You can configure how long Search & Browse clients will wait to establish a connection to the Search & Browse server, and to Coordination Service (Zookeeper). Both timeout values are set to a relatively high value, but if you experience issues browsing to server content, and vizportal and backgrounder logs show timeouts connecting to SOLR, try increasing these settings. If this has no impact, you may be running into limited resources on the Tableau Server computer.

```
searchserver.connection_timeout_milliseconds
```

```
searchserver.zookeeper_session_timeout_milliseconds
```

To change the values use the `tsm configuration set` command:

```
tsm configuration set -k searchserver.connection_timeout_mil-
liseconds -v
```

For more details about the `searchserver.connection_timeout_milliseconds` configuration key, see searchserver.connection_timeout_milliseconds.

Zookeeper connection health check timeout at startup

When Tableau Server is starting, resource usage is high, especially related to CPU usage. If Search & Browse does not make a connection to Coordination Service (zookeeper), it will fail to start. To account for this, Tableau Server performs a health check on the Coordination Service before starting Search & Browse.

If your Tableau Server computer is especially busy, or if Search & Browse fails to start, increase this timeout value.

An error is written to the control-searchserver.log files when this health check fails: `Failed zookeeper health check. Refusing to start SOLR.`

To increase the amount of time Tableau Server waits for a successful health check, set the value of `searchserver.startup.zookeeper_healthcheck_timeout_ms` using the `tsm configuration set` command.

```
tsm configuration set -k searchserver.startup.zookeeper_
healthcheck_timeout_ms -v <nnnnnn>
```

For more details about the `searchserver.startup.zookeeper_healthcheck_timeout_ms` configuration key, see searchserver.startup.zookeeper_healthcheck_timeout_ms.

## Tableau Statistical Service

The Tableau Statistical Service manages the statistical engine behind Explain Data and predictive modeling functions on Tableau Server. This service is available in Tableau Server 2022.1 through 2023.1.x.

> **Note:** The Statistical Service was retired in version 2023.3.0 and no longer shows up on the status page or in the output of the tsm status command.

Server configuration

The Tableau Statistical Service is automatically installed on any node where VizQL is installed.

| | |
|---|---|
| **Process** | Tableau Statistical Service |
| **Status** | Status of the Tableau Statistical Service process is visible on the Status Page and can be accessed using the TSM CLI to view. For more information, see View Server Process Status |

| | |
|---|---|
| **Logging** | Logs generated by the Tableau Statistical Service process are located in `/var/opt/tableau/tableau_server/data/tabsvc/logs/statsservice`. For more information, see Tableau Server Logs and Log File Locations |

Impact if the Tableau Statistical Service fails

If the Tableau Statistical Service stops working, Explain Data will be unavailable, and views that contain calculations with predictive functions MODEL_PERCENTILE and MODEL_QUANTILE won't render.

Performance

If there is increased usage of Explain Data or predictive modeling functions on Tableau Server, you may benefit from installing additional instances of the Tableau Statistical Service on nodes running VizQL. For more information on configuring the topology of a Tableau Server node, see Configure Nodes.

Log files

The Statistical Service creates two sets of log files:

- `control_statsservice*.log`: These logs will contain information about the service starting and being enabled.
- `stdout_statsservice_*.log`: These logs will contain information about status and errors.

For more information, see Tableau Server Logs and Log File Locations.

## Tableau Server TSM Maintenance Services

There are three TSM Maintenance Services that are installed on every node of the cluster: Database Maintenance, Backup/Restore, and Site Import/Export.

| | |
|---|---|
| **Processes** | Database Maintenance, Backup/Restore, and Site Import/Export. |

| | |
|---|---|
| **Status** | Status of the TSM Maintenance services are not visible on the Status Page. Use the TSM CLI to view status. For more information, see View Server Process Status |
| **Logging** | Logs generated by the the Service Manager process are located in `/var/-opt/tableau/tableau_server/data/tabsvc/logs/`, in the `data-basemaintenance`, `backuprestore`, and `siteimportexport` directories. For more information, see Tableau Server Logs and Log File Locations |

These services remain stopped unless a specific maintenance task that requires them is initiated by the administrator. Additional high-availability configuration is not required for these services. These services are used only for maintenance tasks such as backup and restore and should not impact the functioning of Tableau Server for the end users.

## Tableau Server VizData Service

The VizData Service (vizdataservice) is the new service that handles the connections to published data sources on Tableau Server. Workbook queries to the published data sources on the Tableau Server are processed by the VizData Service. Prep Flow and Data Catalog queries are handled by the Data Server.

To ensure high availability of VizData Service, configure one or more VizData Service processes on multiple nodes in the Tableau Server cluster.

**Note:** As of 2024.2.3, at least one instance of VizData Service is required for an installation of Tableau Server.

| | |
|---|---|
| **Process** | VizData Service |
| **Status** | Status of the VizData Service process is visible on the Status Page. For more information, see View Server Process Status |
| **Logging** | Logs generated by the VizData Service process are located in `/var/-opt/tableau/tableau_server/data/tabsvc/logs/vizdata-` |

| | |
|---|---|
| | `service`. For more information, see Tableau Server Logs and Log File Locations |

What happens when a VizData Service fails? Requests to the published data sources being handled by that instance will fail (unable to render workbook view), but subsequent requests will be routed to other running VizData Service instances. Assuming the node containing the failed VizData Service is still running, the failed processes should be automatically restarted by Tableau Server.

The `control_vizdataservice_node*.log` contains information about the services starting and being enabled.

The `vizdataservice_node*.log` contains the errors or problems encountered.

The VizData Service will replace a portion of client traffic from Data Server to VizData Service when clients query and connect to the published data sources on the Tableau Server. If the VizData service process fails, the queries running through the VizData service will fail. The workbooks will lose the ability to query or connect to the published data sources.

Recommendations

We recommend you configure an instance of VizData Service on a node with the same instances as Data Server and have both services enabled on a node to provide and manage connections to publish data sources on Tableau Server for various clients.

We recommend you configure an instance of VizData Service on each of the nodes where you deploy the Data Server. Together the services will provide and manage connections to published data sources on Tableau Server. Adding additional instances of VizData Service to other nodes provides duplication of processes and reduces the possibility of workbook downtime with VizData Service nodes.

Eventually the VizData Service will replace the Data Server in terms of the connection to the published data source on the Tableau Server. In the meantime it will still coexist with Data Server service for backward compatibility.

## Tableau Server VizData Native Service

The VizData Native Service is the core service that communicates with VizData Service and manages the published data source connection and session on Tableau Server. The service is internally managed by Tableau Server, and cannot be configured by an administrator. The instances of VizData Native Service are automatically configured on any node that has instances of VizData Service, with a one-to-one mapping.

| | |
|---|---|
| **Process** | VizData Native Service |
| **Status** | Status of the VizData Native Service process is visible on the Status Page. For more information, see View Server Process Status |
| **Logging** | Logs generated by the VizData Native Service process are located in `/var/-opt/tableau/tableau_server/data/tabsvc/logs/vizdatan-ativeservice`. For more information, see Tableau Server Logs and Log File Locations |

If the VizData Native Service fails, the process is automatically restarted by Tableau Server within seconds. Any errors or problems are logged in `nativeapi_vizdatan-ativeservice_*.txt`.

The `control_vizdatanativeservice_node*.log` contains information about the services starting and being enabled.

Instances of VizData Native Service are automatically scaled up or down on each node to match the number of instances of VizData Service and managed internally by Tableau. There is nothing an administrator can configure related to the service.

To ensure a healthy publish data source connection, both the VizData Service and the VizData Native Service should run in healthy statuses to serve the requests. By default, both services are added to the nodes that have the Data Server installed after update or clean installation.

## Tableau Server VizQL Data Service

The VizQL Data Service (VDS) is an API that allows you to access published data sources in Tableau through programmatic queries rather than visualizations.

To make VizQL Data Service highly available, configure one or more VizQL Data Service processes to run on multiple nodes of the cluster.

| | |
|---|---|
| **Process** | VizQL Data Service |
| **Status** | Status of the VizQL Data Service process is visible on the Status Page unless the service has been disabled. For more information, see View Server Process Status |
| **Logging** | Logs generated by the VizQL Data Service process are located in `/var/-opt/tableau/tableau_server/data/tabsvc/logs/vizqldata-service`. For more information, see Tableau Server Logs and Log File Locations |

What happens if a VizQL Data Service process fails? Queries running through the VizQL Data Service process will fail, resulting in all programmatic queries losing direct access to published data sources in customer applications, automate workflows, etc. The Tableau Server UI and viz creation are not dependent on VizQL Data Service to function.

The default VizQL Data Service process running on a node is one. High availability requires configuring redundant VizQL Data Service and VizData Service instances. If multiple VizQL Data Service processes are running, then the failure of a single process will result in the failure of any queries and the loss of query result at the time of its failure. Any future requests will be routed to the other working VizQL Data Service processes on the Tableau Server cluster.

## Tableau Server VizQL Server

The VizQL Server loads and renders views, and computes and executes queries. To achieve high availability for the VizQL Server process, configure one or more instances to run on multiple nodes.

| | |
|---|---|
| **Process** | VizQL Server |
| **Status** | Status of theVizQL Server process is visible on the Status Page. For more information, see View Server Process Status |
| **Logging** | Logs generated by theVizQL Server process are located in `/var/-opt/tableau/tableau_server/data/tabsvc/logs/vizqlserver`. For more information, see Tableau Server Logs and Log File Locations |

What happens if a VizQL Server process fails? If there is only one VizQL Server process and it fails, then Tableau Server will no longer be able to render any views. High availability requires configuring redundant VizQL processes. A fairly typical configuration consists of two to four VizQL Server processes on each node.

This simultaneously serves the need for high availability and scalability. If multiple VizQL Server processes are running, then the failure of a single process will result in the failure of any requests and the loss of session data at the time of its failure. Any future requests will be routed to the other working VizQL Server processes on the Tableau Server cluster.

## Tableau Prep Conductor

The Tableau Prep Conductor process runs flows and processes flows for ingestion by Data Catalog. It leverages the scheduling and tracking functionality of Tableau Server so you can automate running flows to update the flow output. Starting in 2020.4 Data Management is only needed to schedule flows to run on Tableau Server. For more information, see Tableau Prep Conductor.

| | |
|---|---|
| **Process** | Tableau Prep Conductor |
| **Status** | Status of the Tableau Prep Conductor process is visible on the Status Page. For more information, see View Server Process Status |
| **Logging** | Logs generated by the Tableau Prep Conductor process are located in `/var/-opt/tableau/tableau_server/data/tabsvc/logs/flow-processor`. For more information, see Tableau Server Logs and Log File Locations |

Tableau Prep Conductor uses the following components to run flows:

- **Backgrounder:** Tableau Prep Conductor uses the Backgrounder process to run flows. Backgrounder is single threaded, so each instance of the Backgrounder process on a node can run one flow at a time. By adding more Backgrounders to a node, you can increase the number of flows that can be run in parallel on that node. The Backgrounder processes can be up to half the number of the physical cores of that node.
- **Connectors:** Prep Conductor uses the supported Tableau Data connectors to connect to data. For a list of supported Connectors, see Supported Connectors.
- **Data Engine:** Any changes to data or transformation steps in your flow that cannot be pushed to the underlying data source are processed using the Data Engine process. For example, SQL Server does not natively support regular expressions. When connecting to SQL Server, Tableau Prep lets you write regular expression calculations. Tableau Prep Conductor uses Data Engine to temporarily load the data and then perform the regular expression.

Performance and Scale Recommendations

- **Isolate flows to a separate node:** Running Tableau Prep Conductor on a separate node will isolate flow workflows from other Tableau workloads. This is highly recommended since Prep flows are CPU and RAM intensive.
- **Manage flow schedules:** You can control flow execution by creating flow schedules. These schedules let you determine when flows run, how frequently they run, the priority of that schedule, and whether to run items in that schedule serially or in parallel.
- **Add resources:** When scaling your Tableau Prep Conductor environment, we recommend scaling up to an 8 physical cores box per node running as many as 4 backgrounders on each. As you need more resources, we recommend adding more nodes to your server environment.

You can monitor user activity and performance of flows using Administrative views. For more information, see Monitor Flow Health and Performance.

By default, Tableau Prep Conductor is automatically enabled on a node where backgrounder is enabled. If the node role is set to exclude flows, then Tableau Prep Conductor is not installed on that node. For more information, see  Workload Management through Node Roles.

It is recommended that you enable Tableau Prep Conductor on a dedicated node to run flows. For more information, see the following topics:

- For new Tableau Server installations, see Step 1 (New Install): Install Tableau Server with Tableau Prep Conductor.
- To enable Tableau Prep Conductor on an existing installation of Tableau Server, see Step 1 (Existing Install): Enable Tableau Prep Conductor.

## Tableau Prep Flow Authoring

The Tableau Prep Flow Authoring process provides the interactive Prep Flow experience in the browser, which lets users create and interact with flows on Tableau Server to clean and prepare data. For more information, see Create and Interact with Flows on the Web. It was added in version 2020.4.

| | |
|---|---|
| **Process** | Tableau Prep Flow Authoring |
| **Status** | Status of the Tableau Prep Flow Authoring process is visible on the Status Page. For more information, see View Server Process Status |
| **Logging** | Logs generated by the Tableau Prep Flow Authoring process are located in `/var/opt/tableau/tableau_server/data/tabsvc/logs/flowed-itor`. For more information, see Tableau Server Logs and Log File Locations |

Tableau Prep Flow Authoring is enabled by default. It uses these components:

- **Tableau Prep Minerva Service**: Used by Tableau Prep Flow Authoring for querying datasources. By default, it is automatically enabled on a node where Tableau Prep Flow Authoring is enabled.

- **Data Engine**: The Data Engine creates data extracts and processes queries. By default, it is automatically enabled on a node where Tableau Prep Flow Authoring is enabled.
- **Gateway**: The Gateway process handles all requests to Tableau Server from browsers, Tableau Desktop, and other clients. By default, it is automatically enabled on a node where Tableau Prep Flow Authoring is enabled.

Performance and Scale Recommendations

Tableau Prep Flow Authoring can be CPU and RAM intensive. It is recommended to monitor server and adjust your deployment as necessary by isolating flow authoring to a separate node or adding server resources.

Isolate flow authoring to a separate node

Running Tableau Prep Flow Authoring on a separate node will isolate flow authoring workflows from other Tableau workloads. If you have a busy server with many extract refreshes, and a lot of viz editing and viewing and you don't want to cause disruption to this workload, then it is recommended to isolate Prep Flow Authoring to its own server node. This means that all flow editing is directed to a dedicated node. For more information see Configure Nodes.

> **Note:** Prep Web Authoring uses shared services such as the Application Server (VizPortal), the PostgreSQL repository, the Cache Server, and Hyper. If those services are already at capacity, they might also need additional resources because of the additional Prep Web Authoring load. For Prep Web Authoring to work, the cache server must be running on the lowest-numbered node where it is set up. For example, if the cache server is configured on nodes 2, 3, and 4, but it is down on node 2, Prep Web Authoring will not function. For more details see Cache Server not running in the lowest numbered node in the Knowledge Base.

If you are running Tableau Server on a multi-node cluster, you can dedicate one or more nodes for running Backgrounder. Using the Backgrounder process, you can isolate background workloads such as Tableau Prep Conductor from all your interactive workloads such

as Prep Flow Authoring and VizQL Server. For more information, see Tableau Server Backgrounder Process and  Workload Management through Node Roles.

For core and user-based deployments, it's strongly recommended that at least one node be dedicated to flows for best performance. While you can run flows on any licensed Server core, the additional resource cores purchases should only run Tableau Prep Conductor, and not extract refreshes or VizQL processes.

Add resources

As you need more resources, you can add more nodes to your server environment. When planning your nodes, several factors can influence your decision on how much additional hardware you need to allocate.

The main things to consider when planning your nodes are:

- The number of concurrent users or concurrent sessions you expect during peak hours. The number of concurrent sessions per user can be set using the TSM option `maestro.sessionmanagement.maxConcurrentSessionPerUser`. For more information, see tsm configuration set Options.
- The number of data input nodes your flows have on average and the amount of data they have. The maximum row sampling limit can be set using the TSM option `maestro.app_settings.sampling_max_row_limit`. For more information, see tsm configuration set Options.
- The complexity of the flows being authored and the number of nodes. Node types like joins, unions, aggregates, and pivots will, in general, require more resources.

License additional offerings

Additional licenses for Data Management and Advanced Management are required for configuring nodes.

| OFFERING | Allows you to: |
| --- | --- |
| Data Management | Configure a node to run only flows, or configure a node to run all jobs except flows. Tableau Prep Conductor must be running on the node. |

| OFFERING | Allows you to: |
| --- | --- |
| | The Data Management license includes Tableau Prep Conductor, which enables you to schedule and track flows. The license is for a single Tableau Server deployment, which can be role-based or core-based.<br><br>As a Creator, Data Management is not required to create and edit flows directly on your server. |
| Advanced Management | Configure where the different types of workloads are processed through node rules. For example, you can run flows on one node and subscriptions and alerts on another node. |

Topology and Configuration

To make Tableau Prep Flow Authoring highly available, configure two instances of Tableau Prep Flow Authoring on nodes when enabling it.

Here is an example of a two node configuration:

## Tableau Server Dynamic Topology Changes

With the introduction of TSM, Tableau Server also introduced the ability to make certain topology changes or updates without restarting the server. These are known as dynamic topology changes, and are possible with the Backgrounder and VizQL Server processes.

You can increase or decrease the number of backgrounder or VizQL Server instances on a node without requiring a Tableau Server restart if the node already has at least one instance of the process running. You must be only changing the number of instances of Backgrounder

or VizQL Server. If you also add or remove another process, or if you are adding the first instance of Backgrounder or VizQL Server to a node or removing the last instance of either from the node, Tableau Server will require a restart.

Dynamic configuration changes

Beginning with version 2020.2.0 of Tableau Server, certain configuration changes can also be made dynamically using configuration keys. You can make dynamic topology changes at the same time you make dynamic configuration changes, without needing to restart Tableau server. For more information about dynamic configuration changes, see Tableau Server Release Notes in What's New and Changed for 2020.2 in Tableau Server.

Example Scenarios

To better understand why this might be useful, consider these examples:

- Backgrounder—At the end of a sales quarter your sales team is using Tableau Server to keep track of their numbers. Dashboards that depend on extracts are showing sales people how they are doing. Any delay in extract refreshes means your team is not seeing the most up-to-date numbers. You can add additional backgrounders to any node that already has at least one backgrounder or VizQL Server, and increase the throughput of extract refreshes, helping to guarantee the numbers are up-to-date as your team finished up their quarter. Later, after the quarterly push, you can reduce the backgrounder instances again to return Tableau Server to its original configuration.
- VizQL Server—Similarly, if Tableau Server is unable to keep up with view refreshes, you can quickly add additional VizQL Server instances to any node that already has at least one instance of either VizQL Server or backgrounder configured. In the above backgrounder example, you might want to remove VizQL Servers temporarily, to accommodate additional backgrounders, and then re-add them back before your users arrive in the morning.

Making dynamic topology changes

You can make dynamic topology changes using the TSM Web UI, or on the command line. To use the Web UI, sign in to TSM using a browser, and on the Configuration tab, update the number of backgrounder or VizQL Server instances for the node you are updating. For details, see Configure Nodes. To make your changes using the TSM CLI, at a command prompt, run the

tsm topology set-process command. For details, see Changing the number of processes on a node.

Impact of dynamic topology changes

When making dynamic topology changes that remove existing instances of VizQL Server or backgrounder, the instances are removed immediately. Be aware of the following potential impacts to users and currently running jobs:

- Backgrounder—Any currently running jobs are terminated. The normal Tableau Server retry logic will restart these jobs, using another backgrounder instance.
- VizQL Server—Any currently active sessions are terminated. Users may see an error message. Refreshing the browser should clear the error.

Best practices

Tableau recommends you test any dynamic topology changes you plan on using, before implementing them in your production environment. This will help you fully understand potential impacts to your users and scheduled refreshes and subscriptions, and allow you to most efficiently take advantage of the flexibility offered by dynamic topology.

Automating dynamic topology changes

You can automate dynamic topology changes. For example, if you have most of your extract refreshes scheduled overnight, and know your server has extra capacity because users are not signed in, you can use a script or other automated deployment tool to add backgrounder instances when they can be most efficiently used, and then remove them before the start of the work day.

To automatically get the status of processes, use the `tsm status -v` command and parse the output in your script. Alternately, you can use the TSM REST API get server status. The API is currently in alpha. For more details, see Get server status.

