is part of the OpenLDAP project.

- We recommend validating the LDAP configuration before initializing the server, see Configure Initial Node Settings.

Use one of the configuration file templates below to create a json file. After you have filled in the options with the appropriate values, pass the json file and apply settings with the following commands:

```bash
    tsm settings import -f path-to-file.json

    tsm pending-changes apply
```

The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`. 

- 1080 -
Configuration templates

Select an identity store configuration template to edit:

- Local
- LDAP - Active Directory
- OpenLDAP - GSSAPI Bind
- OpenLDAP - Simple Bind

For more explanation about configuration files, entities, and keys see Configuration File Example.

Local

Configure local as the identity store type if your organization does not already have an Active Directory or LDAP server for user authentication. When you select local as the identity store type, you use Tableau Server to create and manage users.

```
{
  "configEntities":{
    "identityStore": {
      "_type": "identityStoreType",
      "type": "local"
    }
  }
}
```

Important

The LDAP configuration templates below are examples. The templates, as presented, will not configure LDAP connectivity in your organization. You must work with your directory administrator to edit the LDAP template values for a successful deployment.

Additionally, all files that are referenced in configEntities must be located on the local computer. Do not specify UNC paths.
LDAP - Active Directory

Configure this option to connect to Active Directory with GSSAPI (Kerberos) bind. Tableau Server uses the LDAP protocol to connect to Active Directory. GSSAPI (Kerberos) bind is used to authenticate Tableau Server service to Active Directory. Tableau Server includes support for Active Directory schema. Therefore, if you set the "directoryServiceType" option to "activedirectory" then you do not need to provide schema info in the "identityStoreSchemaType" option.

If you are installing Tableau Server for Linux into Active Directory, and the computer where you are installing Tableau Server is already joined to the domain, then the computer will already have a Kerberos configuration file and a keytab file. Strictly speaking, you can use these files for GSSAPI bind, but we don't recommend using them. Instead, contact your Active Directory administrator and request a keytab specifically for the Tableau Server service.

```json
{
  "configEntities": {
    "identityStore": {
      "_type": "identityStoreType",
      "type": "activedirectory",
      "domain": "your-domain.lan",
      "nickname": "YOUR-DOMAIN-NICKNAME",
      "directoryServiceType": "activedirectory",
      "bind": "gssapi",
      "kerberosKeytab": "<path to local key tab file>",
      "kerberosConfig": "/etc/krb5.conf",
      "kerberosPrincipal": "your-principal@YOUR.DOMAIN"
    }
  }
}
```

We recommend binding to Active Directory with GSSAPI. However, you can connect with simple bind and LDAPS. To connect with simple bind, change bind to simple, remove
the three Kerberos entities, and add the `port/sslPort, username, and password` options. The following example shows Active Directory with simple bind json.

```
{
  "configEntities":{
    "identityStore": {
      "_type": "identityStoreType",
      "type": "activedirectory",
      "domain": "your-domain.lan",
      "nickname": "YOUR-DOMAIN-NICKNAME",
      "directoryServiceType": "activedirectory",
      "hostname": "optional-ldap-server",
      "sslPort": "636",
      "bind": "simple",
      "username": "username",
      "password": "password"
    }
  }
}
```

**OpenLDAP - GSSAPI bind**

Use the template below to configure OpenLDAP with GSSAPI bind. Do not use this template if your organization is running Active Directory. If you are installing into Active Directory, use the template above, LDAP - Active Directory.

In most cases, organizations that use OpenLDAP with GSSAPI (Kerberos) will use a keytab file to store credentials. In the following example, a keytab file is used for authentication credentials.

However, you can provide credentials through the `username and password` entities.
You can also specify both a keytab and a username and password pair. In this case, Tableau Server will attempt to use the keytab, but if authentication fails for any reason it will fallback and use the username and password credentials.

```json
{
    "configEntities": {
        "identityStore": {
            "_type": "identityStoreType",
            "type": "activedirectory",
            "domain": "your-domain.lan",
            "nickname": "YOUR-DOMAIN-NICKNAME",
            "directoryServiceType": "openldap",
            "bind": "gssapi",

            }
        }
    }
}
Configuration template reference

Shared identity store options

type
Where you want to store user identity information. Either local or activedirectory. (If you want to connect to any LDAP server, select activedirectory.)

domain
The domain of the computer where you installed Tableau Server.

nickname
The nickname of the domain. This is also referred to as the NetBIOS name in Windows environments. The nickname option is required for all LDAP entities. If your organization does not require a nickname/NetBIOS, then pass a blank key, for example: "nickname": "".

LDAP GSSAPI bind options

directoryservicetype
The type of directory service that you want to connect to. Either activedirectory or openldap.

bind
The way that you want to authentication communication from the Tableau Server service to the LDAP directory service. Enter gssapi for GSSAPI (Kerberos).

kerberosConfig
The path to the Kerberos configuration file on the local computer. If you are installing into Active Directory, we don't recommend using the existing Kerberos configuration
file or keytab file that may already be on the domain-joined computer. See Identity Store.

kerberosKeytab
   The path to the Kerberos keytab file on the local computer. It is recommended that you create a keytab file with keys specifically for Tableau Server service and that you do not share the keytab file with other applications on the computer. For example, on Linux, you might place the keytab file in the /var/opt/tableau/keytab directory.

kerberosPrincipal
   The service principal name for Tableau Server on the host machine. The keytab must have permission for this principal. Do not use the existing system keytab at /etc/krb5.keytab. Rather, we recommend that you register a new service principal name. To see principals in a given keytab, run the klist -k command. See Understanding Keytab Requirements.

domain
   In Windows Active Directory environments, specify the domain where Tableau Server is installed, for example, "example.lan". In LDAP directories, specify the root domain name in the same format. For example, if your root is "dc=my,dc=root", specify "my.root".

LDAP simple bind options

directoryservicetype
   The type of directory service that you want to connect to. Either activedirectory or openldap.

bind
   The way that you want to secure communication to the directory service. Enter simple for LDAP unless you are connecting to an LDAP server with Kerberos. For Kerberos, enter gssapi.
In Windows Active Directory environments, specify the domain where Tableau Server is installed, for example, "example.lan". In LDAP directories, specify the root domain name in the same format. For example, if your root is "dc=my,dc=root", specify "my.root".

hostname
The hostname of the LDAP server. You can enter a hostname or an IP address for this value.

port
Use this option to specify the non-secure port of the LDAP server. Plaintext is usually 389.

sslPort
Use this option to specify the secure port of the LDAP server. We recommend secure LDAP for simple bind. LDAPS is usually port 636.

username
The user name that you want to use to connect to the directory service. For LDAP servers, enter the distinguished name (DN) of the user that you want to use to connect. For example, you might enter cn=username,dc=your-local-domain,dc=lan.

password
The password of the user that you want to use to connect to the LDAP server.

identityStoreSchemaType **options**

If you configure an LDAP connection to an LDAP server, you can enter schema information specific to your LDAP server in the identityStoreSchemaType object. If you are connecting to Active Directory ("directoryServiceType": "activedirectory"), then do not configure these options.

userBaseFilter
The filter that you want to use for users of Tableau Server. For example, you might specify an object class attribute and an organization unit attribute.
userUsername
The attribute that corresponds to user names on your LDAP server.

userDisplayName
The attribute that corresponds to user display names on your LDAP server.

userEmail
The attribute that corresponds to user email addresses on your LDAP server.

userCertificate
The attribute that corresponds to user certificates on your LDAP server.

userThumbnail
The attribute that corresponds to user thumbnail images on your LDAP server.

userJpegPhoto
The attribute that corresponds to user profile images on your LDAP server.

groupBaseFilter
The filter that you want to use for groups of users of Tableau Server. For example, you might specify an object class attribute and an organization unit attribute.

ggroupName
The attribute that corresponds to group names on your LDAP server.

groupEmail
The attribute that corresponds to group email addresses on your LDAP server.

groupDescription
The attribute that corresponds to group descriptions on your LDAP server.
The attribute that describes the list of users in a group.

distinguishedNameAttribute
The attribute that stores the distinguished names of users. This attribute is optional, but it greatly improves the performance of LDAP queries.

serverSideSorting
Whether the LDAP server is configured for server-side sorting of query results. If your LDAP server supports server-side sorting, set this option to true. If you are unsure whether your LDAP server supports this, enter false, as misconfiguration may cause errors.

rangeRetrieval
Whether the LDAP server is configured to return a range of query results for a request. This means that groups with many users will be requested in small sets instead of all at once. LDAP servers that support range retrieval will perform better for large queries. If your LDAP server supports range retrieval, set this option to true. If you are unsure whether your LDAP server supports range retrieval, enter false, as misconfiguration may cause errors.

groupClassNames
By default Tableau Server looks for LDAP group object classes containing the string “group”. If your LDAP group objects do not fit the default class name, override the default by setting this value. You can provide multiple classnames separated by commas. For example: "basegroup, othergroup".

userClassNames
By default Tableau Server looks for LDAP user object classes containing the string “user” and “inetOrgPerson”. If your LDAP user objects do not use these default class names, override the default by setting this value. You can provide multiple classnames separated by commas. For example: "userclass1, userclass2".

kerberosSettings Entity

Before you configure Kerberos authentication, review Kerberos Requirements.
Use the configuration file template below to create a json file. After you have filled in the options with the appropriate values, pass the json file and apply settings with the following commands:

```
tsm settings import -f /path/to/file.json
```
```
tsm pending-changes apply
```

The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

**Configuration template**

Use this template to configure Kerberos settings.

All entity options are case sensitive.

For more explanation about configuration files, entities, and keys see Configuration File Example.

After you have finished with the initial configuration of Kerberos authentication, use the `tsm authentication kerberos <commands>` sub-category to set additional values.

```
{
  "configEntities": {
    "kerberosSettings": {
      "_type": "kerberosSettingsType",
      "enabled": "true",
      "keytabFile": "/path/to/keytab_file"
    }
  }
}
```
Configuration file reference

The following list includes all of the options that can be included with the "kerberosSettings" entity set.

Option            Value

enabled
  Options: true or false.
  Enables Kerberos authentication.

keytabFile
  Required.
  Path to valid Kerberos keytab file.

dBClasses
  Comma-separated list of database classes for global credentials. May be required for connecting to Cloudera data sources.

mutualSSLSettings Entity

Before you configure mutual SSL, review Configure SSL for External HTTP Traffic to and from Tableau Server.

The mutualSSLSettings entity combines both SSL and mutual SSL configuration. Mutual SSL requires that external SSL has been enabled and properly configured.

The TSM entities use JSON and key-value pairs. Use the configuration file template below to create a .json file. Provide values for the appropriate keys for your environment, and then pass the .json file to Tableau Server with the following commands:

tsm settings import -f <path-to-file.json>
tsm pending-changes apply

The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

Configuration template

Use this template to configure mutual SSL settings.

All entity options are case sensitive.

For more explanation about configuration files, entities, and keys see Configuration File Example.

```json
{
   "configEntities": {
      "mutualSSLSettings": {
         "_type": "mutualSSLSettingsType",
         "sslEnabled": true,
         "proxyLogin": false,
         "clientCertRequired": true,
         "caCertFile": "required",
         "keyFileName": "required",
         "keyPassphrase": "",
         "chainFile": "",
         "revocationFile": "",
         "redirect": false,
         "fallbackToPassword": true,
         "protocols": "",
         "cipherSuite": ""
      }
   }
}
```
"forceHttpsForPublicEmbed": false
}
}

Configuration file reference

sslEnabled

Enable SSL. This is a prerequisite to enabling mutual SSL.

clientCertRequired (MutualSSL)

Set to true to enable mutual SSL authentication. Set to false to disable.

cacertFile (MutualSSL)

Required.

Specify the CA-issued certificate file for two-way SSL. The file path must be readable by Tableau Server.

certFileName

Specify the file that contains the concatenation of PEM encoded CA certificates that form the certificate chain for the server certificate.

Alternatively the referenced file can be the same as cacertFile when the CA certificates are directly appended to the server certificate for convenience.

keyFileName

If the key is not combined with the certificate, use this configuration key to point to the key file. If you have both an RSA and a DSA private key, you can configure both in parallel (for example, to also allow the use of DSA ciphers).
keyPassphrase

Optional. Passphrase for the certificate file. The passphrase you enter will be encrypted while at rest.

**Note:** If you create a certificate key file with a passphrase, you cannot reuse the SSL certificate key for SAML.

revocationFile

Specifies the file path for an SSL CA Certificate Revocation List (.crl) file.

Redirect

Default: true. Specifies whether Tableau Server should redirect http requests as https requests to the appropriate endpoint.

clientCertMapping (MutualSSL)

Specifies the method for retrieving the user name from the certificate.

Accepted values: ldap, upn, cn

- For a server using local authentication, the default setting is `upn` (User Principal Name).

- When Tableau Server authentication is configured for Active Directory (AD), the default is `ldap` (Lightweight Directory Access Protocol). This tells the server to go to AD to validate the user, and it ignores the names inside the certificate.

You can set `cn` for either authentication type to use the CN in the Subject DN in the certificate.

For more information, see Mapping a Client Certificate to a User During Mutual Authentication.

fallbackToPassword (MutualSSL)

Set to true to give users the option to sign in to Tableau Server through their user
name and password if mutual SSL authentication fails. Set to false to disallow this fallback option.

**protocols**

List the Transport Layer Security (TLS) protocol versions you want to allow or disallow.

**Default value:** "all -SSLv2 -SSLv3"

However, we recommend the using the following setting:

"all -SSLv2 -SSLv3 -TLSv1 -TLSv1.1"

For more information, see tsm security external-ssl enable. For general information, see the Apache online documentation.

**cipherSuite**

List ciphers to allow or disallow for SSL.

**Default value:** "HIGH:MEDIUM:!aNULL:!MD5:!RC4"

However, we recommend that you add Triple-DES to the list of disabled cipher suites, and set this key to:

"HIGH:MEDIUM:!aNULL:!MD5:!RC4!3DES"

For more information, see the --cipher-suite option in tsm security external-ssl enable CLI reference.

**proxyLogin**

**Default:** false. Indicates that Tableau Server uses a proxy for SSL on sign-in only. It controls the protocol the server reports to Tableau Desktop for sign-in APIs.

**forceHTTPForPublicEmbed**

**Default value:** false. Forces the code for embedded views to use SSL.
openIDSettings Entity

Before you configure OpenID authentication, review Requirements for Using OpenID Connect.

Use the configuration file template below to create a json file. After you have filled in the options with the appropriate values, pass the json file and apply settings with the following commands:

```shell
tsm settings import -f path-to-file.json

tsm pending-changes apply
```

The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

Configuration template

Use this template to configure OpenID settings.

All entity options are case sensitive.

For more explanation about configuration files, entities, and keys see Configuration File Example.

After you have finished with the initial configuration of OIDC, use the `tsm authentication openid <commands>` sub-category to set additional values.

```json
{
  "configEntities": {
    "openIDSettings": {
      "_type": "openIDSettingsType",
      "enabled": true,
      "clientId": "required",
```
"clientSecret": "required",
"configURL": "required if staticFile value is not set",
"staticFile": "required if configURL value is not set",
"externalURL": "required"
}

Configuration file reference

The following list includes all of the options that can be included with the "openIDSettings" entity set.

_type

Required.
Do not change.

enabled

Required.
Set to true.

clientId

Required.
 Specifies the provider client ID that your IdP has assigned to your application. For example, "laakjwdlnaoiloadjkwha".

clientSecret

Required.
Specifies the provider client secret. This is a token that is used by Tableau to verify the authenticity of the response from the IdP. This value is a secret and should be kept securely.

For example, “fwahfkjaw72123=“.

configURL

Required.

Specifies provider configuration URL. If you do not specify a configuration URL, then delete this option and specify a path and file name for `staticFile` instead.

staticFile

Required.

Specifies the local path to the static OIDC discovery JSON document. If you do not specify a static file, then delete this option and specify a url for `configURL` instead.

externalURL

Required.

The URL of your server. This is typically is the public name of your server, such as http://example.tableau.com.

connectionTimeout

Optional.

Specifies connection timeout span in seconds. Default is 10.

readTimeout

Optional.

Specifies read timeout span in seconds. Default is 30.
ignoreDomain

Set this to true if the following are true:

- You are using email addresses as usernames in Tableau Server
- You have provisioned users in the IdP with multiple domain names
- You want to ignore the domain name portion of the email claim from the IdP

Before you proceed, review the user names that will be used as a result of setting this option to true. User name conflicts may occur. In the case of a user name conflict, the risk of information disclosure is high. See Requirements for Using OpenID Connect.

ignoreJWK

Set this to true if your IdP does not support JWK validation. In this case, we recommend authenticating communication with your IdP using mutual TLS or another network layer security protocol. Default is false.

customScope

Specifies a custom scope user-related value that you can use to query the IdP. See Requirements for Using OpenID Connect.

idClaim

Change this value if your IdP does not use the subclaim to uniquely identify users in the ID token. The IdP claim that you specify should contain a single, unique string.

usernameClaim

Change this value to the IdP claim that your organization will use to match user names as stored in Tableau Server.

clientAuthentication

Specifies custom client authentication method for OpenID Connect.
To configure Tableau Server to use the Salesforce IdP, set this value to `client_secret_post`.

**iFramedIDPEnabled**

Set to `true` to allow IdP displayed in an iFrame. The IdP must disable clickjack protection to allow iFrame presentation.

**samlSettings Entity**

This article contains a template and reference for configuring server-wide SAML on Tableau Server, using a configuration file with keys and values for the `samlSettings` entity. This information supplements the SAML configuration steps in Configure Server-Wide SAML.

To create a SAML configuration template and apply it to Tableau Server, you complete the following steps:

1. Review the following two sections that describe the template and how it’s structured (Template categories and definitions and `samlSettings` configuration template).

2. Paste the JSON code shown in the template into a new text file, and save it using a `.json` extension.

3. Use the SAML configuration entity reference to help you provide values where required.

4. Add optional key/value pairs specific to your environment.

5. Pass the configuration file to Tableau Server.

**Template categories and definitions**

The template uses placeholders for each key value. These placeholders are categorized as follows:
• **Required**: Attributes with the "required" value must be replaced with valid data before you run the configuration command. Review the configuration file reference for valid values.

• **Hard-coded**: Attribute names that are prepended with an underscore (_), for example "_type" hold hard-coded values. Do not change these values.

• **Default values**: Attributes that are set to a value that is not "required" are default values. These are required attributes that you can change as appropriate for your environment.

• **Empty sets**: Values that are empty (" ") can be passed as they are, or you can provide a value for your installation.

All entity options are case sensitive.

**samlSettings configuration template**

Paste this code into a text file and customize it for your environment, using the reference below.

```json
{
  "configEntities": {
    "samlSettings": {
      "_type": "samlSettingsType",
      "enabled": true,
      "returnUrl": "required",
      "entityId": "required",
      "certFile": "required",
      "keyFile": "required",
      "idpMetadataFile": "required",
      "idpDomainAttribute": "",
      "idpUsernameAttribute": "required"
    }
  }
}
```
SAML configuration entity reference

The following table includes all of the options you can include with the "samlSettings" entity set.

idpMetadataFile

Required. The path and file name for the XML file generated by the IdP. The XML metadata must include the user name attribute (assertion).

If you completed the steps described in Configure Server-Wide SAML the value you enter here would be:

/var/opt/tableau/tableau_server/data/saml/<metadata-file.xml>

enabled

true | false

Required. Indicates whether SAML authentication is enabled and can be configured on the server.

returnURL

The SAML return URL configured in the IdP. This is typically the external URL that Tableau Server users enter in their browser to access the server, such as http://tableau-server.

Notes

- http://localhost does not work for an external server.

- Adding a trailing slash to the URL (http://tableau-server/) is not supported.
entityId

Required. IdP entity ID value.

Typically the same as the Tableau Server return URL. The entity ID that you enter is used as a base for generating site-specific entity IDs. For example, if you enter "http://tableau-server", an individual site configured for SAML might display an entity ID something like the following:

http://tableau-server-/samlservice/public/sp/metadata?alias=48957410-9396-430a-967c-75b-db6e002a0

certFile

Enter the location and file name of the x509 certificate (.crt) file for SAML. For example:

/var/opt/tableau/tableau_server/data/saml/<file.crt>

For more information, see SAML Requirements and Configure Server-Wide SAML.

keyFile

Specify the location of the RSA or DSA private key (.key) file that accompanies the certificate file and is not password protected. For example:

/var/opt/tableau/tableau_server/data/saml/<file.key>

For more information, see SAML Requirements and Configure Server-Wide SAML.

idpDomainAttribute

Optional. This value is used when Tableau Server includes user accounts from multiple domains. Specify the fully qualified domain name (FQDN) of the domain you want to be the default. For example tableauserver.mycompany.com.

If you do not provide a value for this key, the value used depends on the Tableau Server user authentication setting:
- For local authentication, the value `local` is used.

- For Active Directory, Tableau uses the FQDN from the configuration setting `wgserver.domain.default`.

To get the value for `wgserver.domain.default`, you can run the following command:

```
tsm configuration get --key wgserver.domain.default
```

`idpUsernameAttribute`

Required. In the IdP metadata, find the attribute that is used to specify user name values, and enter the name of that attribute. For example, `username`.

`idpEmailAttribute`

Optional. In the IdP metadata, the name of the attribute the IdP uses to specify users’ email adderesses.

`idpDisplayNameAttribute`

Optional. In the IdP metadata, the name of the attribute the IdP uses to specify users’ display names.

`idpAttributeUseDefaultDomain`

`true` | `false`

Optional. The default value is true for a single domain or for multiple domains when you do not specify a value for `idpDomainAttribute`. The default value is false if you specify a non-default value for `idpDomainAttribute`.

`desktopNoSAML`

`true` | `false`

Allow users to use SAML authentication when they sign in from Tableau Desktop.
By default this is not set, so the effective behavior is equivalent to setting it to false. If single sign-on from Tableau client applications does not work with your IdP, you can set this to true to disable SAML authentication through Tableau Desktop.

`appNoSAML`

true | false

Allow using SAML to sign in from older versions of Tableau Mobile app. Devices running Tableau Mobile app version 19.225.1731 and higher ignore this option. To disable devices running Tableau Mobile app version 19.225.1731 and higher, disable SAML as a client login option on Tableau Server.

`logoutEnabled`

true | false

Specifies whether SAML logout is enabled for Tableau Server. The default is true. This setting applies only if SAML authentication is enabled for the server.

`logoutUrl`

Enter the URL to redirect to after users sign out of the server. By default this is the Tableau Server sign-in page. You can specify an absolute or a relative URL.

`maxAuthenticationAge`

Specifies the maximum number of seconds allowed between a user’s authentication and processing of the AuthNResponse message. The default value is 7200 (2 hours).

`maxAssertionTime`

Specifies the maximum number of seconds, from creation, that a SAML assertion is usable. Default value is 3000 (50 minutes).

`sha256Enabled`
true | false

Indicates whether the SAML certificate is an SHA-2 (256 or 512 bit) certificate. Default value is false. If you use the same certificate for SAML as you do for SSL, you will most likely set this to true.

signRequests

true | false

Default value is true.

iFramedIdpEnabled

true | false

Default value is false, meaning that when users select the sign-in button on an embedded view, the IdP’s sign-in form opens in a pop-up window.

When you set it to true, and a server SAML user who is already signed in navigates to a web page with an embedded view, the user will not need to sign in to see the view.

You can set this to true only if the IdP supports signing in within an iframe. The iframe option is less secure than using a pop-up, so not all IdPs support it. If the IdP sign-in page implements clickjack protection, as most do, the sign-in page cannot display in an iframe, and the user cannot sign in.

If your IdP does support signing in via an iframe, you might need to enable it explicitly. However, even if you can use this option, it disables Tableau Server clickjack protection for SAML, so it still presents a security risk.

port

The port that handles SAML authentication traffic.

Default value: 80

If your server is configured for SSL (recommended), set this to 443.
singleLogoutSupported

true | false

Enable or disable SAML single logout (SLO). This value is not set by default, so effectively it behaves as if the value were set to false. To set it to true, the IdP must support SLO.

siteSpecific

enabled | disabled

Specifies whether the server is configured to support site-specific SAML authentication, in which you can configure sites to use different IdPs or IdP applications. Set to disabled by default. If you set to enabled, you then configure a site’s SAML settings in the Tableau Server web UI. Sign in to the site on which you want to use SAML, and go to the Authentication tab on the Settings page.

Pass the configuration file to Tableau Server

After you have provided an appropriate value for each entity you include in the configuration template, use the following commands to pass the .json file and apply settings to Tableau Server.

tsm settings import -f path-to-file.json

tsm pending-changes apply

See also

After you complete the initial SAML configuration, use tsm authentication mutual-ssl <commands> to set additional values.

For the command-line reference for configuring SAML, see tsm authentication saml <commands>.
sapHanaSettings Entity

Use the sapHanaSettings entity to configure SAML delegation for SAP HANA.

Review Configure SAP HANA SSO before you continue.

Use the configuration file template below to create a json file. After you have filled in the options with the appropriate values, pass the json file and apply settings with the following commands:

```
tsm settings import -f path-to-file.json
```

```
tsm pending-changes apply
```

The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

**SAP HANA SAML settings**

The settings in the template below specify the settings for Tableau Server in a SAML delegation scenario with SAP HANA.

**Configuration template**

Use this template to configure trusted authentication settings.

All that are referenced in configEntities must be located on the local computer. Do not specify UNC paths.

All entity options are case sensitive.

For more explanation about configuration files, entities, and keys see Configuration File Example.
{  
  "configEntity": {  
    "sapHanaSettings": {  
      
      
      
      }  
  }  
}

Configuration file reference

This table includes all of the options that can be included with the "gatewaySettings" entity set.

enabled

    Required.

    Values: true or false

textual

usernameFormat

    Values: username, domain_and_username, or email

    Specifies user name credential format.

usernameCase

    Values: lower, upper, or preserve

    Specifies user input name case.

certFile
Specifies file path and name for the certificate file on the local computer.

For example, "/var/opt/tableau/tableau_server/data/saml/saml_cert.crt".

**keyFile**

Specifies file path and name for the certificate key on the local computer.

For example, "/var/opt/tableau/tableau_server/data/saml/saml_key.der".

**trustedAuthenticationSettings Entity**

Before you configure trusted authentication, review Trusted Authentication.

Use the configuration file template below to create a json file. After you have filled in the options with the appropriate values, pass the json file and apply settings with the following commands:

```
 tsm settings import -f /path/to/file.json
 tsm pending-changes apply
```

The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

**Configuration template**

Use this template to configure trusted authentication settings.

All entity options are case sensitive.

For more explanation about configuration files, entities, and keys see Configuration File Example.
After you have finished with the initial configuration of trusted authentication, use the tsm authentication trusted <commands> sub-category to set additional values.