A sample script to set four instances of backgrounder on node2 might look like this:

```
echo Adding/Removing Processes
tsm topology set-process -pr backgrounder -n node2 -c 4
tsm pending-changes apply
echo Done!
```

Additional information

Tableau Server Processes

## Server Process Limits

When you reconfigure processes for Tableau Server, there is a limit to the amount that you can increase the number of process instances. By default, the limit is set to eight. If your machine has enough RAM and CPU cores, and you want to go above this limit, you can change the limit using the `service.max_procs` configuration option. For each process instance, Tableau recommends that the machine running the process have at least 1 GB of RAM and 1 logical CPU core.

To change the maximum number of processes allowed:

1. Type the following command, where `number` is the maximum number of process instances you want to allow:

   ```
   tsm configuration set -k service.max_procs -v <number>
   ```

   For example:

   ```
   tsm configuration set -k service.max_procs -v 10
   ```

2. Next type:

   ```
   tsm pending-changes apply
   ```

   If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart

behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see tsm pending-changes apply.

# Tableau Services Manager Ports

The processes and services that make up the components of Tableau Services Manager (TSM) and Tableau Server on Linux  use various ports to communicate. By default, most these ports are assigned (mapped) dynamically from a predefined range of ports. The port assignments are made for each service or process when it is installed. You can control what ports are used in a variety of ways.

A small subset of processes do not use dynamic port mapping and behave uniquely. For more information, see Ports that are not dynamically mapped, below.

**Note:** This operation includes steps that you may need to perform using the TSM command line.

## Ephemeral port use

If your operating system is configured to use ephemeral ports, your Tableau traffic may be routed through these, even when configured as described below. This happens at the OS level and is not something you can configure in Tableau. If you want to control port usage, consult your operating system documentation on how to limit ephemeral port usage.

## Firewall requirements

If you are running a firewall on the computer where you will be installing Tableau Server, then you will need to open the following default ports for Tableau Server traffic. All port numbers, except 443 can be changed.

| Port | TCP/UDP | Used by ... | TYPE OF INSTALLATION | |
|---|---|---|---|---|
| | | | All | Distributed / High Avail-ability |
| 80 | TCP | Gateway | X | |
| 443 | TCP | SSL. When Tableau Server is configured for SSL, the application server redirects requests to this port. Do not change this port. | X | |
| 8850 | TCP | Tableau Services Manager. | X | |
| 8060 | TCP | PostgreSQL database. | X | |
| 8061 | TCP | PostgreSQL backup verification port | X | |
| 8000-9000 | TCP | Range of ports reserved by default for dynamic mapping of Tableau processes | | X |
| 27000-27009 | TCP | Range of ports used by Tableau Server for License service. This range must be open on the node running the License service and accessible from other nodes. By default, the initial node runs the License service. | X | |

See Configure Local Firewall.

## Port assignment

There are two approaches you can use for port assignment or mapping in TSM:

- **Dynamic port assignment**. This is the default and requires the least intervention by the administrator.

- **Manual port assignment**. This option requires an administrator to individually assign each port.

If you change port assignments and you are running a local firewall, see Local firewall configuration.

## Dynamic port assignment

You can control which ports are used by changing the range of ports available to the dynamic assignment process. Doing this leaves dynamic port assignment in place but restricts the ports that can be chosen. With dynamic port assignment in place, you can still choose to assign ports for certain processes manually. This approach enables you to assign specific ports to specific processes, while leaving the others to be mapped dynamically. Using dynamic mapping, with or without some individually assigned ports is the easiest approach, and should satisfy the requirements of most customers. Dynamically assigned ports are preserved if you export your Tableau Server configuration.

By default, ports are assigned for each service or process from available ports between 8000 to 9000. This assignment takes place when services are installed for the first time on a node. After Tableau Server is initialized, you can see which ports are being used by which services or processes by running this command:

```
tsm topology list-ports
```

If you have a multi-node cluster, ports on all nodes are listed.

Changing the port range

For organizations that have specific requirements for ports being used, the easiest way to control this is to change the range from which ports are dynamically selected. You need to do this at installation, by specifying a minimum and maximum port for the range in your configuration file.

> **Note:** The minimum allowable size of your port range will depend on your server installation and how many services or processes you are running. As a general best practice you should not restrict the range too tightly because port assignment is done by selecting random ports within the range, and if you do not allow a large enough range, selection may fail to find an available port.

To limit the range from which available ports are chosen to those between 8300 and 8600, your configuration file would include an entry similar to this:

```
"configKeys": {
    "ports.range.min": "8300",
    "ports.range.max": "8600"
}
```

Blocking specific ports within the range

Beginning with version 2021.1.0, you can specify certain ports that are within the dynamically assigned range but should not be used by Tableau. This is useful if you have other software on your Tableau Server computers that rely on ports within the range Tableau is using.

To specify ports within the range that should not be used by TSM and Tableau Server, use the `ports.blocklist` configuration key:

```
tsm configuration set -k ports.blocklist -v <port>[,<port>,<port>]
```

For example:

```
tsm configuration set -k ports.blocklist -v 8000,8088, 8090
```

Disabling dynamic port assignment

If you need more control of port assignment than you can get through a combination of restricting port range and individually assigning ports, you can disable dynamic port mapping at initial server configuration. Disabling dynamic port mapping requires you to manually assign every port for every process, so we don't recommend this unless you need to control every single port assignment.

If you disable dynamic port mapping, you must configure the port for each process on each node of your installation.

To disable dynamic mapping, your configuration file would include an entry similar to this:

```
"configKeys": {
    "service.port_remapping.enabled": false
}
```

**Important:** When you disable dynamic port assignments, the License service port range is not included. This range (27000-27009) must be open on the node running the License service and accessible from other nodes. By default, the initial node runs the License service.

## Manual port assignment

You can disable automatic port assignment entirely and assign a port for each process individually. If you do this, you must assign a port for every process on every node. You can assign ports either in a configuration file, when the processes are first installed, or after installation, using a TSM command. Only ports assigned at process installation are preserved if you export your Tableau Server configuration.

You can specify individual ports for specific processes, whether or not dynamic mapping is enabled. You might do this if you want a process to use a particular port, or if you've disabled dynamic mapping. There are two ways to specify ports for processes: during installation or after installation.

Configuring ports during installation

We recommend configuring port assignment during the installation process as described here. Changing ports after installation is a much more labor-intesive process.

To configure ports during installation, create a json file that specifies your port configuration. This process is similar to defining a non-default port range, but instead you specify a particular port for a specific service or process. If you are going to assign specific ports, this

approach is the most robust way to do so because the port mapping is preserved if you export the server configuration and topology settings using the `tsm settings export` command.

To define ports at installation, add information to your configuration file to specify the node (`workerN`), process (`servicename`) and instance ID (`instanceid`), port type (`porttype`), and the port to be used. The format looks like this:

```
workerN.{servicename}_{instanceid}.{porttype}.port:X
```

Where:

- `workerN` is an optional parameter and identifies the node for which the remapping applies. Node numbers start with zero (0).
  We recommend you do not include this parameter unless you need to map different ports for the same service on different nodes. If you leave this parameter off, you can map a service port on the initial node, or map the same service port on multiple nodes.
- `servicename` is the name of the process or service that will use the port.
- `instanceid` is the instance of the process. If you are going to be configuring multiple instances of a process on one node, you would need to increment this value for each instance. Start the instanceid at zero (0) and increment it by one (1) for each instance of the process. For services that only install a single instance on any given node, this must be left off.
- `porttype` If setting the primay port, do not include this option.
- `port` is the port the process or service should use.

For example, to set the port for the first instance of the file store process on the initial node to 8500, you would include a configuration file entry similar to this:

```
"configKeys": {
    "filestore_0.port: "8500"
}
```

The example above does not include the optional workerN parameter, so sets the port on all nodes in the cluster. It also leaves off the porttype option because it is setting the primary filestore port.

**Important**: When specifying port changes with a configuration file, you must include the `--force-keys` parameter with the `tsm settings import` command.

Configuring ports after installation

If you need to change ports after you have installed Tableau Server, use the `tsm topology set-ports` command. This approach allows you to specify a port for a specific process after that process has been installed. You are restricted by these limits:

- You must set ports individually, on each node.
- After you set an individual port, you must run `tsm restart`.
- The port assignments are not preserved if you need to import a Tableau Server configuration using `tsm settings import`.
- Port names use a different syntax for tsm commands than the syntax that is required for configKeys. The table at the end of this topic provides a syntax reference.

For example, to set second instance of the file store on the initial node to use port 8500:

```
tsm topology set-ports --node-name node1 --port-name filestore --
port-value 8500 --instance 2
```

The following example shows how to use shorthand commands to set the JMX ports:

```
tsm topology set-ports -n node1 --port-name vizqlserver:jmx.rmi -pv
9403 -i 1
```

```
tsm topology set-ports -n node1 --port-name vizqlserver:jmx -pv
9404 -i 2
```

**Note**: Port entries are not validated when you enter them. Therefore, if you use a port that is already assigned, or if you mistype the syntax for a command, Tableau will not give an error until you restart. After restarting, you may see a generic error, *The reconfigure async job failed.*

If you add an incorrect `portname:type` with a valid port, you cannot delete the

incorrect entry. To update the port, you must reassign an unused port to that value to free up the port again.

Ports that are not dynamically mapped

The Tableau Server repository uses two ports that are not dynamically mapped. These each have a default port that you can override using the `tsm configuration set` command and a process-specific parameter.

| Port names | Port (default) | Description |
|---|---|---|
| pgsql.port | 8060 | Port for the Tableau Repository (PostgreSQL database).<br><br>To override this port:<br><br>`tsm configuration set -k pgsql.port -v <port>` |
| pgsql.verify_restore.port | 8061 | Port for verifying the integrity of a repository backup.<br><br>to override this port:<br><br>`tsm configuration set -k pgsql.verify_restore.port -v <port>` |

Because these ports do not use the dynamic port mapping system, they do not show up in the output of the `tsm topology list-ports` command. To see the value of these you need to use the `tsm configuration get -k <config.value>` command. For example:

```
tsm configuration get -k pgsql.port
```

### Controlling port remapping with initialize-tsm

Port assignments are made when services are installed. This means that in order to manually map ports for the TSM-specific processes, you need to assign the ports when you run the initialize-tsm script. The script includes options to specify ports for individual TSM services, as well as options for defining the minimum and maximum of the port range used with dynamic mapping, and you can disable dynamic mapping.

The table below lists the options for ports when running the initialize-tsm script.

## Table: initialize-tsm script port options

| Script option | Parameter | Description |
|---|---|---|
| -i | <port> | Sets the Coordination Service client port. |
| -e | <port> | Sets the Coordination Service peer port. |
| -m | <port> | Sets the Coordination Service leader port. |
| -n | <port> | Sets the TSM agent file transfer port. |
| -o | <port> | Sets the TSM Controller port. |
| -l | <min-port> | Sets the bottom of the port range used for dynamically mapping ports. |
| -r | <max-port> | Sets the top of the port range used for dynamically mapping ports. |
| --disable-port-remapping | | Disables dynamic port mapping. If you do this you must assign ports for every service or process used by TSM and Tableau Server. For more |

| Script option | Parameter | Description |
|---|---|---|
| | | information, see Manual port assignment above. |

## Dynamically mapped ports

This table lists the processes or services that use dynamically mapped ports.

| Port names: syntax for json file (configKeys) | Port names: syntax for tsm CLI | Description |
|---|---|---|
| activemqserver.port | activemqserver:primary | ActiveMQ Service service port. |
| activemqserver.openwire.port | activemqserver:openwire | ActiveMQ Service openwire port. |
| appzookeeper_0.client.port | appzookeeper:client | Coordination Service client port. |
| appzookeeper_0.peer.port | appzookeeper:peer | Coordination Service peer port. |
| appzookeeper_0.leader.port | appzookeeper:leader | Coordination Service leader port. |
| backgrounder_0.port | backgrounder | Backgrounder primary port. |
| backgrounder_0.debug.port | backgrounder:debug | Backgrounder debug port. |
| backgrounder_0.jmx.port | backgrounder:jmx | Backgrounder jmx port. |
| backgrounder_0.jmx.rmi.port | backgrounder:jmx.rmi | Backgrounder jmx rmi port. |

| Port names: syntax for json file (configKeys) | Port names: syntax for tsm CLI | Description |
|---|---|---|
| backgrounder_0.recommendations.trainer.port | backgrounder:recommendations.trainer | Backgrounder recommendations port. |
| backuprestore.port | backuprestore | Backup/Restore service port. |
| cacheserver_0.port | cacheserver | Cache server port. |
| clustercontroller.status.port | clustercontroller:status | Cluster Controller status port. |
| clustercontroller.storage.port | clustercontroller:storage | Cluster Controller storate port. |
| databasemaintenance.port | databasemaintenance | Database Maintenance port. |
| dataserver_0.port | dataserver | Data server primary port. |
| dataserver_0.debug.port | dataserver:debug | Data server debug port. |
| dataserver_0.jmx.port | dataserver:jmx | Data server jmx port. |
| dataserver_0.jmx.rmi.port | dataserver:jmx.rmi | Data server jmx rmi port. |
| filestore.port | filestore | File store primary port. |
| filestore.status.port | filestore:status | File Store status |

| Port names: syntax for json file (configKeys) | Port names: syntax for tsm CLI | Description |
|---|---|---|
| | | port. |
| gateway.port | gateway | Gateway port. This defaults to 80, and if that is not available, to 8080. If that is not available, it tries 8000. That sequence is followed whether or not dynamic port assignment is enabled or not. If none of those ports are available and dynamic mapping is enabled, it takes an available port within the defined range. The gateway port must be the same on all nodes in a multi-node cluster, so if port 80 is selected on the initial node this is the port that will be used on all nodes and if it is |

| Port names: syntax for json file (configKeys) | Port names: syntax for tsm CLI | Description |
|---|---|---|
| | | unavailable on one of the other nodes, gateway port selection will fail. |
| hyper.port | hyper | Data engine primary port. |
| hyper.connection.port | hyper:connection | Data engine connection port. |
| indexandsearchserver.port | indexandsearchserver | Index and Search server primary port. |
| indexandsearchserver.transport.port | indexandsearchserver:transport | Index and Search server transport port. |
| licenseservice.vendor_daemon.port | licenseservice:vendor_daemon | License service vendor daemon port. Used for licensing-related communications between nodes in a multi-node installation. |
| samlservice.port | samlservice | SAML service port. |
| siteimportexport.port | siteimportexport | Site Import/Export port. |

| Port names: syntax for json file (configKeys) | Port names: syntax for tsm CLI | Description |
|---|---|---|
| tabadmincontroller.port | tabadmincontroller | TSM Controller port. |
| tabadminagent.columbo.port | tabadminagent:columbo | Administration Agent service discovery port |
| tabadminagent.filetransfer.port | tabadminagent:filetransfer | TSM Agent file transfer port. |
| vizportal_0.authentication.port | vizportal:authentication | Application server authentication port. |
| vizportal_0.authorization.port | vizportal:authorization | Application server authorization port. |
| vizportal_0.maintenance.port | vizportal:.maintenance | Application server maintenance port. |
| vizportal_0.microservice.extensions.port | vizportal:.microservice:extensions | Application server extensions port. |
| vizportal_0.monolith_grpc.port | vizporta:monolith_grpc | Application server GRPC port. |
| vizportal_0.publishing.port | vizportal:publishing | Application server publishing port. |
| vizportal_0.recommendations.port | vizportal:recommendations | Application server recom- |

| Port names: syntax for json file (configKeys) | Port names: syntax for tsm CLI | Description |
|---|---|---|
| | | mendations port. |
| vizportal_0.port | vizportal | Application server primary port. |
| vizportal_0.debug.port | vizportal:debug | Application server debug port. |
| vizportal_0.jmx.port | vizportal:jmx | Application server jmx port. |
| vizportal_0.jmx.rmi.port | vizportal:jmx.rmi | Application server jmx rmi port. |
| vizqlserver_0.port | vizqlserver | VizQL server primary port. |
| vizqlserver_0.debug.port | vizqlserver:debug | VizQL server debug port. |
| vizqlserver_0.jmx.port | vizqlserver:jmx | VizQL server jmx port. |
| vizqlserver_0.jmx.rmi.port | vizqlserver:jmx.rmi | VizQL server jmx rmi port. |

## Enable the JMX Ports

To help you work through a problem with Tableau Server, Tableau Support may ask you to enable the server's JMX ports. These ports can be useful for monitoring and troubleshooting, usually with a tool like JConsole. In versions 2022.1 and later, the JMX ports can be enabled

securely and this is the recommended method. In versions earlier than 2022.1, you can only enable the ports unsecured.

Enable secure JMX ports

Beginning with version 2022.1 of Tableau Server, you can enable JMX ports securely. This procedure explains how to enable secure JMX. To enable JMX in earlier versions, see Enable unsecured JMX ports below.

To enable secure JMX ports on Tableau Server:

1. Log on as a user with `sudo` access to the computer where TSM is installed.
2. Run this command:

   ```
   tsm maintenance jmx enable
   ```

   The command has several options you can provide when running it. If you do not provide any options when you run the command, you will be prompted for options based on the answers you give.

   For example:

   ```
   C:\Windows\system32>tsm maintenance jmx enable
   We do not recommend you enable JMX unsecured on a production
   environment. Would you like to enable security features for
   JMX?
   (y/n): y
   JMX access is readonly by default. Would you like to add read-
   write access?
   (y/n): n
   Would you like to enable SSL?
   (y/n): y
   Would you like to require client authentication (mTLS)?
   (y/n): n
   Enabling JMX with the specified settings. This will perform a
   server restart. Do you want to continue?
   ```

```
(y/n): y
Starting enable JMX asynchronous job.
```

For more information on the command and its options, see tsm maintenance jmx enable.

## Enable unsecured JMX ports

For versions of Tableau Server earlier than 2022.1.0, if you are enabling JMX ports they can only be enabled unsecured.

**Important** Enabling unsecured JMX ports can introduce some security risk. We strongly recommend using secure JMX. If you do not have a version of Tableau Server that supports this, be aware of the risk and mitigate it by limiting access to the JMX ports to the fewest number of clients that's practical for your scenario. You typically limit access using the host's firewall rules, an external security device, or routing rules.

To enable unsecured JMX ports on Tableau Server:

1. Stop the server.
2. Enter the following command:

   ```
   tsm configuration set -k service.jmx_enabled -v true
   ```

3. Apply pending changes:

   ```
   tsm pending-changes apply
   ```

   If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart

behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see tsm pending-changes apply.

4. Restart the Coordination Service and TSM Administration Controller (as *tableau* system account):

   ```
   sudo su -l tableau -c "systemctl --user restart appzookeeper_0.service"
   ```

   ```
   sudo su -l tableau -c "systemctl --user restart tabad-mincontroller_0.service"
   ```

   It may take a few minutes for tabadmincontroller to restart. If you attempt to apply pending changes in the next step before the controller has fully restarted, TSM will not be able to connect to the controller. You can verify that the controller is running by using the `tsm status -v` command. Tableau Server Administration Controller should be listed as "is running".

5. Start the server.

How the JMX Ports Are Determined

By default, the JMX ports assigned dynamically, from within a range of available ports. For details on how port assignment is done, and how to override dynamic mapping, see Tableau Services Manager Ports.

# ATRDiag.exe Command Line Reference

You can use the ATRDiag command line utility to manage licensing issues related to the login-based license management and authorization-to-run (ATR) features.

## Synopsis

```
ATRDiag -dumpATR -showAll -showVerbose -product ["Tableau Desktop"]["Tableau Prep"]["Tableau Server"]

-subProduct {subProduct} -version {version} -setVersion {version}
```

```
-container -serverDataPath {path}

-log [Trace][Debug][Info][Warn][Error][Fatal][Off] -status -
deleteAllATRs

-deleteInvalidATRs -deleteATR {atrIdToDelete}

-enableATRFeature -disableATRFeature -enableLBLMFeature -dis-
ableLBLMFeature

-requireLBLMFeature -setDuration {seconds}
```

**Note:** All ATRDiag options are case-insensitive.

## Options

`-dumpATR`

Display a valid authorization-to-run (ATR) on the command prompt (if present). Use `-version/-product/-subProduct/-version` to control which ATR is dumped if more than one is valid.

`-showAll`

Enumerate the contents of the registry to see available ATRs.(some of which might not be valid).

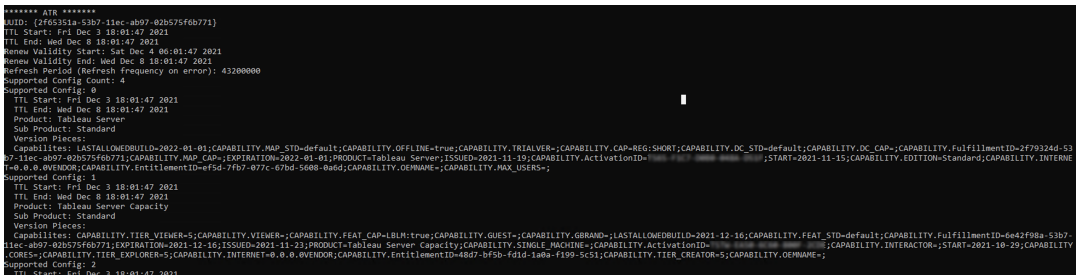
`-showVerbose`

Enumerate the contents of the registry and use `-version/-product/-subProduct/-version` to provide per-product.

`-product ["Tableau Desktop"]["Tableau Prep"]["Tableau Server"]`

Defaults to "Tableau Desktop". Must specify "Tableau Server" to display Server ATR.

For example: `atrdiag -product "Tableau Server"`



`-subProduct {subProduct}`

Defaults to "Professional".

`-container`

Container mode, only for Tableau Server. Must specify `-product "Tableau Server"`.

`-serverDataPath`

The location of Server data under Container mode. Defaults to `"/var/-opt/tableau/tableau_server/"`.

`-version {version}`

No default; a valid value for this field is "Tableau 2021.1".

`-setVersion {version}`

Persist a default value for -version.

`-log [Trace][Debug][Info][Warn][Error][Fatal][Off]`

Display ATR log information.

`-status`

Provide ATR feature status (enabled or disabled), the license server, and dump the ATR.

`-deleteAllATRs`

Remove all ATRs present on the machine.

`-deleteInvalidATRs`

Remove all invalid ATRs.

`-deleteATR {atrIdToDelete}`

Remove an ATR by ID.

`-enableATRFeature`

Turn on the ATR feature. Must run as an administrator. For use on Tableau Desktop only.

`-disableATRFeature`

Turn off the ATR feature. Must run as an administrator. For use on Tableau Desktop only.

`-enableLBLMFeature`

Turn on login-based license management (LBLM). Must run as an administrator.

`-disableLBLMFeature`

Turn off login-based license management (LBLM). Must run as an administrator.

`-requireLBLMFeature`

Set the login-based license management (LBLM) feature to required. Must run as an administrator.

`-setDuration {seconds}`

Set `ATRRequestedDurationSeconds` to seconds. Must run as an administrator.

### Global Options

`-h, --help`

Optional.

Show the command help.

## Help Output for initialize-tsm Script

The following help content is the output when you run the following command:

```
sudo ./initialize-tsm -h
```

The initialize-tsm script is installed to `/opt/tableau/tableau_server-/packages/scripts.<version_code>/`.

### Output

```
REQUIRED
--accepteula           Indicate that you have accepted the End User
License Agreement (EULA).
                       You can find the EULA in /opt/tableau/tableau_server-
/packages/docs.<version_code>

OPTIONAL
-c config-name         Set the service configuration name.
                       If not set, the default is "tabsvc".
```

```
-d data-directory      Set a custom location for the data directory
                       if it's not already set. If not set, the default is
                       "/var/opt/tableau/tableau_server".

-b bootstrap-file      Optional. Location of the bootstrap file
downloaded from the Tableau Services Manager
                       on existing node. Must be provided to join existing Tableau
Server cluster.

-u username            Name of the user with admin privileges on
existing Tableau Services Manager.
                       Required if -b option specified.

-p password            Password for the Tableau Services Manager
admin user.
Note: This option was removed beginning in version 2021.3.0 to
improve script security.

-f                     Bypass warning messages.

-g                     Do NOT add the current user to the "tsmad-
min" administrative
                       group, used for default access to Tableau Services Manager,
                       to the "tableau" group, used for easier access to log files.

-a username            The provided username will be used as the
user to be added
                       to the appropriate groups, instead of the user running this
                       script. Providing both -a and -g is not allowed.

-q                             Quiet, suppress output except for errors and warn-
ings.

-i coordinationservice-client-port      Client port for the coordin-
ation service
```

```
-e coordinationservice-peer-port        Peer port for the coordin-
ation service

-m coordinationservice-leader-port      Leader port for the coordin-
ation service

-t licenseservice-vendordaemon-port     Vendor daemon port for the
licensing service

-n agent-filetransfer-port              Filetransfer port for the
agent service

-o controller-port                      Https port for the con-
troller service

-l port-range-min                       Lower port bound for auto-
matic selection

-r port-range-max                       Upper port bound for auto-
matic selection

--disable-port-remapping                Disable automatic port selec-
tion

--unprivileged-user=<value>            Name of the unprivileged account
to run Tableau Server.
Default: "tableau".

--tsm-authorized-group=<value>         Name of the group(s) that allows
authorization to access Tableau Services Manager.
Default: "tsmadmin".

--disable-account-creation                    Do not create groups or user
accounts for Server and TSM authorization.
                                       However, the values in: unprivileged-user an
group will still be used
```

```
                                    in TSM configuration.

--http_proxy=<value>                 Http forward proxy for
Tableau Server. Its value should be http://<proxy_address>:<proxy_
port>/
                                     For example, --http_proxy=http://1.2.3.4:31
proxy=http://example.com:3128/

--https_proxy=<value>                Https forward proxy for
Tableau Server. Its value should be http://<proxy_address>:<proxy_
port>/
                                                                    For example, --https
proxy=http://example.com:3128/
                                                                    Take care to use htt
https_proxy environmental variable.
                                                                    Do not specify the h
https_proxy environmental variable.

--no_proxy=<value>                   Environment variable that directs certain UR
to bypass the forward proxy. For example,
                                     --no_proxy=localhost,127.0.0.1,localaddress,

--[no-]activation-service            Specify whether the Tableau
authorization-to-run (ATR) service should be used to activate
Tableau Server.
                                     This option is ideal for cloud-based or virt
but is available to anyone who
                                     can activate their copy of Tableau Server on
ATR for product activation is a permanent
                                     choice that cannot be undone later. If no op
the Tableau authorization-to-run (ATR) service will be used to
activate Tableau Server.
```

## Help Output for upgrade-tsm Script

The following help content is the output when you run the following command:

```
sudo ./upgrade-tsm -h
```

The upgrade-tsm script is installed to `/opt/tableau/tableau_server-/packages/scripts.<version_code>/`.

### Output

```
Usage: upgrade-tsm --accepteula [optional arguments]

Upgrade Tableau Server cluster to version <version number>.
This script should be run from any Tableau Server cluster node after
Tableau Server <version number> package
has been installed on all nodes.

REQUIRED
--accepteula                              Indicate that you have accep-
ted the End User License Agreement (EULA).
                                         You can find the EULA in docs directory

-u <value>, --username=<value>            TSM administrator user name.
Required if it is run using a non-TSM administrator
                                         account on the initial node, or if upgrading
prior to 2019.2.
-p <value>, --password=<value>            TSM administrator password.
```

```
Required if the --username option is specified.
                                        If a password is required but not provided,
ted for the password.
OPTIONAL
--debug                                  Print each command as it is
run for debugging purposes. Produces extensive
output.
--trust-admin-controller-cert            Do not validate the server
certificate.
--no-prompt                              Suppress script prompts.
You will only be prompted for missing required
                                        parameters, for example, if you specify a us
password. If the
                                        script needs to stop or restart Tableau Serv
without warning or
                                        prompting. Use this if you automate the upgr
with a script.

--external-repository-config-file=filename
                                        Required if upgrading from a Tableau Server
Tableau Server

```

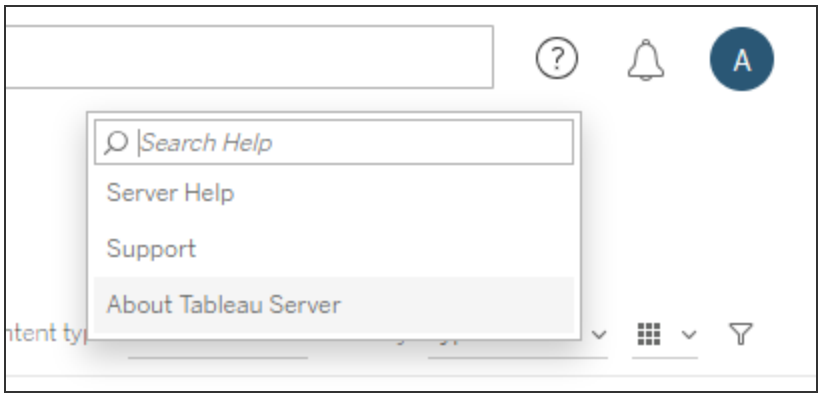
## View Server Version

The version of Tableau Server you are running is important. It determines the functionality and capabilities you have access to. Version is also important when you are upgrading, because in some cases how you upgrade depends on which version you are upgrading from, and which version you are upgrading to. Knowing your version is easy, once you understand how to find it.

- Viewing version in Tableau Server—All server users can view the version of Tableau Server from the Help menu in the server web UI.
- Viewing version in Tableau Services Manager (TSM)—TSM administrators can view the versions of TSM and Tableau Server from the TSM command line (CLI).

### Viewing the server version from the Tableau Server web UI

- While logged into Tableau Server, click the information icon ( ) and **About Tableau Server**.



The version of Tableau Server is listed in the About Tableau Server dialog box:

## Viewing the server version and TSM version from the TSM command line

1. Open a command prompt as administrator on the initial node (the node where TSM is installed).
2. Run the following command:

   ```
   tsm version
   ```

The output displays the versions of Tableau Services Manager (TSM) and Tableau Server.

For example:

```
C:\>tsm version
Tableau Services Manager command line version 20182.18.1214.0751.
Tableau Server version 20182.18.1214.0751.
```

## Short version, long version, and version_code

In most cases, when you need to know your version number, you need to know the "short" version. This version number displays in the About Tableau Server dialog box and is made up of three parts: major, minor, and maintenance versions. The short version number has this format: `nnnn.n.n`. For example: `2018.2.5`.

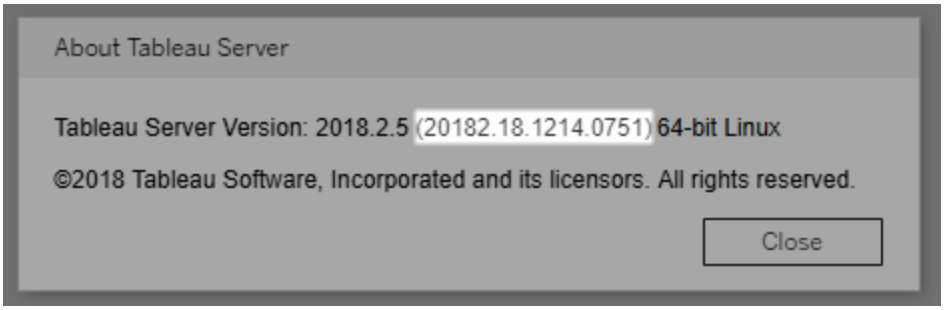
A longer version includes the major and minor version numbers, as well as other build-specific information, and has this format: `nnnnn.nn.nnnn.nnnn`, for example: 20182.18.1214.0751. When you see a reference to `<version_code>` in this documentation, it means this longer version. The most common reference to this `version_code` or long version in the documentation is when we are discussing install locations or paths to the scripts or bin directories.

Tableau Server is installed in a `/packages` directory, with subdirectories that include the long version in the path name. This means that when you are navigating to a location within the `/packages` directory, you need to include the long version. For example, the `/scripts` directory: `/opt/tableau/tableau_server/packages/scripts.<version_code>/`.

For example: `/opt/tableau/tableau server-/packages/scripts.20182.18.1214.0751`

Finding the long version number

This longer version also displays in the About Tableau Server dialog box, in parentheses:



# Configure Einstein Discovery Integration

Beginning with version 2021.1.0, Tableau Server supports integration with Einstein Discovery, making Einstein Discovery predictions available to authors and viewers of workbooks and dashboards. Starting in version 2021.2.0, Einstein Discovery predictions is also now available when authoring flows on the web.

Einstein Discovery in Tableau is powered by salesforce.com. Consult your agreement with salesforce.com for applicable terms.

To integrate Einstein Discovery with Tableau Server, there are several necessary configuration steps, including some in Tableau Server, and some in the Salesforce org running Einstein Discovery. This overview outlines these steps for Dashboard extensions, Analytics extensions, and Tableau Prep extensions, and provides links to specific topics with steps for completing the server configuration.

For details on how to use Einstein Discovery predictions in Tableau, including licensing and permission requirements, see Integrate Einstein Discovery Predictions in Tableau in the Tableau Desktop and Web Authoring Help. For information about adding predictions in flows, see Add Einstein Discovery Predictions to your flow.

## Einstein Discovery dashboard extensions

The Einstein Discovery dashboard extension allow workbook authors to surface real-time predictions in Tableau. The dashboard extension delivers predictions interactively, on-demand, using source data in a Tableau workbook and an Einstein Discovery-powered model deployed in Salesforce.

To configure Tableau Server for the Einstein Discovery dashboard extension you need to do the following:

1. In Tableau Server:
    a. Enable saved OAuth tokens for data connections and extensions in Tableau Server. Allow Saved Access Tokens

   b. Enable Dashboard extensions for the server. See: Manage Dashboard and Viz Extensions in Tableau Server
2. In Salesforce, in the organization running Einstein Discovery:
   a. Configure CORS in Salesforce.com for Einstein Discover Integration in Tableau Server.
   b. In Salesforce, in the organization running Tableau CRM, create a connected app. See Step 1: Create a Salesforce connected app.
3. In Tableau Server, configure server for saved SF OAuth credentials using information from the connected app. Step 2: Configure Tableau Server for Salesforce.com OAuth

## Einstein Discovery analytics extensions

The Einstein Discovery analytics extension gives your users the ability to embed predictions directly in Tableau calculated fields. A table calc script requests predictions from a model deployed in Salesforce by passing its associated prediction ID and input data that the model requires. Use Model Manager in Salesforce to auto-generate a Tableau table calculation script, and then paste that script into a calculated field for use in a Tableau workbook.

To configure Tableau Server for either the Einstein Discovery analytics extension you need to do the following:

1. In Tableau Server:
   a. Enable saved OAuth tokens for data connections and extensions in Tableau Server. Allow Saved Access Tokens
   b. Enable analytics extensions for the server and configure a connection type. See: Configure Connections with Analytics Extensions
2. In Salesforce, in the organization running Einstein Discovery, create a connected app. See Step 1: Create a Salesforce connected app.
3. In Tableau Server, configure server for saved SF OAuth credentials using information from the connected app. Step 2: Configure Tableau Server for Salesforce.com OAuth

## Einstein Discovery Tableau Prep extensions

*Supported in Tableau Server and Tableau Cloud starting in version 2021.2.0*

The Einstein Discovery Tableau Prep extension enables users to embed Einstein predictions directly in their flows when authoring flows on the web.

To configure Tableau Server or Tableau Cloud for the Einstein Discovery Tableau Prep extension you need to do the following:

1. In Tableau Server:
    a. Enable saved OAuth tokens for data connections and extensions in Tableau Server. See Allow Saved Access Tokens
    b. Enable Tableau Prep Extensions for the server. See Enable Tableau Prep Extensions.
2. In Salesforce, in the organization running Einstein Discovery, create a connected app. See Step 1: Create a Salesforce connected app.
3. In Tableau Server, configure server for saved SF OAuth credentials using information from the connected app. Step 2: Configure Tableau Server for Salesforce.com OAuth

## Configure CORS in Salesforce.com for Einstein Discover Integration in Tableau Server

In version 2021.1.0 the ability to integrate Einstein Discovery predictions into Tableau Dashboards was added. You can do this using the Einstein Discovery dashboard extension. A prerequisite for this is configuring Cross-Origin Resource Sharing (CORS) in the Salesforce org that hosts Tableau CRM and includes the model and predictions that are going to be used.

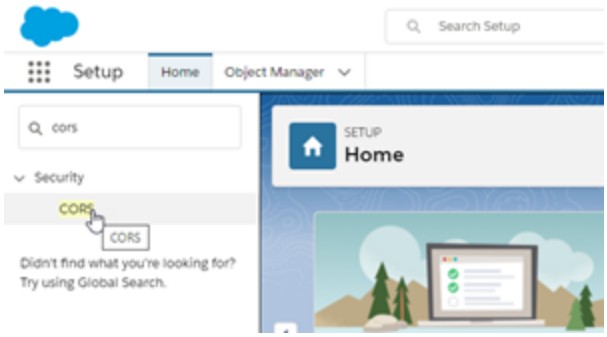
This procedure explains how an administrator in a Salesforce.com organization would do this configuration. You can find more information about CORS in the Salesforce documentation, Configure Salesforce CORS Allowlist.

Configure CORS for Einstein Discovery.

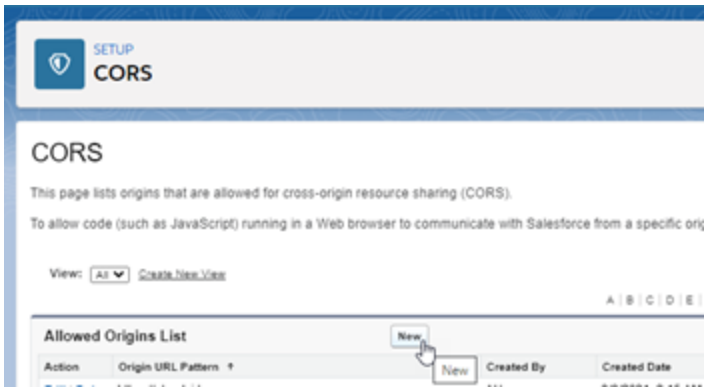
> **Note:** This procedure documents the process in Salesforce Lightning. If you are using the traditional interface, the navigation may be different but the configuration is the same.

1. Sign in to your Salesforce.com developer account, click your user name in the upper-right, and then select **Setup**.

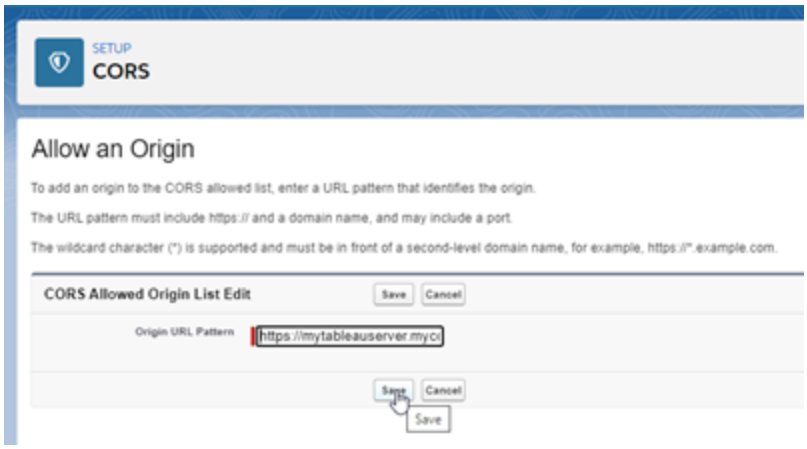
2. In the left navigation column, search for "cors" and select **CORS** .



3. In **CORS**, in the **Allowed Origins List** section, click **New**.



4. In **CORS Allowed Origin List Edit**, enter the URL of your Tableau server, beginning with "https://".



For more information about the URL pattern, see the Salesforce developer documentation: https://developer.salesforce.com/docs/atlas.en-us.chatterapi.meta/chatterapi/extend_code_cors.htm

5. Click **Save**.

## Configure Connections with Analytics Extensions

Tableau supports a set of functions that your users can use to pass expressions to analytics extensions for integration with R, Python, and Einstein Discovery.

**Note**: You can use R and Python scripts to perform complex cleaning operations in your Tableau Prep flows, but configuration and functionality supported can be different. For information see Use R and Python Scripts in your Flow in the Tableau Prep help.

This topic describes how to configure sites on Tableau Server with analytics extensions.

Because Tableau Server provides an authentication mechanism, it can be more secure to expose analytics extensions functionality to users through Tableau Server than in Tableau Desktop.

For more information about user scenarios and configuring Tableau Desktop or Tableau Cloud, see Pass Expressions Analytics Extensions, in the *Tableau Desktop and Web Authoring Help*.

The configuration steps in this article are specific to Workbooks. For information about how you can use R and Python scripts to incorporate predictive modeling data into your flow, see Use R and Python scripts in your flow in the *Tableau Prep Help*.