```
{
    "configEntities": {
        "trustedAuthenticationSettings": {
            "_type": "trustedAuthenticationSettingsType",
            "trustedHosts": "required"
        }
    }
}
```

### Configuration file reference

The following list includes all of the options that can be included with the "trustedAuthenticationSettings" entity set.

**trustedHosts**

Required.

IP address or host names of web servers that request trusted tickets from Tableau Server.

For multiple values, enter the names in a comma-separated list where each value is encapsulated in double-quotes.

For example:

```
tsm authentication trusted configure -th "192.168.1.101", "192.168.1.102", "192.168.1.103"
```

or

```
tsm authentication trusted configure -th "webserv1", "webserv2", "webserv3"
```

The values you specify overwrite previous settings. Therefore, you must include the full list of hosts when you configure this value.
tokenLength

Optional.

The value can be set to any integer between 9 and 255, inclusive.

Determines the number of characters in each trusted ticket. The default setting of 24 characters provides 144 bits of randomness. This option is ignored unless useV2Tickets is set to true, which is not a recommended best practice.

logLevel

Optional.

all | debug | info | warn | error | fatal | off

Default: info

 Specifies logging level for processes related to creating and redeeming trusted tickets. See Change Logging Levels.

timeoutInSeconds

Optional.

Default: 180

Specifies the length of time (in seconds) to invalidate trusted tickets after they are created.

tryCount

Optional.

Integer.

Default: 10

Specifies the number of times to attempt to create a trusted ticket entry.
Optional.

true | false

Default: false

When set to true, tickets are 9 digits long (as in version 8.0 and earlier) and the option tokenLength is ignored. This option is intended for temporary support of legacy code.

**Warning:** Setting this option to true severely and negatively impacts the security strength of trusted ticket authentication.

useV2Tickets

Optional.

true | false

Default: false

Specifies whether Tableau Server should return a legacy URL format for trusted ticket requests. The legacy URL format includes a 24 character, Base64-encoded string. Beginning with Tableau Server 10.3, the URL that is returned has been updated and includes a Base64-encoded UUID and a 24 character secure random string. Only set option this to true if you have deployed trusted tickets with custom code that requires the legacy URL format. We recommend instead, updating your custom code to accept the new URL format.

---

**web-data-connector-settings Entity**

This entity is used to manage web data connector (WDC) settings. To learn more about using WDCs in Tableau Server, see Web Data Connectors in Tableau Server and tsm data-access.
Use the configuration file template below to create a .json file. After you have filled in the options with the appropriate values, pass the .json file and apply settings with the following commands:

```
tsm settings import -f /path/to/file.json

tsm pending-changes apply
```

The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see tsm pending-changes apply.

Web data connector settings

The web data connector (WDC) settings in the template below specify whether WDCs are enabled, whether refresh of WDCs is enabled, and the primary and secondary safe lists. The safe lists (or "whitelists") indicate which WDC URLs are approved for use in your Tableau Server installation, and the domains or URLs that a connector can send requests to and receive requests from.

Configuration template

Use this template to configure the WDC settings.

All entity options are case sensitive.

For more explanation about configuration files, entities, and keys see Configuration File Example.

```json
{
    "configEntities": {
        "web-data-connector-settings": {
            "_type": "webDataConnectorSettingsType",
            "refreshEnabled": true,
            "whitelist": {
```
    "secondaryWhitelist" : [ 
        "(https://dtreskunov.github.io/*)"
    ]
},
"enabled": true
}

Configuration file reference

This table includes all of the options that can be included with the "web-data-connector-settings" entity set.

_type

Required.
Value: "web-data-connector-settings"
Do not change.

refreshEnabled

Set to false to disable refresh of WDCs. Defaults to true.

whitelist

Required.
Can contain one or more matching sets of safe lists and secondary safe lists (one set per WDC). The first URL provided is the safe list, where you specify the WDC URL and port, formatted as follows:

<scheme>://<host>:<port>/<path>
For many WDCs, the `<port>` value is 443 or 80, but you can check the value for your connector by looking at the data source details on Tableau Server or Tableau Online.

**secondaryWhitelist**

Required.

Specifies the domains or URLs that a connector can send requests to and receive requests from. To specify a domain, use a wildcard character (*), as in the following example:

```
https://dtreskunov.github.io/*
```

**enabled**

Set to **false** to disable use of WDCs. Defaults to **true**.

**tabcmd**

Tableau provides the tabcmd command-line utility which you can use to automate site administration tasks on your Tableau Server site. For example, creating or deleting users, projects, and groups.

This utility is included with Tableau Server, and is automatically installed on the initial server node. You can also run it from other computers, even computers that are not part of your Tableau Server installation, but to do so you need to download the tabcmd installer from the Tableau website. For more information, see Install tabcmd below.

**In this article**

- Install tabcmd
- How to use tabcmd
- Examples
Install tabcmd

When Tableau Server or Tableau Online is upgraded to a new version, if an updated version of tabcmd is required, you can download it from the Tableau Releases page on the Tableau website, to avoid issues caused by version incompatibilities. Using an out of date version of tabcmd can cause errors and unpredictable results.

1. Open a web browser and go to the Tableau Server Releases page (do this even if you use Tableau Online).

2. **For Tableau Online**: select the latest release.

   **For Tableau Server (Windows or Linux)**: select the release that matches your server version.

   If the expanded information shows maintenance releases, select the latest maintenance release or the one that matches your server version.

   ![Tableau Server Releases](image)

   This takes you to the release notes page, where you can read about security improvements and resolved issues.

3. Scroll to the **Download Files** section under the resolved issues, select the tabcmd
download link that is compatible with the computer on which you'll run the tabcmd commands.

The remaining steps refer to this computer as “the tabcmd computer.”

4. Save the installer to the tabcmd computer, or a location accessible from that computer (a mounted drive, for example).

5. Complete the installation steps as appropriate for the operating system of the tabcmd computer:

   • **Windows**

   Run the installer.

   We recommend that you install tabcmd to a folder named **tabcmd** at the root of the C:\ drive (**C:\tabcmd**), for convenience when using tabcmd, and to accommodate some limitations with the Windows operating system.

   **Note** The tabcmd Setup program does not add the tabcmd directory to the Windows PATH variable. You can add it manually, or you can include the full path to tabcmd each time you call it.
• **Linux**

  a. Log on as a user with sudo access to the tabcmd computer.

  b. Navigate to the directory where you copied the .rpm or .deb package that you downloaded.

     • On RHEL-like distributions, including CentOS, run the following command:

     ```
     sudo yum install tableau-tabcmd-<version>.noarch.rpm
     ```

     • On Ubuntu, run the following command:

     ```
     sudo gdebi -n tableau-tabcmd-<version>_all.deb
     ```

**How to use tabcmd**

The basic steps for using tabcmd are as follows:

1. Open the Command Prompt as an administrator.

2. On a Windows computer, change to the directory where tabcmd is installed.

   If you are using tabcmd on the Tableau Server on Windows initial node, change to the Tableau Server bin folder. For example:

   ```
   C:\Program Files\Tableau\Tableau Server-\packages\bin.<version_code>
   ```

   If you installed tabcmd on a computer other than the initial node, change to the directory where you installed tabcmd.

   On a Linux computer, you do not need to change to the install directory.

3. Run the tabcmd command.
When you use tabcmd, you must establish an authenticated server session. The session identifies the server or Tableau Online site and the user running the session. You can start a session first, and then specify your command next, or you can start a session and execute a command all at once.

**Important:** If you are using tabcmd to perform more than one task, you must run tasks one after another (serially), rather than at the same time (in parallel).

Commands (such as `login`) and the options (such as `-s`, `-u`, etc.) are not case sensitive, but the values you provide (such as `User@Example.com`) are case sensitive.

**Examples**

The following command demonstrates starting a session with the Tableau Server named `tabserver.mycompany.com`:

```
tabcmd login -s http://tabserver.mycompany.com -u admin -p mypassword
```

The next example shows a command that deletes a workbook named `Sales_Workbook`:

```
tabcmd delete "Sales_Workbook"
```

Here’s how to accomplish all of the above with one command—note that you do not need `login` here:

```
tabcmd delete "Sales_Workbook" -s http://tabserver.mycompany.com -u admin -p mypassword
```

A Tableau Server can run multiple sites. When a workbook is on the Default site of a multi-site server you don’t need to specify Default, the above command is sufficient. However, if the command applies to something on a site other than Default, you need to specify the site ID for that site (see `login`). Here’s the same command for a workbook that’s on the West Coast Sales site (site ID `wsales`):
tabcmd delete "Sales_Workbook" -s http://tableserver.mycompany.com -t wsales -u admin -p mypassword

The options -s, -t, -u, and -p are among the tabcmd global variables, which can be used with any command.

For more information, see tabcmd Commands.

**tabcmd Commands**

Looking for Tableau Server on Windows? See [tabcmd Commands](#).

You can use the following commands with the tabcmd command line tool:

- addusers *(to group)*
- creategroup
- createproject
- createsite
- createsiteusers
- createusers
- delete *workbook-name or datasource-name*
- deletegroup
- deleteproject
- deletesite
- deletesiteusers
- deleteusers
- editdomain
- editsite
- export
- get *url*
- initialuser
- listdomains
- listsites
- login
- logout
publish
publishsamples
refreshextracts
removeusers
runcmd
set
syncgroup
version

**addusers** *group-name*

Adds users to the specified group.

**Example**

```
tabcmd addusers "Development" --users "users.csv"
```

**Options**

```
--users
```

Add the users in the given .csv file to the specified group. The file should be a simple list with one user name per line. User names are not case sensitive. The users should already be created on Tableau Server.

For more information, see CSV Import File Guidelines.

```
--[no-]complete
```

When set to *complete* this option requires that all rows be valid for any change to succeed. If not specified, --complete is used.

**Global options**

The following options are used by all tabcmd commands. The --server, --user, and --password options are required at least once to begin a session. An authentication token
is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

-h, --help
Displays the help for the command.

-c, --use-certificate
Use client certificate to sign in. Required when mutual SSL is enabled.
For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows**: Configure Mutual SSL
- **Linux**: Configure Mutual SSL

-s, --server
The Tableau Server URL, which is required at least once to begin session.

-u, --user
The Tableau Server username, which is required at least once to begin session.

-p, --password
The Tableau Server password, which is required at least once to begin session.

--password-file
Allows the password to be stored in the given .txt file rather than the command line for increased security.

-t, --site
Indicates that the command applies to the site specified by the Tableau Server site ID. If you do not specify a site, the Default site is assumed. Applies only to servers with multiple sites.

-x, --proxy

Host:Port

Uses the specified HTTP proxy.

--no-prompt

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

--no-proxy

When specified, an HTTP proxy will not be used.

--no-certcheck

When specified, tabcmd (the client) does not validate the server’s SSL certificate.

--[no-]cookie

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the no- prefix to not save the session ID. By default the session is saved.

--timeout

Waits the specified number of seconds for the server to complete processing the command. By default the process will timeout in 30 seconds.
Specifies the end of options on the command line. You can use -- to indicate to tabcmd that anything that follows -- should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use -- in a tabcmd command, where -430105/SHEET1 is a required value for the export command.

tabcmd export --csv -f "D:\export10.csv" -- -430105/SHEET1

Top

creategroup group-name

Creates a group. Use addusers (for local groups) and syncgroup (for Active Directory groups) commands to add users after the group has been created.

Example

tabcmd creategroup "Development"

Global options

The following options are used by all tabcmd commands. The --server, --user, and --password options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

-h, --help

Displays the help for the command.

-c, --use-certificate

Use client certificate to sign in. Required when mutual SSL is enabled.
For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows**: Configure Mutual SSL
- **Linux**: Configure Mutual SSL

- `s, --server`
  
  The Tableau Server URL, which is required at least once to begin session.

- `u, --user`
  
  The Tableau Server username, which is required at least once to begin session.

- `p, --password`
  
  The Tableau Server password, which is required at least once to begin session.

- `--password-file`
  
  Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

- `t, --site`
  
  Indicates that the command applies to the site specified by the Tableau Server site ID. If you do not specify a site, the Default site is assumed. Applies only to servers with multiple sites.

- `x, --proxy`
  
  Host:Port

  Uses the specified HTTP proxy.
--no-prompt

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

--no-proxy

When specified, an HTTP proxy will not be used.

--no-certcheck

When specified, tabcmd (the client) does not validate the server's SSL certificate.

--[no-]cookie

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the no- prefix to not save the session ID. By default the session is saved.

--timeout

Waits the specified number of seconds for the server to complete processing the command. By default the process will timeout in 30 seconds.

--

Specifies the end of options on the command line. You can use -- to indicate to tabcmd that anything that follows -- should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use -- in a tabcmd command, where -430105/SHEET1 is a required value for the export command.

```bash
  tabcmd export --csv -f "D:\export10.csv" -- -430105/SHEET1
```

Top
createproject *project-name*

Creates a project.

Using `tabcmd`, you can specify only a top-level project in a project hierarchy. To automate tasks you want to perform on a project within a parent project, use the equivalent Tableau REST API call.

**Example**

`tabcmd createproject -n "Quarterly_Reports" -d "Workbooks showing quarterly sales reports."`

**Options**

- `-n, --name`

  Specifies the name of the project that you want to create.

- `-d, --description`

  Specifies a description for the project.

**Global options**

The following options are used by all `tabcmd` commands. The `--server, --user, and --password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

- `-h, --help`

  Displays the help for the command.
-c, --use-certificate

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows**: Configure Mutual SSL
- **Linux**: Configure Mutual SSL

-s, --server

The Tableau Server URL, which is required at least once to begin session.

-u, --user

The Tableau Server username, which is required at least once to begin session.

-p, --password

The Tableau Server password, which is required at least once to begin session.

--password-file

Allows the password to be stored in the given .txt file rather than the command line for increased security.

-t, --site

Indicates that the command applies to the site specified by the Tableau Server site ID. If you do not specify a site, the Default site is assumed. Applies only to servers with multiple sites.

-x, --proxy

Host:Port
Uses the specified HTTP proxy.

--no-prompt
When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

--no-proxy
When specified, an HTTP proxy will not be used.

--no-certcheck
When specified, tabcmd (the client) does not validate the server's SSL certificate.

--[no-]cookie
When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the no- prefix to not save the session ID. By default the session is saved.

--timeout
Waits the specified number of seconds for the server to complete processing the command. By default the process will timeout in 30 seconds.

--
Specifies the end of options on the command line. You can use -- to indicate to tabcmd that anything that follows -- should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use -- in a tabcmd command, where -430105/Sheet1 is a required value for the export command.

tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
createsite site-name

Creates a site.

Examples

Create a site named West Coast Sales. A site ID of WestCoastSales will be automatically created, the site will have no storage quota limit, and site administrators will be able to add and remove users:

tabcmd createsite "West Coast Sales"

Create a site named West Coast Sales with a site ID of wsales:

tabcmd createsite "West Coast Sales" -r "wsales"

Prevent site administrators from adding users to the site:

tabcmd createsite "West Coast Sales" --no-site-mode

Set a storage quota, in MB:

tabcmd createsite "West Coast Sales" --storage-quota 100

Options

-r, --url

Used in URLs to specify the site. Different from the site name.

--user-quota

Maximum number of users that can be added to the site.

--[no-]site-mode
Allows or denies site administrators the ability to add users to or remove users from the site.

--storage-quota

In MB, the amount of workbooks, extracts, and data sources that can be stored on the site.

Global options

The following options are used by all tabcmd commands. The --server, --user, and --password options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

-h, --help

Displays the help for the command.

-c, --use-certificate

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows**: Configure Mutual SSL
- **Linux**: Configure Mutual SSL

-s, --server

The Tableau Server URL, which is required at least once to begin session.
-u, --user

The Tableau Server username, which is required at least once to begin session.

-p, --password

The Tableau Server password, which is required at least once to begin session.

--password-file

Allows the password to be stored in the given .txt file rather than the command line for increased security.

-t, --site

Indicates that the command applies to the site specified by the Tableau Server site ID. If you do not specify a site, the Default site is assumed. Applies only to servers with multiple sites.

-x, --proxy

Host:Port

Uses the specified HTTP proxy.

--no-prompt

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

--no-proxy

When specified, an HTTP proxy will not be used.

--no-certcheck
When specified, tabcmd (the client) does not validate the server's SSL certificate.

--[no-]cookie

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the no- prefix to not save the session ID. By default the session is saved.

--timeout

Waits the specified number of seconds for the server to complete processing the command. By default the process will timeout in 30 seconds.

--

Specifies the end of options on the command line. You can use -- to indicate to tabcmd that anything that follows -- should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use -- in a tabcmd command, where -430105/SHEET1 is a required value for the export command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/SHEET1
```

Top

createsiteusers filename.csv

Adds users to a site, based on information supplied in a comma-separated values (CSV) file. If the user is not already created on the server, the command creates the user before adding that user to the site.

The CSV file must contain one or more user names and can also include (for each user) a password, full name, license type, administrator level, publisher (yes/no), and email address. For information about the format of the CSV file, see CSV Import File Guidelines.
As an alternative to including administrator level and publisher permissions in the CSV file, you can pass access level information by including the `--role` option and specifying the site role you want to assign users listed in the CSV file.

By default, users are added to the site that you are logged in to. To add users to a different site, include the global `--site` option and specify that site. (You must have permissions to create users on the site you specify.)

If the server contains multiple sites, you cannot add server (system) administrators through the `createsiteusers` command. Use `createusers` instead. If you specify the `ServerAdministrator` site role for the `--role` option, the command returns an error. If the CSV file includes System as value for administrator, the value is ignored and the user is assigned the Unlicensed license type.

If the server contains only one site (the default site), you can specify `system` for the administrator value for a user, or even assign the `ServerAdministrator` site role using the `--role` option, if you want all users in the CSV file to be server administrators.

By default, this command creates users using a synchronous operation (it waits for all operations to complete before proceeding). You can use the `--no-wait` option to specify an asynchronous operation.

Local authentication

If the server is configured to use local authentication, the information in the CSV file is used to create users.

Active Directory authentication

If the server is configured to use Active Directory authentication, user information is imported from Active Directory, and password and friendly name information in the CSV file is ignored. Further, if a user is specified in the CSV file but no corresponding user exists in Active Directory, the user is not added to Tableau Server. For Active Directory users, because the user name is not guaranteed to be unique across domains, you must include the domain as part of the user name. You can specify this as either `domain/username` or
username@domain.com; however, we recommend using the domain/username format. For more information, see User Management in Active Directory Deployments.

Example

tabcmd createsiteusers "users.csv" --role "Explorer"

Options

--admin-type

Deprecated. Use the --role option instead.

--complete

Requires that all rows be valid for any change to succeed. This is the default setting.

--no-complete

Specifies that the command should make changes on the server even if not all rows contain valid information. Rows that contain invalid information are skipped.

--no-publisher

Deprecated. Use the --role option instead.

--nowait

Do not wait for asynchronous jobs to complete.

--publisher

Deprecated. Use the --role option instead.

--role

Specifies a site role for all users in the .csv file. When you want to assign site roles
using the --role option, create a separate CSV file for each site role.

Valid values are ServerAdministrator, SiteAdministratorCreator, SiteAdministratorExplorer, Creator, ExplorerCanPublish, Explorer, Viewer, ReadOnly, and Unlicensed.

The default is Unlicensed for new users and unchanged for existing users. Users are added as unlicensed also if you have a user-based server installation, and if the createsiteusers command creates a new user, but you have already reached the limit on the number of licenses for your users.

Note: On a multi-site Tableau Server, if you want to assign the Server-Administrator site role using the --role option, use the createusers command instead of createsiteusers.

--silent-progress

Do not display progress messages for the command.

Global options

The following options are used by all tabcmd commands. The --server, --user, and --password options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

-h, --help

Displays the help for the command.

-c, --use-certificate

Use client certificate to sign in. Required when mutual SSL is enabled.
For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows**: Configure Mutual SSL
- **Linux**: Configure Mutual SSL

-s, --server

The Tableau Server URL, which is required at least once to begin session.

-u, --user

The Tableau Server username, which is required at least once to begin session.

-p, --password

The Tableau Server password, which is required at least once to begin session.

--password-file

Allows the password to be stored in the given .txt file rather than the command line for increased security.

-t, --site

Indicates that the command applies to the site specified by the Tableau Server site ID. If you do not specify a site, the Default site is assumed. Applies only to servers with multiple sites.

-x, --proxy

Host:Port

Uses the specified HTTP proxy.
--no-prompt

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

--no-proxy

When specified, an HTTP proxy will not be used.

--no-certcheck

When specified, tabcmd (the client) does not validate the server's SSL certificate.

--[no-]cookie

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the no- prefix to not save the session ID. By default the session is saved.

--timeout

Waits the specified number of seconds for the server to complete processing the command. By default the process will timeout in 30 seconds.

--

Specifies the end of options on the command line. You can use -- to indicate to tabcmd that anything that follows -- should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use -- in a tabcmd command, where -430105/SHEET1 is a required value for the export command.

tabcmd export --csv -f "D:\export10.csv" -- -430105/SHEET1

Top
createusers filename.csv

Create users in Tableau Server, based on information supplied in a comma-separated values (CSV) file.

The CSV file must contain one or more user names and can also include (for each user) a password, full name, license type, administrator level, publisher (yes/no), and email address. For information about the format of the CSV file, see CSV Import File Guidelines.

As an alternative to including administrator level and publisher permissions in the CSV file, you can pass access level information by including the --role option and specifying the site role you want to assign users listed in the CSV file.

If the server has only one site (the default site), the user is created and added to the site. If the server has multiple sites, the user is created but is not added to any site. To add users to a site, use createsiteusers.

If you have a user-based server installation, and if the command creates a new user but you have already reached the limit on the number of licenses for your users, the user is added as an unlicensed user.

Local authentication

If the server is configured to use local authentication, the information in the CSV file is used to create users.

Active Directory authentication

If the server is configured to use Active Directory authentication, user information is imported from Active Directory, and password and friendly name information in the CSV file is ignored. Further, if a user is specified in the CSV file but no corresponding user exists in Active Directory, the user is not added to Tableau Server. For Active Directory users, because the user name is not guaranteed to be unique across domains, you must include the domain as part of the user name. You can specify this as either domain/username or user-
name@domain.com; however, we recommend using the domain/username format. For more information, see User Management in Active Directory Deployments.

Example

tabcmd createusers "users.csv" --role "ServerAdministrator"

tabcmd createusers "users.csv"

Options

--admin-type

Deprecated. Use the --role option instead.

--complete

Requires that all rows be valid for any change to succeed. This is the default setting.

--no-complete

Specifies that the command should make changes on the server even if not all rows contain valid information. Rows that contain invalid information are skipped.

--no-publisher

Deprecated. Use the --role option instead.

--nowait

Do not wait for asynchronous jobs to complete.

--publisher

Deprecated. Use the --role option instead.
-r, --role

Specifies a site role for all users in the .csv file. When you want to assign site roles using the --role option, create a separate CSV file for each site role.

Valid values are ServerAdministrator, SiteAdministratorCreator, SiteAdministratorExplorer, Creator, ExplorerCanPublish, Explorer, Viewer, ReadOnly, and Unlicensed.

On a multi-site server, the command does not assign the user to a site. Therefore, the only site roles the command can successfully assign are ServerAdministrator and Unlicensed. If you specify any other site role, the command assigns the Unlicensed role.

On a single-site server, the user is created and added to the default site using the role that you specify.

If you have a user-based server installation, and if the command creates a new user but you have already reached the limit on the number of licenses for your users, the user is added as an unlicensed user.

--silent-progress

Do not display progress messages for the command.

Global options

The following options are used by all tabcmd commands. The --server, --user, and --password options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

-h, --help

Displays the help for the command.
-c, --use-certificate

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows**: Configure Mutual SSL
- **Linux**: Configure Mutual SSL

-s, --server

The Tableau Server URL, which is required at least once to begin session.

-u, --user

The Tableau Server username, which is required at least once to begin session.

-p, --password

The Tableau Server password, which is required at least once to begin session.

--password-file

Allows the password to be stored in the given .txt file rather than the command line for increased security.

-t, --site

Indicates that the command applies to the site specified by the Tableau Server site ID. If you do not specify a site, the Default site is assumed. Applies only to servers with multiple sites.

-x, --proxy

Host:Port
Uses the specified HTTP proxy.

--no-prompt

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

--no-proxy

When specified, an HTTP proxy will not be used.

--no-certcheck

When specified, tabcmd (the client) does not validate the server's SSL certificate.

--[no-]cookie

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the no- prefix to not save the session ID. By default the session is saved.

--timeout

Waits the specified number of seconds for the server to complete processing the command. By default the process will timeout in 30 seconds.

--

Specifies the end of options on the command line. You can use -- to indicate to tabcmd that anything that follows -- should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use -- in a tabcmd command, where -430105/SHEET1 is a required value for the export command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/SHEET1
```
delete **workbook-name** or **datasource-name**

Delet**es** the specified workbook or data source from the server.

This command takes the name of the workbook or data source as it is on the server, not the file name when it was published.

**Example**

```
tabcmd delete "Sales_Analysis"
```

**Options**

- **-r, --project**

  The name of the project containing the workbook or data source you want to delete. If not specified, the “Default” project is assumed.

  Using **tabcmd**, you can specify only a top-level project in a project hierarchy. To automate tasks you want to perform on a project within a parent project, use the equivalent Tableau **REST API** call.

--**workbook**

  The name of the workbook you want to delete.

--**datasource**

  The name of the data source you want to delete.

**Global options**

The following options are used by all **tabcmd** commands. The **--server**, **--user**, and **--password** options are required at least once to begin a session. An authentication token
is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

- **h, --help**
  Displays the help for the command.

- **c, --use-certificate**
  Use client certificate to sign in. Required when mutual SSL is enabled.
  For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

  - **Windows:** Configure Mutual SSL
  - **Linux:** Configure Mutual SSL

- **s, --server**
  The Tableau Server URL, which is required at least once to begin session.

- **u, --user**
  The Tableau Server username, which is required at least once to begin session.

- **p, --password**
  The Tableau Server password, which is required at least once to begin session.

- **--password-file**
  Allows the password to be stored in the given .txt file rather than the command line for increased security.

- **t, --site**
Indicates that the command applies to the site specified by the Tableau Server site ID. If you do not specify a site, the Default site is assumed. Applies only to servers with multiple sites.

-x, --proxy

Host:Port

Uses the specified HTTP proxy.

--no-prompt

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

--no-proxy

When specified, an HTTP proxy will not be used.

--no-certcheck

When specified, tabcmd (the client) does not validate the server's SSL certificate.

--[no-]cookie

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the no- prefix to not save the session ID. By default the session is saved.

--timeout

Waits the specified number of seconds for the server to complete processing the command. By default the process will timeout in 30 seconds.
Specifies the end of options on the command line. You can use -- to indicate to tabcmd that anything that follows -- should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use -- in a tabcmd command, where -430105/Sheet1 is a required value for the export command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

**Top**

**deletegroup** `group-name`

Deletes the specified group from the server.

**Example**

```
tabcmd deletegroup "Development"
```

**Global options**

The following options are used by all tabcmd commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

```
-h, --help
```

Displays the help for the command.