## Server SSL

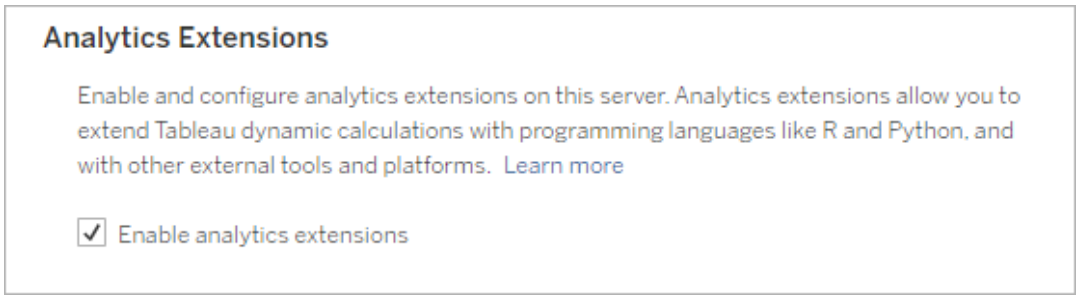
To configure SSL for analytics extensions, you must install a valid certificate on the computer running Tableau Server. The certificate must be trusted by the computer running Tableau Server. The certificate Subject field or one of the SAN entries on must exactly match the URI of the analytics extensions service configuration.

## Enable analytics extensions

Before you configure extensions, you must enable analytics extensions server-wide.

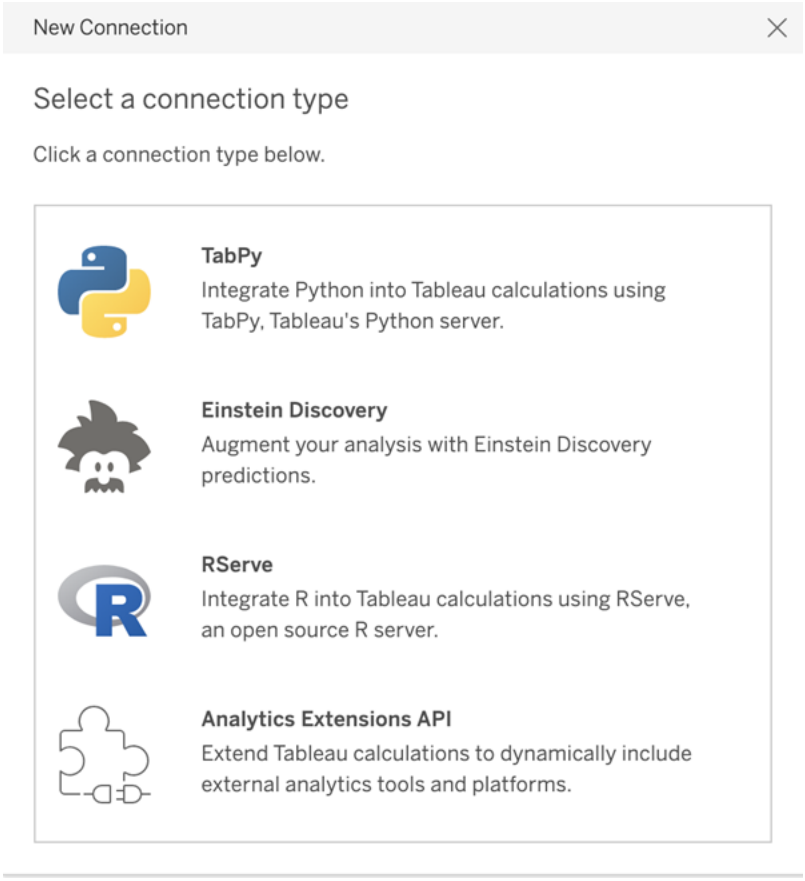
1. Sign in to the Tableau Server Admin Area.
   - If you only have a single site (default) on your server, click **Settings**, and then go to Step 2.
   - If you have multiple sites on your server:
     a. Under **All Sites**, click **Manage all sites**.
     b. Click the **Extensions** tab.

2. Scroll to **Analytics Extensions**, select **Enable analytics extensions**, and then click **Save**.



## Configure analytics extensions settings

1. Sign in to the Tableau Server Admin Area.
2. On the Settings page, click the **Extensions** tab and then scroll to **Analytics Extensions**. (On multi-site deployments of Tableau Server, navigate to the site where you want to configure analytics extensions, and then click **Settings**>**Extensions**.)
3. **Multi-site deployments only**: you must enable Analytics Extensions on each site. Under Analytics Extensions, select **Enable analytics extensions for site**.
4. Under Analytics Extensions, click **Create new connection**.
5. In the **New Connection** dialog, click the connection type you want to add, then enter the configuration settings for your analytics service:



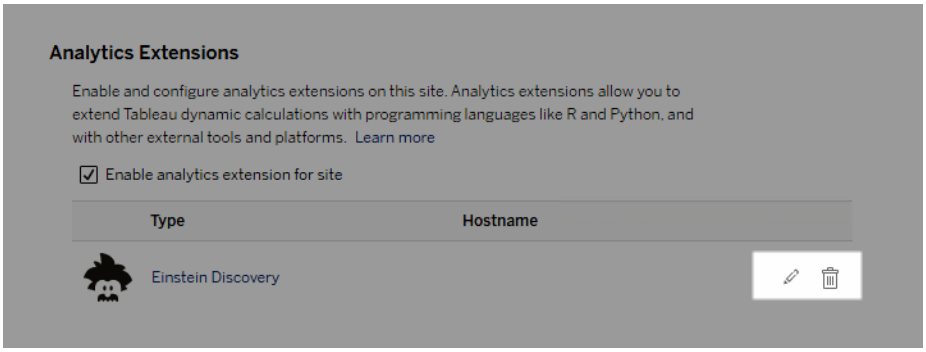
6. The options you need to configure depend on the connection type you choose:

- For an Einstein Discovery connection, click **Enable**.
- For TabPy, RServer, and Analytics Extensions API connections, enter the following information:
  - **Connection Name** (Required): Specify the server type you are connecting to. RSERVE supports connections to R using the RServe package. TABPY supports connections to Python using TabPy, or to other analytics extensions.
  - **Require SSL** (Recommended): Select this option to encrypt the connection to the analytics service. If you specify a `HTTPS` URL in the **Hostname** field, then you must select this option.
  - **Hostname** (Required): Specify the computer name or URL where the analytics service is running. This field is case sensitive.
  - **Port** (Required): Specify the port for the service.
  - **Sign in with a username and password** (Recommended): Select this option to specify user name and password that is used to authenticate to the analytics service.

7. Click **Create**.

Edit or delete an analytics extension connection

To edit or delete a configuration, navigate to **Analytics Extensions** on the **Extensions** tab of your site.



Click the **Edit** or **Delete** icon and follow the prompts to change the configuration.

## Client requirement: Intermediate certificate chain for Rserve external service

You must install a full certificate chain on Tableau Desktop computers (Windows and Mac) that are connecting to a Rserve external connection through Tableau Server. This requirement is due to how Rserve manages the handshake on secure connections.

Importing a root certificate on the Tableau Desktop is not sufficient, the entire certificate chain must be imported onto the client computer.

## Script errors

Tableau cannot verify that workbooks that use an analytics extension will render properly on Tableau Server. There might be scenarios where a required statistical library is available on a user's computer but not on the analytics extension instance that Tableau Server is using.

A warning will be displayed when you publish a workbook if it contains views that use an analytics extension.

> This worksheet contains external service scripts, which cannot be viewed on the target platform until the administrator configures an external service connection.

## Determining analytics extensions usage

Beginning with version 2021.2, analytics extensions configurations are mapped at the workbook level. This allows administrators to use custom views to query the Tableau Repository and determine which workbooks are using which extensions, and how often they are used.

To do this you need to join the workbook connections table to tables showing workbook usage. For details about creating and using custom administrative views, see Collect Data with the Tableau Server Repository and Create Custom Administrative Views.

# Changing the Identity Store

Infrastructure or business changes may require you to change the identity store on Tableau Server. There are two kinds of identity stores: local and external. When you installed Tableau Server you configured either a local identity store or an external identity store.

When you configure Tableau Server with a local identity store, all user and group information is stored and managed in the Tableau Server repository. In the local identity store scenario, there is no external source for users and groups.

When you configure Tableau Server with an external store, all user and group information is stored and managed by an external directory service. Tableau Server must synchronize with the external identity store so that local copies of the users and groups exist in the Tableau Server repository, but the external identity store is the authoritative source for all user and group data. Examples of external identity stores are OpenLDAP and Active Directory.

For more information about the Tableau identity store, see Identity Store.

You can change from local store to an external store, or you can change from an external store to a local store. In either case, to change the identity store type, you complete these steps:

1. Uninstall and then reinstall of Tableau Server. The procedure for full uninstall and clean install are at the end of this topic.
2. Restore content and permissions.

   In these steps the term "restore" does not refer to using the `TSM maintenance restore` command to restore the backup you are making. You cannot restore a backup (`.tsbak`) created on a Tableau Server instance that uses a different identity store than the target Tableau Server. The backup is a best practice safeguard, in case you need to go back to your original Tableau Server configuration.

Warning

Changing the installation type on Tableau Server can be a complicated and time-consuming process. To avoid data loss or orphaning of content or users, you'll need to plan this process carefully. In all cases, user filters applied to workbooks and data sources will need to be updated manually after the change.

Most importantly, determine how you will transition content and permissions to the new identity store after you reinstall Tableau Server.

## Methods for restoring content and permissions

The following list describes two methods for restoring content and permissions after you reinstall Tableau Server. Select the method that best fits with your environmental requirements.

- **Method 1: Use site export and import**—In this method, you start by exporting each site in your existing deployment. Then, you install the new server and configure it for the new identity store type. You then create new users in the default site on the new server. Finally, you import all the original sites. During the import stage, you can map the original identities to the new users that you created in the default site.

  **Note:** When migrating sites between instances of Tableau Server, the target site must be on a version of Tableau Server that is the equal to or later than the version of Tableau Server for the source site. Both the source and target sites must be from supported versions of Tableau Server.

  Because this method exports all content and permissions at each site, it is the best method for organizations that require a high fidelity replica of the content and permissions after the identity store change is complete. Some organizations require an identity store change as the result of an authentication change. In these cases, a different user name syntax is a often a requirement in the new model. This method, which includes a process of mapping original user names to new names, provides flexibility for such scenarios.

- **Method 2: Fresh installation; users republish content**—In this method, you install a new version of Tableau Server and select the new identity store type during setup. You also create new sites. You then create users and give them access, and they republish their workbooks and data sources. Unlike the other method, in this one, you do not reuse any of your existing Tableau Server infrastructure.

  This method is most appropriate for smaller deployments with fairly autonomous and data savvy users. From an administrative perspective, this method is the simplest, since you're not actively porting over content. However, because you rely entirely on users to republish content, this method may not be successful for large organizations or for those where centralized oversight of content is required.

## User filters

User filters are domain-specific. Therefore, when the domain of Tableau Server changes or authentication type changes, filters no longer function as expected. Although the user filters are generated by Tableau Server, after they are set by the user, the filters are stored in the workbooks and data sources. Neither of these methods for changing the identity store modifies the contents of the workbooks or data sources.

As you plan the identity store change, you must also include a final task to correct user filtering in all workbooks and data sources with Tableau Desktop.

## User names and the Tableau Identity store

If you are using Method 1, it's helpful to understand how Tableau Server stores user names in the Tableau identity store. Tableau stores all user identities in the repository, which coordinates content permissions and site membership with various services in Tableau Server. Generally, an identity store configured for Active Directory store user names in the format, `domain\username`. Some organizations use a UPN (`jsmith@domain.lan`).

On the other hand, organizations that configure Tableau Server with local identity store usually create standard, truncated user names, such as `jsmith`.

In all cases, these user names are literal strings that must be unique in the Tableau identity store. If you are changing from one identity store type to another, then your target authentication, SSO, or user provisioning solution may require a specific user name format.

Therefore, to maintain all permissions, content, and user viability, one of the following must be true after you change the identity store type:

- The new user names must match the original user names, or
- The original user names must be updated to match a new format.

If an authentication change is driving the identity store change, then the target authentication scheme will likely impose a user name syntax that is different than your original user names. Method 1 includes a process where you can map original user names to new user names.

It's possible that the original user name format will work with the new authentication type. For example, if you used UPN names in a local identity store deployment, you might be able to use the same user names in an Active Directory deployment. You could also use the `domain\username` format for local identity store, as long as users continue to use that format to sign in to Tableau Server.

If you are changing from local identity store to an external Active Directory store, review the topic, User Management in Deployments with External Identity Stores, as part of your planning process.

## Method 1: Use site export and import

You must use the same version of Tableau Server for the export and import operations.

1. Export all sites on your server. See Export or Import a Site.
2. Back up, remove, and then reinstall .
3. Create new users on Tableau Server. You should have a new user that corresponds to each user on the original server.
4. Import the sites that you exported in Step 1. See Export or Import a Site. During import, you will be prompted to map the new users to the original users.

## Method 2: Fresh installation–users republish content

Even if you do not plan to port content as part of your identity store change, we recommend that you back up the server.

1. Back up, remove, and then reinstall .
2. Create users, sites, and groups.
3. Inform your users of the new Tableau Server, provide them with credentials, and allow them to republish their content.

## Back up, remove, and then reinstall

Both methods include the following steps:

1. Back up Tableau Server
2. Remove Tableau Server.
3. Reinstall Tableau Server with the new identity store type.

Step 1: Back up Tableau Server

As a best practice, you should back up the server before proceeding.

Follow the procedure, Create a backup using the TSM command line interface (CLI). Run the `backup` command with the `-d` option. The `-d` option adds the datestamp.

When you are finished, copy the backup file (`.tsbak`) to a safe location that is not a part of your Tableau Server installation.

Step 2: Remove Tableau Server

You must completely remove Tableau Server from the computer. See Remove Tableau Server from Your Computer.

Step 3: Reinstall Tableau Server with new authentication type

1. Go to the Tableau Customer Portal, sign in with your Tableau user name and password, and then download Tableau Server.
2. Install Tableau Server. See Install and Configure Tableau Server more information. During installation, you will select the new identity store type. See Configure Initial Node Settings.

# External Identity Store Configuration Reference

Tableau Server supports connecting to an external directory using LDAP. In this scenario, Tableau Server imports users from the external LDAP directory into the Tableau Server repository as system users.

This topic provides a description of all LDAP-related configuration options Tableau Server supports. If you are connecting to Active Directory, we strongly recommend that you automatically configure the LDAP connection with Tableau Server as part of Setup, rather than configuring the connection manually. See Configure Initial Node Settings.

The options listed in this reference can be used for any LDAP-compliant directory. If you do not have experience configuring LDAP, then work with your directory administrator, or with an LDAP expert.

This is a reference topic. For more information about how Tableau Server stores and manages users, start with Identity Store.

## Configuration methods

Configuration parameters that enable Tableau Server to connect to your LDAP directory are stored in .yml files. These files are managed and synchronized by various services in Tableau Server. Updating the .yml files must be done using a Tableau Services Manager (TSM) interface.

Do not attempt to update .yml files directly with a text editor. TSM must manage all updates for proper operation.

The .yml configuration files are composed of key-value pairs. For example, the key, `wgserver.domain.username`, takes a username as a value. This key defines the username that will be used to authenticate to the LDAP directory during the bind operation.

There are four different TSM methods that can set yml key values. The four methods are described here, using the `wgserver.domain.username` key as an example to illustrate the different methods:

- configKey key-value pairs—You can update a .yml configuration file key by updating the `wgserver.domain.username` key running tsm configuration set Options, or by including the key in a JSON configuration file under a configKey entity. See Configuration File Example.

  The configKey key-value pairs in a JSON configuration file are the same as those used for `tsm configuration set` but they are set differently. This topic refers to both of these methods as *configKey*.

  Unlike when using configEntities and native tsm commands that are described below, configKey input is not validated. When you set an option with a configKey, the value that you enter is copied as a literal string to the underlying .yml configuration files. For example, for a key where `true` or `false` are the valid inputs, when you configure the key using a configKey key-value pair, you can enter an arbitrary string value and it will be saved for the key. In such cases, invalid values will undoubtedly lead to LDAP configuration errors.

  We recommend using configKeys only when no option exists to set the configuration with the other three options listed below (configEntities, a native tsm command, or the TSM Web UI). When using configKeys be sure to double-check your values and be sure to mind case-sensitivity.

- configEntities JSON—You can update a .yml configuration file by passing the `username` option in a *configEntities* JSON.

  When you configure a value using configEntities options in a JSON file, the values are validated before they are saved. Values are case-sensitive. For details on how to configure a value using configEntities, see the identityStore Entity example. The JSON file is imported with the tsm settings import command. The options available for configEntities are a subset of all the .yml key-value pairs.

Validation means that the import command will only succeed if all the values in the JSON file are valid data types. For example, if you enter `no` for a value that only accepts `true` or `false`, then you will receive an error and the configuration is not imported.

You can only import JSON configuration files only as part of the initial configuration. If you need to make LDAP changes after you have imported the JSON configuration file and initialized Tableau Server, do not attempt to re-import the JSON file. Instead, make individual key changes with native tsm commands if available, or using configKeys and `tsm configuration set`.

- Native tsm commands—You can update a .yml configuration file by passing the `ldapuser` option with the *native tsm command* `tsm user-identity-store`. As with configEntities, values that you enter with the native tsm command are validated before they are saved.

  Not all key-value pairs in a .yml file can be set using native tsm commands.

- TSM GUI—You can set configuration values during Setup, using the TSM GUI. If you are connecting to Active Directory, and configure the Tableau identity store during Setup, with the GUI, then you are prompted for an account with AD read access. The `wgserver.domain.username` key is set when you enter credentials.

  This scenario only works if you are connecting to Active Directory. Tableau Server does not support arbitrary LDAP configuration as part of the GUI Setup process.

Consider using the Tableau Identity Store Configuration Tool to generate your LDAP json configuration file. The Tableau Identity Store Configuration Tool will also generate a list of key/-value pairs that you can set by running tsm configuration set Options. The tool itself is not supported by Tableau. However, using a JSON file created by the tool instead of creating a file manually does not change the supported status of your server.

## Configuring Active Directory

If you are configuring Tableau Server to use Active Directory, we recommend using the TSM Web UI during installation. The TSM Web UI is optimized to configure Tableau Server for Active Directory with the minimum necessary input. See Configure Initial Node Settings.