```
-c, --use-certificate
```

Use client certificate to sign in. Required when mutual SSL is enabled.
For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows**: Configure Mutual SSL
- **Linux**: Configure Mutual SSL

**-s, --server**

The Tableau Server URL, which is required at least once to begin session.

**-u, --user**

The Tableau Server username, which is required at least once to begin session.

**-p, --password**

The Tableau Server password, which is required at least once to begin session.

**--password-file**

Allows the password to be stored in the given .txt file rather than the command line for increased security.

**-t, --site**

Indicates that the command applies to the site specified by the Tableau Server site ID. If you do not specify a site, the Default site is assumed. Applies only to servers with multiple sites.

**-x, --proxy**

Host:Port

Uses the specified HTTP proxy.
--no-prompt

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

--no-proxy

When specified, an HTTP proxy will not be used.

--no-certcheck

When specified, tabcmd (the client) does not validate the server's SSL certificate.

--[no-]cookie

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the no- prefix to not save the session ID. By default the session is saved.

--timeout

Waits the specified number of seconds for the server to complete processing the command. By default the process will timeout in 30 seconds.

--

Specifies the end of options on the command line. You can use -- to indicate to tabcmd that anything that follows -- should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use -- in a tabcmd command, where -430105/SHEET1 is a required value for the export command.

tabcmd export --csv -f "D:\export10.csv" -- -430105/SHEET1

Top
deleteproject *project-name*

Deletes the specified project from the server.

Using `tabcmd`, you can specify only a top-level project in a project hierarchy. To automate tasks you want to perform on a project within a parent project, use the equivalent Tableau REST API call.

**Example**

`tabcmd deleteproject "Designs"`

**Global options**

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

-h, --help

Displays the help for the command.

-c, --use-certificate

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** Configure Mutual SSL
- **Linux:** Configure Mutual SSL

-s, --server
The Tableau Server URL, which is required at least once to begin session.

-u, --user
The Tableau Server username, which is required at least once to begin session.

-p, --password
The Tableau Server password, which is required at least once to begin session.

--password-file
Allows the password to be stored in the given .txt file rather than the command line for increased security.

-t, --site
Indicates that the command applies to the site specified by the Tableau Server site ID. If you do not specify a site, the Default site is assumed. Applies only to servers with multiple sites.

-x, --proxy
Host:Port
Uses the specified HTTP proxy.

--no-prompt
When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

--no-proxy
When specified, an HTTP proxy will not be used.
--no-certcheck

When specified, tabcmd (the client) does not validate the server’s SSL certificate.

--[no-]cookie

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the no- prefix to not save the session ID. By default the session is saved.

--timeout

Waits the specified number of seconds for the server to complete processing the command. By default the process will timeout in 30 seconds.

--

Specifies the end of options on the command line. You can use -- to indicate to tabcmd that anything that follows -- should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use -- in a tabcmd command, where -430105/Saret1 is a required value for the export command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Saret1
```

Top

deletesite *site-name*

Deletes the specified site from the server.

Example

```
tabcmd deletesite "Development"
```
Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

`-h, --help`

Displays the help for the command.

`-c, --use-certificate`

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows**: Configure Mutual SSL
- **Linux**: Configure Mutual SSL

`s, --server`

The Tableau Server URL, which is required at least once to begin session.

`-u, --user`

The Tableau Server username, which is required at least once to begin session.

`-p, --password`

The Tableau Server password, which is required at least once to begin session.

`--password-file`
Allows the password to be stored in the given .txt file rather than the command line for increased security.

- \( t \), --site

    Indicates that the command applies to the site specified by the Tableau Server site ID. If you do not specify a site, the Default site is assumed. Applies only to servers with multiple sites.

- \( x \), --proxy

    Host:Port

    Uses the specified HTTP proxy.

- --no-prompt

    When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

- --no-proxy

    When specified, an HTTP proxy will not be used.

- --no-certcheck

    When specified, tabcmd (the client) does not validate the server's SSL certificate.

- --[no-]cookie

    When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the no- prefix to not save the session ID. By default the session is saved.

- --timeout
Waits the specified number of seconds for the server to complete processing the command. By default the process will timeout in 30 seconds.

--

Specifies the end of options on the command line. You can use -- to indicate to tabcmd that anything that follows -- should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use -- in a tabcmd command, where -430105/Sheet1 is a required value for the export command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

**Top**

deletesiteusers *filename.csv*

Removes users from from the site that you are logged in to. The users to be removed are specified in a file that contains a simple list of one user name per line. (No additional information is required beyond the user name.)

By default, if the server has only one site, or if the user belongs to only one site, the user is also removed from the server. On a Tableau Server Enterprise installation, if the server contains multiple sites, users who are assigned the site role of Server Administrator are removed from the site but are not removed from the server.

If the user owns content, the user’s role is change to Unlicensed, but the user is not removed from the server or the site. The content is still owned by that user. To remove the user completely, you must change the owner of the content and then try removing the user again.

If the user was imported from Active Directory, the user is removed from the site and possibly from the server. However, the user is not deleted from Active Directory.

**Example**
tabcmd deletesiteusers "users.csv"

Global options

The following options are used by all tabcmd commands. The --server, --user, and --password options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

-h, --help

Displays the help for the command.

-c, --use-certificate

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** Configure Mutual SSL

- **Linux:** Configure Mutual SSL

-s, --server

The Tableau Server URL, which is required at least once to begin session.

-u, --user

The Tableau Server username, which is required at least once to begin session.

-p, --password

The Tableau Server password, which is required at least once to begin session.
--password-file

Allows the password to be stored in the given .txt file rather than the command line for increased security.

-t, --site

Indicates that the command applies to the site specified by the Tableau Server site ID. If you do not specify a site, the Default site is assumed. Applies only to servers with multiple sites.

-x, --proxy

Host:Port

Uses the specified HTTP proxy.

--no-prompt

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

--no-proxy

When specified, an HTTP proxy will not be used.

--no-certcheck

When specified, tabcmd (the client) does not validate the server's SSL certificate.

--[no-]cookie

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the no- prefix to not save the session ID. By default the session is saved.
--timeout

Waits the specified number of seconds for the server to complete processing the command. By default the process will timeout in 30 seconds.

--

Specifies the end of options on the command line. You can use -- to indicate to tabcmd that anything that follows -- should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use -- in a tabcmd command, where -430105/SHEET1 is a required value for the export command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/SHEET1
```

Top

deleteusers filename.csv

Deletes the users listed in the specified comma-separated values (.csv) file.

The .csv file should contain a simple list of one user name per line.

Example

tabcmd deleteusers "users.csv"

Options

--[no-]complete

When set to --complete this option requires that all rows be valid for any change to succeed. If not specified, --complete is used.

Global options

The following options are used by all tabcmd commands. The --server, --user, and --
-password options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

-h, --help

Displays the help for the command.

-c, --use-certificate

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows**: Configure Mutual SSL
- **Linux**: Configure Mutual SSL

-s, --server

The Tableau Server URL, which is required at least once to begin session.

-u, --user

The Tableau Server username, which is required at least once to begin session.

-p, --password

The Tableau Server password, which is required at least once to begin session.

--password-file

Allows the password to be stored in the given .txt file rather than the command line for increased security.
-t, --site
Indicates that the command applies to the site specified by the Tableau Server site ID. If you do not specify a site, the Default site is assumed. Applies only to servers with multiple sites.

-x, --proxy
Host:Port
Uses the specified HTTP proxy.

--no-prompt
When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

--no-proxy
When specified, an HTTP proxy will not be used.

--no-certcheck
When specified, tabcmd (the client) does not validate the server's SSL certificate.

--[no-]cookie
When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the no- prefix to not save the session ID. By default the session is saved.

--timeout
Waits the specified number of seconds for the server to complete processing the command. By default the process will timeout in 30 seconds.
--

Specifies the end of options on the command line. You can use -- to indicate to tabcmd that anything that follows -- should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use -- in a tabcmd command, where -430105/SHEET1 is a required value for the export command.

```
    tabcmd export --csv -f "D:\export10.csv" -- -430105/SHEET1
```

**Top**

**editdomain**

Changes the nickname or full domain name of an Active Directory domain on the server. A domain “nickname” is the Windows NetBIOS domain name.

You can modify the nickname for any domain the server is using. In general, you can modify the full domain name for any domain except the one that you used to sign in. However, if the user name that you are currently signed in with exists in both the current domain and the new domain, you can modify the full name for the current domain.

Review User Management in Active Directory Deployments to understand how multiple domains, domain name mapping, and user names interact with Tableau Server.

To see a list of domains, use listdomains.

**Examples**

```
    tabcmd editdomain --id 2 --nickname "new-nickname"

    tabcmd editdomain --id 3 --name "new-name"
```

**Options**

--id
The ID of domain to change. To get a list of domain IDs, use use **listdomains**.

**--name**

The new name for the domain.

**--nickname**

The new nickname for the domain.

**Global options**

The following options are used by all `tabcmd` commands. The **--server**, **--user**, and **--password** options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

**-h, --help**

Displays the help for the command.

**-c, --use-certificate**

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows**: Configure Mutual SSL
- **Linux**: Configure Mutual SSL

**-s, --server**

The Tableau Server URL, which is required at least once to begin session.
-u, --user

The Tableau Server username, which is required at least once to begin session.

-p, --password

The Tableau Server password, which is required at least once to begin session.

--password-file

Allows the password to be stored in the given .txt file rather than the command line for increased security.

-t, --site

Indicates that the command applies to the site specified by the Tableau Server site ID. If you do not specify a site, the Default site is assumed. Applies only to servers with multiple sites.

-x, --proxy

Host:Port

Uses the specified HTTP proxy.

--no-prompt

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

--no-proxy

When specified, an HTTP proxy will not be used.

--no-certcheck
When specified, tabcmd (the client) does not validate the server's SSL certificate.

--[no-]cookie

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the no- prefix to not save the session ID. By default the session is saved.

--timeout

Waits the specified number of seconds for the server to complete processing the command. By default the process will timeout in 30 seconds.

--

Specifies the end of options on the command line. You can use -- to indicate to tabcmd that anything that follows -- should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use -- in a tabcmd command, where -430105/SHEET1 is a required value for the export command.

```
  tabcmd export --csv -f "D:\export10.csv" -- -430105/SHEET1
```

Top

**editsite site-name**

Changes the name of a site or its web folder name. You can also use this command to allow or deny site administrators the ability to add and remove users. If site administrators have user management rights, you can specify how many users they can add to a site.

**Examples**

```
  tabcmd editsite wc_sales --site-name "West Coast Sales"

  tabcmd editsite wc_sales --site-id "wsales"
```
tabcmd editsite wsales --status ACTIVE

tabcmd editsite wsales --user-quota 50

Options

--site-name

The name of the site that's displayed.

--site-id

Used in the URL to uniquely identify the site.

--user-quota

Maximum number of users who can be members of the site.

--[no-]site-mode

Allow or prevent site administrators from adding users to the site.

--status

Set to **ACTIVE** to activate a site, or to **SUSPENDED** to suspend a site.

--storage-quota

In MB, the amount of workbooks, extracts, and data sources that can be stored on the site.

Global options

The following options are used by all **tabcmd** commands. The **--server**, **--user**, and **--**
-password options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

-h, --help

Displays the help for the command.

-c, --use-certificate

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows**: Configure Mutual SSL
- **Linux**: Configure Mutual SSL

-s, --server

The Tableau Server URL, which is required at least once to begin session.

-u, --user

The Tableau Server username, which is required at least once to begin session.

-p, --password

The Tableau Server password, which is required at least once to begin session.

--password-file

Allows the password to be stored in the given .txt file rather than the command line for increased security.
-t, --site

Indicates that the command applies to the site specified by the Tableau Server site ID. If you do not specify a site, the Default site is assumed. Applies only to servers with multiple sites.

-x, --proxy

Host:Port

Uses the specified HTTP proxy.

--no-prompt

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

--no-proxy

When specified, an HTTP proxy will not be used.

--no-certcheck

When specified, tabcmd (the client) does not validate the server’s SSL certificate.

--[no-]cookie

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the no- prefix to not save the session ID. By default the session is saved.

--timeout

Waits the specified number of seconds for the server to complete processing the command. By default the process will timeout in 30 seconds.
Specifies the end of options on the command line. You can use -- to indicate to `tabcmd` that anything that follows -- should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use -- in a `tabcmd` command, where `-430105/S` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

Top

export

Exports a view or workbook from Tableau Server and saves it to a file. This command can also export just the data used for a view.

Note the following when you use this command:

- **Permissions**: To export, you must have the Export Image permission. By default, this permission is Allowed or Inherited for all roles, although permissions can be set per workbook or view.

- **Exporting data**: To export just the data for a view, use the `--csv` option. This exports the summary data used in a view to a .csv file.

- **Specifying the view, workbook, or data to export**:

  - Use part of the URL to identify what to export, specifically the "workbook/view" string as it appears in the URL for the workbook or view. Do not use the “friendly name,” and exclude the `:iid=<n>` session ID at the end of the URL.

  For example, the Tableau sample view Global Temperatures in the Regional workbook has a URL similar to this: `<server_name>/#/views/Regional/GlobalTemperatures?iid=3`
To export the *Global Temperatures* view, use the string `Regional/GlobalTemperatures`.

Do *not* use `Regional/Global Temperatures`, or `Regional/GlobalTemperatures?:iid=3`.

- If the server is running multiple sites and the view or workbook is on a site other than Default, use `-t <site_id>`.

- To export a workbook, get the URL string by opening a view in the workbook, and include the view in the string you use.

  In the above example, to export the *Regional* workbook, use the string `Regional/GlobalTemperatures`.

- To export a workbook, it must have been published with **Show Sheets as Tabs** selected in the Tableau Desktop Publish dialog box.

  - **The saved file’s format**: Your format options depend on what’s being exported. A workbook can only be exported as a PDF using the `--fullpdf` argument. A view can be exported as a PDF (`--pdf`) or a PNG (`--png`).

  - **The saved file’s name and location** (optional): If you don’t provide a name, it will be derived from the view or workbook name. If you don’t provide a location, the file will be saved to your current working directory. Otherwise, you can specify a full path or one that’s relative to your current working directory.

    **Note**: You must include a file name extension such as `.csv` or `.pdf`. The command does not automatically add an extension to the file name that you provide.

- **Dashboard web page objects not included in PDF exports**: A dashboard can optionally include a web page object. If you are performing an export to PDF of a dashboard that includes a web page object, the web page object won’t be included in the
Non-ASCII characters and PDF exports: If you are exporting a view or workbook with a name that includes a character outside the ASCII character set, you need to URL encode (or percent-encode) the character.

For example if your command includes the city Zürich, you need to URL encode it as Z%C3%BCrich:

```
tabcmd export "Cities/Sheet1?locationCity=Z%C3%BCrich" -fullpdf
```

Clearing the Cache to Use Real-Time Data

You can optionally add the URL parameter `?:refresh=yes` to force a fresh data query instead of pulling the results from the cache. If you are using tabcmd with your own scripting and the `refresh` URL parameter is being used a great deal, this can have a negative impact on performance. It's recommended that you use `refresh` only when real-time data is required—for example, on a single dashboard instead of on an entire workbook.

Examples

**Views**

```
tabcmd export "Q1Sales/Sales_Report" --csv -f "Weekly-Report.csv"
```

```
tabcmd export -t Sales "Sales/Sales_Analysis" --pdf -f "C:\Tableau_Workbooks\Weekly-Reports.pdf"
```

```
tabcmd export "Finance/InvestmentGrowth" --png
```

```
tabcmd export "Finance/InvestmentGrowth?:refresh=yes" --png
```

**Workbooks**

```
tabcmd export "Q1Sales/Sales_Report" --fullpdf
```
tabcmd export "Sales/Sales_Analysis" --fullpdf --pagesize tabloid -f "C:\Tableau_Workbooks\Weekly-Reports.pdf"

Options

-f, --filename

Saves the file with the given filename and extension.

--csv

View only. Export the view's data (summary data) in .csv format.

--pdf

View only. Export as a PDF.

--png

View only. Export as an image in .png format.

--fullpdf

Workbook only. Export as a PDF. The workbook must have been published with Show Sheets as Tabs enabled.

--pagelayout

Sets the page orientation (landscape or portrait) of the exported PDF. If not specified, its Tableau Desktop setting will be used.

--pagesize

Sets the page size of the exported PDF as one of the following: unspecified, letter, legal, note folio, tabloid, ledger, statement, executive, a3, a4, a5,
b4, b5, or quarto. Default is letter.

--width

Sets the width in pixels. Default is 800 px.

--height

Sets the height in pixels. Default is 600 px.

Global options

The following options are used by all tabcmd commands. The --server, --user, and --password options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

-h, --help

Displays the help for the command.

-c, --use-certificate

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- Windows: Configure Mutual SSL
- Linux: Configure Mutual SSL

-s, --server

The Tableau Server URL, which is required at least once to begin session.
-u, --user

The Tableau Server username, which is required at least once to begin session.

-p, --password

The Tableau Server password, which is required at least once to begin session.

--password-file

Allows the password to be stored in the given .txt file rather than the command line for increased security.

-t, --site

Indicates that the command applies to the site specified by the Tableau Server site ID. If you do not specify a site, the Default site is assumed. Applies only to servers with multiple sites.

-x, --proxy

Host:Port

Uses the specified HTTP proxy.

--no-prompt

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

--no-proxy

When specified, an HTTP proxy will not be used.

--no-certcheck
When specified, tabcmd (the client) does not validate the server’s SSL certificate.

```
- [no-] cookie
```

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the no- prefix to not save the session ID. By default the session is saved.

```
- [no-] timeout
```

Waits the specified number of seconds for the server to complete processing the command. By default the process will timeout in 30 seconds.

```
-
```

Specifies the end of options on the command line. You can use -- to indicate to tabcmd that anything that follows -- should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use -- in a tabcmd command, where -430105/Sheet1 is a required value for the export command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

Top

get url

Gets the resource from Tableau Server that's represented by the specified (partial) URL. The result is returned as a file.

Note the following when you use this command:

- **Permissions**: To get a file, you must have the Download/Web Save As permission. By default, this permission is allowed or inherited for all roles, although permissions can be set per workbook or view.
• **Specifying a view or workbook to get:** You specify a view to get using the "'/views/<workbookname>/<viewname>.<extension>" string, and specify a workbook to get using the "'/workbooks/<workbookname>.<extension>" string. Replace <workbookname> and <viewname> with the names of the workbook and view as they appear in the URL when you open the view in a browser and replace <extension> with the type of file you want to save. Do not use the session ID at the end of the URL (?:iid=<n>) or the "friendly" name of the workbook or view.

For example, when you open a view *Regional Totals* in a workbook named *Metrics Summary*, the URL will look similar to this:

'/views/MetricsSummary_1/RegionalTotals?:iid=1

Use the string /views/MetricsSummary_1/RegionalTotals.<extension> to get the view.

Use the string /workbooks/MetricsSummary_1.<extension> to get the workbook.

• **File extension:** The URL must include a file extension. The extension determines what’s returned. A view can be returned in PDF, PNG, or CSV (summary data only) format. A Tableau workbook is returned as a TWB if it connects to a published data source or uses a live connection, or a TWBX if it connects to a data extract.

**Note:** If you are downloading a view to a PDF or PNG file, and if you include a --filename parameter that includes the .pdf or .png extension, you do not have to include a .pdf or .png extension in the URL.

• **The saved file’s name and location** (optional): The name you use for --filename should include the file extension. If you don’t provide a name and file extension, both will be derived from the URL string. If you don’t provide a location, the file is
saved to your current working directory. Otherwise, you can specify a full path or one that’s relative to your current working directory.

- **PNG size** (optional): If the saved file is a PNG, you can specify the size, in pixels, in the URL.

**Clearing the cache to use real-time data**

You can optionally add the URL parameter `?:refresh=yes` to force a fresh data query instead of pulling the results from the cache. If you are using tabcmd with your own scripting, using the `refresh` parameter a great deal can have a negative impact on performance. It’s recommended that you use `refresh` only when real-time data is required—for example, on a single dashboard instead of on an entire workbook.

**Examples**

**Views**

```
tabcmd get "/views/Sales_Analysis/Sales_Report.png" --filename "Weekly-Report.png"
```

```
tabcmd get "/views/Finance/InvestmentGrowth.pdf" -f "Q1Growth.pdf"
```

```
tabcmd get "/views/Finance/InvestmentGrowth" -f "Q1Growth.pdf"
```

```
tabcmd get "/views/Finance/InvestmentGrowth.csv"
```

```
tabcmd get "/views/Finance/InvestmentGrowth.png?:size=640,480" -f growth.png
```

```
tabcmd get "/views/Finance/InvestmentGrowth.png?:refresh=yes" - f growth.png
```

**Workbooks**
tabcmd get "/workbooks/Sales_Analysis.twb" -f "C:\Tableau_Workbooks\Weekly-Reports.twb"

Global options

The following options are used by all tabcmd commands. The --server, --user, and --password options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

-h, --help

Displays the help for the command.

-c, --use-certificate

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows**: Configure Mutual SSL
- **Linux**: Configure Mutual SSL

-s, --server

The Tableau Server URL, which is required at least once to begin session.

-u, --user

The Tableau Server username, which is required at least once to begin session.

-p, --password
The Tableau Server password, which is required at least once to begin session.

```
--password-file
```

Allows the password to be stored in the given .txt file rather than the command line for increased security.

```
-t, --site
```

Indicates that the command applies to the site specified by the Tableau Server site ID. If you do not specify a site, the Default site is assumed. Applies only to servers with multiple sites.

```
-x, --proxy
```

Host:Port

Uses the specified HTTP proxy.

```
--no-prompt
```

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

```
--no-proxy
```

When specified, an HTTP proxy will not be used.

```
--no-certcheck
```

When specified, tabcmd (the client) does not validate the server's SSL certificate.

```
--[no-]cookie
```

When specified, the session ID is saved on login so subsequent commands will not
need to log in. Use the no- prefix to not save the session ID. By default the session is saved.

--timeout

Waits the specified number of seconds for the server to complete processing the command. By default the process will timeout in 30 seconds.

--

Specifies the end of options on the command line. You can use -- to indicate to tabcmd that anything that follows -- should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use -- in a tabcmd command, where -430105/SHEET1 is a required value for the export command.

```
  tabcmd export --csv -f "D:\export10.csv" -430105/SHEET1
```

Top

initialuser

Create the initial administrative user on a server that does not have an initial administrative user defined.

Enclose values in single quotes.

**Note:** The `tabcmd initialuser` command does not require authentication to Tableau Server, but you must run the command on the initial server node.

**Examples**

```
  tabcmd initialuser --username 'admin' --password 'password' --server http://localhost
```
tabcmd initialuser --username 'admin' --password 'password' --friendly 'Tableau Admin' --server http://localhost

To prompt for the password in the shell, do not include the --password parameter in the command. For example:

```
tabcmd initialuser --username 'admin' --server http://localhost
```

Options

- f, --friendly

  Creates the initial administrative user with the display name.

Global options

The following options are used by all `tabcmd` commands. The --server, --user, and --password options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

- h, --help

  Displays the help for the command.

- c, --use-certificate

  Use client certificate to sign in. Required when mutual SSL is enabled.

  For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:
- **Windows**: Configure Mutual SSL
- **Linux**: Configure Mutual SSL

- **-s, --server**
  The Tableau Server URL, which is required at least once to begin session.

- **-u, --user**
  The Tableau Server username, which is required at least once to begin session.

- **-p, --password**
  The Tableau Server password, which is required at least once to begin session.

- **--password-file**
  Allows the password to be stored in the given .txt file rather than the command line for increased security.

- **-t, --site**
  Indicates that the command applies to the site specified by the Tableau Server site ID. If you do not specify a site, the Default site is assumed. Applies only to servers with multiple sites.

- **-x, --proxy**
  Host:Port
  Uses the specified HTTP proxy.

- **--no-prompt**
  When specified, the command will not prompt for a password. If no valid password is
provided the command will fail.

--no-proxy

When specified, an HTTP proxy will not be used.

--no-certcheck

When specified, tabcmd (the client) does not validate the server’s SSL certificate.

--[no-]cookie

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the no- prefix to not save the session ID. By default the session is saved.

--timeout

Waits the specified number of seconds for the server to complete processing the command. By default the process will timeout in 30 seconds.

--

Specifies the end of options on the command line. You can use -- to indicate to tabcmd that anything that follows -- should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use -- in a tabcmd command, where -430105/Sheet1 is a required value for the export command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

Top
listdomains

Displays a list of the Active Directory domains that are in use on the server, along with their nicknames and IDs. If the server is configured to use local authentication, the command returns only the domain name local.

Example

tabcmd listdomains

Global options

The following options are used by all tabcmd commands. The --server, --user, and --password options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

-h, --help

Displays the help for the command.

-c, --use-certificate

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows:** Configure Mutual SSL
- **Linux:** Configure Mutual SSL

-s, --server

The Tableau Server URL, which is required at least once to begin session.
-u, --user

The Tableau Server username, which is required at least once to begin session.

-p, --password

The Tableau Server password, which is required at least once to begin session.

--password-file

Allows the password to be stored in the given .txt file rather than the command line for increased security.

-t, --site

Indicates that the command applies to the site specified by the Tableau Server site ID. If you do not specify a site, the Default site is assumed. Applies only to servers with multiple sites.

-x, --proxy

Host:Port

Uses the specified HTTP proxy.

--no-prompt

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

--no-proxy

When specified, an HTTP proxy will not be used.

--no-certcheck
When specified, tabcmd (the client) does not validate the server's SSL certificate.

--[no-]cookie

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the no- prefix to not save the session ID. By default the session is saved.

--timeout

Waits the specified number of seconds for the server to complete processing the command. By default the process will timeout in 30 seconds.

--

Specifies the end of options on the command line. You can use -- to indicate to tabcmd that anything that follows -- should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use -- in a tabcmd command, where -430105/SHEET1 is a required value for the export command.