## Configuration reference table

| **configEntities option**<br><br>**(Options are case sensitive)** | **Native tsm command** | **configKey**<br><br>**(Used with tsm configuration set command or in the configKeys section of a JSON file)** | **Scenario** | **Notes** |
|---|---|---|---|---|
| type | N/A | wgserver.authenticate | AD, LDAP, Local | Where you want to store user identity information. Values: `local` or `activedirectory`.<br><br>If you want to connect to any LDAP server, enter `activedirectory`. |
| sslPort | N/A | wgserver.domain.ssl_port | AD, LDAP | Use this option to specify the secure port of the LDAP server. We recommend secure LDAP for simple bind. LDAPS is usually port 636. |
| N/A | N/A | wgserver.domain.ldap.starttls.enabled | AD, LDAP | Values: `true` or `false`.<br><br>Beginning with version 2021.2, this key is set to `true` by default when Tableau Server is configured to connect to Active Directory. As a result, simple bind to LDAP directory is |

| | | | | |
|---|---|---|---|---|
| | | | | encrypted when a valid SSL/TLS certificate is present in the Tableau key store. For more information, see Configure Encrypted Channel to LDAP External Identity Store.<br><br>This key is set to `false` by default when Tableau Server is configured to connect to a an arbitrary (but not Active Directory) LDAP server.<br><br>This key was introduced (but not set) in version 2021.1. |
| port | N/A | wgserver.domain.port | AD, LDAP | Use this option to specify the non-secure port of the LDAP server. Plaintext is usually 389. |
| domain | domain | wgserver.domain.default | AD | In Active Directory environments, specify the domain where Tableau Server is installed, for example, "example.lan".<br><br>For non-AD LDAP: the string you enter for this value is displayed in the "Domain" column of user management tools. You can enter an arbitrary string, but the key cannot be blank.<br><br>This key is redundant with wgserver.domain.fqdn. The values for both keys must be the same. |

| | | | | |
|---|---|---|---|---|
| | | | | Native tsm command: Uses tsm user-identity-store set-connection [options] command. |
| username | ldapu-ser-name | wgserv-er.domain.username | A-D, LD-AP | The user name that you want to use to connect to the directory service.<br><br>The account that you specify must have permission to query the dir-ectory service.<br><br>For Active Directory, enter the user-name, for example, `jsmith`.<br><br>For LDAP servers, enter the dis-tinguished name (DN) of the user that you want to use to connect. For example, `"cn=-=jsmith,dc=example,dc=lan"`.<br><br>Native tsm command: Uses tsm user-identity-store set-connection [options] command. |
| password | ldap-pass-word | wgserv-er.domain.password | A-D, LD-AP | The password of the user account that you will use to connect to the LDAP server.<br><br>Native tsm command: Uses tsm user-identity-store set-connection [options] command. |
| dir-ect-orySer- | N/A | wgserv-er.-domain.- | A-D, LD- | The type of LDAP directory service that you want to connect to. Values:`activedirectory` or `open-` |

| viceType | | directoryservice.type | AP | `ldap`. |
|---|---|---|---|---|
| ker-ber-osPrincipal | ker-bprin-cipal | wgserv-er.-domain.ldap.principal | A-D, LD-AP | The service principal name for Tableau Server on the host machine. The keytab must have permission for this principal. Do not use the existing system keytab at `/etc/kr-b5.keytab`. Rather, we recommend that you register a new service prin-cipal name. To see principals in a given keytab, run the `klist -k` com-mand. See Understanding Keytab Requirements.<br><br>Native tsm command: Uses tsm user-identity-store set-connection [options] command. |
| hostname | host-name | wgserv-er.-domain.ldap.host-name | A-D, LD-AP | The hostname of the LDAP server. You can enter a hostname or an IP address for this value. The host that you specify here will be used for user-/group queries on the primary domain. In the case where user/group queries are in other domains, Tableau Server will query DNS to identify the appro-priate domain controller.<br><br>Native tsm command: Uses tsm user-identity-store set-connection [options] command. |
| mem-ber-sRetriev-alPageSize | N/A | wgserv-er.-domain.ldap.mem-ber- | A-D, LD-AP | This option determines the maximum number of results returned by an LDAP query. |

| | | | | |
|---|---|---|---|---|
| | | s.retrieval.page.size | | For example, consider a scenario where Tableau Server is importing an LDAP group that contains 50,000 users. Attempting to import such a large number of users in a single operation is not a best practice. When this option is set to 1500, Tableau Server imports the first 1500 users in the first response. After those users are processed, Tableau Server requests the next 1500 users from the LDAP server, and so forth.<br><br>We recommend that you modify this option only to accommodate the requirements of your LDAP server. |
| N/A | N/A | wgserver.domain.ldap.connectionpool.enabled | AD, LDAP | When this options is set to `true`, Tableau Server will attempt to reuse the same connection when sending queries to the LDAP server. This behavior decreases the overhead of having to re-authenticate with the LDAP server on each new request. Connection pooling only works with simple bind and TSL/SSL bind connections. Connection pooling is not supported for GSSAPI bind connections. |
| N/A | N/A | wgserver.domain.accept_list | AD | Allows connection from Tableau Server to secondary Active Directory domains. A secondary domain is one that Tableau Server connects to for |

| | | | | |
|---|---|---|---|---|
| | | | | user synchronization, but is a domain where Tableau Server is not installed. To ensure that Tableau Server can connect to other Active Directory domains, you must specify the trusted domains by setting the `wgserver.domain.accept_list` option with TSM. For more information, see wgserver.domain.accept_list. |
| N/A | N/A | wgserver.domain.whitelist | AD | **Important:** Deprecated as of version 2020.4.0. Use wgserver.domain.accept_list instead.<br><br>Allows connection from Tableau Server to secondary Active Directory domains. A secondary domain is one that Tableau Server connects to for user synchronization, but is a domain where Tableau Server is not installed. To ensure that Tableau Server can connect to other Active Directory domains, you must specify the trusted domains by setting the `wgserver.domain.whitelist` option with TSM. For more information, see wgserver.domain.whitelist . |
| kerberosConfig | kerbconfig | No direct mapping | AD, LDAP | The path to the Kerberos configuration file on the local computer. If you are installing into Active Directory, we don't recommend using the existing Kerberos configuration file or |

| | | | | |
|---|---|---|---|---|
| | | | | keytab file that may already be on the domain-joined computer. See Identity Store<br><br>Native tsm command: Uses tsm user-identity-store set-connection [options] command. |
| ker-ber-osKeytab | kerb-keyta-b | No direct mapping | A-D, LD-AP | The path to the Kerberos keytab file on the local computer. It is recommended that you create a keytab file with keys specifically for Tableau Server service and that you do not share the keytab file with other applications on the computer. For example, on Linux, you might place the keytab file in the `/var/-opt/tableau/keytab` directory.<br><br>Native tsm command: Uses tsm user-identity-store set-connection [options] command. |
| nickname | N/A | wgserv-er.domain.nickname | A-D, LD-AP | The nickname of the domain. This is also referred to as the NetBIOS name in Windows/Active Directory environments. The `nickname` option is required for all LDAP entities. The value cannot be null. If your organization does not require a nickname/NetBIOS, then pass a blank key, for example: `""`. |

| | | | | |
|---|---|---|---|---|
| root | N/A | wgserv-er.domain.ldap.root | LD-AP | If you do not use a dc component in the LDAP root or you want to specify a more complex root you need to set the LDAP root. Use the "o=my,u=root" format. For example, for the domain, `example.lan`, the root would be `"o=example,u=lan"`. |
| server-SideSorting | N/A | wgserv-er.-domain.ldap.server_side_sorting | LD-AP | Whether the LDAP server is con-figured for server-side sorting of query results. If your LDAP server supports server-side sorting, set this option to `true`. If you are unsure whether your LDAP server supports this, enter `false`, as misconfiguration may cause errors. |
| rangeRetri-eval | N/A | wgserv-er.-domain.ldap.range_retrieval | LD-AP | Whether the LDAP server is con-figured to return a range of query res-ults for a request. This means that groups with many users will be requested in small sets instead of all at once. LDAP servers that support range retrieval will perform better for large queries. If your LDAP server supports range retrieval, set this option to `true`. If you are unsure whether your LDAP server supports range retrieval, enter `false`, as mis-configuration may cause errors. |
| bind | N/A | wgserv-er.domain.ldap.bind | LD-AP | The way that you want to secure com-munication to the directory service. Enter `simple` for LDAP unless you are connecting to an LDAP server with Kerberos. For Kerberos, enter |

| | | | | |
|---|---|---|---|---|
| | | | | `gssapi`. |
| N/A | N/A | wgserv-er.-domain.ldap.domain_custom_ports | LD-AP | **Note**: This key is only supported for Tableau Server on Linux.<br><br>Allows you to map child domains and their LDAP ports. Domain and port are separated by a colon (:) and each domain:port pair is separated by a comma (,) using this format: `FQDN1:-port,FQDN2:port`<br><br>Example: `tsm configuration set -k wgserv-er.domain.ldap.domain_cus-tom_ports -v child-domain1.lan:3269,child-domain2.lan:3269,child-domain3.lan:389` |
| dis-tin-guishedNa-meAttribute | N/A | wgserv-er.-domain.ldap.d-nAttribute | LD-AP | The attribute that stores the dis-tinguished names of users. This attrib-ute is optional, but it greatly improves the performance of LDAP queries.<br><br>**Important**: Do not set this option as part of the initial configuration. Only set this after you have val-idated overall LDAP functionality. |

| | | | | |
|---|---|---|---|---|
| | | | | You must have a dnAttribute set in your organization before setting this key. |
| groupBaseDn | N/A | wgserver.domain.ldap.group.baseDn | LDAP | Use this option to specify an alternative root for groups. For example, if all of your group are stored in the base organization called "groups," then enter `"o=groups"`. |
| N/A | classnames | wgserver.domain.ldap.group.classnames | LDAP | By Default, Tableau Server will look for "group", "groupOfNames", or "groupOfURLs". If your LDAP group objects do not fit the default class name, override the default by setting this value. You can provide multiple classnames separated by commas.<br><br>If your group names include commas, you must escape them with a backslash (\). For example, if you have a group name, `groupOfNames, top`, then enter `"groupOfNames\, top"`.<br><br>Tableau LDAP implementation interprets LDAP objects as either user or group. Therefore, be sure that you are entering the most specific class name. Overlapping class names between users and groups may cause |

| | | | | |
|---|---|---|---|---|
| | | | | conflicts.<br><br>Native tsm command: Uses tsm user-identity-store set-group-mappings [options] command. |
| groupBase-Filter | base-filter | wgserv-er.-domain.ldap.-group.baseFilter | LD-AP | The filter that you want to use for groups of users of Tableau Server. You might specify an object class attribute and an organization unit attribute. For example:<br><br>`"(&(objectClass-s=groupofNames)(ou=Group))"`<br><br>If `"(&(objectClass-s=inetOrgPerson)(ou=People))"` doesn't work in your LDAP implementation, then specify the base filter that works for your Tableau user base.<br><br>This is a required key. It cannot be blank.<br><br>Native tsm command: Uses tsm user-identity-store set-group-mappings [options] command. |
| groupName | group-name | wgserv-er.-domain.ldap.-group.name | LD-AP | The attribute that corresponds to group names on your LDAP server.<br><br>Native tsm command: Uses tsm user-identity-store set-group-mappings |

| | | | | |
|---|---|---|---|---|
| | | | | [options] command. |
| groupEmail | group-email | wgserv-er.-domain.ldap.-group.email | LD-AP | The attribute that corresponds to group email addresses on your LDAP server.<br><br>Native tsm command: Uses tsm user-identity-store set-group-mappings [options] command. |
| groupDe-scription | descr-iption | wgserv-er.-domain.ldap.-group.description | LD-AP | The attribute that corresponds to group descriptions on your LDAP server.<br><br>Native tsm command: Uses tsm user-identity-store set-group-mappings [options] command. |
| member | mem-ber | wgserv-er.-domain.ldap.-group.member | LD-AP | Specify the LDAP attribute that con-tains a list of distinguished names of users that are part of that group.<br><br>Native tsm command: Uses tsm user-identity-store set-group-mappings [options] command. |
| N/A | N/A | wgserv-er.-domain.ldap.-group.memberURL | LD-AP | Specify the name of the LDAP attrib-ute that stores the LDAP query for dynamic groups. |
| user-BaseDn | N/A | wgserv-er.-domain.ldap.user-.baseDn | LD-AP | Use this option to specify an altern-ative root for users. For example, if all of your users are stored in the base organization called "users," then enter |

| | | | | |
|---|---|---|---|---|
| | | | | "o=users". |
| N/A | class-name-s | wgserv-er.-domain.ldap.user-.classnames | LD-AP | By default Tableau Server looks for LDAP user object classes containing the string “user” and “inetOrgPerson”. If your LDAP user objects do not use these default class names, override the default by setting this value. You can provide multiple classnames separated by commas. For example: "userclass1, userclass2".<br><br>If your names include commas, you must escape them with a backslash (\). For example, if you have a name, Names, top, then enter "Names\, top".<br><br>Native tsm command: Uses tsm user-identity-store set-user-mappings [options] command. |
| user-BaseFilter | base-filter | wgserv-er.-domain.ldap.user-.baseFilter | LD-AP | The filter that you want to use for users of Tableau Server. You might specify an object class attribute and an organization unit attribute.<br><br>For example:<br><br>"(&(objectClass-s=inetOrgPerson) (ou=People))"<br><br>Native tsm command: Uses tsm user- |

| | | | | |
|---|---|---|---|---|
| | | | | identity-store set-user-mappings [options] command. |
| user-Username | ldapu-ser-name | wgserv-er.-domain.ldap.user-.username | LD-AP | The attribute that corresponds to user names on your LDAP server.<br><br>Native tsm command: Uses tsm user-identity-store set-user-mappings [options] command. |
| user-Dis-playName | dis-play-name | wgserv-er.-domain.ldap.user-.displayname | LD-AP | The attribute that corresponds to user display names on your LDAP server.<br><br>Native tsm command: Uses tsm user-identity-store set-user-mappings [options] command. |
| userEmail | email | wgserv-er.-domain.ldap.user-.email | LD-AP | The attribute that corresponds to user email addresses on your LDAP server.<br><br>Native tsm command: Uses tsm user-identity-store set-user-mappings [options] command. |
| user-Certificate | cer-tific-ate | wgserv-er.-domain.ldap.user-.usercertificate | LD-AP | The attribute that corresponds to user certificates on your LDAP server.<br><br>Native tsm command: Uses tsm user-identity-store set-user-mappings [options] command. |
| N/A | thum-bnail | wgserv-er.-domain.ldap.user- | LD-AP | The attribute that corresponds to user thumbnail images on your LDAP server. |

| | | | | |
|---|---|---|---|---|
| | | .thumbnail | | Native tsm command: Uses tsm user-identity-store set-user-mappings [options] command. |
| user-JpegPhoto | jpeg-photo | wgserv-er.-domain.ldap.user-.jpegphoto | LD-AP | The attribute that corresponds to user profile images on your LDAP server.<br><br>Native tsm command: Uses tsm user-identity-store set-user-mappings [options] command. |
| memberOf | mem-berof | wgserv-er.-domain.ldap.user-.memberof | LD-AP | Group that the user is a member of.<br><br>Native tsm command: Uses tsm user-identity-store set-user-mappings [options] command. |
| groupClass-Names | N/A | wgserv-er.-domain.ldap.-group.classnames | LD-AP | By Default, Tableau Server will look for "group", "groupOfNames", or "groupOfURLs". If your LDAP group objects do not fit the default class name, override the default by setting this value.<br><br>For configEntity: This option takes a list of strings, which requires passing each class in quotes, separated by a comma (no space) and within brack-ets. For example: `["basegroup","othergroup"]`.<br><br>For configKey: Enter each class, sep-arated by a comma (no space) and within double quotes. For example: |

| | | | | |
|---|---|---|---|---|
| | | | | "basegroup,othergroup”. |
| user-ClassName-s | N/A | wgserv-er.-domain.ldap.user-.classnames | LD-AP | By default Tableau Server looks for LDAP user object classes containing the string “user” and “inetOrgPerson”. If your LDAP user objects do not use these default class names, override the default by setting this value.<br><br>For configEntity: This option takes a list of strings, which requires passing each class in quotes, separated by a comma (no space) and within brack-ets. For example: ["user-class1",userclass2”].<br><br>For configKey: Enter each class, sep-arated by a comma (no space) and within double quotes. For example: "userclass1,userclass2”. |

Calculated configKeys

The following Kerberos-related configKeys are calculated and set according to multiple envir-onmental inputs. As such, they must be set by the native tsm command or configEntities. Do not attempt to set these configKeys manually.

| **Calculated configKey** | **To use the native TSM command:** | **To use configEntity json:** |
|---|---|---|
| wgserver.domain.ldap.kerberos.conf,<br><br>cfs.ldap.kerberos.conf | Set the Kerberos configuration file location with the `kerbconfig` | Set the Kerberos con-figuration file location with the `ker-berosConfig` con-figEntity option. |

| | | |
|---|---|---|
| | option of tsm user-identity-store set-connection [options] command. | |
| wgserver.domain.ldap.kerberos.keytab,<br><br>cfs.ldap.kerberos.keytab | Set the Kerberos keytab file location with the `kerb-keytab` option of tsm user-identity-store set-connection [options] command. | Set the Kerberos ketytab file location with the `kerberosKeytab` configEntity option. |

Unsupported configKeys

Some unsupported configKeys are present in underlying .yml configuration files. The following keys are not intended for standard deployments. Do not configure these keys:

- wgserver.domain.ldap.kerberos.login
- wgserver.domain.ldap.guid
- wgserver.domain.fqdn: this key is redundant with wgserver.domain.default. The values for both keys must be the same. Only update wgserver.domain.fqdn if the value does not match wgserver.domain.default.

## Basic Product Data

By default Tableau products send usage data to Tableau so that we can understand how customers use our software, and gain insights into where they are successful and where they might run into problems that we can address. For example, this data can help us learn where upgrades are commonly failing and allow us to make product changes to address those issues, or identify what portion of our user base needs informed about a security issue that applies to a specific version of Tableau Server. You can disable the sending of this data at installation time, or later. For details on how to do this, see the instructions for Tableau Desktop or Tableau Server.

Even when you disable the sending of product usage data, certain basic product data is sent to Tableau. This Basic Product Data includes information about products and their processes, including which product or process is running, when they start up, what operating system they are running on, licensing information, which machine or cluster of machines has sent the data (using unique pseudonymized identifiers), and whether the product is configured to send product usage data.

You can disable the sending of Basic Product Data at the machine level, or at the enterprise level, by blocking traffic sent to **prod.telemetry.tableausoftware.com**.

## Disabling sharing of Basic Product Data on individual computers

> **Important:** This procedure involves modifying your local `hosts` file. If you do not know what this is, you should not change it. You should only make this change if you understand the implications of making changes to the file, know how to change the file, and have made a backup of the file for safety.

Modifying `hosts` files changes network behavior for computers. Detailed instructions for modifying `hosts` files are provided by operating system providers such as Microsoft, Apple or Linux Distributions.

1. Make a copy of your existing hosts file and save it to a computer that is not your Tableau computer. This is your backup, in case you need to reverse your changes. Do not start modifying the file until you have made a backup copy of it.
2. Modify your computer's `hosts` file to include these lines:

```
# Stops sending Product Usage to Tableau (prod.tele-
metry.tableausoftware.com).
# Learn more here: http:\\tableau.com\derived-data
127.0.0.1    prod.telemetry.tableausoftware.com
```

The first and second lines are comments, explaining the third line.

The third line prevents all traffic to `prod.telemetry.tableausoftware.com` (`http://-prod.telemetry.tableausoftware.com/`) from leaving your local machine by sending it to the Internal host loopback address. The data does not get sent outside the computer.

### Disabling the sharing of Basic Product Data at the enterprise level

To disable sending of Basic Product Data on an enterprise level, modify your Network Firewall to prevent outbound traffic to `prod.telemetry.tableausoftware.com`.

This domain is used by Tableau to receive the Basic Product Data about process launch and shutdown. It is also used for the more general Product Usage Data. Blocking traffic to this domain it you will prevent both kinds of data from being sent.

Traffic to this domain will occur on Ports 80 (for initial registration of our Product Data clients) and on Port 443 (for all subsequent traffic). To completely prevent product data from being sent, block all traffic to this domain.

For details on how to configure your network firewall, refer to your vendor or your internal IT department. Tableau cannot provide these instructions.

# Archived Content

## This is archived content

Deployments on public clouds continue to be supported but the content for third-party public cloud deployments is no longer updated.

For the latest Tableau Server deployment content, see the Enterprise Deployment Guide and the Deploy section of Tableau Server help.

For those customers who have access, we recommend Tableau Cloud. For more details, see:

# Self-Host Tableau Server in a Public Cloud Service

## This is archived content

Deployments on public clouds continue to be supported but the content for third-party public cloud deployments is no longer updated.

For the latest Tableau Server deployment content, see the Enterprise Deployment Guide and the Deploy section of Tableau Server help.

For those customers who have access, we recommend Tableau Cloud. For more details, see:

- Tableau Cloud Manual Migration Guide
- Tableau Cloud Trial for Admin
- Tableau Cloud: Get Started for Admin

## Introduction

Even if you don't have your own infrastructure and server hardware, you can deploy an enterprise-level Tableau Server installation in the cloud. Building a cloud-based solution has many benefits over an on-premises installation. For example, the overall total cost of ownership for building a Tableau Server solution in the cloud is normally much less than a similar on-premises solution because you don't have to buy all of the expensive hardware. In addition, the cloud can provide better uptime, reliability, and fault-tolerance, especially if you deploy your solution across different regions and availability zones.

> Looking for Tableau Server on Windows? See Self-Host Tableau Server in a Public Cloud Service.

You can build and scale your Tableau environment in the following cloud environments:

- **Amazon Web Services** - You install and manage Tableau Server on Amazon Web Services (AWS). For more information, see Install Tableau Server in the AWS Cloud.

- **Google Cloud Platform** - You install and manage Tableau Server on the Google Cloud Platform. For more information, see Install Tableau Server on the Google Cloud Platform.
- **Microsoft Azure** - You install and manage Tableau Server on Microsoft Azure. For more information, see Install Tableau Server on Microsoft Azure.
- **Alibaba Cloud** - You install and manage Tableau Server on Alibaba Cloud. For more information, see Install Tableau Server in the Alibaba Cloud.

# About Tableau Advanced Management on Tableau Server

**Important:** As of September 16, 2024, Advanced Management is no longer available as an independent add-on option. Advanced Management capabilities are only available if you previously purchased Advanced Management, or if you purchase certain license editions - either Tableau Enterprise (for Tableau Server or Tableau Cloud) or Tableau+ (for Tableau Cloud).

Tableau Advanced Management is a collection of features for  Tableau Server which provide enhanced security, manageability, and scalability capabilities. The Advanced Management capabilities are available to you if you have Tableau Enterprise.

**Note:** Tableau Advanced Management includes several Tableau Server features and two separately installed tools: Tableau Content Migration Tool and the Tableau Resource Monitoring Tool. For more information, see the feature table later in this topic.

# Advanced Management Licensing Requirements

Advanced Management is licensed on a per Deployment basis, which may be User-Based or Core-Based. A Deployment includes a licensed production Tableau Server installation and two licensed non-production Tableau Server installations that support the production installation. For more information on Deployment, see the EULA Documentation.

- Advanced Management can only be activated on a licensed Tableau Server Deployment. This means that your Tableau Server must be first activated with a valid key that is either User-Based or Core-Based, before applying the Advanced Management product key. For more information on how to acquire the Advanced Management capabilities and get the product key, contact your account manager.
- When the product key is active and enabled, you can use all the features that are included in Advanced Management.
- When the Advanced Management product key is removed or deactivated, you will no longer be able to use the features that require a valid Advanced Management license. Any associated data will not be deleted. Each feature might have slight differences on what happens when the license expires. For more information on the individual features use the links in the table below.

The following table lists the features that are included and require a valid Advanced Management license:

| Feature | Description | Requirements to use the feature | Version |
|---|---|---|---|
| About Tableau Resource Monitoring Tool | Provides a comprehensive look at the health of Tableau Server. With the Resource Monitoring Tool you can identify issues that cause slow load times, extract failures, and other critical issues and | The installation of Tableau Server that you are monitoring must have an Advanced Management license. | Available in 2019.3 and later.<br>Linux support was introduced in |

| Feature | Description | Requirements to use the feature | Version |
|---|---|---|---|
| | can help you proactively address the issues that impact end user experience. | | version 2020.4. |
| About Tableau Content Migration Tool | The Content Migration Tool provides an easy way to copy or migrate content between Tableau Server projects, sites and deployments. You can do this between projects on separate Tableau Server installations (for instance, between a development instance of Tableau Server and a production instance of Tableau Server), or between projects on a single Tableau Server installation. | • Both the source Tableau Server (Server that you are moving the content from) and the target Tableau Server (Server that you are moving the content to) must have a valid Advanced Management license.<br>• The Content Migration Tool must be installed on a version of Microsoft Windows that supports .NET 4.6.1 (Windows 7 or later, Windows Server 2008R2 or later). | Available in version 2019.3 and later. |
| Activity Log | The Activity Log writes log | The Tableau Server | Available in |

| Feature | Description | Requirements to use the feature | Version |
|---|---|---|---|
| | events to the vizportal logs folder on the local hard drive for further analysis and auditing. | must have a valid Advanced Management license. | version 2022.3 and later. |
| Tableau Server External Repository | Allows you to deploy Tableau Server Repository external to Tableau Server. The Tableau Server Repository is a PostgreSQL database that stores data about all user interactions, extract refreshes, and more. | The Tableau Server that is using an external repository must have a Advanced Management license. | Available in version 2019.3 and later.<br>- AWS supported on Tableau Server version 2019.3 and later.<br>- Azure supported on Tableau Server version 2020.4 and later. |
| Workload Management through Node Roles | Using node roles, you can configure where certain types of workloads are processed on your Tableau Server installation. The node roles features allows you to dedicate and scale resources to specific workloads (ex: extract refreshes, subscriptions). | The Tableau Server must have a valid Advanced Management license. | Available in version 2019.3 and later. |

| Feature | Description | Requirements to use the feature | Version |
|---|---|---|---|
| Tableau Server Key Management System | Gives you additional functionality to configure Tableau Server to use AWS as the KMS for extract encryption. | Tableau Server must have a valid Advanced Management license. | Available in version 2019.3 and later.<br><br>- AWS supported on Tableau Server version 2019.3 and later.<br><br>- Azure supported on Tableau Server version 2021.1 and later. |
| Tableau Server External File Store | Allows you to use network attached storage(NAS) as your File Store. This removes the need to run File Store locally on your Tableau Server | Tableau Server must have a valid Advanced Management license. | Available in version 2020.1 and later. |
| Tableau Backgrounder Resource Limits | The Tableau Server Resource Limits Manager tracks backgrounder resource usage in relation to the set resource limits to make sure the resource limits are applied correctly. | Tableau Server must have a valid Advanced Management license. | Available in version 2022.1 and later. |
| Tableau Server | Tableau Server Independent | Tableau Server must | Available in |

| Feature | Description | Requirements to use the feature | Version |
|---|---|---|---|
| Independent Gateway | Gateway allows you to install a Tableau Server-managed reverse proxy on a separate computer. Install Independent Gateway in your DMZ to provide security for your Server installation and all your data. The Independent Gateway can be used in a variety of configurations, and can be scaled to meet your client connection demands. | have a valid Advanced Management license. | version 2022.1 and later. |

## Activating the Advanced Management product key

The Advanced Management license is applied to a Tableau Server Installation and can be used for both User-Based and Core-Based installations.

Here is a quick overview of how you can activate Advanced Management on your Tableau Server Installation.

## Use the TSM web interface

1. Open TSM in a browser:

   https://<tsm-computer-name>:8850

2. Click **Licensing** on the **Configuration** tab. Click **Activate License**.

3. Enter or paste your Advanced Management product key and click **Activate**.

4. On the **Register** page, enter your registration information and click **Register**.

5. Follow the prompts and restart Tableau Server after registration is complete.

> **Note:** If this is a new Tableau Server installation, and you apply an Advanced Management Key before you apply the Tableau Server product key, you will see an error. You may however, continue the installation and apply the Tableau Server product key using the same steps described above.

## Use the TSM CLI

1. Open a command prompt as administrator on a node in the Tableau Server cluster.
2. Run the following command with your Advanced Management product key to activate the license:

   ```
   tsm licenses activate -k <server-management-add-on-product key>
   ```

   > **Note:** If this is a new Tableau Server installation, run the command twice, first with the Tableau Server product key and then with an Advanced Management product key.

3. Apply the changes and restart the Server:

   ```
   tsm pending-changes apply
   ```

### Who can do this

Only Server Administrators can activate Advanced Management license keys.

## About Tableau Resource Monitoring Tool

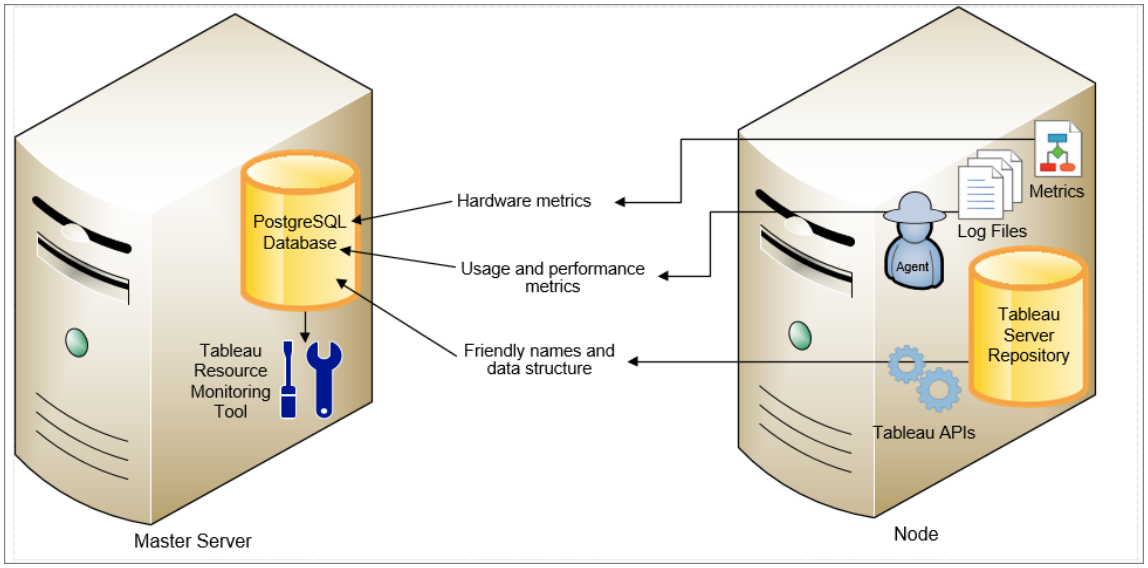
This document gives you an overview of the Tableau Resource Monitoring Tool.

## What is Resource Monitoring Tool?

The Resource Monitoring Tool is a tool that you can use to monitor the health and performance of your Tableau Server. It gathers data from your Tableau Server to provide a comprehensive look at the health of Tableau Server. Using this tool, you can identify the cause of slow load times, extract failures, and other critical issues. To use the Resource Monitoring Tool, you must have Advanced Management enabled on your server. For more information on Advanced Management, see About Tableau Advanced Management on Tableau Server

The Resource Monitoring Tool has two main components: Resource Monitoring Tool Server (RMT Server) and Agent.

- The RMT Server is where the data from Tableau Server is collated and served up through a web interface. This is also where you can configure, monitor, and analyze the health and performance of Tableau Server.
- An Agent runs on each of the nodes in your Tableau cluster to monitor their performance and activity. The following diagram illustrates the interaction between a Tableau Server node and the RMT Server.



## Get Started with Tableau Resource Monitoring Tool

This article will help you get started with Tableau Resource Monitoring Tool. It contains links to other articles about information you need to prepare before installing Resource Monitoring Tool, links to upgrade and other useful resources.

In an effort to align with our company values of Equality, we have changed non-inclusive terminology where possible. Because changing terms in certain places can causing a breaking change, we maintain the existing terminology. So, you may continue to see the terms in CLI commands and options, installation folders, configuration files. and other instances. For more information, see About Tableau Help.

Pre-Installation

Product Compatibility with Tableau Server

The Resource Monitoring Tool can be installed to monitor supported Tableau Server versions.

The table below lists the version compatibility between Resource Monitoring Tool(RMT) and Tableau Server:

| RMT Version | OS support | Tableau Server Version |
|---|---|---|
| 2025.1.x | Windows, Linux | 2022.3.x, 2023.1.x, 2023.3.x, 2024.2.x, 2025.1.x |
| 2024.2.x | Windows, Linux | 2022.3.x, 2023.1.x, 2023.3.x, 2024.2.x |
| 2023.3.x | Windows, Linux | 2022.3.x, 2023.1.x, 2023.3.x |
| 2023.1.x | Windows, Linux | 2022.3.x, 2023.1.x |
| 2022.3.x | Windows, | 2022.3.x |

| RMT Version | OS support | Tableau Server Version |
|---|---|---|
| | Linux | |

Resource Monitoring Tool Server (RMT Server) and Agent Compatibility

Generally, we recommend that you install the same version of RMT Server and Agent to be sure that they are compatible. If you have Agents using versions not compatible with the RMT Server version, a critical incident is logged. For more information, see Agent Incidents.

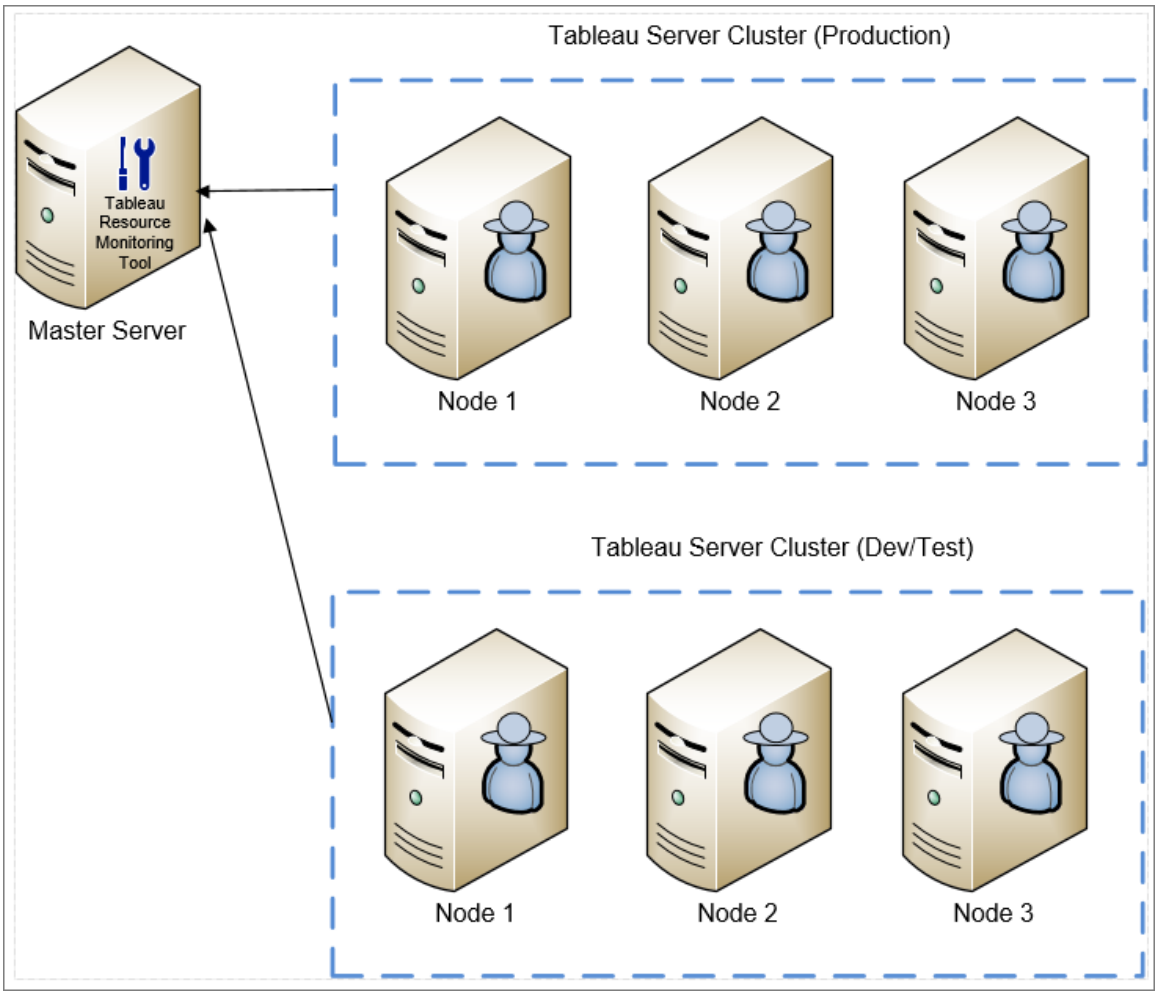
Concepts and Terms

Get familiar with the concepts and terms used in the Resource Monitoring Tool topics. For more information, see Concepts.

Setup Architecture

The Resource Monitoring Tool has two main components: Resource Monitoring Tool Server (RMT Server) and Agent. The RMT Server should be installed on its own machine, and the Agent is installed on each node of your Tableau Server Cluster. For a more details about the setup architecture, see Install the Tableau Resource Monitoring Tool.

A high level view of the Resource Monitoring Tool setup. This diagram shows a three node Tableau Server Cluster.



## Minimum Hardware Requirements and Recommendations for Resource Monitoring Tool

Resource Monitoring Tool handles all of the processing, aggregation, storage, and web interface to the monitoring data collected from your Tableau Server installation. For production use, the machine you install Resource Monitoring Tool on should meet or exceed the minimum hardware recommendations. For more details, see Minimum Hardware Requirements and Recommendations for Tableau Resource Monitoring Tool.

Pre-Installation Checklist for Resource Monitoring Tool

Before you install Resource Monitoring Tool, review these action items and complete any necessary steps: Pre-Installation Checklist - Tableau Resource Monitoring Tool

Troubleshoot

Be sure to check our Troubleshoot Tableau Resource Monitoring Tool Issues for answers to common questions before contacting support.

Concepts

This document briefly explains some of Tableau Resource Monitoring Tool core concepts and defines some terminology you will see often.

In an effort to align with our company values of Equality, we have changed non-inclusive terminology where possible. However, you may continue to see the terms in CLI commands and options and other instances. For more information, see About Tableau Help.

Agent

Resource Monitoring Tool Agent runs as a background service on each of your Tableau servers. It must be installed on all the nodes in a Tableau Server installation that you want to monitor.

The agent is a lightweight process that monitors the Tableau activity and general performance of the server it is installed on. It reports those details back to the Resource Monitoring Tool Server.

Resource Monitoring Tool Server (RMT Server)

The Resource Monitoring Tool Server hosts the web application that users interact with. It also does much of the background processing to collate and monitor the data from the agents. We will use the term **RMT Server** to refer to this component.

Environment

**Environment** is the term used to refer to a single node Tableau Server installation, or a Tableau Server cluster. In the RMT Server web interface, each node of the Tableau Server is called a **Server**.

Resource Monitoring Tool can monitor multiple Tableau Server installations. For example, you may have both production and staging Tableau Servers. In Resource Monitoring Tool, you can create two environments (*Production* and *Staging*) and monitor both of those Tableau Server clusters.

Environment Status

The *environment status* indicates the state of the current Tableau environment. The status is determined by the number and type of incidents and the status of Tableau's various processes. The following sections will describe what each status means in these terms.

### OK

No warning or critical incidents have occurred today and there are not currently any failed processes.

### Warning

The Environment is in a **Warning** state when any of the following are true:

- At least one warning incident has occurred today.
- A process is **Unlicensed**.
- A process is **Offline**.

### Critical

The Environment is in a **Critical** state when any of the following are true:

- At least one critical incident has occurred today.
- The Primary Gateway is **Offline**.
- All instances of a process are **Unlicensed**.
- All instances of a process are **Offline**.

Server

**Server** is the term used to refer to each of nodes in the Tableau Server installation. Every machine that you install the Resource Monitoring Tool Agent on is considered a Server.

Pre-Installation Checklist - Tableau Resource Monitoring Tool

The following topic provides prerequisites for installing Tableau Resource Monitoring Tool. It also describes the operating system permissions required for the service accounts used.

Machine, Network, and Account Requirements

> **Note:** Resource Monitoring Tool (RMT) server and agent are not Federal Information Processing Standard (FIPS) 140-2 compliant, and will not function properly on operating systems running with FIPS mode enabled.

Complete the following prerequisites before installing the Tableau Resource Monitoring Tool.

1. Make sure you have administrative privileges for all computers that will run the Resource Monitoring Tool. This includes the computer running the RMT Server, and all the Tableau Server nodes in the installation you will be monitoring with Resource Monitoring Tool.

2. Open port 5672 to inbound TCP traffic on the computer running the RMT Server

   The Resource Monitoring Tool Agent application sends the data that it collects through port 5672, so the machine where the RMT Server is installed will need to allow inbound TCP traffic on that port.

3. Open the following ports:

- Open port 80 to inbound TCP traffic on the computer running the RMT Server

  This is the port on which the RMT Server will host the web interface. Note that we can change the port number during installation if there is a 3rd party service already using it. To make the web interface accessible from outside the RMT Server, this port will need to be opened.

- Open port 443 to inbound TCP traffic on the computer running the Resource Monitoring Tool RMT Server.

  This is the port on which connections come from the Agent when testing the connection to the RMT Server.

- Open port 5672 and 5671 (TLS connections) to outbound TCP traffic on all Agent nodes.

  The Agent application sends the data that it collects to the RMT Server using this port.

- Open port 80 to outbound TCP traffic on all Agent computers.

  Periodically, the Agent will make requests to the RMT Server web interface.

- Open port 443 to outbound TCP traffic on all Agent computers.

  This is the port on which the Agent tests its connection to the RMT Server.

For more information on ports and communications, see Tableau Resource Monitoring Tool Communication Ports.

4. Verify that all Agent computers can contact the RMT Server.

   The web interface hosted by the RMT Server is bound to a specific hostname or IP address during the setup process. It will only answer requests sent to that specific hostname. For example, if the RMT Server is configured to be hosted at http://RMTServer/

but the Agents can only contact the RMT Server through http://myrmt-server.myserver.com/ then the requests will not go through.

5. Gather credentials for a Tableau Server Administrator account.

   Resource Monitoring Tool will use the Tableau Server web API to collect information about the content, so it will need credentials for a user that is a Tableau server administrator and can access all sites, projects, etc. We recommend creating one dedicated to Resource Monitoring Tool, but it can be any user that is a Tableau Server administrator.