```
  tabcmd export --csv -f "D:\export10.csv" -- -430105/SHEET1
```

**Top**

**listsites**

Returns a list of sites to which the logged in user belongs.

**Example**

```
  tabcmd listsites --username adam --password mypassword
```

**Global options**

The following options are used by all tabcmd commands. The --server, --user, and --
-password options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

-h, --help

Displays the help for the command.

-c, --use-certificate

Use client certificate to sign in. Required when mutual SSL is enabled.
For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- Windows: Configure Mutual SSL
- Linux: Configure Mutual SSL

-s, --server

The Tableau Server URL, which is required at least once to begin session.

-u, --user

The Tableau Server username, which is required at least once to begin session.

-p, --password

The Tableau Server password, which is required at least once to begin session.

--password-file

Allows the password to be stored in the given .txt file rather than the command line for increased security.
-t, --site

Indicates that the command applies to the site specified by the Tableau Server site ID. If you do not specify a site, the Default site is assumed. Applies only to servers with multiple sites.

-x, --proxy

Host:Port

Uses the specified HTTP proxy.

--no-prompt

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

--no-proxy

When specified, an HTTP proxy will not be used.

--no-certcheck

When specified, tabcmd (the client) does not validate the server's SSL certificate.

--[no-]cookie

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the no- prefix to not save the session ID. By default the session is saved.

--timeout

Waits the specified number of seconds for the server to complete processing the command. By default the process will timeout in 30 seconds.
--

Specifies the end of options on the command line. You can use -- to indicate to tabcmd that anything that follows -- should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use -- in a tabcmd command, where -430105/SHEET1 is a required value for the export command.

tabcmd export --csv -f "D:\export10.csv" -- -430105/SHEET1

Top

Login

Logs in a Tableau Server user.

Use the --server, --site, --username, --password global options to create a session.

Note: When you use the tabcmd login command, you cannot use SAML single sign-on (SSO), even if the server is configured to use SAML. To log in, you must pass the user name and password of a user who has been created on the server. You will have the permissions of the Tableau Server user that you’re signed in as. For more information, see Set Users’ Site Roles and Content Permissions and Ownership.

If you want to log in using the same information you’ve already used to create a session, just specify the --password option. The server and user name stored in the cookie will be used.

If the server is using a port other than 80 (the default), you will need to specify the port.

You need the --site (-t) option only if the server is running multiple sites and you are logging in to a site other than the Default site. If you do not provide a password you will be
prompted for one. If the --no-prompt option is specified and no password is provided the command will fail.

Once you log in, the session will continue until it expires on the server or the logout command is run.

**Example**

Logs user jsmith in to the Tableau Server running on their local machine:

`tabcmd login -s http://localhost -u jsmith -p password`

Logs administrator in to the Sales site on sales-server:

`tabcmd login -s http://sales-server -t Sales -u administrator -p password`

`tabcmd login -s http://sales-server:8000 -t Sales -u administrator -p password`

Logs administrator in to the Sales site on sales-server using SSL, but does not validate the server's SSL certificate:

`tabcmd login --no-certcheck -s https://sales-server -t Sales -u administrator -p password`

Establishes a forward proxy and port for localhost:

`tabcmd login --proxy myfwdproxyserver:8888 -s http://localhost -u jsmith -p password`

Logs user jsmith in to the reverse proxy using SSL:

`tabcmd login -s https://myreverseproxy -u jsmith -p password`
Options

-s, --server

If you are running the command from a Tableau Server computer that's on your network, you can use http://localhost. Otherwise, specify the computer's URL, such as http://bigbox.myco.com or http://bigbox.

For Tableau Online specify the URL https://online.tableau.com.

-t, --site

Include this option if the server has multiple sites, and you are logging in to a site other than the default site.

The site ID is used in the URL to uniquely identify the site. For example, a site named West Coast Sales might have a site ID of west-coast-sales.

-u, --username

The user name of the user logging in. For Tableau Online, the user name is the user's email address.

-p, --password

Password for the user specified for --username. If you do not provide a password you will be prompted for one.

--password-file

Allows the password to be stored in the given filename.txt file rather than the command line, for increased security.

-x, --proxy

Use to specify the HTTP proxy server and port (Host:Port) for the tabcmd request.
--no-prompt

Do not prompt for a password. If no password is specified, the `login` command will fail.

--no-proxy

Do not use an HTTP proxy server.

--cookie

Saves the session ID on login. Subsequent commands will not require a login. This value is the default for the command.

--no-cookie

Do not save the session ID information after a successful login. Subsequent commands will require a login.

--timeout SECONDS

The number of seconds the server should wait before processing the `login` command. Default: 30 seconds.

Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

-h, --help

Displays the help for the command.
-c, --use-certificate

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows**: Configure Mutual SSL
- **Linux**: Configure Mutual SSL

-s, --server

The Tableau Server URL, which is required at least once to begin session.

-u, --user

The Tableau Server username, which is required at least once to begin session.

-p, --password

The Tableau Server password, which is required at least once to begin session.

--password-file

Allows the password to be stored in the given .txt file rather than the command line for increased security.

-t, --site

Indicates that the command applies to the site specified by the Tableau Server site ID. If you do not specify a site, the Default site is assumed. Applies only to servers with multiple sites.

-x, --proxy

Host:Port
Uses the specified HTTP proxy.

--no-prompt

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

--no-proxy

When specified, an HTTP proxy will not be used.

--no-certcheck

When specified, tabcmd (the client) does not validate the server's SSL certificate.

--[no-]cookie

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the no- prefix to not save the session ID. By default the session is saved.

--timeout

Waits the specified number of seconds for the server to complete processing the command. By default the process will timeout in 30 seconds.

--

Specifies the end of options on the command line. You can use -- to indicate to tabcmd that anything that follows -- should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use -- in a tabcmd command, where -430105/SHEET1 is a required value for the export command.

```
    tabcmd export --csv -f "D:\export10.csv" -- -430105/SHEET1
```
logout

Logs out of the server.

Example

tagcmd logout

Top

publish filename.twb(x), filename.tds(x), or filename.hyper

Publishes the specified workbook (.twb(x)), data source (.tds(x)), or extract (.hyper) to Tableau Server.

If you are publishing a workbook, by default, all sheets in the workbook are published without database user names or passwords.

The permissions initially assigned to the workbook or data source are copied from the project that the file is published to. Permissions for the published resource can be changed after the file has been published.

If the workbook contains user filters, one of the thumbnail options must be specified.

Example

tagcmd publish "analysis.twbx" -n "Sales_Analysis" --db-username "jsmith" --db-password "secret-password"

tagcmd publish "analysis_sfdc.hyper" -n "Sales Analysis" --oauth-username "user-name" --save-oauth

If the file is not in the same directory as tagcmd, include the full path to the file.

Example
tabcmd publish "\\computer\volume\Tableau Workbooks\analysis.twbx" -n "Sales_Analysis" --db-username "jsmith" --db-password "secret-password"

```
tabcmd publish "\\computer\volume\Tableau Workbooks\analysis_sfdc.hyper" -n "Sales Analysis" --oauth-username "username" --save-oauth
```

Options

- `n, --name`

  Name of the workbook or data source on the server. If omitted, the workbook, data source, or data extract will be named after filename.

- `o, --overwrite`

  Overwrites the workbook, data source, or data extract if it already exists on the server.

- `r, --project`

  Publishes the workbook, data source, or data extract into the specified project. Publishes to the “Default” project if not specified.

  Using `tabcmd`, you can specify only a top-level project in a project hierarchy. To automate tasks you want to perform on a project within a parent project, use the equivalent Tableau REST API call.

- `--db-username`

  Use this option to publish a database user name with the workbook, data source, or data extract.

- `--db-password`

  Use this option to publish a database password with the workbook, data source, or data extract.
extract.

`--save-db-password`

Stores the provided database password on the server.

`--oauth-username`

The email address of the user account. Connects the user through a preconfigured OAuth connection, if the user already has a saved access token for the cloud data source specified in `--name`. Access tokens are managed in user preferences.

For existing OAuth connections to the data source, use this option instead of `--db-username` and `--db-password`.

`--save-oauth`

Saves the credential specified by `--oauth-username` as an embedded credential with the published workbook or data source.

Subsequently, when the publisher or server administrator signs in to the server and edits the connection for that workbook or data source, the connection settings will show this OAuth credential as embedded in the content.

If you want to schedule extract refreshes after publishing, you must include this option with `--oauth-username`. This is analogous to using `--save-db-password` with a traditional database connection.

`--thumbnail-username`

If the workbook contains user filters, the thumbnails will be generated based on what the specified user can see. Cannot be specified when `--thumbnail-group` option is set.

`--thumbnail-group`

If the workbook contains user filters, the thumbnails will be generated based on what
the specified group can see. Cannot be specified when --thumbnail-username option is set.

--tabbed

When a workbook with tabbed views is published, each sheet becomes a tab that viewers can use to navigate through the workbook. Note that this setting will override any sheet-level security.

--append

Append the extract file to the existing data source.

--replace

Use the extract file to replace the existing data source.

--disable-uploader

Disable the incremental file uploader.

--restart

Restart the file upload.

Global options

The following options are used by all tabcmd commands. The --server, --user, and --password options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

-h, --help
Displays the help for the command.

-c, --use-certificate

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows**: Configure Mutual SSL
- **Linux**: Configure Mutual SSL

-s, --server

The Tableau Server URL, which is required at least once to begin session.

-u, --user

The Tableau Server username, which is required at least once to begin session.

-p, --password

The Tableau Server password, which is required at least once to begin session.

--password-file

Allows the password to be stored in the given .txt file rather than the command line for increased security.

-t, --site

Indicates that the command applies to the site specified by the Tableau Server site ID. If you do not specify a site, the Default site is assumed. Applies only to servers with multiple sites.
-x, --proxy

    Host:Port

    Uses the specified HTTP proxy.

--no-prompt

    When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

--no-proxy

    When specified, an HTTP proxy will not be used.

--no-certcheck

    When specified, tabcmd (the client) does not validate the server’s SSL certificate.

--[no-]cookie

    When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the no- prefix to not save the session ID. By default the session is saved.

--timeout

    Waits the specified number of seconds for the server to complete processing the command. By default the process will timeout in 30 seconds.

--

    Specifies the end of options on the command line. You can use -- to indicate to tabcmd that anything that follows -- should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows
how you might use -- in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

Top

publishsamples

Description

Publishes Tableau Sample workbooks to the specified project. Any existing samples will be overwritten.

Syntax

```
tabcmd publishsamples -n [project name] [Global options]
```

Example

Publish samples to the Inside Sales project on the Default site, as user jsmith.

```
tabcmd publishsamples -n "Inside Sales" -t "" -s localhost -- username "jsmith" --password "secret-password"
```

Options

```
-n, --name
```

Required. Publishes the Tableau samples into the specified project. If the project name includes spaces, enclose the entire name in quotes.

Using `tabcmd`, you can specify only a top-level project in a project hierarchy. To automate tasks you want to perform on a project within a parent project, use the equivalent Tableau REST API call.

Global options
The following options are used by all `tabcmd` commands. The `-server`, `-user`, and `-password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

-h, --help

Displays the help for the command.

-c, --use-certificate

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows**: Configure Mutual SSL
- **Linux**: Configure Mutual SSL

-s, --server

The Tableau Server URL, which is required at least once to begin session.

-u, --user

The Tableau Server username, which is required at least once to begin session.

-p, --password

The Tableau Server password, which is required at least once to begin session.

--password-file

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.
-t, --site

Indicates that the command applies to the site specified by the Tableau Server site ID. If you do not specify a site, the Default site is assumed. Applies only to servers with multiple sites.

-x, --proxy

Host:Port

Uses the specified HTTP proxy.

--no-prompt

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

--no-proxy

When specified, an HTTP proxy will not be used.

--no-certcheck

When specified, tabcmd (the client) does not validate the server's SSL certificate.

-[no-]cookie

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the no- prefix to not save the session ID. By default the session is saved.

--timeout

Waits the specified number of seconds for the server to complete processing the command. By default the process will timeout in 30 seconds.
Specifies the end of options on the command line. You can use -- to indicate to tabcmd that anything that follows -- should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use -- in a tabcmd command, where -430105/Sheet1 is a required value for the export command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

Top

refreshextracts *workbook-name* or *datasource-name*

Performs a full or incremental refresh of extracts belonging to the specified workbook or data source.

This command takes the name of the workbook or data source as it appears on the server, not the file name when it was published. Only an administrator or the owner of the workbook or data source is allowed to perform this operation.

Examples

```
tabcmd refreshextracts --datasource sales_ds

tabcmd refreshextracts --project "Sales External" --datasource sales_ds

tabcmd refreshextracts --workbook "My Workbook"

```

Options

```
--incremental

Runs the incremental refresh operation.
```
--synchronous

Adds the full refresh operation to the queue used by the Backgrounder process, to be run as soon as a Backgrounder process is available. If a Backgrounder process is available, the operation is run immediately. The refresh operation appears on the Background Tasks report.

During a synchronous refresh, `tabcmd` maintains a live connection to the server while the refresh operation is underway, polling every second until the background job is done.

--workbook

The name of the workbook containing extracts to refresh. If the workbook has spaces in its name, enclose it in quotes.

--datasource

The name of the data source containing extracts to refresh.

--project

Use with `--workbook` or `--datasource` to identify a workbook or data source in a project other than `Default`. If not specified, the Default project is assumed.

Using `tabcmd`, you can specify only a top-level project in a project hierarchy. To automate tasks you want to perform on a project within a parent project, use the equivalent Tableau REST API call.

--url

The name of the workbook as it appears in the URL. A workbook published as “Sales Analysis” has a URL name of “SalesAnalysis”.

Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and --
-password options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

-h, --help
   Displays the help for the command.

-c, --use-certificate
   Use client certificate to sign in. Required when mutual SSL is enabled.
   For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:
   - Windows: Configure Mutual SSL
   - Linux: Configure Mutual SSL

-s, --server
   The Tableau Server URL, which is required at least once to begin session.

-u, --user
   The Tableau Server username, which is required at least once to begin session.

-p, --password
   The Tableau Server password, which is required at least once to begin session.

--password-file
   Allows the password to be stored in the given .txt file rather than the command line for increased security.
-t, --site

Indicates that the command applies to the site specified by the Tableau Server site ID.
If you do not specify a site, the Default site is assumed. Applies only to servers with multiple sites.

-x, --proxy

Host:Port

Uses the specified HTTP proxy.

--no-prompt

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

--no-proxy

When specified, an HTTP proxy will not be used.

--no-certcheck

When specified, tabcmd (the client) does not validate the server’s SSL certificate.

--[no-]cookie

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the no- prefix to not save the session ID. By default the session is saved.

--timeout

Waits the specified number of seconds for the server to complete processing the command. By default the process will timeout in 30 seconds.
Specifies the end of options on the command line. You can use -- to indicate to `tabcmd` that anything that follows -- should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use -- in a `tabcmd` command, where `430105/SHEET1` is a required value for the `export` command.

```
  tabcmd export --csv -f "D:\export10.csv" -- 430105/SHEET1
```

**Top**

removeusers `group-name`

Removes users from the specified group.

**Example**

```
  tabcmd removeusers "Development" --users "users.csv"
```

**Options**

`--users`

Remove the users in the given `.csv` file from the specified group. The file should be a simple list with one user name per line.

`--[no-]complete`

Requires that all rows be valid for any change to succeed. If not specified `--complete` is used.

**Global options**

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and --
-password options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

-h, --help

Displays the help for the command.

-c, --use-certificate

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- Windows: Configure Mutual SSL
- Linux: Configure Mutual SSL

-s, --server

The Tableau Server URL, which is required at least once to begin session.

-u, --user

The Tableau Server username, which is required at least once to begin session.

-p, --password

The Tableau Server password, which is required at least once to begin session.

--password-file

Allows the password to be stored in the given .txt file rather than the command line for increased security.
-t, --site

Indicates that the command applies to the site specified by the Tableau Server site ID. If you do not specify a site, the Default site is assumed. Applies only to servers with multiple sites.

-x, --proxy

Host:Port

Uses the specified HTTP proxy.

--no-prompt

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

--no-proxy

When specified, an HTTP proxy will not be used.

--no-certcheck

When specified, tabcmd (the client) does not validate the server's SSL certificate.

--[no-]cookie

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the no- prefix to not save the session ID. By default the session is saved.

--timeout

Waits the specified number of seconds for the server to complete processing the command. By default the process will timeout in 30 seconds.
--

Specifies the end of options on the command line. You can use -- to indicate to tabcmd that anything that follows -- should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use -- in a tabcmd command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

Top

`runschedule schedule-name`

Runs the specified schedule.

This command takes the name of the schedule as it is on the server.

For Tableau Online, the command can be run within the scope of a single site, using site administrator permissions.

Example

```
tabcmd runschedule "5AM Sales Refresh"
```

Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

```
-h, --help
```

Displays the help for the command.
-c, --use-certificate

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows**: Configure Mutual SSL
- **Linux**: Configure Mutual SSL

-s, --server

The Tableau Server URL, which is required at least once to begin session.

-u, --user

The Tableau Server username, which is required at least once to begin session.

-p, --password

The Tableau Server password, which is required at least once to begin session.

--password-file

Allows the password to be stored in the given `.txt` file rather than the command line for increased security.

-t, --site

Indicates that the command applies to the site specified by the Tableau Server site ID. If you do not specify a site, the Default site is assumed. Applies only to servers with multiple sites.

-x, --proxy

Host:Port
Uses the specified HTTP proxy.

--no-prompt

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

--no-proxy

When specified, an HTTP proxy will not be used.

--no-certcheck

When specified, tabcmd (the client) does not validate the server's SSL certificate.

--[no-]cookie

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the no- prefix to not save the session ID. By default the session is saved.

--timeout

Waits the specified number of seconds for the server to complete processing the command. By default the process will timeout in 30 seconds.

--

Specifies the end of options on the command line. You can use -- to indicate to tabcmd that anything that follows -- should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use -- in a tabcmd command, where -430105/SHEET1 is a required value for the export command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/SHEET1
```
set setting

Enables the specified setting on the server. Details about each setting can be seen on the Maintenance page on the server.

Use an exclamation mark in front of the setting name to disable the setting. You can enable or disable the following settings:

- `allow_scheduling`
- `embedded_credentials`
- `remember_passwords_forever`

Example

tabcmd set embedded_credentials

Global options

The following options are used by all tabcmd commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

- `-h, --help`
  Displays the help for the command.

- `-c, --use-certificate`
  Use client certificate to sign in. Required when mutual SSL is enabled.
For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows**: Configure Mutual SSL
- **Linux**: Configure Mutual SSL

- **s**, **--server**
  
The Tableau Server URL, which is required at least once to begin session.

- **u**, **--user**
  
The Tableau Server username, which is required at least once to begin session.

- **p**, **--password**
  
The Tableau Server password, which is required at least once to begin session.

- **--password-file**
  
  Allows the password to be stored in the given .txt file rather than the command line for increased security.

- **t**, **--site**
  
  Indicates that the command applies to the site specified by the Tableau Server site ID. If you do not specify a site, the Default site is assumed. Applies only to servers with multiple sites.

- **x**, **--proxy**
  
  Host:Port
  
  Uses the specified HTTP proxy.
--no-prompt

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

--no-proxy

When specified, an HTTP proxy will not be used.

--no-certcheck

When specified, tabcmd (the client) does not validate the server's SSL certificate.

[--no-]cookie

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the no- prefix to not save the session ID. By default the session is saved.

--timeout

Waits the specified number of seconds for the server to complete processing the command. By default the process will timeout in 30 seconds.

--

Specifies the end of options on the command line. You can use -- to indicate to tabcmd that anything that follows -- should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use -- in a tabcmd command, where -430105/Sheet1 is a required value for the export command.

tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
syncgroup *group-name*

Synchronizes a Tableau Server group with an Active Directory group. If the Tableau Server group does not already exist, it is created and synchronized with the specified Active Directory group.

If the group name itself includes an "@" (other than as the domain separator) you need to refer to the symbol using the hex format "\0x40".

**Example**

```bash
tabcmd syncgroup "Development"

 tabcmd syncgroup "Dev\0x40West"
```

**Note:** If you synchronize a group that you are a member of, changes that you make using this command do not apply to your user. For example, if you use this command to remove the administrator right from users in a group that you are a member of, you are still an administrator when the command finishes.

**Options**

--no-publisher

   Deprecated. Use the --role option instead.

--overwritesiterole

   Allows a user’s site role to be overwritten with a less privileged one when using --role. By default, a user site role can be promoted when using --role, but cannot be demoted. Because the --overwritesiterole option will demote user site roles, use it with caution.

--publisher
Deprecated. Use the `--role` option instead.

- `r, --role`
  Specifies a site role for users in the group. The default is Unlicensed.

--silent-progress

Do not display progress messages for the command.

Global options

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and `--password` options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

- `h, --help`
  Displays the help for the command.

- `c, --use-certificate`
  Use client certificate to sign in. Required when mutual SSL is enabled.

  For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

  - **Windows**: Configure Mutual SSL
  - **Linux**: Configure Mutual SSL

- `s, --server`
  The Tableau Server URL, which is required at least once to begin session.
-u, --user

The Tableau Server username, which is required at least once to begin session.

-p, --password

The Tableau Server password, which is required at least once to begin session.

--password-file

Allows the password to be stored in the given .txt file rather than the command line for increased security.

-t, --site

Indicates that the command applies to the site specified by the Tableau Server site ID. If you do not specify a site, the Default site is assumed. Applies only to servers with multiple sites.

-x, --proxy

Host:Port

Uses the specified HTTP proxy.

--no-prompt

When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

--no-proxy

When specified, an HTTP proxy will not be used.

--no-certcheck
When specified, tabcmd (the client) does not validate the server's SSL certificate.

`--[no-]cookie`

When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the `no-` prefix to not save the session ID. By default the session is saved.

`--timeout`

Waits the specified number of seconds for the server to complete processing the command. By default the process will timeout in 30 seconds.

`--`

Specifies the end of options on the command line. You can use `--` to indicate to `tabcmd` that anything that follows `--` should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use `--` in a `tabcmd` command, where `-430105/Sheet1` is a required value for the `export` command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/Sheet1
```

**Top**

**version**

Displays the version information for the current installation of the tabcmd utility.

**Example**

`tabcmd version`

**Global options**

The following options are used by all `tabcmd` commands. The `--server`, `--user`, and -
-password options are required at least once to begin a session. An authentication token is stored so subsequent commands can be run without including these options. This token remains valid for five minutes after the last command that used it.

-h, --help

Displays the help for the command.

-c, --use-certificate

Use client certificate to sign in. Required when mutual SSL is enabled.

For information about configuring the certificate, start with the following topic appropriate for your Tableau Server OS:

- **Windows**: Configure Mutual SSL
- **Linux**: Configure Mutual SSL

-s, --server

The Tableau Server URL, which is required at least once to begin session.

-u, --user

The Tableau Server username, which is required at least once to begin session.

-p, --password

The Tableau Server password, which is required at least once to begin session.

--password-file

Allows the password to be stored in the given .txt file rather than the command line for increased security.
-t, --site
  Indicates that the command applies to the site specified by the Tableau Server site ID. If you do not specify a site, the Default site is assumed. Applies only to servers with multiple sites.

-x, --proxy
  Host:Port
  Uses the specified HTTP proxy.

--no-prompt
  When specified, the command will not prompt for a password. If no valid password is provided the command will fail.

--no-proxy
  When specified, an HTTP proxy will not be used.

--no-certcheck
  When specified, tabcmd (the client) does not validate the server's SSL certificate.

--[no-]cookie
  When specified, the session ID is saved on login so subsequent commands will not need to log in. Use the no- prefix to not save the session ID. By default the session is saved.

--timeout
  Waits the specified number of seconds for the server to complete processing the command. By default the process will timeout in 30 seconds.
--

Specifies the end of options on the command line. You can use -- to indicate to tabcmd that anything that follows -- should not be interpreted as an option setting and can instead be interpreted as a value for the command. This is useful if you need to specify a value in the command that includes a hyphen. The following example shows how you might use -- in a tabcmd command, where -430105/SHEET1 is a required value for the export command.