   **Note:** RMT does not support SAML but can work with a Server installation that uses SAML SSO. To do this you need a local identity store configured for Tableau Server, and must set a password locally for the administrator account that will be used by RMT.

6. Enable access to the Tableau Server repository database. **This is required starting in version 2022.3**.

   Resource Monitoring Tool accesses the repository database directly for performance reasons. For this to work, access to the repository must be enabled, with a password set for the "readonly" database user. For details, see Enable access to the Tableau Server repository.

7. If you want to use SSL connections between Resource Monitoring Tool and Tableau Server Repository, make sure Tableau Server is configured to use SSL for internal Postgres connections. For more information, see Configure SSL for Internal Postgres Communication.

   The Resource Monitoring Tool allows you to use either the certificate file (`server.crt`) or thumbprint for the SSL connections. The certificate file for the Postgres database is installed to:

   ```
   /var/opt/tableau/tableau_server/data/tabsvc/config/pgsql_<version>/security
   ```

If you plan to use the certificate file (`server.crt`), copy the certificate file generated by Tableau Server for internal Postgres SSL connections, to the machine where you plan to install the RMT Server. Make sure that the Operating System trusts the certificate.

8. Confirm that the REST API is enabled on Tableau Server (this is the default). Use the `tsm configuration get -k api.server.enabled` command to do this. A return value of `true` means the REST API is enabled. To enable the REST API, use the `tsm configuration set` command. For more information, see api.server.enabled.

9. Review the size of Tableau Server logs. Once Agent Server is installed and configured, the Resource Monitoring Tool processes relevant historical data from Tableau Server logs before data is displayed. If there is a large amount of historical log data, it may take a while to process the information. This might result in a delay of processing newer events on the Server.

   If you are concerned about the delay, and not having historical information does not concern you, you can do the following to clean up the existing files:

   - Remove Unneeded Files, and consider Log File Snapshots (Archive Logs) before you remove log files.

   **Note:** Performance data like CPU usage and memory usage are not gathered using historical log data and are collected after Agent is installed and configured so cleaning up historical data does not affect performance data.

10. (optional) Gather connection information for a SMTP server that the RMT Server can access.

    If you want email notifications, you need to provide the RMT Server with the server name, username and password (if any), and port number for a SMTP Server that it can use to send the email, and the TLS version. Currently, TLS version 1.2 is required, but

TLS version 1.3 is also supported. If you want to use TLS version 1.3, make sure you have Open SSL 1.1.1f or greater on the machine where RMT Server will be installed. For more information, see Email notifications

11. (optional) Verify operating system service account permissions for non-default accounts.

    You may need to do this is your organization has specific security requirements that require you to use already-defined system accounts or users.

    You can find details on the default permissions here: Default Installation Permissions - Tableau Resource Monitoring Tool

## Who can do this

To do all the steps described above you need be an admin on the machine that you are installing Resource Monitoring Tool, and be a Tableau Server Administrator.

Minimum Hardware Requirements and Recommendations for Tableau Resource Monitoring Tool

Tableau Resource Monitoring Tool handles all of the processing, aggregation, storage, and web interface to the monitoring data collected from your Tableau Server installation.

RMT Server Minimum Hardware Recommendations

For production use, the machine that you install Resource Monitoring Tool on should meet or exceed the hardware recommendations below:

- 8 physical CPU cores (16 vCPUs)
- CPUs must support SSE4.2 and POPCNT instruction sets
- 64GB RAM
- 500GB Disk Space for RMT Server
- SSD drive or similar for performance

For RMT Server installations that match the minimum hardware specified above, the Resource Monitoring Tool can provide performance reporting for a Tableau Server deployments serving up to 10,000 views per hour.

For deployments with more view loads per hour, or very high numbers of background jobs, data delays may occur. In these cases, you may need to upgrade your hardware.

Resource Monitoring Tool Agent - Resource Utilization

The Resource Monitoring Tool Agent monitors the operating system and Tableau Server processes and log files and sends performance metrics and Tableau log data to the Resource Monitoring Tool for near real time processing. The Agent needs to be installed on every machine that is running Tableau Server.

On Tableau Server installations that match Minimum Hardware Requirements and Recommendations for Tableau Server, here is what to expect:

- We typically see the Agent using 0-5% CPU on average with infrequent spikes above that. Our performance target is an average of 10% CPU usage or less.
- The agent typically uses 200 MB RAM or less with infrequent spikes during periods of heavier Tableau Server activity.
- A minimum of 10 GB free disk space is recommended for the machine where Agent is installed.

Installing in a Cloud Environment

Resource Monitoring Tool can be installed on a virtual machine in any cloud environment that you may be using for your Tableau Servers. The virtual machine where RMT Server is installed will need to meet the same minimum hardware requirements described above.

Who can do this

To install Resource Monitoring Tool, you must be all the following:

- Administrator on the machine you are installing Resource Monitoring Tool.
- Tableau Server Administrator.
- Resource Monitoring Tool Administrator.

Default Installation Permissions - Tableau Resource Monitoring Tool

The following topic provides the default permissions set on various system accounts or groups during installation. If your environment or organization requires you to use non-default accounts, this helps you determine what permissions are necessary for Resource Monitoring Tool (RMT) to function properly.

**Note:** Resource Monitoring Tool (RMT) server and agent are not Federal Information Processing Standard (FIPS) 140-2 compliant, and will not function properly on operating systems running with FIPS mode enabled.

Windows installations

By default Tableau Resource Monitoring Tool creates these accounts when installed:

- NT SERVICE\TableauResourceMonitoringTool
- NT SERVICE\TableauResourceMonitoringToolPostgreSQL
- NT SERVICE\TableauResourceMonitoringToolRabbitMQ

If you want or need to use other accounts in place of the default accounts, you can specify these after installation using the `rmt-admin` command line utility. For details, see rmtadmin Command Line Utility .

The permissions used by these default service accounts are shown below, as well as the minimum required permissions. Your service accounts should match the minimum permissions or the default permissions:

| Service Account | Resource | Default permissions | Required minimum permissions |
|---|---|---|---|
| Tableau | | | |

| Service Account | Resource | Default permissions | Required minimum permissions |
|---|---|---|---|
| Resource Monitoring Tool Master | | | |
| | Application files<br>`Tableau Resource Monitoring Tool\master` | Full control: read, write, execute, modify | Full control |
| | Log directories and files<br>`Tableau Resource Monitoring Tool\master\logs` | Full control: read, write, execute, modify | Read, write |
| | Configuration directory<br>`Tableau Resource Monitoring Tool\master\config` | Full control: read, write, execute, modify | Full control |
| | | | |
| Tableau Resource Monitoring Tool Post-greSQL | | | |
| | Application directory<br>`Tableau Resource Monitoring Tool\-prerequisites\postgresql<nn>` | Full control: read, write, execute, modify | Full control |
| | Data directory | Full control: | Full control |

| Service Account | Resource | Default permissions | Required minimum permissions |
|---|---|---|---|
| | `Tableau Resource Monitoring Tool\data\postgresql<nn>` | read, write, execute, modify | |
| | Logs directory<br>`Tableau\Tableau Resource Monitoring Tool\master\logs\pgsql` | Full control: read, write, execute, modify | Read, write . |
| | | | |
| Tableau Resource Monitoring Tool RabbitMQ | | | |
| | Data directory<br>`Tableau Resource Monitoring Tool\data\rabbitmq` | Full control: read, write, execute, modify | Full control |
| | Application files<br>`Tableau Resource Monitoring Tool\prerequisites\rabbitmq`<br>`Tableau Resource Monitoring Tool\prerequisites\erlang` | Full control: read, write, execute, modify | Full control |
| | Log files<br>`Tableau Resource Monitoring Tool\master\logs\rabbitmq` | Full control: read, write, execute, modify | Read, write |

| Service Account | Resource | Default permissions | Required minimum permissions |
|---|---|---|---|
| | | | |
| Tableau Resource Monitoring Tool Agent | | | |
| | Application files<br>`Tableau Resource Monitoring Tool\agent` | Full control: read, write, execute, modify | Full control |
| | Log directory and files<br>`Tableau Resource Monitoring Tool\agent\logs` | Full control: read, write, execute, modify | Read |
| | Configuration directory<br>`Tableau Resource Monitoring Tool\agent\config` | Full control: read, write, execute, modify | Full control |

Linux installations

By default Tableau Resource Monitoring Tool creates certain accounts when installed. If you want or need to use groups and users in place of the defaults, you can specify these after installation using the `rmt-admin` command line utility. For details, see rmtadmin Command Line Utility .

The default permissions used by these service accounts are shown below. Your permissions should match these permissions:

| Service Account | Resource | per-missions |
|---|---|---|
| Tableau Resource Monitoring Tool Master | | |
| | Application files<br><br>`/var/opt/tableau/tabrmt/master` | Owner - Full permissions (read, write, execute)<br><br>Group - read, write, execute<br><br>Others - read, execute |
| | Log directories and files<br><br>`/var/opt/tableau/tabrmt/master/logs` | Owner - Full permissions (read, write, execute)<br><br>Group - read, write, execute<br><br>Others - read, execute |
| | Configuration directory<br><br>`/var/opt/tableau/tabrmt/master/config` | Owner - Full permissions |

| **Service Account** | **Resource** | **per-missions** |
|---|---|---|
| | | (read, write, execute)<br><br>Group - read, write, execute<br><br>Others - read, execute |
| | | |
| Tableau Resource Monitoring Tool Post-greSQL | | |
| | Application directory<br><br>`/op-t/tableau/tabrmt/prerequisites/postgresql13` | Owner - Full permissions (read, write, execute)<br><br>Group - read, execute<br><br>Others - read, execute |
| | Service directory<br><br>`/var/opt/tableau/tabrmt/data/postgresql13/pg_` | Owner - Full permissions (read, write, |

| Service Account | Resource | per-missions |
|---|---|---|
| | * | execute)<br><br>Group - none<br><br>Others - none |
| | Data directory<br><br>/var/opt/tableau/tabrmt/data/postgresql13/ | Owner - Full permissions (read, write, execute)<br><br>Group - read, write, execute<br><br>Others - read, execute |
| | Logs directory<br><br>/var/opt/tableau/tabrmt/master/logs/pgsql | Owner - Full permissions (read, write, execute)<br><br>Group - read, write, execute<br><br>Others - execute |
| | Other directories under the PostgreSQL directory not mentioned above | Owner - read, write |

| Service Account | Resource | per-missions |
|---|---|---|
| | /var/-opt/tableau/tabrmt/data/postgresql13/<not men-tioned above> | Group - none<br>Others - none |
| | /var/-opt/tableau/tabrmt/data/postgresql13/base<br>/var/-opt/tableau/tabrmt/data/postgresql13/global | Owner - Full permissions (read, write, execute)<br>Group - none<br>Others - none |
| | /var/-opt/t-ableau/tabrmt/data/postgresql13/certificates | Owner - Full permissions (read, write, execute)<br>Group - Full permissions (read, write, execute)<br>Others - execute |
| | | |
| Tableau Resource Monitoring | | |

| Service Account | Resource | per-missions |
|---|---|---|
| Tool Rab-bitMQ | | |
| | Data directory<br>`/var/opt/tableau/tabrmt/data/rabbitmq` | Owner - Full permissions (read, write, execute)<br>Group - read, write, and execute<br>Others - read, execute |
| | Application files<br>`/var/-opt/t-ableau/tabrmt/rabbitmq/prerequisites/rabbitmq`<br>`/var/-opt/t-ableau/tabrmt/rabbitmq/prerequisites/erlang` | Owner - Full permissions (read, write, execute)<br>Group - read,ex-ecute<br>Others - read, execute |
| | Log files<br>`/var/opt/tableau/tabrmt/master/logs/rabbitmq` | Owner - Full permissions (read, write, execute)<br>Group - |

| Service Account | Resource | per-missions |
|---|---|---|
| | | read, write, and execute<br><br>Others - execute |
| | Other directories (under `/rabbitmq` directory)<br><br>`/var/-opt/tableau/tabrmt/data/rabbitmq/certificates`<br><br>`/var/opt/tableau/tabrmt/data/rabbitmq/mnesia` | Owner - Full permissions (read, write, execute)<br><br>Group - read, write, and execute<br><br>Others - execute |
| | `/var/opt/tableau/tabrmt/data/rabbitmq/<other than mentioned>` | Owner - read, execute<br><br>Group - read, execute<br><br>Others - none |
| | | |
| Tableau Resource Monitoring Tool Agent | | |

| Service Account | Resource | per-missions |
|---|---|---|
| | Application files<br><br>`/var/opt/tableau/tabrmt/agent` | Owner - Full permissions (read, write, execute)<br><br>Group - read, write, and execute<br><br>Others - read, execute |
| | Log directory and files<br><br>`/var/opt/tableau/tabrmt/agent/logs` | Owner - Full permissions (read, write, execute)<br><br>Group - read, write, and execute<br><br>Others - read, execute |
| | Configuration directory<br><br>`/var/opt/tableau/tabrmt/agent/config` | Owner - Full permissions (read, write, execute)<br><br>Group - read, write, and execute |

| Service Account | Resource | per-missions |
|---|---|---|
| | | Others - read, execute |

## Who can do this

To do all the steps described above you need be an admin on the machine that you are installing Resource Monitoring Tool, and be a Tableau Server Administrator.

Resource Monitoring Tool (RMT) Services

The Resource Monitoring Tool has two main components: Resource Monitoring Tool Master (RMT Server) and RMT Agent.

- The RMT Master is where the data from Tableau Server is collated and served up through a web interface. This is also where you can configure RMT, and monitor and analyze the health and performance of Tableau Server.
- An Agent runs on each of the nodes in your Tableau Server cluster to monitor their performance and activity.

This topic describes the services installed with RMT. The tables below list the services installed on the RMT Server machine, and those installed on the RMT Agent machines.

| **RMT Server services** | | | |
|---|---|---|---|
| **Name** | **Purpose** | **Log file location**<br><br>Windows: `C:\Program Files\Tableau\Tableau Resource Monitoring Tool\master\logs\` | **Notes** |

| | | | |
|---|---|---|---|
| | | Linux: `/var/-opt/t-ableau/tabrmt/master/logs`<br><br>**Note:** For additional information about log files, see: Tableau Resource Monitoring Tool Log Files. | |
| Host | Used during installation and also to ensure the other processes are running. | Windows: `host\YYYYMMDD.log`<br><br>Linux: `host/YYYMMDD.log` | Responsibilities:<br>• Process watcher: Makes sure other processes are running.<br>• Config File Watcher: Detects and responds to changes in configuration files. |
| Backgrounder | Processes the information sent from the agents and | Windows: `background\YYYYMMDD-pts.log`<br><br>Linux: `background/YYYYMMDD-pts.-log` | Responsibilities:<br>• rmtadmin: command line utility |

| | | | |
|---|---|---|---|
| | maintains the postgres data RMT collects. Also provides admin command line utility. Generates incidents and notifications based on information processed. | | that exposes command line functionality for administrator.<br>• Agent Data Processing: Handles data collection and processing from various agents<br>• TS Status Polling: Periodically polls Tableau Server (TS) status, ensuring the system is active and healthy. |

| | | | |
|---|---|---|---|
| | | | • Incident Analysis: Analyzes incidents, like errors, failures, reaching thresholds for different measures.<br>• Data Cleanup: Responsible for cleaning up old data.<br>• Ad Hoc Graph Info Collection: Collects data for on-demand for monitoring.<br>• Notifications: |

| | | | |
|---|---|---|---|
| | | | Manages sending notifications for alerts and incidents.<br>• Data Archiving (Disabled): involve archiving old data to free up resources or for compliance. This is currently disabled. |
| Director | Kind of a coordination process, and one of it's primary responsibilities is to query the Tableau Server for licenses | Windows: `director\YYYYMMDD-pts.log`<br>Linux: `director/YYYYMMDD-pts.-log` | Responsibilities:<br>• Cluster Status: Monitors the health and status of the server cluster and |

| | | | |
|---|---|---|---|
| | status, and sets the system wide status. | | sets the system wide status.<br>• Licensing: query the Tableau Server for licenses status.<br>• Graph Scraping: Extracts data for monitoring and reporting. Likely has access to server database.<br>• Database Upgrade: Handles updates to the database schema or version |

| | | | |
|---|---|---|---|
| | | | • Daily Aggregate Processing: Executes daily processing tasks, like aggregating data for reports or analysis. |
| Web | Runs the web server. Provides user interface. Registers Agents for information gathering | Windows: `web\YYYYMMDD-pts.log`<br><br>Linux: `web/YYYYMMDD-pts.log` | Responsibilities:<br><br>• Agent Registration: Manages the registration of agents that monitor or collect data on Tableau server.<br><br>• Config UI: Provides a user inter- |

| | | | |
|---|---|---|---|
| | | | face for configuring various system settings and parameters.<br>• Performance / Activity / Content UI: Offers a UI for users to view performance metrics, activity logs, and content-related data in the system. |
| PostgreSQL | Local data repository | Windows: `pgsql\*.log and *.csv`<br>Linux: `pgsql/*.log and *.csv` | |
| RabbitMQ | Message broker | Windows: `\master\logs\rabbitmq\*.log`<br>Linux: `master/logs/*.log` | |

## Install the Tableau Resource Monitoring Tool

The Tableau Resource Monitoring Tool has two components: RMT Server and Agent.

Resource Monitoring Tool prerequisites and the RMT Server must be installed on dedicated hardware to guarantee they have the necessary resources, and that there is no contention for machine resources with other programs or software. These should not be installed on your Tableau Server computer, except in exceptional cases (for example, for limited demonstration purposes in non-production environments).

Agents are installed on all nodes of Tableau Server that you want to monitor.

The installer for installing Resource Monitoring Tool can be found on the Advanced Management Download site. Download all the files that start with **Tabrmt**.

In an effort to align with our company values of Equality, we have changed non-inclusive terminology where possible. Because changing terms in certain places can causing a breaking change, we maintain the existing terminology. So, you may continue to see the terms in CLI commands and options, installation folders, configuration files. and other instances. For more information, see About Tableau Help.

Installation version history

This section calls out significant changes to the installation process. Use this section to understand what changes have been made depending on your current version and the version you are upgrading to.

- Starting in version **2022.3**, you have the option to configure RabbitMQ messaging service and the PostgreSQL database used by Resource Monitoring Tool on a cloud platform. Currently, AWS AMQ for RabbitMQ, and Amazon RDS for PostgreSQL database are supported. With this addition, you can choose to install the repository and message queue service with RMT Server on the same machine or separately on the AWS platform.
- Starting in version **2020.4**, the Resource Monitoring Tool can be installed on Linux machines. Previously Resource Monitoring Tool installation was only supported on Windows machines.

Before Installing the Resource Monitoring Tool

- Review the following requirements and instructions:
  - Minimum Hardware Requirements and Recommendations for Tableau Resource Monitoring Tool
  - Pre-Installation Checklist - Tableau Resource Monitoring Tool
  - The following OS is supported:

    - AlmaLinux:

      Version 2023.3.1 and later: AlmaLinux 8.x, AlmaLinux 9.x

    - Amazon Linux:

      Version 2023.3.1 and later: Amazon Linux 2, Amazon Linux 2023

      Version 2023.3.0 and earlier: Amazon Linux 2

    - CentOS:

      Version 2023.3.1 and later: Stream 8.x, Stream 9.x

    - Oracle:

      Version 2023.3.1 and later: Oracle 8.x, Oracle 9.x

    - Red Hat Enterprise Linux (RHEL):

Version 2023.3.1 and later: 9.x, 8.3+

Version 2023.3.0: 9.x, 8.3+

Version 2023.1.x and earlier: 8.3+

- Rocky Linux:

  Version 2023.3.1 and later: Rocky Linux 8.x, Rocky Linux 9.x

- Ubuntu:

  Version 2023.1.1 and later: the latest versions of Ubuntu 16.04 LTS, 18.04 LTS (not 17.04), 20.04 LTS, 22.04

  Version 2023.1.0: the latest versions of Ubuntu 16.04 LTS, 18.04 LTS (not 17.04), and 20.04 LTS

  Version 2022.3 and earlier: the latest versions of Ubuntu 16.04 LTS and 18.04 LTS (not 17.04)

**Additional notes on Linux distributions:**

- Red Hat Enterprise Linux (RHEL), CentOS, and Amazon Linux distributions are collectively referred to in this documentation as RHEL-like.
- Previous versions of CentOS and Ubuntu are not supported because Tableau Server requires systemd for process management.
- The version of the installer with the file suffix, .deb, installs on Ubuntu distributions.