```
tabcmd export --csv -f "D:\export10.csv" -- -430105/SHEET1
```

Troubleshooting

Troubleshoot Tableau Server on Linux

Follow the suggestions in this topic to resolve common issues with Tableau Server. For additional troubleshooting steps based on process status viewed on the Status page, see Troubleshoot Server Processes.

- **General Troubleshooting Steps**
  - Clean install
  - Disk space
  - Remove old log files
  - Manually gather logs
  - Restart server
- **Installing**
  - Hardware requirements
  - Timeouts
  - Temporary database
  - Parallels
  - Tableau doesn’t start - restart
  - Tableau doesn't start - hostname changed
  - Initial admin user
  - Fonts
- Initializing
  - Existing tableau user
  - Unsupported locale
  - en_US.utf8 missing
  - Status 10
  - Reinstall
- Activating
- Reindexing
- Restarting
  - Fails
  - Additional node
- Backup/Restore
- File locations
  - basefilepath
- TSM commands
- Firewall ports
- OpenID
- Administrative Views
- Changing user locale

The following table displays the default locations of the installation, data, logs, and scripts directories:

<table>
<thead>
<tr>
<th>Directory</th>
<th>Default location</th>
</tr>
</thead>
<tbody>
<tr>
<td>Installation</td>
<td>/opt/tableau/tableau_server</td>
</tr>
<tr>
<td>Data</td>
<td>/var/opt/tableau/tableau_server/data</td>
</tr>
<tr>
<td>Logs</td>
<td>/var/opt/tableau/tableau_server/data/tabsvc/logs/</td>
</tr>
<tr>
<td>Scripts</td>
<td>/opt/tableau/tableau_server-/packages/scripts.&lt;version_code&gt;/</td>
</tr>
</tbody>
</table>

General Troubleshooting Steps

Many Tableau Server issues can be addressed or tested with one or more of these basic steps:
- Clean install — Install Tableau Server on Linux on a computer that has never had Tableau installed on it. If you are reusing a computer or VM that has had a previous version of Tableau Server installed, follow the steps in Remove Tableau Server from Your Computer to clean Tableau off your computer before you install the new version.

If you run into problems installing Tableau Server you may need to entirely remove Tableau from your computer and do a clean install. See Remove Tableau Server from Your Computer for details.

- Disk space — Make sure there is enough disk space on each computer running Tableau Server. Limited disk space can cause a failure to install, a failure to upgrade, or problems running Tableau Server.

- Remove old log files — If you are running out of disk space you can clean up old Tableau Server log files. These can take up space and as a best practice you should remove them regularly.

Version 10.5.x

If you have version 10.5.1 and higher, run this command at a terminal prompt to clean up log files you do not need:

tsm maintenance cleanup

Version 10.5.0

If you are running version 10.5.0 of Tableau Server on Linux, the cleanup command is not available and you need to run these commands at a terminal prompt:

```
sudo find /var/opt/tableau/tableau_server- /data/tabsvc/temp/* -mtime +2 -type f -delete
```

```
sudo find /var/opt/tableau/tableau_server- /data/tabsvc/logs/* -mtime +2 -type f -delete
```
Important: The Linux file system makes it possible to delete files that are open and if you do this the Tableau processes may not be able to recreate the files. This will result in empty log files. To fix this you can stop Tableau Server, restart the TSM Controller, and restart Tableau again:

1. Stop Tableau Server:

   tsm stop

2. Restart the TSM Controller:

   sudo systemctl restart tabadmincontroller_0.service

3. Wait several minutes for the controller to restart. You can confirm the controller has restarted with this command:

   tsm status -v

   When you can run that command and the Tableau Server Administration Controller is listed as 'running' the controller has restarted.

4. Start Tableau Server:

   tsm start

• Manually gather logs

   If you cannot run tsm maintenance ziplogs for any reason (for example, if you have a critical failure before you run tsm initialize), you can manually collect and zip the logs by running these commands in a terminal window:

   cd /var/opt/tableau/tableau_server/data/tabsvc/

   cp /var/opt/tableau/tableau_server/logs/app-install.log logs

   cp ~/.tableau/tsm/tsm.log logs
tar -czvf ~/logs.tar.gz logs

This creates a file called logs.tar.gz in your home directory. You can upload or send this file to Tableau.

- **Restart server**—Restart Tableau Server. Issues related to indexing and processes not fully started can be resolved by restarting Tableau Server in a controlled way. To restart Tableau Server, use the `tsm restart` command. This will stop all the processes associated with Tableau Server and then restart them.

- **Edit installation and configuration files using Linux**

You should edit or create any files used to install or configure Tableau Server on Linux using a Linux operating system. Files created using Microsoft Windows will cause errors in Tableau Server on Linux installation and configuration because Linux operating systems end files with a line-feed (LF) character, whereas Windows ends files with a carriage-return character and a line-feed character (CR LF). Non-Linux (CR LF) file endings can cause errors during Automated Installation of Tableau Server if they appear in the `config.json`, `reg_templ.json` or `secrets` files used by the automated installer. Non-Linux (CR LF) file endings can also cause errors during registration or when configuring identity store settings or gateway settings.

- **Check systemd logs**

If Tableau Server will not start, and you do not find anything useful in the Tableau logs (see Work with Log Files for more information) you can check the logs at `/var/\-logs/messages` for messages related to the TSM Service starting and stopping.

**Installing Tableau Server**

Install fails due to hardware requirements

Tableau Server cannot install if the computer you are installing on does not meet the minimum hardware requirements. For details on requirements, see Before you install....
Install fails due to timeouts

If you install Tableau Server on a computer with limited resources, for example, a computer that just meets the minimum hardware requirements, you can run into problems where tsm commands timeout due to slow response. You can specify a longer timeout by using the global --request-timeout option on all tsm commands. For more information on the --request-timeout option, see for example, tsm initialize.

Install fails with "Failed to initialize the instance of the temporary database"

Tableau Server on Linux only supports UTF-8 character encoding. If your Linux locale is missing the UTF-8 encoding, your installation can fail with an error similar to this one:

Failed to initialize the instance of the temporary database

To check if your locale is using UTF-8 encoding, run the `localectl` command at a command prompt. The resulting output should look something like this (your locale may be different):

```
[tableauserver-centos1a ~]$ localectl
System Locale: LANG=en_US.UTF-8
[tableauserver-centos1a ~]$
```

If the `LANG` value does not include .UTF-8 then you need to run `localectl` to add it:

```
sudo localectl set-locale LANG=<your_locale>.UTF-8
```

**Note:** In some cases `localectl` may not complete (timeout) if your version of `systemd` is old. Updating `systemd` may fix this problem and allow you to set the UTF-8 encoding. On RHEL-like systems, use this command to update `systemd`:

```
sudo yum update systemd
```

Installation fails on a virtual machine in Parallels

Parallels is currently not supported. If you install Tableau Server on a Linux virtual machine in Parallels, the install might fail.
Tableau Server doesn't start

If Tableau Server does not start or is running in a degraded state, run the `tsm restart` command. This will shut down any processes that are running, and restart Tableau Server.

Cannot start Tableau Server after installation

Tableau Server might not start if your computer's hostname changes after installation. One of the main reasons why the hostname might change is if you use the cloud-init package on CentOS. If you use the cloud-init package, *reboot the computer* where you want to install Tableau Server before you begin the installation process. Alternatively, you can fix the hostname without rebooting by running the following command:

```
sudo hostnamectl set-hostname 'hostnamectl --static'
```

The cloud-init package is commonly used to initialize new virtual machines, configure SSH public key authentication, and more. For example, some CentOS images use cloud-init, and cloud-init is commonly used in OpenStack deployments. However, the version of cloud-init included by default in the CentOS 7.x repositories (cloud-init 0.7.5-10.el7.centos.1) has a known issue that prevents your computer from displaying its Fully Qualified Domain Name (FQDN) along with its hostname until after it restarts.

Because the Tableau Server installation process uses your computer’s hostname to configure server processes and generate TLS certificates, Tableau Server might not start if it is configured to use a hostname without the FQDN.

To determine if your computer is displaying the correct hostname, run the `hostnamectl` command. In the following example, the command displays a transient hostname which indicates that it will not return the FQDN and must be restarted.

```
$ hostnamectl
    Static hostname: server01.example.com
    Transient hostname: server01
[...]```
Alternatively, in the following example, the command displays the correct hostname and FQDN:

```bash
$ hostnamectl
  Static hostname: server01.example.com
[...]
```

Cannot create initial administrator account with multiple Active Directory (AD) domains

When you create the initial administrator account on Tableau Server, you might see the following error if you selected AD as the authentication type:

```
Failed to authenticate username and password
```

This occurs when Tableau Server attempts to connect to multiple AD domains. For example, you might see this error if you install Tableau Server on a computer that is part of one domain and you attempt to authenticate AD users that are part of another domain.

Fonts

Tableau Server uses the fonts installed on the system to render workbooks based on the fonts used when a workbook was created. When a font is not available, Tableau Server will use the closest equivalent based on font families; this is true for both Windows and Linux Servers. On Linux Servers missing fonts may be more obvious because Linux ships with fewer included fonts than Windows and OS/X systems do. This matters because many workbooks are authored in Tableau Desktop on Windows or on Mac.

Tableau Server on Linux ships with the following fonts:

- Arial
- Courier
- Georgia
- Times New Roman
- Verdana
- Trebuchet MS
- Tableau Font
Workbooks which use fonts other than these may appear differently than expected when viewed on Tableau Server on Linux, due to missing fonts. To resolve this issue, install the appropriate fonts onto all nodes in your Tableau Server installation.

Support for Asian character sets

If you see empty boxes where you expect to see Asian characters in workbooks that are displayed on Tableau Server, then you should install the language-appropriate font packages in your Linux environment.

Initializing Tableau Server

TSM initialization fails because the tableau user account exists but is not a member of the group tableau

When you install and initialize Tableau Services Manager (TSM) and Tableau Server, the initialization script (initialize-tsm) creates the users and groups needed to run, or confirms that the existing ones are configured with the required characteristics. By default the script creates a user called tableau and adds it to a group called tableau. If a tableau user already exists but is not part of the tableau group, the script fails with a warning.

If this happens you can fix the conflict by using a --unprivileged-user flag to specify a different user, and the user will be created and added to the tableau group.

For example, to specify a user named tableauserver, you would run the script from the /opt/tableau/tableau_server/packages/scripts.<version_code> directory using this command:

```
sudo ./initialize-tsm --unprivileged-user="tableauserver" --acceptable
```

For a complete list of options that can be used with the initialize-tsm script, use the -h option:

```
sudo ./initialize-tsm -h
```
Error initializing Tableau Server on unsupported system locale

If you attempt to install Tableau Server on a computer with a locale that is not one of the eight supported locales, you will get an error during installation.

Tableau Server will run on a system using one of the following locales:

Any other locale will generate the error.

Error initializing Tableau Server when en_US.utf8 is not included in locale list

If you attempt to install Tableau Server on a computer that does not have en_US.utf8 in the locale list, the initialization will fail with an error. To see if en_US.utf8 is included, type locale -a at a shell prompt.

If en_US.utf8 is not listed, you can en_us to the locale list by typing sudo locale-gen en_US.UTF-8 at a shell prompt on Ubuntu, or sudo localedef -i en_US -f UTF-8 at a shell prompt on RHEL-like distributions.

Error: status 10 - initializing Tableau Server when data directory path includes a period

If you attempt to install Tableau Server and specify a data directory with a path that includes a period ("."), initialization will fail with errors including:

Connection timed out

and

ERROR: TSM services returned status 10

To avoid this issue, choose a data directory that does not include a period in its path.

Error initializing Tableau Server after reinstallation

If you uninstall and reinstall Tableau Server, you can encounter an error initializing Tableau Server. For example, you might see the following error:
ERROR com.t-ableausoftware.tabadmin.webapp.asyncjobs.JobStepRunner - Running step WaitForConfigure failed

com.t-ableau-software.tabadmin.webapp.exceptions.ServiceFailedStateException

This error occurs when artifacts remain from a previous installation that cause services to fail to start. To prevent this error, use the **tableau-server-obliterate** script in the /opt/tableau/tableau_server/packages/scripts.<version_code> folder. For more information about completely removing Tableau Server, see Remove Tableau Server from Your Computer.

**Activating Tableau Server**

Tableau Server license activation fails

In certain cases activation of the Tableau product key using the **tsm licenses activate -k <product_key>** command fails with an error:

License Server not available

This can happen if your computer is unable to connect through TCP port 443 to the Tableau licensing server at licensing.tableau.com.

To resolve this you need to configure your network and/or host-based firewalls to allow access to that address and port, or activate Tableau offline. For more information, see Activate Tableau Server Offline.

**Reindexing Tableau Server Search & Browse**

Problems that can be solved by reindexing Search & Browse

Symptoms of an index that needs to be rebuilt include:

- A blank list of sites when a user attempts to log in
- A blank list of projects when a user tries to select a project
- Missing content (workbooks, views, dashboards)
- Unexpected or inaccurate alerts (for example, an "refresh failed" alert on a workbook that does not include an extract)

If you see any of these behaviors, rebuild the Search & Browse index using the tsm maintenance reindex-search command.

Restarting Tableau Server

Restarting Tableau Server or applying changes fails

If one of the Tableau Server services fails, you might see an error when you attempt to restart the server or apply configuration changes.

To see if a failed service is causing the error, type the following command:

```plaintext
tsm status -v
```

To find out why a service failed, view the tabadminagent and tabadmincontroller log files in the data directory. For example, a service might fail because of concurrency issues or port configuration issues. Please include any issues you encounter in your feedback.

As a workaround, you can attempt to resolve the failure by removing and re-adding the service in TSM. Once the service has started, you can retry your previous configuration change or retry restarting the server with the tsm restart command.

Error restarting Tableau Server after adding or configuring a node

If you add a or configure the node without a Gateway process, Tableau Server might fail to restart and you could see errors like these:

```plaintext
ERROR : com.tableau.software.tabadmin.configuration.PortConfigurationExtractor - Unable to find port config key worker1.gateway.port
```

and
Message: Missing port configuration value for key 'worker1.gateway.port'

These errors appear in the gateway.log file and occur when a Tableau Server node is configured with either an Application Server or VizQL Server but without a Gateway. A Gateway process is required if either Application Server or VizQL Server is running on a node.

Backup/Restore

Problems related to restoring a backup created by Tableau Server can be the result of permissions issues. Proper permissions are necessary for both the file that TSM is restoring, and the location of the file. When TSM handles the backup, it puts the file in a default location and sets permissions appropriately. You can run into permission problems if you are restoring a backup that was copied to your Linux server, or a backup from a non-default location on your server. For details about using a non-default location, including how to change the location, see tsm File Paths.

Errors may include:

Server Was Denied Access to File

or

Restoring the backup '<backup>.tsbak' was unsuccessful

or

Comparing authentication methods failed

The Tableau Server backup and restore processes must have:

- Read permission—The processes need to access the .tsbak backup file directly.

- Execute permission—The processes also require execute permissions to the directory structure in which the .tsbak file is placed.
When TSM creates a backup in the default location, it sets the permissions it needs. If you copy a file to the Linux server, or move it to a non-default directory, the permissions may not allow the TSM processes proper access. You need to verify that both the file, and the directory tree that contains it, allow access by the TSM user tableau. The file permissions must give the tableau user read access to the .tsbak file. You can do this by setting the group on the file to the tableau group, and giving that group read access. The directory permissions must give the tableau user read access. You can do this by setting the group on the directory to the tableau group, and giving that group read and execute access on the directories.

For detailed information about TSM and file permissions, see Files and Permissions in TSM.

File locations

Changing basefilepath does not change the location of an existing file

Several tsm commands write files to default locations. You can change these default locations for each command using a tsm set command, but doing so does not move any existing files from the original location to the new one, and it does not create the new location. You are responsible for creating the new location, and for making sure it has the correct permissions to allow tsm access to any files in the location, and the entire directory structure that contains the files.

For more information about changing default locations for backup, restore, site import and export, and ziplogs files, see tsm File Paths.

For information about tsm permissions, see Files and Permissions in TSM.

TSM commands

TSM command line does not show progress for long-running tasks

If you run a tsm command such as restore or ziplogs that takes more than 2 hours to complete, the command will continue to run until completion on the server. To display the progress of the job, use the tsm jobs reconnect command.
Opening Firewall ports

Manually opening firewall ports on Ubuntu

The current version of Tableau Server does not support the ufw firewall that is used on Ubuntu. For customers that do not want to install firewalld on Ubuntu, another option is to manually open those ports. The following steps will confirm that ufw is running, and open TCP ports 8850 and 80 to connections from any source address:

1. Run the following command to confirm ufw is running:

   ```
   sudo ufw status
   ```

   If the result is Status: inactive, you will need to enable ufw and ensure that you can continue to connect via ssh, which is outside the scope of these release notes.

2. Run the following command to allow access to port 8850:

   ```
   sudo ufw allow 8850
   ```

3. Run the following command to allow access to port 80:

   ```
   sudo ufw allow 80
   ```

OpenID fails on first sign-in attempt

If you have configured Open ID Connect authentication for Tableau Server, the first sign-in attempt fails. To successfully log in, users must retry authentication after the initial failure.

Administrative views do not display

The Status tab of Tableau Server includes links to visualizations that display server metrics. These visualizations require the PostgreSQL driver to access the appropriate data from the Tableau Server repository. The PostgreSQL driver is not installed automatically, so if you have not installed the driver, the views will not display. For more information, see Database Drivers.
Note: To use administrative views, the PostgreSQL driver must be installed on any node that runs the VizQL Server process.

Changing locale on view

When you change your user locale after opening a view, any subsequent attempt to open the view will fail with an "unexpected error." You can still open views that you have not previously opened.

To work around this issue, sign out of Tableau Server after changing your locale, and then sign back in. All views will display properly.

Work with Log Files

Tableau Server creates log files as a normal part of its activities. You may need to use the server log files when you are troubleshooting issues with Tableau Server or if Tableau Support requests logs from you to help you resolve an issue.

You can create a zipped log file archive using the `tsm maintenance ziplogs` command. The zipped archive contains copies of the logs you can unzip and look at, or send to Tableau Support. Once you have a copy of the archive, you can delete the archive from your server. For more information on log file archives, see Log File Snapshots (Archive Logs).

This collection of topics provides information about how to create log file archives, the contents of specific log files, and details about when and how you might want to look at a log.

Investigating Tableau Server Issues

The range and complexity of possible issues with Tableau Server means that there is no simple process you can use to investigate all problems, but a general approach would include these steps:

1. **Clean up** existing log files to reduce their size. For more information, see For more information, see Remove Unneeded Files.
2. **Set the appropriate logging level.** This is something that Tableau Support will instruct you on. For more information, see Change Logging Levels.

3. **Reproduce the issue** you are troubleshooting so the logs capture the events related to the problem.

4. **Create an archive** of the logs. For more information see Log File Snapshots (Archive Logs).

   **Important:** Use this archive when looking at the log files. You should not edit, move or delete any files directly on the server.

5. **Review the TSM Administration Controller log** (/tabadmincontroller/tabadmincontroller_node<n>-<n>.log) to understand any configuration or deployment done by TSM from the command line, Web UI, or API, including jobs started by TSM. Start with the controller log. This is where you'll get most useful information.

6. **Review the Apache logs** (/httpd/access.####_##_##_##_##_#.log and /httpd/error.log) for requests that may be related to the issue you are investigating.

The Apache logs will contain a fair amount of "noise" that does not apply to issues you are experiencing.

- If you find a request that seems to be related to your issue, search the vizqlserver directory for entries that include the unique request ID from the Apache logs.
- Look for the response code and message associated with the request ID.
- Search for the name of the workbook, view, dashboard, or data source that is related to your issue. Make sure to look for a relevant timestamp.
- If you find a request that seems to be related to your issue, look at the response code associated with the request. (200s are good, 500s indicate problems.)
- Locate the unique request ID associated with the request you've identified (the unique request ID is a 24 character alphanumeric string at the very end of the request).

7. **Review the log archive** further to search for other messages and possible errors.

   - Use the request ID from the Apache logs to search the `vizqlserver` folder of the log archive for files containing related log entries. Look for indications of a problem (for example, error messages or long-running queries).

8. **Review script logging**.

   Tableau Server includes logs for most of the bash scripts that are included in the `scripts` directory at `/opt/tableau/tableau_server-/packages/scripts.<version_code>/`. *These logs are saved to the `/var/tmp` directory each time a script is run.*

   - `<install_drive>\<install\path>\logs`

   by default:
   - `C:\ProgramData\Tableau\Tableau Server\logs`

9. **Contact support**

   If you are not able to solve the issue yourself, or if requested by Tableau Support, send the zipped archive to Tableau.

### Server Log File Locations

By default, Tableau Server log file archives are gathered in a zip file called `logs.zip`, but you can specify a different filename when you create the archive with the `tsm main-tenance ziplogs` command. You can copy the archive from the server to a local computer and open it there, or send it to Tableau Support.

Looking for Tableau Server on Windows? See [Server Log File Locations](#).
When you unzip the archive, a series of zip files are created that start with the directory names shown below, and that end with a version number. These zip files contain the log files from the corresponding directories. The table in this topic explains the possible contents of these zip files, along with the original location the files came from on Tableau Server, the process that created the log files, and details about the files.

Tableau Server Log and Configuration File Locations

The Tableau Server log files are found in the following directory: /var/-opt/tableau/tableau_server/data/tabsvc/logs/

Logs not included in the ziplog archive

The tsm maintenance ziplogs command creates an archive of most of the Tableau Server logs, but some logs are not zipped up in the archive. Important logs not included in a log file archive:

- The TSM log. The tsm.log file is located in <home dir>/.tableau/tsm.
- The install log. The app-install.log file is located in /var/-opt/tableau/tableau_server/logs.
- The upgrade log. The app-upgrade.log file is located in /var/-opt/tableau/tableau_server/logs.

Bash script logging

Tableau Server includes logs for most of the bash scripts that are included in the scripts directory at /opt/tableau/tableau_server/packages/scripts.<version>. These logs are not included in the log file archive. Instead, the logs are saved to the /var/tmp directory each time a script is run.

**Log File Snapshots (Archive Logs)**

Tableau Server includes functionality to generate a snapshot of log files for archival purposes. If you plan to clean up and delete old log files as part of regular server maintenance,
you may consider archiving log files to an off-server storage location before deleting them.

Or, if you are working with Tableau Support on a case, the support engineer may request a server log file snapshot.

This topic describes:

- How to generate a log file snapshot
- How to send the snapshot directly to Tableau Support from the Tableau Server administration tools
- How to download the snapshot
- How to delete archived logs

In this article
Use the TSM web interface
Use the TSM CLI

Use the TSM web interface

1. Open TSM in a browser:
   https://<tsm-computer-name>:8850. For more information, see Sign in to Tableau Services Manager Web UI.

2. Click the Maintenance.

3. Generate a log file snapshot.

   An options dialog displays:
b. On the Options page, enter or select the options you want, including a **Description**, time **Range** of log files to be included, and the optional types of logs to be included, then click **Generate Log File Snapshot**.

The log file snapshot is saved to a fixed location on the computer where TSM and Tableau Server are installed. If you have a multi-node installation, the snapshot is saved to the initial node of the cluster. The location is specified by the `basefilepath_log_archives` variable.

By default the snapshot is saved to:

/var/opt/tableau/tableau_server/data/tabsvc/files/log-archives

You can find the current location by querying the `basefilepath.log_archives` setting, and change the location by specifying a new value for `basefilepath.log_archive`. For more information, see tsm File Paths.

4. After you generate the snapshot, you can select it and upload it to Technical Support, download it to your local machine, or delete it:
5. To download a local copy of the snapshot or to delete it, select the snapshot under Log Files and then select the appropriate Action.

Uploading log snapshots for Tableau Support

1. Click the Maintenance tab.

2. Select the snapshot you want to send.

3. Click Upload to Technical Support Case.

4. In the dialog that displays, enter the Support Case Number and your Contact
Use the TSM CLI

You create a snapshot archive of Tableau Server log files using the `tsm maintenance ziplogs` command.

By default, this command creates a zip file containing all of the log files. If you are running a distributed installation of Tableau Server, perform this step from the initial node. Logs from all nodes will be included in the zip file.

**Note:** If you cannot run the `ziplogs` command successfully, you can manually zip the Tableau Server logs. For more information, see Manually gather logs.

To create a log file snapshot:
1. On the initial node, open a terminal session.

2. Type the following command:

   ```bash
   tsm maintenance ziplogs -l -f <filename>
   ```

   where `<filename>` is name of the zipped archive file you want to create. Choose a unique name with no spaces. If an existing ziplog with the same file name already exists the creation of the file will fail unless you include the `-o` option to force an overwrite, delete the existing file, or specify a different name in the command.

   You can specify a time range for the snapshot and you can also specify which types of logs to include. For more information, see `tsm maintenance ziplogs`.

   The log file snapshot is saved to a fixed location on the computer where TSM and Tableau Server are installed. If you have a multi-node installation, the snapshot is saved to the initial node of the cluster. The location is specified by the `basefilepath_log_archives` variable.

   By default the log file snapshot is saved to:

   ```
   /var/opt/tableau/tableau_server/data/tabsvc/files/log-archives
   ```

   You can find the current location by querying the `basefilepath.log_archives` setting, and change the location by specifying a new value for `basefilepath.log_archive`. For more information, see `tsm File Paths`.

Sending log archives to Tableau Support

You can send log files to Tableau Support as a part of a customer support case (a customer support case number is required). Before sending a log file, use `tsm maintenance ziplogs` command to combine the log files into a single zip file archive. If you are creating the archive to send to Tableau Support, see the Knowledge Base for information about how to upload large files.
In a terminal session, type the following command:

tsm maintenance send-logs -f <zip file name> -c <case number> -e <email address>

where <case number> is your support case number, <email address> is your contact email for this support case, and <zip file name> is the file name of your archive with .zip file extension.

Change Logging Levels

By default, Tableau Server logs events at the Info level. You can change this if you need to gather more information (if you are working with Tableau Support, for example). As a best practice you should not increase logging levels except when troubleshooting an issue.

Increasing the log level to debug or trace increases the amount of information being logged and can have a significant impact to performance. You should only set a logging level to debug when investigating a specific issue. Reproduce the issue and then reset the logging level back to info.

Logging Levels

The following logging levels are listed in order of increasing amount of information logged:

- off
- fatal
- error
- warn
- info (the default)
- debug
- trace

Note: Logging levels for new TSM processes are set at info and cannot be changed easily. If you are working with Tableau Technical Support and they determine that logs for these processes are needed, they can help you change the logging level temporarily.
Processes impacted by this limitation include: Administration Agent, Administration Controller, Client File Service, Service Manager, Database Maintenance, and Backup/Restore.

Change Logging Levels

Set logging levels for Tableau Server using one of several `tsm configuration set` commands. The command you use depends on which component of Tableau Server you want to change the logging level for.

<table>
<thead>
<tr>
<th>Configuration key</th>
<th>Location of affected logs</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;process&gt;.native_api.log.level</code></td>
<td><code>/vizqlserver/*txt</code></td>
</tr>
<tr>
<td><code>vizportal.log.level</code></td>
<td><code>/vizportal/*log</code></td>
</tr>
<tr>
<td><code>vizqlserver.log.level</code></td>
<td><code>/vizqlserver/*.log</code></td>
</tr>
</tbody>
</table>

Valid process names are: backgrounder, vizportal, vizqlserver, or dataserver

For more information, see `tsm configuration set` Options.

You need to stop Tableau Server before changing the logging levels, and restart it afterward. If you are running a distributed installation of Tableau Server, set logging levels from the initial node.

To change the logging level:
1. Stop Tableau Server by typing:

    tsm stop

2. Set the logging level to by typing `tsm configuration set -k <config.key> -v <config_value>`

    where `<config.key>` is `<process>.native_api.log.level`, `vizportal.log.level`, or `vizqlserver.log.level`

    and `<config_value>` is a valid logging level.

   Examples:

   • `tsm configuration set -k backgrounder.native_api.log.level -v debug`
   • `tsm configuration set -k vizqlserver.log.level -v warn`
   • `tsm configuration set -k vizportal.log.level -v debug`

3. Apply pending changes by running the `tsm pending-changes apply` command.

4. Start Tableau Server by running the following command:

    tsm start

Reset Logging Levels

After you gather the information related to the issue you are investigating, reset the logging levels so there is no lingering performance impact.

Reset the logging level back to its default (info) using the appropriate command with a `-d` option.

Examples:
• tsm configuration set -k backgrounder.native_api.log.level -d
• tsm configuration set -k vizportal.log.level -d
• tsm configuration set -k vizqlserver.log.level -d

Troubleshoot Tableau Server Install and Upgrade

Follow the suggestions in this topic to resolve common issues with Tableau Server. For additional troubleshooting steps based on process status viewed on the Status page, see Troubleshoot Server Processes.

In this article

• General Troubleshooting Steps
• Common Tableau Server Install Issues
• Common Tableau Server Upgrade Issues
• Troubleshooting connections to TSM
• Starting Tableau Server
• Reindexing Tableau Server Search & Browse
• Activating Tableau Server

General Troubleshooting Steps

Many Tableau Server issues can be addressed with some basic steps:

1. Make sure there is enough disk space on each computer running Tableau Server. Limited disk space can cause a failure to install, a failure to upgrade, or problems running Tableau Server.

2. Restart Tableau Server. Issues related to indexing and processes not fully started can
be resolved by restarting Tableau Server in a controlled way. To restart Tableau Server, use the `tsm restart` command. This will stop all the processes associated with Tableau Server and then restart them.

Common Tableau Server Install Issues

Unable to log into TSM or Tableau Server (sign in screen redisplays after entering credentials)

Using Internet Explorer or Edge, if you enter your credentials into the TSM or Tableau Server sign-in screen and the page redisplays without signing you in, verify that the hostname or domain in your URL does not include an underscore (_). If the hostname or domain of the Tableau Server computer includes an underscore (_) Internet Explorer or Edge browsers will not set a cookie, so the page will redisplay without signing you in. To work around this, use "localhost" or the IP address of the computer in the URL. For example: https://localhost:8850.

For more information, see the Tableau Knowledge Base.

Multiple install attempts fail

If you attempt to install Tableau Server and the install fails, any subsequent installation attempts are likely to fail unless you run the `tableau-server-obliterate` script to clean Tableau off the computer.

A failed install attempt can leave the computer in a state that causes subsequent attempts to also fail with errors that don't seem directly related to a previous install attempt. One possible error is:

```
Enabling and starting all services
+ services=(appzookeeper* tabadmincontroller* tabsvc*
license service* fnplicense service* tabadminagent* cli-
entfileservice*)
+ systemctl_user enable appzookeeper_0.service
'tabadmincontroller*' 'tabsvc*' 'license service*'`
```
fnplicenseservice_0.service 'tabadminagent*' 'clientfileservice*'
++ id -ru a_tabadminpoc
+ local unprivileged_uid=222954
+ su -l a_tabadminpoc -c 'XDG_RUNTIME_DIR=/run/user/222954 systemctl --user enable appzookeeper_0.service tabadmincontroller* tabsvc* licenseservice* fnplicenseservice_0.service tabadminagent* clientfileservice*' Failed to execute operation: No such file or directory

To fix this problem, run the tableau-server-obliterate script to clean up any leftover remnants of the previous install attempt and then restart the computer. For more information, see Running the tableau-server-obliterate script.

Important: If you created a backup of Tableau (<file>.tsbak) you want to keep (for example, to restore to your new installation), copy that file to a safe location on another computer to guarantee it is not removed when you clean up your Tableau computer.

Install fails due to hardware requirements

Tableau Server cannot install if the computer you are installing on does not meet the minimum hardware requirements. The requirements apply to all computers on which you are installing Tableau Server. For details on minimum hardware requirements, see Minimum Hardware Requirements and Recommendations for Tableau Server.

Common Tableau Server Upgrade Issues

Upgrade logs location
The upgrade log, app-upgrade.log, is located in /var/opt/tableau/tableau_server/logs.
Upgrade multi-node, initializing additional node fails with "Enter your credentials again" error

If you attempt to initialize an additional node when upgrading Tableau Server and see this error:

Enter your credentials again. The credentials you enter must provide administrative access to the computer where you generated the configuration file.

this is an indication that the node is unable to connect to or communicate with the initial node. This can happen for multiple reasons:

- The credentials you entered are not valid or you mistyped them. The credentials must be for a user who has administrative permissions on the computer where Tableau Server was first installed. You do not need to use the credentials of the user who created the bootstrap file but doing so will ensure you are using valid credentials.

- The local firewall of the computer you are trying to add is not allowing communication to the initial node. For more information, see Local firewall configuration.

- The nodes are on different subnets. In distributed installations, all nodes should be installed on the same subnet. For more information, see Distributed Requirements.

Upgrading fails due to lack of disk space

If there is not enough disk space for the Tableau Server Setup program to run and do the upgrade, the installation will fail. The amount of disk space required will depend on the size of your repository database and the number and size of your extracts. As a part of upgrading to version 9.0, the Setup program migrates extracts to the new File Store and this takes space.

To free up disk space:
1. Create a log archive snapshot using the `tsm maintenance ziplogs` command. After you create the ziplogs file, save it to a safe location that is not part of your Tableau Server installation.

2. Clean up unnecessary files using the `tsm maintenance cleanup` command. For more information, see Remove Unneeded Files.

**Troubleshooting connections to TSM**

**Starting Tableau Server**

Tableau Server cannot determine if it fully started

In some instances Tableau Server may report that it could not determine if all components started properly on startup. A message displays: "Unable to determine if all components of the service started properly."

If you see this message after starting, verify that Tableau Server is running as expected by using a `tsm status -v` command.

If the status shows as running ("Status: RUNNING"), then the server successfully started and you can ignore the message. If the status is DEGRADED or STOPPED, see "Tableau Server doesn't start" in the next section.

Tableau Server doesn't start

If Tableau Server does not start or is running in a degraded state, run the `tsm restart` command from a command prompt. This will shut down any processes that are running, and restart Tableau Server.

**Reindexing Tableau Server Search & Browse**

Problems that can be solved by reindexing Search & Browse

Symptoms of an index that needs to be rebuilt include:
A blank list of sites when a user attempts to log in
A blank list of projects when a user tries to select a project
Missing content (workbooks, views, dashboards)
Unexpected or inaccurate alerts (for example, an "refresh failed" alert on a workbook that does not include an extract)

If you see any of these behaviors, rebuild the Search & Browse index using the tsm maintenance reindex-search command.

Activating Tableau Server

Tableau Server license activation fails

In some instances Tableau Server license activation may fail. Error messages can range from a very generic one:

- An error has occurred

To more specific messages:

- Function flxActCommonLicSpcPopulateFromTS returned error 50030, 71521,
- No license found for 'Tableau Server'

To resolve this issue, try these solutions in the order listed:

Confirm you can access the licensing server

The Tableau licensing service was moved to a new data center on October 6, 2018. This means any environments that required special configuration (static IP safe listing for example) to access licensing.tableau.com or licensing.tableausoftware.com will need to be updated before you can activate, refresh, or deactivate a Tableau product key.

Tableau Server needs to connection to the following internet locations for licensing purposes:
- license.licensing.tableau.com:443
- atr.license.licensing.tableau.com:443
- o.ss2.us
- ocsp.rootg2.amazontrust.com
- ocsp.rootca1.amazontrust.com
- ocsp.sca1b.amazontrust.com
- crt.sca1b.amazontrust.com
- crt.rootca1.amazontrust.com
- ocsp.sca0a.amazontrust.com
- crt.sca0a.amazontrust.com
- ocsp.sca1a.amazontrust.com
- crt.sca1a.amazontrust.com
- ocsp.sca2a.amazontrust.com
- crt.sca2a.amazontrust.com
- ocsp.sca3a.amazontrust.com
- crt.sca3a.amazontrust.com
- ocsp.sca4a.amazontrust.com
- crt.sca4a.amazontrust.com

Requests to the above domains may be on port 80 or 443.
Verify the date and time

Verify the date and time on the initial Tableau Server computer is correct. If the clock is set to a time and date earlier than the current date, Tableau Server cannot be activated.

Force the product key to be read again

1. On the initial Tableau Server computer, sign in as administrator and open a command prompt.

2. Change to the Tableau Server bin directory. By default this is:

   /opt/tableau/tableau_server/packages/bin.<version_code>/

3. Type the following commands:

   tsm stop
   ./lmreread
   tsm start

Send the contents of trusted storage to Tableau Support

If FlexNet Licensing Services is installed and running but you’re still seeing an error, there might be a problem with the Tableau product key information. To resolve this issue, complete the following steps to create a file of the key Tableau licensing information located in trusted storage.

1. On the initial Tableau Server computer, sign in as administrator and open a command prompt.

2. Type the following command:

   serveractutil -view > <machine_name>-LicResults.txt

   This creates the <machine_name>-LicResults.txt file in your current directory. If you don’t have write permissions for that location and see an error, change to a location where you do have permission to create a file and run the command again.
3. Contact Tableau Support (http://www.tableau.com/support/request) and include the <machine_name>-LicResults.txt file that you created.

Troubleshoot Server Sign in Problems

There are several different sign in options between Tableau Services Manager (TSM) and Tableau Server.

- **TSM**—If you are not able to sign into TSM, make sure you are using credentials for a user who has administrative rights to the computer where TSM is installed. This user may or may not also be a Tableau Server administrator. This is true whether you are signing in to the Web UI or the CLI. For more information, see Sign in to Tableau Services Manager Web UI.

- **Tableau Server**—
  - Administrators: if you are signing into Tableau Server as an administrator, you must use credentials for a user who has an administrator role in Tableau Server. You create the initial administrator when you first install Tableau, but can add other users as administrators once Tableau is installed and running. For more information, see Sign in to Tableau Server Admin Pages.
  - Non-administrative users: If you are signing into Tableau Server as a user, you need to be use credentials for a user who has been added to Tableau Server. For more information, see Sign in to Tableau Server or Online.

**Note:** If users with valid credentials are unable to sign into Tableau Server, make sure you have not added a node without applying pending changes. If you have a pending new node, signing into Tableau Server may not be possible.

If you have problems signing into Tableau Services Manager (TSM) or Tableau Server, confirm that you are not running into one of these issues:
Unable to log into TSM or Tableau Server (sign in screen redisplays after entering credentials)

Using Internet Explorer or Edge, if you enter your credentials into the TSM or Tableau Server sign-in screen and the page redisplays without signing you in, verify that the hostname or domain in your URL does not include an underscore (_). If the hostname or domain of the Tableau Server computer includes an underscore (_) Internet Explorer or Edge browsers will not set a cookie, so the page will redisplay without signing you in. To work around this, use "localhost" or the IP address of the computer in the URL. For example: https://localhost:8850.

For more information, see the Tableau Knowledge Base.

Troubleshoot Licensing

This topic includes instructions for troubleshooting issues related to Tableau Server licensing.

Handle an unlicensed server

Tableau offers two licensing models: user-based and core-based. To learn more about user-based and core-based licensing, see Licensing Overview.

User-based licensing requires each active user account to be covered by a license. User-based licenses have a defined capacity, or number of users that they allow. Each user is assigned a unique user name on the server and is required to identify themselves when connecting to the server.

Core-based licensing has no constraints on the number of user accounts in the system, but it does restrict the maximum number of processor cores that Tableau Server can use. You can install Tableau Server on one or more machines to create a cluster, with the restriction that the total number of cores in all the machines does not exceed the number of cores you have licensed and that all of the cores on a particular machine are covered by the license.
Unlicensed User-Based Server

The most common reason for a server that has user-based licensing to be unlicensed is an expired product key or an expired maintenance contract.

Unlicensed Core-Based Server

A core-based server can become unlicensed for a variety of reasons, such as when Tableau Server nodes running licensed processes cannot contact the Tableau Server node running the License Manager service. To learn more about licensed processes, see Tableau Server Processes.

When the server is unlicensed you may not be able to start or administer the server. You can, however, manage your licenses using the tsm licenses command.

Troubleshoot user-based licensing

This section provides information about resolving issues that can occur when adding the user-based Viewer, Explorer and Creator licenses to Tableau Server or Tableau Online, or when these licenses expire. The highest available license type is Creator, followed by Explorer, and finally Viewer. To learn more about user-based licensing, see Licensing Overview.

A user or administrator is unlicensed due to license expiration

To avoid having users unexpectedly become unlicensed or move to another site role, you should always do one of the following before the license that they are currently using expires:

- Renew and activate a replacement license. If a user occupies a Creator, Explorer or viewer license and their license expires, they will use another license of the same type, if available.
- Change the site role of those users to allow the use of a license that is not due to expire.

To learn how site roles can be changed to require a different license, see Set Users’ Site Roles.
The reassignment of users to new licenses is governed by the following logic:

- When a Server Administrator user occupies a Creator license and their license expires (with no replacement licenses available), they are reassigned to an Explorer license if any Explorer licenses are available. This license reassignment occurs in order of most recent login. Server Administrators displace other users who might be currently using an Explorer license. If no Creator or Explorer licenses are available a Server Administrator becomes unlicensed.

- When a non-Server Administrator user occupies a Creator license and their license expires (with no replacement licenses available), they become unlicensed. To avoid having these users become unlicensed, change their site role prior to license expiration. This is especially important for users in the Site Administrator Creator site role, who must move to the Site Administrator Explorer site role before their Creator license expires to avoid losing Site Administrator capabilities.

- When a non-Server Administrator user occupies an Explorer or Viewer license and their license expires (with no replacement licenses available), they are upgraded to a higher license type, if licenses of that type are available. Specifically, the following occurs when a license expires:
  - Users who occupy an Explorer license will move to a Creator license, if available (with no change to site role).
  - Users who occupy a Viewer license will move to an Explorer license, if available. If no Explorer licenses are available, these users will move to a Creator license, if available (with no change to site role).
  - If no licenses are available at the higher license types, those users are moved to Unlicensed.

Users are reassigned to a new license as described above in order of most recent login, with lower license types reassigned first (first Viewer, then Explorer, and then Creator).

For example: Two users with a Viewer license, a user with the Creator license, and two Server Administrators with a Creator license all have their licenses expire. Four unexpired Explorer licenses are available for these users. In this situation, the following occurs in the order shown below:

1. The user with a Viewer license who logged in most recently is reassigned to an Explorer license.
2. The second user with a Viewer license is reassigned to an Explorer license.
3. The Server Administrator user with a Creator license who logged in most recently is reassigned to an Explorer license, and then the second Server Administrator with a Creator license is reassigned to the remaining Explorer license.
4. The user with the Creator license becomes unlicensed.

Server Administrator site role is unchanged when using a Creator license

Server Administrators gain Creator capabilities if Creator licenses are available in Tableau Server, with no change to their site role name. All other Tableau Server and Tableau Online users gain Creator licenses only if assigned to a site role that includes Creator in its name.

Licenses are not immediately available

When you add a role-based license to Tableau Server, those licenses become available to all users when you restart Tableau Server. If you don’t restart Tableau Server, role-based licenses become available to all users within 24 hours.

A user with a Viewer license cannot open Tableau Server or Tableau Online workbooks from Tableau Desktop

A user with a Viewer license who also has a separate Tableau Desktop license will be unable to open workbooks on Tableau Server or Tableau Online using Tableau Desktop. To open workbooks such using Tableau Desktop, that user will need an Explorer or Creator license on Tableau Server or Tableau Online.

Handle an Unlicensed VizQL Server Process

There are several status indicators on the Tableau Server Status page that help you understand the state of Tableau Server processes. An orange-color status box, "Unlicensed", indicates that one of the VizQL server processes is unable to retrieve the Tableau Server license information.
There may be several reasons why the process is unable to access this information. For example, there may be network issues preventing a VizQL process, which is running on an additional node, from communicating with the initial node machine. Or, the process may be getting sent more requests than it can accept at that time and can't handle the licensing request. As a result, some of your users may be able to access views while others cannot.

To resolve the problem, stop, then start Tableau Server.

Tableau Services Manager (TSM) Command Timeout

When Tableau Server is configured with two instances of the repository and failover to the backup repository occurs, TSM attempts to restart the original repository so that it is available as a backup. If this cannot be done for any reason, subsequent TSM commands can fail due to timeouts while waiting for the original repository to recover.

Commands that can be impacted include:

- tsm maintenance restore
- tsm maintenance reindex-search
• tsm reset
• tsm security regenerate-internal-tokens
• tsm sites export
• tsm sites import

If any of these commands is failing, and you have a repository that is not recovering, remove the repository from the server topology, apply pending changes, and re-add it.

Cookie Restriction Error

When a user signs in to Tableau Server, a session cookie is stored in their local browser. The stored cookie is how Tableau Server maintains that the signed in user has been authenticated and can access the server. Because the cookie is set with the same domain or subdomain as the browser's address bar, it is considered a first-party cookie. If a user's browser is configured to block first-party cookies, they will be unable to sign in to Tableau Server.

When a user signs in to Tableau Server via an embedded view, or in an environment where trusted authentication has been configured, the same thing happens: a cookie is stored. In this case, however, the browser treats the cookie as a third-party cookie. This is because the cookie is set with a domain that's different from the one shown in the browser's address bar. If a user's web browser is set to block third-party cookies, authentication to Tableau Server will fail. To prevent this from occurring, web browsers must be configured to allow third-party cookies.

Troubleshoot Subscriptions

"The view snapshot in this email could not be properly rendered."

If you receive a subscription with this error message, there could be several reasons:

• **Missing credentials**: Some views are published with embedded credentials. You may receive the above error if the embedded credentials are now out-of-date, or if the view was republished without the embedded credentials.

• **Database temporarily down**: If the view has a live database connection and the
database was temporarily down when the subscription was being generated, you might receive the above error.

- **Background process timeout**: By default, the background process that handles subscriptions times out after 30 minutes. In the majority of cases, this is plenty of time. However, if the background process is handling an extraordinarily large and complex dashboard, that may not be enough time. You can check the Background Tasks for Non Extracts admin view to see if that's the case. To increase the timeout threshold, use the `tsm configuration set subscriptions.timeout` command.

**Can't subscribe**

If you can see a view on Tableau Server and it has a subscription icon ( Hispana ) in the upper right corner, you can subscribe to it.

Two things need to be in place for you to subscribe to a view: Tableau Server needs to be correctly configured (described in Set Up a Server for Subscriptions) and the view you're subscribing to must either have embedded credentials for its data source or not rely on credentials at all. Examples of the latter include a workbook that connects to an extract that isn't being refreshed, or a workbook whose data is in a file that was included with the workbook at publish time. Embedding credentials is a step that happens in Tableau Desktop (see the Tableau Help for details).

**No subscription icon**

It's possible to see a view on Tableau Server but be unable to subscribe to it. This happens for one of three reasons:

- **No subscriptions have been scheduled**: If no subscriptions have been scheduled, the subscription icon will not appear. To set a schedule for subscriptions, see Create or Modify a Schedule.
- **The view uses a live database connection**: Views with live database connections, where you're prompted for your database credentials when you first click the view, aren't available for subscription. A subscription includes a view (or workbook), data, and a schedule. To deliver the data required for the view, Tableau Server either needs embedded database credentials or data that doesn't require credentials. Where live
database connections are concerned, Tableau Server doesn’t have the credentials, only the individual users do. This is why you can only subscribe to views that either don’t require credentials or have them embedded.

- **Tableau Server is configured for trusted authentication**: You may also be able to see a view but be unable to subscribe to it (no subscription icon) if Tableau Server is configured for trusted authentication. See [Ensure Access to Subscriptions](#) for more information.

**Receiving invalid or "broken" subscriptions**

If you configured subscriptions on test or development instances of Tableau Server in addition to your in-production instance, disable subscriptions on your non-production instances. Keeping subscriptions enabled on all instances can result in your users receiving subscriptions that appear to be valid, but which don’t work, or receiving subscriptions even though they’ve unsubscribed from the view or workbook.

**Subscriptions not arriving ("Error sending email. Can't send command to SMTP host.")**

You may see the above error in Windows Event Viewer if subscriptions aren't arriving and your SMTP server is using encrypted (SSL) sessions. Subscriptions are only supported for unencrypted SMTP connections. The solution is to use an unencrypted SMTP server. (If you’re experiencing this error, note that Tableau Server will still indicate that subscriptions are being sent in the Background Tasks for Non Extracts admin view.)

**Custom scripts not working after upgrade to 8.1**

To support better session management, starting with version 8.1, a hash tag (#) was added to the end of view URLs. If you had custom subscriptions scripting that generated views as PDFs or PNGs you may need to update your scripts to allow for the hash tag.

For example, prior to version 8.1, view URLs use this syntax: `http://tableauserver/views/SuperStore/sheet1`. To generate a view as a PNG, `.png` could be added to the end of the URL. For example, `http://tableauserver/views/SuperStore/sheet1.png`. 
In versions 8.1, 8.2, or 8.3, view URLs use this syntax: `http://tableauserver/views/SuperStore/sheet1#1`. To generate a PNG, add `.png` before the hash tag. For example: `http://tableauserver/views/SuperStore/sheet1.png#1`

Custom scripts not working after upgrade to 9.0

In version 9.0, the session ID at the end of server URLs is indicated by an "iid" parameter, `:iid=<n>`. For example, `http://localhost/#/views/Sales2015/SalesMarginsByAreaCode?iid=1`. This parameter replaces the hash tag "#<n>" used for the session ID in 8.x versions of Tableau Server.

If you use custom subscriptions scripts that generate views as PDFs or PNGs, you may need to update your scripts by removing the hash tag and number (#<n>), and inserting the `?iid=` session ID parameter before the number.

To generate a PNG in version 9.0 and later, add `.png` before the session ID: `http://tableauserver/views/SuperStore/sheet1.png?iid=2`

Troubleshoot Performance of Workbooks with Calculations

In most cases, you can expect to see similar or better performance after upgrading your Tableau Server from versions 10.4 or earlier to 10.5 or later. However, for workbooks that use complex calculations, you may see performance issues after you upgrade. This article describes how to test and troubleshoot performance issues for workbooks that have calculations and use extracts as the data source after you have upgraded your Tableau Server from versions 10.4 or earlier to 10.5 or later.

If you have not yet upgraded to Tableau Server 10.5 or later, we strongly recommend that you set up a test environment and test your workbook performance before you upgrade your production Tableau Server. For more details, see Test Workbook Performance.
If you have already upgraded to Tableau Server 10.5 or later, and you are experiencing slow response times, use the guidance provided in this topic to help troubleshoot performance issues.

Since Linux was first released in 10.5, this only applies when you are migrating from Tableau Server versions 10.4 or earlier on Windows to Linux 10.5 or later.

Here are the scenarios that most likely describe your environment after upgrading to Tableau Server 10.5 or later:

- Recently upgraded, and majority of the extracts are still in .tde format
- Recently upgraded and majority of extracts are in .hyper format
- Upgraded a while ago, workbooks have changed since upgrade

Scenario: You upgraded your Tableau Server recently. You are experiencing slow response times and the majority of your extracts have not been refreshed, so they are still in .tde format.

1. Disable any scheduled or automated extract refreshes.

2. Enable the following setting on Tableau Server to check the number of query nodes required for Tableau to generate the workbook and display an error when the set limit is exceeded. The error message might say something like: "Logical Query tree has 2348182 nodes, maximum number allowed is 1000000....":

   Use TSM CLI to run the following commands:

   ```
   tsm configuration set -k native_api.node_limit_checker_pre_rewrite_disable -v false
   tsm pending-changes apply
   ```

   **Note:** This setting is only available in Tableau Server 10.5.3 or later. While enabling this setting improves the reliability and stability of Tableau Server, you may see errors on a very small percentage of workbooks when you enable this
1. Setting. For example, the Tableau team saw errors on 0.01% of the workbooks with this setting enabled on Tableau Online.

3. Test the workbooks by viewing or interacting with them. You should see an error message informing you about exceeding the node limits on workbooks that have performance issues. The error message might say something like: "Logical Query tree has 2348182 nodes, maximum number allowed is 1000000....".

4. Use Tableau Desktop to troubleshoot your workbook performance. Run this command to enable the node limit check in your Tableau Desktop:

   `tableau.exe -DNodeLimitCheckerPreRewriteDisable=false`

   **Note:** This setting is only available in Tableau Desktop 10.5.3 or later.

   In Tableau Desktop, download and open the workbooks that displayed the error message about high node limits in step 2. Try optimizing the performance of workbooks using methods described in Best Practices for Creating Calculations in Tableau. If successful, publish these workbooks to Tableau Server. If you are still experiencing performance issues, continue to the next step.

5. For workbooks that load successfully, but the overall response times is slower after upgrade, try using the Compute Calculations Now option. If you have a large number of workbooks that fall under this category, consider enabling the server-wide setting to retain materialized calculations for all extracts when they are upgraded from .tde to .hyper:

   Use TSM CLI to run the following commands:

   `tsm configuration set -k native_api.preserve_calculations_on_hyper_refresh_conversion -v true`
**Considerations for turning on this setting:**

Turn this setting on only if the majority of your workbooks require calculations to be materialized. There are resource and time costs associated with this setting, which are as follows:

- When this setting is set to true, the extract file size will increase, affecting the overall disk space.
- Extracts with materialized calculations take a longer time to refresh than extracts without materialized calculations.

This setting only affects extracts that have not yet upgraded to .hyper. Extracts already upgraded to .hyper before turning on this setting, will not have the calculations materialized. This setting will also not affect workbooks and extracts published from Tableau Desktop, or any new extract refreshes published to Tableau Server that do not use the **Compute Calculations Now** option.

**Note:** This setting is only available in Tableau Server 10.5.3 or later.

6. Enable extract refresh schedules.

Scenario: You upgraded your Tableau Server recently. You are experiencing slow response times and a majority of your extracts have been refreshed and upgraded from .tde to .hyper.

1. Restore the backup you made before you upgraded your production Tableau Server.

**Note:** This method assumes that your workbooks have not changed significantly since the upgrade and, or it is OK to go back to the state just before upgrade.

2. Disable any scheduled extract refreshes.
3. Enable the following setting on Tableau Server to check the number of query nodes required for Tableau to generate the workbook and display an error when the set limit is exceeded. The error message might say something like: "Logical Query tree has 2348182 nodes, maximum number allowed is 1000000....":

Use TSM CLI to run the following commands:

```bash
tsm configuration set -k native_api.node_limit_checker_pre_rewrite_disable -v false
tsm pending-changes apply
```

**Note:** This setting is only available in 10.5.3 or later. While enabling this setting improves the reliability and stability of Tableau Server, you may see errors on a very small percentage of workbooks with when you enable this setting. For example, the Tableau team saw errors on 0.01% of the workbooks with this setting enabled on Tableau Online.

4. Test the workbooks by viewing or interacting with them. You should see an error message informing you that you are exceeding the node limits on workbooks that have performance issues. The error message might say something like: "Logical Query tree has 2348182 nodes, maximum number allowed is 1000000....".

5. Use Tableau Desktop to troubleshoot your workbook performance. Run this command to enable the node limit check in your Tableau Desktop:

```bash
tableau.exe -DNodeLimitCheckerPreRewriteDisable=false
```

Download and open the workbooks that displayed the error message using Tableau Desktop. Try optimizing the performance of workbooks using methods described in [Best Practices for Creating Calculations in Tableau](#). If successful, then publish them
to Tableau Server. If you are still experiencing performance issues, continue to the next step.

6. For workbooks that load successfully, but the overall response time is slower after upgrade, try using the **Compute Calculations Now** option. If you have a large number of workbooks that fall under this category, consider enabling the server-wide setting to retain materialized calculations for all extracts when they are upgraded from .tde to .hyper:

Use TSM CLI to run the following commands:

```
tsm configuration set -k native_api.preserve_calculations_on_hyper_refresh_conversion -v true

dm pending-changes apply
```

**Considerations for turning on this setting:**

Turn this setting on only if majority of your workbooks require calculations to be materialized. There are resource and time costs associated with this setting, which are as follows:

- When this setting is set to true, the extract file size will increase, affecting the overall disk space.

- Extracts with materialized calculations take a longer time to refresh than extracts without materialized calculations.

This setting only affects extracts that have not yet upgraded to .hyper. Extracts already upgraded to .hyper before turning on this setting will not have the calculations materialized. This setting will also not affect workbooks and extracts published from Tableau Desktop, or any new extract refreshes published to Tableau Server that do not use the Compute Calculations Now option.
7. Enable extract refresh schedules.

Scenario: You upgraded your Tableau Server a while ago and you are experiencing slow response times. It is not practical for you to roll back using the backup you made prior to upgrade because your workbooks have changed since the upgrade, and the extracts have been upgraded to .hyper format.

If you fall under this scenario, and you find that your workbooks require materialized calculations, turning on the optimization setting on refresh will not work for you as this setting only works when upgrading from .tde to .hyper. You will need to test your workbooks individually for performance issues, and optimize them manually and republish to Tableau Server.

1. If you see high memory and CPU consumption by VizQL Server when viewing workbooks with extracts, in addition to slower workbook response times, then you can enable the following setting on Tableau Server to help prevent the VizQL process from consuming the memory resources on the machine that might result in critical server issues. This setting checks the number of query nodes required for Tableau to generate the workbook and displays an error when the set limit is exceeded:

Use TSM CLI to run the following commands:

```
tsm configuration set -k native_api.node_limit_checker_pre_rewrite_disable -v false

tsm pending-changes apply
```

Note: While enabling this setting improves the reliability and stability of Tableau Server, you may see errors on a very small percentage of workbooks when you
enable this setting. For example, the Tableau team saw errors on 0.01% of the workbooks with this setting enabled on Tableau Online.

2. Test the workbooks by viewing or interacting with them. Look for workbooks where you might see an error message that says something like: "**Logical Query tree has 2348182 nodes, maximum number allowed is 1000000...**".

3. Use Tableau Desktop to troubleshoot the workbooks that you identified in step 2. Run this command to enable the node limit check in your Tableau Desktop:

   `tableau.exe -DNodeLimitCheckerPreRewriteDisable=false`

   Download and open the workbooks that displayed the error message using Tableau Desktop. Try optimizing the performance of workbooks using methods described in the [Best Practices for Creating Calculations in Tableau](#) topic and publish them to Tableau Server. If you are still seeing performance issues, continue to the next step.

4. Use the **Compute Now** option to materialize calculations in your extract.

### Server Administrator Reference

#### Tableau Server Processes

This topic describes the options for setting the process configuration. To configure Tableau Server processes, you need to specify which processes and how many instances should run on each node. You do this using the `tsm topology set-process` command. For more information, see Changing the number of processes on a node.

Looking for Tableau Server on Windows? See [Tableau Server Processes](#).
Except where explicitly noted in the table below, applying changes in processes will stop Tableau Server if it is running when you apply those changes. After changes are applied, Tableau Server is returned to the state it was in before process configuration, so if the server was running, it will be restarted.

**Important:** Your process topology will depend on your organizational needs.

### Licensed processes

Some of the processes that are installed as a part of Tableau Server are "licensed" processes. Licensed processes need a valid Tableau Server license in order to run. Other processes that are installed as a part of Tableau Server are not tied to a valid license. This has the following impact:

- Every licensed process needs to regularly contact the Tableau Server License Manager service that runs on the initial Tableau Server computer to verify they are licensed. If they cannot confirm there is a valid license, for example, if the initial node is not available, the process will not run and Tableau Server may not function properly or reliably.

- If you have a core-based Tableau Server license, the cores on any node with a licensed process will count against the total count of licensed cores.

The "Licensed" column in the table below identifies those processes that require a valid license, and which impact the count of cores in core-based licenses.

Tableau Server Coordination Service

The Coordination Service is built on Apache ZooKeeper, an open-source project, and coordinates activities on the server, guaranteeing a quorum in the event of a failure, and serving as the source of "truth" regarding the server topology, configuration, and state. The service is installed automatically on the initial Tableau Server node, but no additional instances are installed as you add additional nodes. Because the successful functioning of Tableau Server depends on a properly functioning Coordination Service, we recommend
that for server installations of three or more nodes, you add additional instances of the Coordination Service by deploying a new Coordination Service ensemble. This provides redundancy and improved availability in the event that one instance of the Coordination Service has problems.

The hardware for your cluster can have some effect on how well the Coordination Service runs. In particular:

- Memory. The Coordination Service maintains state information in memory. By design, the memory footprint is small, and is typically not a factor in overall server performance.

- Disk speed. Because the service stores state information on disk, it benefits from fast disk speed on the individual node computers.

- Connection speed between nodes. The service communicates continuously between cluster nodes; a fast connection speeds between nodes helps with efficient synchronization.

Configuration for the Coordination Service

The Coordination Service is installed automatically on the initial node of Tableau Server. If you are running a single-node installation, you do not need to do anything to deploy or configure the Coordination Service. If your installation includes three or more nodes, you'll be prompted to configure a Coordination Service ensemble when you add your third node. This is not required, but is highly recommended as the Coordination Service serves a key function for high availability, acting as the source of "truth" about server topology, configuration, and state.

To configure a Coordination Service ensemble, use the TSM CLI and add the Coordination Service to the nodes you want running it. For details on how to deploy a Coordination Service ensemble, see Deploy a Coordination Service Ensemble.
The Coordination Service Quorum

To ensure that the Coordination Service can work properly, the service requires a *quorum*—a minimum number of instances of the service. This means that the number of nodes in your installation impacts how many instances of the Coordination Service you want to configure in your ensemble.

Number of Coordination Service instances to use

The maximum number of Coordination Service instances you can have in an ensemble on Tableau Server depends on how many Tableau Server nodes you have in your deployment. Configure a Coordination Service ensemble based on these guidelines:

<table>
<thead>
<tr>
<th>Total number of server nodes</th>
<th>Recommended number of Coordination Service nodes in ensemble (must be 1, 3, or 5)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-2 nodes</td>
<td>1 node</td>
<td>This is the default and requires no changes unless you want to move the Coordination Service off your initial node and onto your additional node.</td>
</tr>
<tr>
<td>3-4 nodes</td>
<td>3 nodes</td>
<td></td>
</tr>
<tr>
<td>5 or more nodes</td>
<td>5 nodes</td>
<td>Five is the maximum number of Coordination Service instances you can install.</td>
</tr>
</tbody>
</table>

If you reduce the number of nodes

If you reduce the nodes in your cluster from three (or more) to two nodes, a warning tells you Tableau Server can no longer support high availability:
A minimum of three Tableau Server nodes are required for high availability. You can add a third node now, or continue with only two nodes. Continuing with only two nodes means Tableau Server will not be highly available. You can always add a third node later. Click OK to continue with 2 nodes, or Cancel to go back and add a node.

If you continue, Tableau Server will run, but you will not have any automatic failover of the repository.

Viewing Coordination Service Status

The Coordination Service is not included in the listing when you View Server Process Status. To see the state of the service, you can use the tsm status command:

tsm status -v

The output from the command shows you whether the service is running:

node1: TABLEAUSVR01
Status: RUNNING
'Tableau Server Gateway 0' is running.
'Tableau Server Application Server 0' is running.
'Tableau Server VizQL Server 0' is running.
'Tableau Server VizQL Server 1' is running.

'Tableau Server Data Server 1' is running.
'Tableau Server Data Engine 0' is running.
'Tableau Server File Store 0' is running.
'Tableau Server Repository 0' is running (Active Repository).
'Tableau Server Administration Agent 0' is running.
'Tableau Server Administration Controller 0' is running.
'Tableau Server Service Manager 0' is running.
'Tableau Server License Manager 0' is running.
'Tableau Server Client File Service 0' is running.
'Tableau Server Database Maintenance 0' is stopped.
'Tableau Server Backup/Restore 0' is stopped.
'Tableau Server Site Import/Export 0' is stopped.
'Tableau Server SAML Service 0' is stopped.

Tableau Server Data Engine

Hyper is Tableau's in-memory Data Engine technology optimized for fast data ingests and analytical query processing on large or complex data sets. Starting in Tableau 10.5 release, Hyper powers the Data Engine in Tableau Server, Tableau Desktop, Tableau Online, and Tableau Public. The Data Engine is used when creating, refreshing or querying extracts. It is also used for cross-database joins to support federated data sources with multiple connections.

In this article

Memory and CPU usage
Server configuration, Scalability, and Performance

Memory and CPU usage

The Data Engine is designed to leverage all available CPU and memory on the machine to provide the fastest response times.
CPU usage

Hyper technology leverages the new instruction sets in CPU and is capable of parallelizing and scaling to all the available cores. Hyper technology is designed to scale to many cores efficiently, and also to maximize the use of each single core as much as possible. This means that you can expect to see the CPU being fully used during query processing. Adding more CPU is expected to result in performance improvement.

Modern operating systems such as Microsoft Windows, Apple macOS, and Linux have mechanisms to make sure that even if a CPU is fully used, incoming and other active processes can run simultaneously. In addition, to manage overall resource consumption and to prevent overloading and completely starving other processes running on the machine, the Data Engine monitors itself to stay within the limits set in the Tableau Server Resource Manager (SRM). Tableau Server Resource Manager monitors the resource consumption and notifies Data Engine to reduce the usage when it exceeds the predefined limit.

Since the Data Engine is designed to utilize the available CPU, it is normal to see spikes in CPU usage at times. If however, you see high CPU usage (ex: 95%) for extended periods of time (an hour or more), this can mean a couple of things:

- There is a high load of queries. This can happen if a server is under stress due to overload of multiple client requests and the queries are queueing up. If this happens often, it is an indication that more hardware is required to serve the clients. Adding more CPU in this case should help to improve performance.

- There is one long running query. In this case, the Tableau Server resource Manager will stop long running queries based on the timeout settings. This was also true for the Tableau Server versions earlier than version 10.5

For more information on Tableau Server Resource Manager, see General Performance Guidelines.
Memory usage

Memory usage of the Data Engine depends on the amount of data required to answer the query. The Data Engine will try to run this in-memory first. A working set memory is allocated to store an intermediate data structure during query processing. In most cases, systems have enough memory to do these types of processing, but if there isn't enough available memory, or if more than 80% of RAM is utilized, the Data Engine shifts to spooling by temporarily writing to disk. The temporary file get deleted after the query has been answered. Therefore, spooling is an indication that more memory may be needed. Memory usage should be monitored and upgraded appropriately to avoid performance issues caused by spooling.

To manage memory resources on the machine, the maximum memory limit for Data Engine is set by Tableau Server Resource Manager (SRM).

Server configuration, Scalability, and Performance

- A single instance of Data Engine is automatically installed per node where an instance of File Store, Application Server (VizPortal), VizQLServer, Data Server, or Backgrounder is installed. The Data Engine can scale by itself and uses as much CPU and memory as needed, thus removing the need for multiple instances of the Data Engine. For more information on the server processes, see Tableau Server Processes.

- The instance of Data Engine installed on the node where File Store is installed is used for querying data for view requests. The instance of Data Engine installed on the node where backgrounder is installed is used for extract creation and refreshes. This is an important consideration when you are doing performance tuning. For more information, see Performance Tuning Examples.

- Data Server, VizQL Server, and the Application Server (VizPortal) all use the local instance of Data Engine to do cross-database joins and create shadow extracts. Shadow extract files are only created when you work with workbooks that are based
on non-legacy Excel or text, or statistical files. Tableau creates a shadow extract file in order to load the data more quickly.

- In Tableau Server 10.5 one instance of Data Engine is installed automatically when you install backgrounder. The backgrounder process uses the single instance of Data Engine (hyperd.exe) installed on the same node.

Scalability:

You can scale up with the new Data Engine: Since cores are fully utilized, adding more cores makes individual queries execute faster which in turn allows for more queries to execute in less time.

Memory usage should be monitored and upgraded appropriately to avoid the performance issues caused by spooling.

For more information on Scalability, see Tableau Server Scalability.

Performance:

As mentioned in the beginning of this topic, in most cases you can expect to see performance improvements when you upgrade to Tableau 10.5 or later. However, in some cases you may see performance issues like slower response times, especially for workbooks with complex calculations. To test your workbooks to see if should expect performance issues, we recommend that you test this before you upgrade. For more information, see Test Workbook Performance. If you have already upgraded your Tableau Server, see Troubleshoot Performance of Workbooks with Calculations.

For more information on performance, start with General Performance Guidelines, and Performance Tuning

Performance benefits

Starting in 10.5, Hyper technology has been integrated with Tableau Data Engine to give you the following key benefits:
• **Faster extract creation**: With Hyper technology, extracts are generated almost as fast as the source system can deliver data, no sorting needed.

• **Support for larger extracts**: Prior to this release, you might have not been able to get all your data into a single extract. With Hyper technology, much larger amounts of data can be included in a single extract.

• **Faster analysis of extracts**: In many cases you will see faster querying of data for larger extracts, or workbooks with complex calculations.

Here are some reasons why the Data Engine powered by Hyper performs better on larger or complex extracts and is optimized for faster querying:

• **Hyper technology is designed to consume data faster**. Unlike in previous versions, the Data Engine does not do any post processing like sorting. With Hyper, post processing steps like sorting are not needed giving the Data Engine the ability to perform better with larger extracts.

• **Hyper technology is memory-optimized**. This means that when needed, all data lives in memory. This results in fast data access times.

• **Hyper technology is CPU optimized**. This means that Data Engine now fully parallelizes the query execution and utilizes available CPU in such a way that query execution time scales almost linearly with the number of cores in the machine.

• **Hyper is a compiling query engine**. Queries are either interpreted or compiled to the machine code for maximum performance and allowing the Data Engine to get most performance out of modern hardware (CPU, large main-memory capacities).

• **Hyper technology uses advanced query optimizations to make queries faster**. Along with many additional advanced techniques such as, materializing min and max values for each column, mini-indices to optimize search ranges, more granular data block-level dictionaries, advanced logic for join and sub-query performance optimizations, the new Data Engine offers many improvements over the previous Tableau Data Engine in terms of performance and scalability.
**Tableau Server File Store**

The Tableau Server File Store process controls the storage of extracts. When the file store is installed, an instance of the Data Engine is also installed unless the node already has an instance of the data engine. In highly available (HA) environments, the File Store ensures that extracts are synchronized to other file store nodes so they are available if one file store node stops running.

<table>
<thead>
<tr>
<th>Process</th>
<th>File Store</th>
</tr>
</thead>
<tbody>
<tr>
<td>File name</td>
<td>filestore.exe</td>
</tr>
<tr>
<td>Status</td>
<td>Status of the File Store process is visible on the Status Page. For more information, see View Server Process Status</td>
</tr>
<tr>
<td>Logging</td>
<td>Logs generated by the repository are located in /var/opt/tableau/tableau_server/data/tabsvc/logs/filestore. For more information, see Server Log File Locations</td>
</tr>
</tbody>
</table>

The decommission Command

If you want or need to remove a file store you should decommission the file store first, using the tsm topology filestore decommission command. If you don't decommission the filestore before you attempt to remove it, you will be prompted to do so. Decommissioning puts the file store into read-only mode and copies any unique data contained in the file store to the other file store(s) in the cluster. While a file store is being decommissioned, this shows on the Status page, and once all unique content has been copied to other file store nodes, the decommissioned node shows as ready to be removed.

**Tableau Server Gateway Process**

The Tableau Server gateway process is an Apache web server component (httpd.exe). Its role is to handle requests to the server from all clients—Tableau Desktop, mobile devices, a proxy, a load balancer, etc.
The server runs a single instance of the gateway process; you can't run more than one per machine.

<table>
<thead>
<tr>
<th>Process</th>
<th>Gateway</th>
</tr>
</thead>
<tbody>
<tr>
<td>File name</td>
<td>httpd.exe</td>
</tr>
<tr>
<td>Status</td>
<td>Status of the Gateway is visible on the Status Page. For more information, see View Server Process Status</td>
</tr>
<tr>
<td>Logging</td>
<td>Logs generated by the repository are located in /var/-opt/tableau/tableau_server/data/tabsvc/logs/httpd. For more information, see Server Log File Locations</td>
</tr>
</tbody>
</table>

Port assignment

By default, the gateway process listens for requests on port 80 (for HTTP requests) and 443 (for SSL requests). When you install Tableau Server on a computer, part of the server configuration makes sure that this port is open in the computer's firewall. If the computer is running a different process that requires port 80 for HTTP, you can change the port assignment for the gateway process during installation. (You cannot change the SSL/HTTPS port.)

If you need to set the HTTP port after installation, then run the following TSM command, where node is the node number (for example, node1) and nn is the new port number:

tsm topology set-ports --node-name node --port-name gateway:primary --port-value nn
If you are running Tableau Server with a reverse proxy server, you will need to configure other port and host-related settings on Tableau Server. See Configuring Proxies for Tableau Server.

Log files for the gateway process

The gateway process creates two sets of log files:

- **Activity logs.** The name for these log files has the format `access.yy_mm_dd_hh_mm_ss.log`.

- **Error logs.** All errors are logged in a single file named `error.log`.

For more information, see Log File Snapshots (Archive Logs).

Gateway processes in a cluster

If your server environment is distributed across multiple machines, you can run a single gateway process on each node of the cluster. The most common scenario for running a gateway process on multiple computers in the cluster is that you have a load balancer in front of the cluster. In this scenario, the load balancer distributes requests to any gateway in the cluster. If you need to take a node off line (for example, to perform maintenance on that node), you can disable the load balancer’s routing to that machine. When the maintenance is complete, you can re-enable the node on the load balancer.

You must have a gateway process running on at least one computer in the cluster. If you remove the gateway process from the primary server, you must make sure that another computer in the cluster is running the gateway process. You must also make sure that that computer is reachable by clients.

If the Tableau Server is configured to use SSL, you must make sure that the certificate for SSL support is in the same location on each computer in the cluster that has the gateway process running. For more information about using SSL, see Configure SSL for External HTTP Traffic to and from Tableau Server.
Similarly, if the server installation uses a custom logo, the logo must be in the same location on every computer that is running the gateway process.

If you need to change the port number that the gateway process listens on, as explained earlier, you can use the configuration dialog box or run the following command for each worker computer that is running the gateway process:

```bash
tsm topology set-ports --node-name node --port-name gateway:primary --port-value nn
```

Configuring Proxies for Tableau Server

Add a Load Balancer

Tableau Server Repository

Tableau Server Repository is a database that stores server data. This data includes information about Tableau Server users, groups and group assignments, permissions, projects, data sources, and extract metadata and refresh information.

<table>
<thead>
<tr>
<th>Process</th>
<th>Repository</th>
</tr>
</thead>
<tbody>
<tr>
<td>File name</td>
<td>postgres.exe</td>
</tr>
<tr>
<td>Status</td>
<td>Status of the Repository is visible on the Status Page. For more information, see View Server Process Status</td>
</tr>
<tr>
<td>Logging</td>
<td>Logs generated by the repository are located in <code>/var/-opt/tableau/tableau_server/data/tabsvc/logs/pgsql</code>. For more information, see Server Log File Locations</td>
</tr>
</tbody>
</table>

Preferred active repository

When you configure Tableau Server you have the option to specify a node as the preferred active repository. When Tableau Server is configured for repository failover, the preferred active repository node is the one used for the active repository. This is an optional step, and if
you do not specify a preferred active repository node, Tableau Server will select the active repository node on startup.

To configure the preferred active repository, use the `tsm configuration set` command to configure the `pgsql.preferred_host` option:

```
 tsm configuration set -k pgsql.preferred_host -v "<host_name>"
```

**Note:** The `host_name` is case-sensitive and must match the node name shown in the output of `tsm status -v`.

Configure a preferred active repository node if you want Tableau Server to select a specific node on startup. You might want to do this if you have a particular server you want to use for your active repository (a computer with more disk space or memory for example), or if you are using custom administrative views. Custom administrative views have embedded connection information that refers to the repository for which you created the views. For more information on connecting to the Tableau Server repository, see Collect Data with the Tableau Server Repository.

**The failoverrepository Command**

If failover occurs and your passive repository becomes the active repository, it remains the active repository until either Tableau Server restarts or you use the `tsm topology failover-repository` command to switch back. Specify the repository you want to be the active one, or specify that the preferred active repository (if configured) should be made active again. For more information, see `tsm topology failover-repository`.

**Tableau Server Dynamic Topology Changes**

With the introduction of TSM, Tableau Server also introduced the ability to make certain topology changes or updates without restarting the server. These are known as dynamic
topology changes, and are possible with the backgrounder and VizQL Server processes.

You can increase or decrease the number of backgrounder or VizQL Server instances on a node that already has at least one of these processes running, without any Tableau Server downtime. If you have a node already running backgrounder, you add additional instances of backgrounder or VizQL Server to the node without restarting Tableau. You can do the same with VizQL Server node running VizQL Server, adding or removing instances of either backgrounder or VizQL Server. You must be only changing the number of instances of backgrounder or VizQL Server. If you also add or remove another process, you need to restart Tableau Server. For example, if you have a node running four instances of VizQL Server, you can remove all those instances and add one or more instances of backgrounder instead, without restarting Tableau Server, taking advantage of dynamic topology changes.

Example Scenarios

To better understand why this might be useful, consider these examples:

- **Backgrounder**—At the end of a sales quarter your sales team is using Tableau Server to keep track of their numbers. Dashboards that depend on extracts are showing sales people how they are doing. Any delay in extract refreshes means your team is not seeing the most up-to-date numbers. You can add additional backgrounders to any node that already has at least one backgrounder or VizQL Server, and increase the throughput of extract refreshes, helping to guarantee the numbers are up-to-date as your team finished up their quarter. Later, after the quarterly push, you can reduce the backgrounder instances again to return Tableau Server to its original configuration.

- **VizQL Server**—Similarly, if Tableau Server is unable to keep up with view refreshes, you can quickly add additional VizQL Server instances to any node that already has at least one instance of either VizQL Server or backgrounder configured. In the above backgrounder example, you might want to remove VizQL Servers temporarily, to accommodate additional backgrounders, and then re-add them back before your users arrive in the morning.

Making dynamic topology changes

You can make dynamic topology changes using the TSM Web UI, or on the command line. To use the Web UI, sign in to TSM using a browser, and on the Configuration tab, update the number of backgrounder or VizQL Server instances for the node you are updating. For
details, see Configure Nodes. To make your changes using the TSM CLI, at a command prompt, run the `tsm topology set-process` command. For details, see Changing the number of processes on a node.

Automating dynamic topology changes

You can automate dynamic topology changes. For example, if you have most of your extract refreshes scheduled overnight, and know your server has extra capacity because users are not signed in, you can use a script or other automated deployment tool to add backgrounder instances when they can be most efficiently used, and then remove them before the start of the work day.

A sample script to set four instances of backgrounder on node2 might look like this:

```
    echo Adding/Removing Processes
    tsm topology set-process -pr backgrounder -n node2 -c 4
    tsm pending-changes apply
    echo Done!
```

Additional information

Tableau Server Processes

Server Process Limits

When you reconfigure processes for Tableau Server, there is a limit to the amount that you can increase the number of process instances. By default, the limit is set to eight. If your machine has enough RAM and CPU cores, and you want to go above this limit, you can change the limit using the `service.max_procs` configuration option. For each process instance, Tableau recommends that the machine running the process have at least 1 GB of RAM and 1 logical CPU core.

To change the maximum number of processes allowed:

1. Type the following command, where `number` is the maximum number of process instances you want to allow:
tsm configuration set -k service.max_procs -v <number>

For example:

```
tsm configuration set -k service.max_procs -v 10
```

2. Next type:

```
tsm pending-changes apply
```

The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. For more information, see `tsm pending-changes apply`.

Tableau Services Manager Ports

The processes and services that make up the components of Tableau Services Manager (TSM) and Tableau Server on Linux use various ports to communicate. By default, most these ports are assigned (mapped) dynamically from a predefined range of ports. The port assignments are made for each service or process when it is installed. You can control what ports are used in a variety of ways.

A small subset of processes do not use dynamic port mapping and behave uniquely. For more information, see Ports that are not dynamically mapped, below.

**Note:** This operation includes steps that you may need to perform using the TSM command line.

Port assignment

There are two approaches you can use for port assignment or mapping in TSM:
• **Dynamic port assignment.** This is the default and requires the least intervention by the administrator.

• **Manual port assignment.** This option requires an administrator to individually assign each port.

If you change port assignments and you are running a local firewall, see Local firewall configuration.

**Dynamic port assignment**

You can control which ports are used by changing the range of ports available to the dynamic assignment process. Doing this leaves dynamic port assignment in place but restricts the ports that can be chosen. With dynamic port assignment in place, you can still choose to assign ports for certain processes manually. This approach enables you to assign specific ports to specific processes, while leaving the others to be mapped dynamically. Using dynamic mapping, with or without some individually assigned ports is the easiest approach, and should satisfy the requirements of most customers. Dynamically assigned ports are preserved if you export your Tableau Server configuration.

By default, ports are assigned for each service or process from available ports between 8000 to 9000. This assignment takes place when services are installed for the first time on a node. After Tableau Server is initialized, you can see which ports are being used by which services or processes by running this command:

```bash
tsm topology list-ports
```

If you have a multi-node cluster, ports on all nodes are listed.

**Changing the port range**

For organizations that have specific requirements for ports being used, the easiest way to control this is to change the range from which ports are dynamically selected. You need to do this at installation, by specifying a minimum and maximum port for the range in your configuration file.
Note: The minimum allowable size of your port range will depend on your server installation and how many services or processes you are running. As a general best practice you should not restrict the range too tightly because port assignment is done by selecting random ports within the range, and if you do not allow a large enough range, selection may fail to find an available port.

To limit the range from which available ports are chosen to those between 8300 and 8600, your configuration file would include an entry similar to this:

```
"configKeys": {
    "ports.range.min": "8300",
    "ports.range.max": "8600"
}
```

Disabling dynamic port assignment

If you need more control of port assignment than you can get through a combination of restricting port range and individually assigning ports, you can disable dynamic port mapping at initial server configuration. Disabling dynamic port mapping requires you to manually assign every port for every process, so we don’t recommend this unless you need to control every single port assignment.

If you disable dynamic port mapping, you must configure the port for each process on each node of your installation.

To disable dynamic mapping, your configuration file would include an entry similar to this:

```
"configKeys": {
    "service.port_remapping.enabled": false
}
```
Important: When you disable dynamic port assignments, the License service port range is not included. This range (27000-27009) must be open on the node running the License service and accessible from other nodes. By default, the initial node runs the License service.

Manual port assignment

You can disable automatic port assignment entirely and assign a port for each process individually. If you do this, you must assign a port for every process on every node. You can assign ports either in a configuration file, when the processes are first installed, or after installation, using a TSM command. Only ports assigned at process installation are preserved if you export your Tableau Server configuration.

You can specify individual ports for specific processes, whether or not dynamic mapping is enabled. You might do this if you want a process to use a particular port, or if you’ve disabled dynamic mapping. There are two ways to specify ports for processes:

- At install, using a configuration file. This is similar to defining a non-default port range, but instead you specify a particular port for a specific service or process. If you are going to assign specific ports, this approach is the most robust way to do so because the port mapping is preserved if you export the server configuration and topology settings using the `tsm settings export` command.

To define ports at installation, add information to your configuration file to specify the node (`workerN`), process (`servicename`) and instance ID (`instanceid`), port type (`porttype`), and the port to be used. The format looks like this:

`workerN.{servicename}_{instanceid}.porttype.port:X`

Where:

- `workerN` is an optional parameter and identifies the node for which the remapping applies. Node numbers start with zero (0).
  We recommend you do not include this parameter unless you need to map
different ports for the same service on different nodes. If you leave this parameter off, you can map a service port on the initial node, or map the same service port on multiple nodes.

- servicename is the name of the process or service that will use the port.
- instanceid is the instance of the process. If you are going to be configuring multiple instances of a process on one node, you would need to increment this value for each instance. Start the instanceid at zero (0) and increment it by one (1) for each instance of the process. For services that only install a single instance on any given node, this must be left off.
- porttype If setting the primary port, do not include this option.
- port is the port the process or service should use.

For example, to set the port for the first instance of the file store process on the initial node to 8500, you would include a configuration file entry similar to this:

```
"configKeys": {
   "filestore_0.port": "8500"
}
```

The example above does not include the optional workerN parameter, so sets the port on all nodes in the cluster. It also leaves off the porttype option because it is setting the primary filestore port.

**Important:** When specifying port changes with a configuration file, you must include the `--force-keys` parameter with the `tsm settings import` command.

- After install, using the `tsm topology set-ports` command. This approach allows you to specify a port for a specific process after that process has been installed. You are restricted by these limits:
  
  - You must set ports individually, on each node.
  - The port assignments are not preserved if you need to import a Tableau Server configuration using `tsm settings import`.  
  
- 1317 -
To set second instance of the file store on the initial node to use port 8500:

```bash
tsm topology set-ports --node-name node1 --port-name filestore --port-value 8500
```

Ports that are not dynamically mapped

The Tableau Server repository uses two ports that are not dynamically mapped. These each have a default port that you can override using the `tsm configuration set` command and a process-specific parameter.

<table>
<thead>
<tr>
<th>Port names</th>
<th>Port (default)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pgsq1l.port</td>
<td>8060</td>
<td>Port for the Tableau Repository (PostgreSQL database). To override this port:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>tsm configuration set -k pgsq1l.port &lt;port&gt;</code></td>
</tr>
<tr>
<td>pgsq1l.verify_restore.port</td>
<td>8061</td>
<td>Port for verifying the integrity of a repository backup. To override this port:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>tsm configuration set -k pgsq1l.verify_restore.port &lt;port&gt;</code></td>
</tr>
</tbody>
</table>

Because these ports do not use the dynamic port mapping system, they do not show up in the output of the `tsm topology list-ports` command. To see the value of these you need to use the `tsm configuration get -k <config.value>` command. For example:

```bash
tsm configuration get -k pgsq1l.port
```
Controlling port remapping with initialize-tsm

Port assignments are made when services are installed. This means that in order to manually map ports for the TSM-specific processes, you need to assign the ports when you run the initialize-tsm script. The script includes options to specify ports for individual TSM services, as well as options for defining the minimum and maximum of the port range used with dynamic mapping, and you can disable dynamic mapping.

The table below lists the options for ports when running the initialize-tsm script.

Table: initialize-tsm script port options

<table>
<thead>
<tr>
<th>Script option</th>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-i</td>
<td>&lt;port&gt;</td>
<td>Sets the Coordination Service client port.</td>
</tr>
<tr>
<td>-e</td>
<td>&lt;port&gt;</td>
<td>Sets the Coordination Service peer port.</td>
</tr>
<tr>
<td>-m</td>
<td>&lt;port&gt;</td>
<td>Sets the Coordination Service leader port.</td>
</tr>
<tr>
<td>-n</td>
<td>&lt;port&gt;</td>
<td>Sets the TSM agent file transfer port.</td>
</tr>
<tr>
<td>-o</td>
<td>&lt;port&gt;</td>
<td>Sets the TSM Controller port.</td>
</tr>
<tr>
<td>-l</td>
<td>&lt;min-port&gt;</td>
<td>Sets the bottom of the port range used for dynamically mapping ports.</td>
</tr>
<tr>
<td>-r</td>
<td>&lt;max-port&gt;</td>
<td>Sets the top of the port range used for dynamically mapping ports.</td>
</tr>
<tr>
<td>Script option</td>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>--disable-port-remapping</td>
<td></td>
<td>Disables dynamic port mapping. If you do this you must assign ports for every service or process used by TSM and Tableau Server. For more information, see Manual port assignment above.</td>
</tr>
</tbody>
</table>

Dynamically mapped ports

This table lists the processes or services that use dynamically mapped ports.

<table>
<thead>
<tr>
<th>Port names</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>You must define each of these for every node if you disable dynamic port mapping.</td>
<td></td>
</tr>
<tr>
<td>appzookeeper_0.client.port</td>
<td>Coordination Service client port.</td>
</tr>
<tr>
<td>appzookeeper_0.peer.port</td>
<td>Coordination Service peer port.</td>
</tr>
<tr>
<td>appzookeeper_0.leader.port</td>
<td>Coordination Service leader port.</td>
</tr>
<tr>
<td>backgrounder_0.port</td>
<td>Backgrounder primary port.</td>
</tr>
<tr>
<td>backgrounder_0.debug.port</td>
<td>Backgrounder debug port.</td>
</tr>
<tr>
<td>backgrounder_0.jmx.port</td>
<td>Backgrounder jmx port.</td>
</tr>
<tr>
<td>backgrounder_0.jmx.rmi.port</td>
<td>Backgrounder jmx rmi port.</td>
</tr>
<tr>
<td>backgrounder_0.recommendations.trainer.port</td>
<td>Backgrounder recommendations port.</td>
</tr>
<tr>
<td>backuprestore.port</td>
<td>Backup/Restore service port.</td>
</tr>
<tr>
<td>cacheserver_0.port</td>
<td>Cache server port.</td>
</tr>
<tr>
<td>Port names</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>clustercontroller.status.port</td>
<td>Cluster Controller status port.</td>
</tr>
<tr>
<td>clustercontroller.storage.port</td>
<td>Cluster Controller storage port.</td>
</tr>
<tr>
<td>databasemaintenance.port</td>
<td>Database Maintenance port.</td>
</tr>
<tr>
<td>dataserver_0.port</td>
<td>Data server primary port.</td>
</tr>
<tr>
<td>dataserver_0.debug.port</td>
<td>Data server debug port.</td>
</tr>
<tr>
<td>dataserver_0.jmx.port</td>
<td>Data server jmx port.</td>
</tr>
<tr>
<td>dataserver_0.jmx.rmi.port</td>
<td>Data server jmx rmi port.</td>
</tr>
<tr>
<td>filestore.port</td>
<td>File store primary port.</td>
</tr>
<tr>
<td>filestore.status.port</td>
<td>File Store status port.</td>
</tr>
<tr>
<td>gateway.port</td>
<td>Gateway port. This defaults to 80, and if that is not available, to 8080. If that is not available, it tries 8000. That sequence is followed whether or not dynamic port assignment is enabled or not. If none of those ports are available and dynamic mapping is enabled, it takes an available port within the defined range. The gateway port must be the same on all nodes in a multi-node cluster, so if port 80 is selected on the initial node this is the port that will be used on all nodes and if it is unavailable on one of the other nodes, gateway port selection will fail.</td>
</tr>
<tr>
<td>hyper.port</td>
<td>Data engine primary port.</td>
</tr>
<tr>
<td>hyper.connection.port</td>
<td>Data engine connection port.</td>
</tr>
<tr>
<td>licenseservice.vendor_dae-</td>
<td>License service vendor daemon port. Used for licensing-related communications between nodes in a multi-node installation.</td>
</tr>

</table>

Enable the JMX Ports

To help you work through a problem with Tableau Server, Tableau Support may ask you to enable the server’s JMX ports. These ports can be useful for monitoring and troubleshooting, usually with a tool like JConsole.

To enable the JMX ports on Tableau Server:

1. Stop the server.
2. Enter the following command:
   ```
   tsm configuration set -k service.jmx_enabled -v true
   ```
3. Apply pending changes:
   ```
   tsm pending-changes apply
   ```

   The `pending-changes apply` command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt
using the --ignore-prompt option, but this does not change the restart behavior. For more information, see tsm pending-changes apply.

4. Start the server.

**Important** Enabling JMX ports can introduce some security risk. To mitigate this risk, it is important to limit access to the JMX ports to the fewest number of clients that's practical for your scenario. You typically limit access using the host's firewall rules, an external security device, or routing rules.

How the JMX Ports Are Determined

By default, the JMX ports assigned dynamically, from within a range of available ports. For details on how port assignment is done, and how to override dynamic mapping, see Tableau Services Manager Ports.

**Help Output for initialize-tsm Script**

The following help content is the output when you run the following command:

```
sudo ./initialize-tsm -h
```

The initialize-tsm script is installed to /opt/tableau/tableau_server-/packages/scripts.<version_code>/.

**Output**

**REQUIRED**
--accepteula Indicate that you have accepted the End User License Agreement (EULA).

You can find the EULA in /opt/tableau/tableau_server-/packages/docs.<version_code>

**OPTIONAL**
-c config-name Set the service configuration name.
If not set, the default is "tabsvc".

-d data-directory
Set a custom location for the data directory if it's not already set. If not set, the default is "/var/opt/tableau/tableau_server".

-b bootstrap-file
Optional. Location of the bootstrap file downloaded from the Tableau Services Manager on existing node. Must be provided to join existing Tableau Server cluster.

-u username
Name of the user with admin privileges on existing Tableau Services Manager. Required if -b option specified.

-p password
Password for the Tableau Services Manager admin user.

-f
Bypass warning messages.

-g
Do NOT add the current user to the "tsadmin" administrative group, used for default access to Tableau Services Manager or to the "tableau" group, used for easier access to log files.

-a username
The provided username will be used as the user to be added to the appropriate groups, instead of the user running this script. Providing both -a and -g is not allowed.

-q
Quiet, suppress output except for errors and warnings.
-i coordinationservice-client-port Client port for the coordination service

-e coordinationservice-peer-port Peer port for the coordination service

-m coordinationservice-leader-port Leader port for the coordination service

-n agent-filetransfer-port Filetransfer port for the agent service

-o controller-port Https port for the controller service

-l port-range-min Lower port bound for automatic selection

-r port-range-max Upper port bound for automatic selection

--disable-port-remapping Disable automatic port selection

--unprivileged-user=<value> Name of the unprivileged account to run Tableau Server. Default: "tableau".

--tsm-authorized-group=<value> Name of the group(s) that allows authorization to access Tableau Services Manager. Default: "tsmadmin".

--disable-account-creation Do not create groups or
user accounts for Server and TSM authorization. However, the values in: unprivileged-username, privileged-username, and tsm-authorized-groupname will still be used in TSM configuration.

--debug Print each command as it is run for debugging purposes. Produces extensive output.

View Server Version

The version of Tableau Server you are running is important. It determines the functionality and capabilities you have access to. Version is also important when you are upgrading, because in some cases how you upgrade depends on which version you are upgrading from, and which version you are upgrading to. Knowing your version is easy, once you understand how to find it.

- Viewing version in Tableau Server—All server users can view the version of Tableau Server from the Help menu in the server web UI.
- Viewing version in Tableau Services Manager (TSM)—TSM administrators can view the versions of TSM and Tableau Server from the TSM command line (CLI).

Viewing the server version from the Tableau Server web UI

- While logged into Tableau Server, click the information icon (i) and About Tableau Server.
The version of Tableau Server is listed in the About Tableau Server dialog box:

Viewing the server version and TSM version from the TSM command line

1. Open a command prompt as administrator on the initial node (the node where TSM is installed).

2. Run the following command:

   `tsm version`

The output displays the versions of Tableau Services Manager (TSM) and Tableau Server.

For example:

```
C:\>tsm version
Tableau Services Manager command line version
20182.18.1214.0751.
Tableau Server version 20182.18.1214.0751.
```
Short version, long version, and version_code

In most cases, when you need to know your version number, you need to know the "short" version. This version number displays in the About Tableau Server dialog box and is made up of three parts: major, minor, and maintenance versions. The short version number has this format: nnnn.n.n. For example: 2018.2.5.

A longer version includes the major and minor version numbers, as well as other build-specific information, and has this format: nnnnn.nn.nnnn.nnnn, for example: 20182.18.1214.0751. When you see a reference to <version_code> in this documentation, it means this longer version. The most common reference to this version_code or long version in the documentation is when we are discussing install locations or paths to the scripts or bin directories.

Tableau Server is installed in a /packages directory, with subdirectories that include the long version in the path name. This means that when you are navigating to a location within the /packages directory, you need to include the long version. For example, the /scripts directory: /opt/tableau/tableau_server-/packages/scripts.<version_code>/.

For example: /opt/tableau/tableau_server-/packages/scripts.20182.18.1214.0751

Finding the long version number

This longer version also displays in the About Tableau Server dialog box, in parentheses:
Manage Dashboard Extensions in Tableau Server

Dashboard extensions are web applications that run in custom dashboard zones and can interact with the rest of the dashboard using the Tableau Extensions API. Dashboard extensions give users the ability to interact with data from other applications directly in Tableau.

**Note:** You must be a server administrator to enable dashboard extensions on the server, or to block specific extensions from running. You must be a server administrator to add extensions to the safe list and to control the type of data the extensions can access. The server administrator can also configure whether users on the site will see prompts when they add or view extensions in a dashboard.

For information about using dashboard extensions in Tableau, see Use Dashboard Extensions.

- Test extensions for security
Before you run extensions on Tableau Server

Dashboard extensions are web applications and could be running on any computer set up as a web server. This includes local computers, computers in your domain, and third-party web sites. Because extensions could be hosted on third-party sites and could have access to the data in the dashboard, you want to only allow the extensions you trust. See Test extensions for security.

For security, the default settings for dashboard extensions on Tableau Server limit the dashboard extensions that are allowed to run.

- By default, only extensions that use the HTTPS protocol are allowed, which guarantees an encrypted channel for sending and receiving data (the only exception is for http://localhost).

- By default, when extensions are enabled on Tableau Server, only extensions that require summary data (the aggregated data) from the view are allowed.

- If the extension requires full data (access to the underlying data) the extension will not be able to run on Tableau Server unless you explicitly add the extension to the safe list and grant the extension access to full data.

Control dashboard extensions access to data

Server administrators can control a global setting to allow extensions for all sites on the server. Server administrators can also put extensions on a global block list to prevent them from running. By default, extensions are enabled on the server (with the constraints previously described). To change this setting for the server, go to Manage All Sites > Settings > Extensions. If the server just has a single site, the global controls appear on the settings page for the site.

Server administrators can control whether to enable extensions for the site and whether to enable the default behavior (or policy) for extensions. That is, the default policy is that only extensions that request summary data are allowed to run on the site, and that all users will
see prompts asking for permission to run. To change these settings for the site go to Settings > Extensions.

Server administrators can add or remove extensions from the safe list for a site. When you add an extension to the safe list, you can control whether to allow the extension to have access to full data.

Identifying an extension

As a web application, an extension is associated with a URL. You use this URL to test and verify the extension. You also use the URL to add the extension to the safe list to allow full data access, or to the block list to prohibit any access.

If you have the extension manifest file (.trex), an XML file that defines properties for the extension, you can find the URL from the <source-location> element.

```xml
<source-location>
    <url>https://www.example.com/myExtension.html</url>
</source-location>
```

If you have added the extension to the dashboard, you can find the URL from the extension properties. From the More Options menu, click About.
The About dialog box lists the name of the extension, the author of the extension, the website of the author, along with the URL of the extension.

Add extensions to the safe list and configure user prompts

To ensure that users can use extensions that are trusted, you can add them to the safe list for the site.

On the safe list, you can control whether to grant the extension full data access. You can also control whether users will see a prompt asking them to allow the extension access to data. If the extension does not require full data access, you don’t need to add it to the safe list. However, you might want to add an extension to the safe list so that you can configure whether or not users see the prompts. When you hide the prompt from users, the extension can run immediately.

1. Go to Settings > Extensions.

2. Under Enable Specific Extensions, add the URL of the extension. See Identifying an extension.

3. Choose to Allow or Deny the extension Full Data Access.

   Full data access is access to the underlying data in the view, not just the summary or aggregated data. Full data access also includes information about the data sources, such as the names of the connection, fields, and tables. In most cases, if you are
adding an extension to the safe list so that it can run, you will also want to allow the extension to have access to full data, if the extension requires it. Before adding extensions to the safe list, be sure to Test extensions for security.

4. Choose to Show or Hide the User Prompts.

Users see the prompts by default when they are adding an extension to a dashboard, or when they are interacting with a view that has an extension. The prompt tells users details about the extension and whether the extension has access to full data. The prompt gives users the ability to allow or deny the extension from running. You can hide this prompt from users, allowing the extension to run immediately.

Block specific extensions

The default global policy allows unknown extensions to run, provided that they only access summary data. Server administrators can keep specific extensions from running by adding them to the block list for the server. If an extension is on the global block list it overrides any settings for the extension on the safe list for a site.

1. To add an extension to the blocked list for the server, go to Manage All Sites > Settings > Extensions. On single-site installations, the block list is on the site Extensions settings page.

2. Under Block Specific Extensions, add the URL of the extension. See Identifying an extension.

Test extensions for security

Dashboard extensions are web applications that interact with data in Tableau using the Extensions API. Dashboard extensions contain JavaScript and could be hosted on sites outside of your domain. Because of this and the potential vulnerabilities, such as cross-site scripting, you should test and vet dashboard extensions before users use them in dashboards on Tableau Desktop, and before you allow extensions on Tableau Server.
Examine the source files

Dashboard extensions are web applications and include various HTML, CSS, and JavaScript files, and an XML manifest file (*.trex) that defines the properties in the extension. In many cases, the code for a dashboard extension is publicly available on GitHub and can be examined there or downloaded. In the manifest file (*.trex), you can find the source location, or URL indicated where the extension is hosted, the name of the author, and the website of the author or company to contact for support. The `<source-location>` element specifies in the URL, the `<author>` element, specifies the name of the organization and the web site to contact for support (website="SUPPORT_URL"). The web site is the Get Support link user see in the About dialog box for the extension.

Many dashboard extensions reference external JavaScript libraries, such as the jQuery library or API libraries for third parties. Validate that the URL for external libraries points to a trusted location for the library. For example, if the connector references the jQuery library, make sure that the library is on a site that is considered standard and safe.

All extensions are required to use HTTPS protocol (https://) for hosting their extensions. You should examine the source files for the extension to ensure that any reference to external libraries is also using HTTPS or is hosted on the same web site as the extension. The one exception to the requirement of HTTPS is if the extension is hosted on the same computer as Tableau (http://localhost).

To the extent possible, make sure you understand what the code is doing. In particular, try to understand how the code is constructing requests to external sites, and what information is being sent in the request. In particular, check if any user-supplied data is validated to prevent cross-site scripting.

Understand data access

The Tableau Extensions API provides methods that can access the names of the active tables and fields in the data source, the summary descriptions of the data source connections, and the underlying data in a dashboard. If an extension uses any of these methods in a view, the extension developer must declare that the extension requires full data permission in the manifest file (*.trex). The declaration looks like the following.
Tableau uses this declaration to provide a prompt to users at run time that gives them the option of allowing this access or not. If the extension uses any one of these four methods, without declaring full-data permission in the manifest file, the extension will load but the method calls will fail.

For information about how an extension accesses data from the dashboard, and the JavaScript methods used, see Accessing Underlying Data in the Tableau Extensions API. To get a better understanding about what the extension can find out about the data, you can use the DataSources sample dashboard extension (available from the Tableau Extensions API GitHub repository) to see what data is exposed when the `getDatasourcesAsyncc()` method is called.

Test the extension in an isolated environment

If possible, test the dashboard extension in an environment that is isolated from your production environment and from user computers. For example, add a dashboard extensions to a safe list on a test computer or virtual machine that’s running a version of Tableau Server that is not used for production.

Monitor traffic created by the dashboard extension

When you test a dashboard extension, use a tool like Fiddler, Charles HTTP proxy, or WireShark to examine the requests and responses that the extension makes. Make sure that you understand what content the extension is requesting. Examine the traffic to be sure that the extension is not reading data or code that is not directly related to the purpose of the extension.

Changing the Identity Store

Infrastructure or business changes may require you to change the identity store on Tableau Server. There are two kinds of identity stores: local and external. When you installed
Tableau Server you configured either a local identity store or an external identity store.

When you configure Tableau Server with a local identity store, all user and group information is stored and managed in the Tableau Server repository. In the local identity store scenario, there is no external source for users and groups.

When you configure Tableau Server with an external store, all user and group information is stored and managed by an external directory service. Tableau Server must synchronize with the external identity store so that local copies of the users and groups exist in the Tableau Server repository, but the external identity store is the master source for all user and group data. Examples of external identity stores are OpenLDAP and Active Directory.

For more information about the Tableau identity store, see Identity Store.

You can change from local store to an external store, or you can change from an external store to a local store. In either case, to change the identity store type, you complete these steps:

1. Uninstall (including manual deletion of directories) and then reinstall of Tableau Server. The procedure for full uninstall and clean install are at the end of this topic.
2. Restore content and permissions.

**Warning**

Changing the installation type on Tableau Server can be a complicated and time-consuming process. To avoid data loss or orphaning of content or users, you'll need to plan this process carefully. In all cases, user filters applied to workbooks and data sources will need to be updated manually after the change.

Most importantly, determine how you will transition content and permissions to the new identity store after you reinstall Tableau Server.
Methods for restoring content and permissions

The following list describes two methods for restoring content and permissions after you reinstall Tableau Server. Select the method that best fits with your environmental requirements.

- **Method 1: Use site export and import**—In this method, you start by exporting each site in your existing deployment. Then, you install the new server and configure it for the new identity store type. You then create new users in the default site on the new server. Finally, you import all the original sites. During the import stage, you can map the original identities to the new users that you created in the default site.

Because this method exports all content and permissions at each site, it is the best method for organizations that require a high fidelity replica of the content and permissions after the identity store change is complete. Some organizations require an identity store change as the result of an authentication change. In these cases, a different user name syntax is often a requirement in the new model. This method, which includes a process of mapping original user names to new names, provides flexibility for such scenarios.

- **Method 2: Fresh installation; users republish content**—In this method, you install a new version of Tableau Server and select the new identity store type during setup. You also create new sites. You then create users and give them access, and they republish their workbooks and data sources. Unlike the other method, in this one, you do not reuse any of your existing Tableau Server infrastructure.

This method is most appropriate for smaller deployments with fairly autonomous and data savvy users. From an administrative perspective, this method is the simplest, since you’re not actively porting over content. However, because you rely entirely on users to republish content, this method may not be successful for large organizations or for those where centralized oversight of content is required.

User filters

User filters are domain-specific. Therefore, when the domain of Tableau Server changes or authentication type changes, filters no longer function as expected. Although the user filters
are generated by Tableau Server, after they are set by the user, the filters are stored in the workbooks and data sources. Neither of these methods for changing the identity store modifies the contents of the workbooks or data sources.

As you plan the identity store change, you must also include a final task to correct user filtering in all workbooks and data sources with Tableau Desktop.

User names and the Tableau Identity store

If you are using Method 1, it's helpful to understand how Tableau Server stores user names in the Tableau identity store. Tableau stores all user identities in the repository, which coordinates content permissions and site membership with various services in Tableau Server. Generally, an identity store configured for Active Directory stores user names in the format, domain\username. Some organizations use a UPN (jsmith@domain.lan).

On the other hand, organizations that configure Tableau Server with local identity store usually create standard, truncated user names, such as jsmith.

In all cases, these user names are literal strings that must be unique in the Tableau identity store. If you are changing from one identity store type to another, then your target authentication, SSO, or user provisioning solution may require a specific user name format.

Therefore, to maintain all permissions, content, and user viability, one of the following must be true after you change the identity store type:

- The new user names must match the original user names, or
- The original user names must be updated to match a new format.

If an authentication change is driving the identity store change, then the target authentication scheme will likely impose a user name syntax that is different than your original user names. Method 1 includes a process where you can map original user names to new user names.

It's possible that the original user name format will work with the new authentication type. For example, if you used UPN names in a local identity store deployment, you might be able to use the same user names in an Active Directory deployment. You could also use the
domain\username format for local identity store, as long as users continue to use that format to sign in to Tableau Server.

If you are changing from local identity store to an external Active Directory store, review the topic, User Management in Active Directory Deployments, as part of your planning process.

Method 1: Use site export and import

1. Export all sites on your server. See Export or Import a Site.
2. Back up, remove, and then reinstall.
3. Create new users on Tableau Server. You should have a new user that corresponds to each user on the original server.
4. Import the sites that you exported in Step 1. See Export or Import a Site. During import, you will be prompted to map the new users to the original users.

Method 2: Fresh installation—users republish content

Even if you do not plan to port content as part of your identity store change, we recommend that you back up the server.

1. Back up, remove, and then reinstall.
2. Create users, sites, and groups.
3. Inform your users of the new Tableau Server, provide them with credentials, and allow them to republish their content.

Back up, remove, and then reinstall

Both methods include the following steps:

1. Back up Tableau Server
2. Remove Tableau Server.
3. Reinstall Tableau Server with the new identity store type.

Step 1: Back up Tableau Server

As a best practice, you should back up the server before proceeding.

Follow the procedure, Create a backup using the TSM command line interface (CLI). Run the backup command with the −d option. The −d option adds the datestamp.
When you are finished, copy the backup file (.tsbak) to a safe location that is not a part of your Tableau Server installation.

Step 2: Remove Tableau Server

You must completely remove Tableau Server from the computer. See Remove Tableau Server from Your Computer.

Step 3: Reinstall Tableau Server with new authentication type

1. Go to the Tableau Customer Portal, sign in with your Tableau user name and password, and then download Tableau Server.

2. Install Tableau Server. See Install and Configure Tableau Server more information. During installation, you will select the new identity store type. See Configure Initial Node Settings.