  As of July 2022, Debian distributions are no longer supported. For more information, see this Tableau Community post.

- Custom kernels are not supported.

- Make sure the Tableau Server installation you are going to be monitoring is licensed with the Advanced Managementlicense. You must have a valid Advanced Management license to use the Resource Monitoring Tool.

- Review the size of Tableau Server logs. Once Agent is installed and configured, the Resource Monitoring Tool processes relevant historical data from Tableau Server logs before data is displayed. If there is a large amount of historical log data, it may take a while to process the information which in turn might result in a delay of processing newer events on the Server.

  If you are concerned about the delay, and not having historical information does not concern you, you can do the following to clean up the existing files:

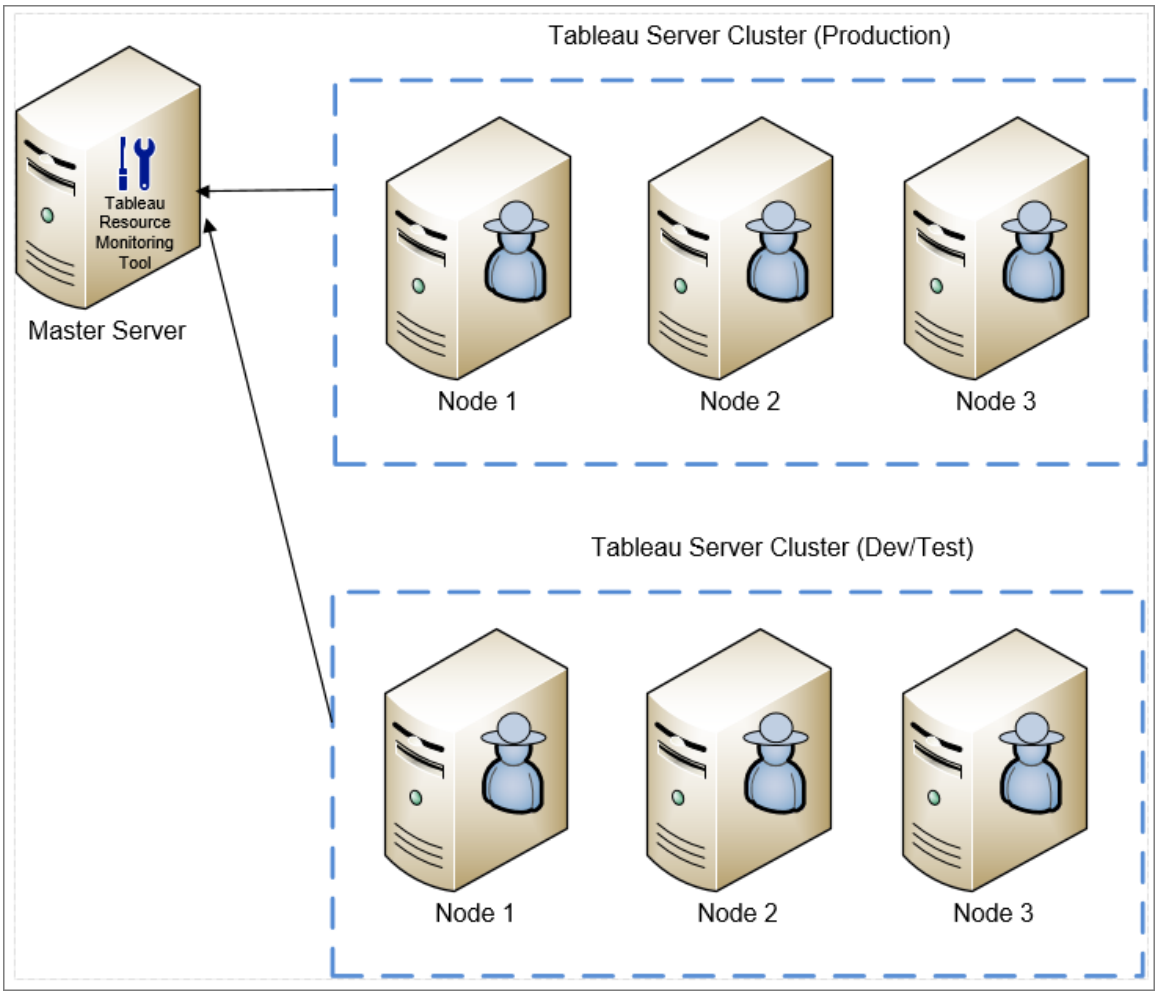
  - Remove Unneeded Files, and consider Log File Snapshots (Archive Logs) before you remove log files.

  > **Note:** Performance data like CPU usage and memory usage are not gathered using historical log data and are collected after Agent is installed and configured so cleaning up historical data does not affect performance data.

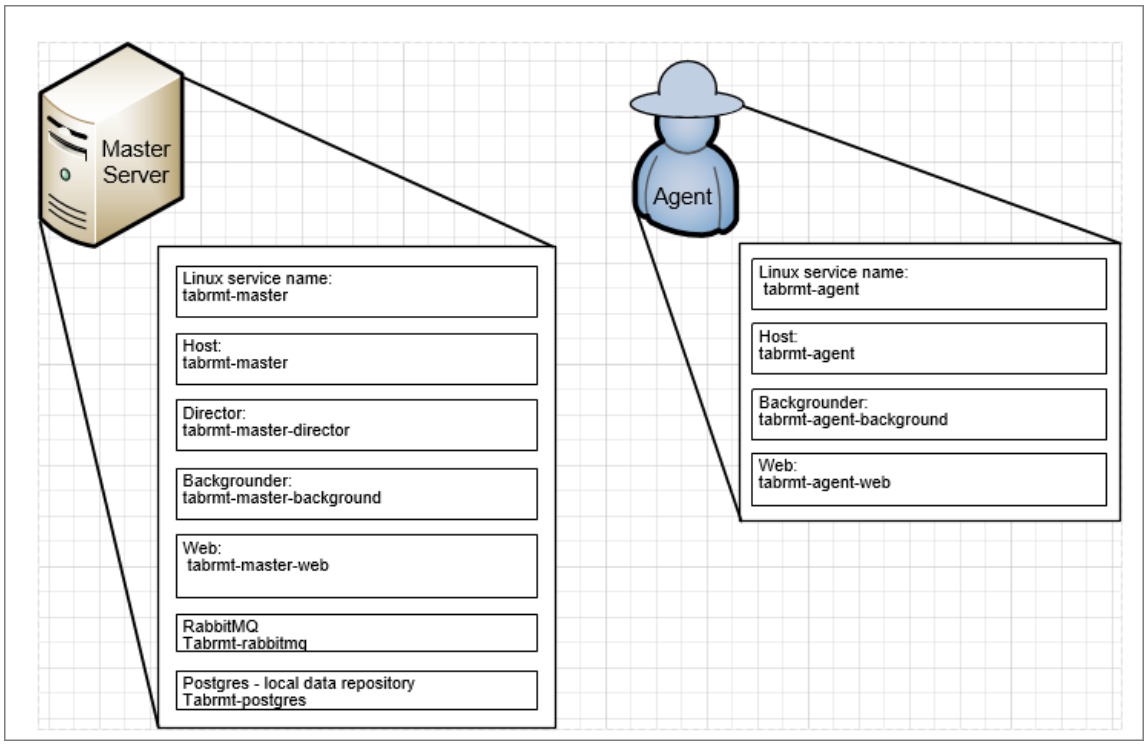
- Enable the readonly built-in user for Tableau Server Repository. This user is used when installing the Resource Monitoring Tool Agent. **This is required starting in version 2022.3.** For more information, see Collect Data with the Tableau Server Repository.
- Determine if you want to configure the repository and message queue service external to Resource Monitoring Tool.

Setup Architecture

A high level view of the Resource Monitoring Tool setup. This diagram shows two Tableau Server clusters monitored by the RMT Server.



A detailed view of the Resource Monitoring Tool components installed on the RMT Server and Agent.



Installation Overview

The RMT Server can be installed on either operating system and does not depend on the operating system that Agent is installed on. This means you can install RMT Server and Agent on different operating systems.

However, Agent is installed on the Tableau Server Cluster nodes, so the operating system choice for the Agent depends on the Tableau Server installation.

You can monitor multiple Tableau Server clusters using the same Resource Monitoring Tool. Each Tableau cluster should be set up as a separate environment.

External Configuration

The repository and the message queue service can both be hosted external to RMT Server on the AWS platform. For hosting the repository, use the AWS RDS instance and for message queue use AWS AMQ. For more details on the configuration, step-by-step instructions, and other details, see:

- External Repository for Tableau Resource Monitoring Tool
- External Message Queue Service (RabbitMQ) for Tableau Resource Monitoring Tool

Installation on Linux

You can install RMT Server and Agent using the command line on Linux operating systems.

Here are the steps to installing Resource Monitoring Tool:

1. Install the RMT Server using command line.

   When you start the Resource Monitoring Toolinstaller, the setup program will install certain programs required to run Resource Monitoring Tool first. The programs installed are RabbitMQ, Erlang, and a dedicated PostgreSQL database. It will then proceed to install the RMT Server.

2. Install the Agent using command line.

   Install the Agent on every one of your Tableau Server nodes. The Agent sends information about Tableau Server usage and performance to the RMT Server for reporting.

HTTPS

As a best practice, you should use HTTPS to protect sensitive information and user credentials.

The **Require HTTPS** setting in the Server configuration is used for communications between the users and the RMT Server. It is also used when you register an Agent. Regular agent communications between Agent and RMT to collect data is done through Rabbit MQ.

Initially, the RMT Server is installed with a self-signed certificate and will use that certificate for HTTPS communication which includes communication during Agent registration. You can use your own certificate to replace the self-signed certificate. This can be done during RMT Server install in the Server Configuration page or after the installation is complete.

## SSL Certificate Mode and Requirements

The resource monitoring tool supports the following modes of using SSL Certificates:

- **Default:** This mode uses the default self-signed certificate supplied by the installer.
- **Local:** This mode allows you to specify a file-based certificate in the `/var/-opt/tableau/tabrmt/master/config` folder.

Follow these guidelines and requirements for your certificate:

- You must have a HTTPS certificate (like X.509) for the appropriate domains. This depends on your local security policies and certificate requirements. For example, if the Resource Monitoring Tool is using a CName or SSL passthrough proxy then you might need to use a SAN certificate. For multiple sub-domains, wildcard certificates are supported.
- The Resource Monitoring Tool supports only PKCS #12 and PEM formats.
- The Resource Monitoring Tool web server requires a certificate and a private key, and optionally chain-of-trust.

  The private key can be either RSA or DSA.

  These can be provided in a single file or grouped files.

  - Single file examples:
    - PKCS #12: A single file with the .pfx or .p12 file extensions.
    - PEM: PEM-encoded certificate + private key (plus optionally intermediate CAs chaining up to root CA), in a single file with the .pem extension. The items in the file does not have to be in any specific order.
  - Grouped file examples:
    - PEM-encoded certificate in a .crt or .cer file PLUS
    - PEM-encoded private key in a .key file PLUS (optionally)
    - PEM-encoded certificate authority in one or more .ca files

Default File and Directory locations:

## RMT Server:

- Installation directory: `/opt/tableau/tabrmt/master`
- Configuration file: `/var/opt/tableau/tabrmt/master/config.json`
- Logs: `/var/opt/tableau/tabrmt/master/logs`

### Agent:

- Installation directory: `/opt/tableau/tabrmt/agent`
- Bootstrap: `/var/opt/tableau/tabrmt/agent/bootstrap`
- Logs: `/var/opt/tableau/tabrmt/agent/logs`

Who can do this

To install Resource Monitoring Tool, you must have all the following:

- User account with full sudo access.
- Tableau Server Administrator site role.
- Resource Monitoring Tool Administrator account.

Next Step

Install the RMT Server:

- Using web interface
- Using command line

Install the RMT Server Using Web Interface

The Resource Monitoring Tool Server (RMT Server) hosts the web application that users interact with. It also does much of the background processing to collate and monitor the data from the Agents. The RMT Server must be installed on dedicated hardware.

> Installation through web interface is currently only supported for Windows Installations. If you want to install on Linux, see Install the RMT Server Using Command Line.

**To install the RMT Server:**

There are three main steps to installing the RMT Server:

- Installing the Server software
- Configuring the RMT Server
- Creating a new environment.

The detailed step by step process is described below:

1. **Installing the Server software:**
    1. Run the RMT Server setup program.
    2. After reading the EULA, select **I agree to the license terms and conditions**, and click **Install**.
    3. If the User Account Control dialog opens, click **Yes** to allow the installer to make changes.
    4. The RMT Server installer will first install certain prerequisites as the first step. The prerequisites include RabbitMQ, Erlang, and a PostgreSQL database. The PostgreSQL database is used to store usage data gathered from Tableau Server. It will then proceed to install the RMT Server.
    5. At the end of the installation, a **Server Configuration** web page opens.
2. **Configure the RMT Server:**
    1. The page should already be filled in. Make any updates to the values if needed.

        **Note:** Make a note of the **Host Name**. The web interface used to access the RMT Server uses this format: *https://<hostname>*.

    2. By default, Resource Monitoring Tool uses a self-signed certificate to use for the HTTPS communications with the RMT Server. To leverage your own certificate, replace the thumbprint value with the one for the certificate you want to use. Check the **Require HTTPS** option if you want to mandate secure HTTPS communications.

        Checking the **Require HTTPS** option will also require you to choose a certificate mode and provide additional details if necessary. Mainly there are three options to choose from:

    1. **Default:** This mode uses the default self-signed certificate supplied by the installer.

    2. **Local:** This mode allows you to specify a file-based certificate in the Resource Monitoring Tool**/config** folder. When **Local** mode is selected, the **Certificate Name** field becomes available. The options listed will correspond with the certificate file groups located in the **/config** folder.

    3. **Store:** This mode allows you to enter the thumbprint of a certificate in the Windows certificate store.

       The **Password** field will only be used if the selected certificate requires a password.

3. Test the Server Configuration by clicking **Test Server Configuration**.

4. The **Password** section allows you to configure the password requirements that will apply to the user accounts and will be applied to the Administrative user account you will create a little later.

5. In the **Authentication** section, you can configure the timeout period for the sessions. If the user does not access the session for the set timeout period then the session will expire and they will need to log in again. By default, this is set to 240 minutes. You can also enable the **Sliding Expiration** option to reset the time out period when a session is accessed within the time out period.

6. Click **Save and Restart Server**.

7. When the server has restarted, you are prompted to create an administrative user and password.

8. After signing in using the administrative credentials you just created in the previous step, the Resource Monitoring Tool you will see a message that no Environment has been created. Click **Add an environment** to setup a new

environment.

3. **Create a New Environment:**

    1. Create a new environment: Fill in the details of the environment, like the name an identifier. The Tableau Server REST API and the Tableau Server Repository configurations are used to communicate with Tableau Server. The Tableau Server Repository configuration is optional, but is a preferred method to access Tableau Server.

        You have the option to configure secure encrypted connection when RMT connects to Tableau Server Repository. In order to use SSL connections between RMT and Tableau Server Repository database, Tableau Server must be configured to use SSL. For more information, see Configure SSL for Internal Postgres Communication.

    2. Tableau Repository Configuration:

        In the **Tableau Repository Configuration** section:

        1. In the **SSL Mode** drop down box, select **Prefer SSL** or **Require SSL** to configure SSL connections to Tableau Repository. Choosing **Disable** means SSL will never be used to make Tableau Server Repository connections.

            In the **Prefer SSL** mode, the Resource Monitoring Tool will use SSL in the first attempt, and if that fails the subsequently attempts a non-encrypted connection.

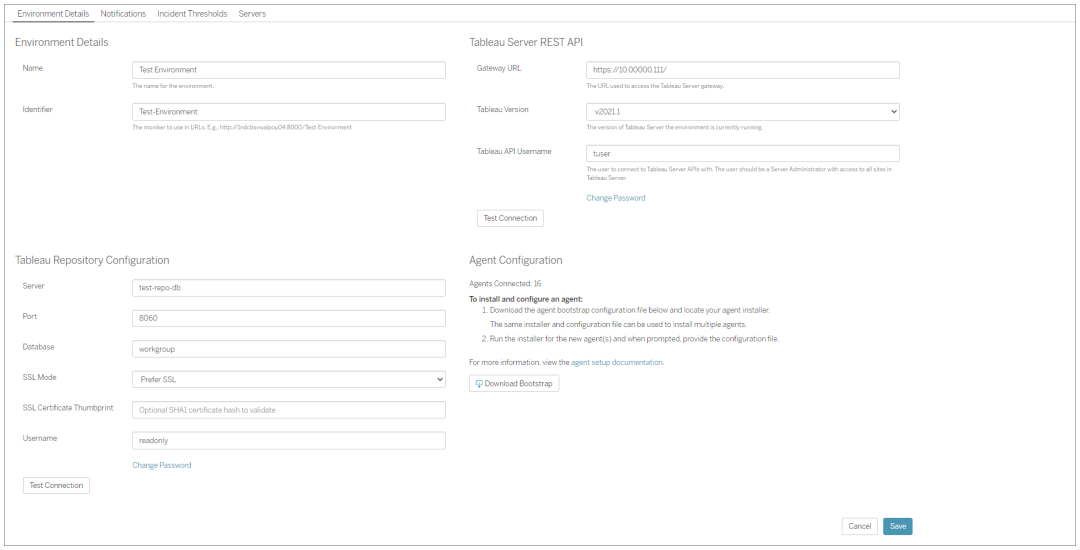
            In the **Require SSL** mode, if the SSL connection fails, the connections to Tableau Server Repository will fail entirely. In this case, Tableau Server REST API connections will be used to communicate with Tableau Server.

        2. You can choose to either supply the thumbprint that was generated by Tableau Server, or copy the **server.crt** file to the Resource Monitoring

Tool Master Server machine. If you choose to copy the certificate file, you don't have to supply the thumbprint. For more information, see Configure Postgres SSL to Allow Direct Connections from Clients.

4. Click **Save**. You will see a new section added to the page - **Agent Configuration**. This section allows you to download the bootstrap file needed to install and configure Agents.

   **Note:** If you make any updates to the Environment configurations, you must click **Save** before downloading the Bootstrap file.



Who can do this

To install Resource Monitoring Tool, you must have all the following:

- Administrator permissions on the machine you are installing Resource Monitoring Tool.
- Tableau Server Administrator site role.
- Resource Monitoring Tool Administrator account.

Next Step

Install the Agent Using the Web Interface

Install the Agent Using the Web Interface

The Agent is a lightweight process that consumes minimal server resources and sends data to the Resource Monitoring Tool Server (RMT Server). Install the Resource Monitoring Tool Agent on each of your Tableau Server nodes. To install and register an Agent, download the Agent bootstrap configuration file and save it to a location that is accessible from the Resource Monitoring Tool Agent nodes.

> Installation through web interface is currently only supported for Windows Installations. If you want to install on Linux, see Install the Agent Using Command Line.

Before you install

- Download the bootstrap file. **Bootstrap files are only valid for 24 hours after downloading. You will need to regenerate the bootstrap file if the one you are using is older than 24 hours.**
- Agent registration will need to communicate both through a https endpoint and RabbitMQ to complete. Make sure both ports 443 and 5672 are open for these communications.

Steps to download the Agent bootstrap file

Use the following steps if you have not yet downloaded the bootstrap file from the RMT Server.

1. Using the web interface (*https://<hostname>*) on the RMT Server, from the **Admin** menu, select **Environments**.
2. The bootstrap file can be downloaded directly from the environment overview tab on the home page.

> **Note:** If you haven't created an environment as part of the RMT Server setup, follow steps 12- 15 described in the Install the RMT Server Using Web Interface topic.

3. Save the bootstrap configuration file to a location that is accessible from the Tableau Server nodes where you will be installing Resource Monitoring Tool Agent.

Steps to install Agent

> Installation through web interface is currently only supported for Windows Installations. If you want to install on Linux, see Install the Agent Using Command Line.

Who can do this

To install Resource Monitoring Tool, you must have all the following:

- Administrator permissions on the machine you are installing Resource Monitoring Tool.
- Tableau Server Administrator site role.

Next Steps

Resource Monitoring Tool Server Configuration

Install the RMT Server Using Command Line

The Resource Monitoring Tool Server (RMT Server) hosts the web application that users interact with. It also does much of the background processing to collate and monitor the data from the Agents. The RMT Server must be installed on dedicated hardware.

This topic describes the steps you can use to install the RMT Server using command line. Command line installation is supported on both Windows and Linux operating systems.

In an effort to align with our company values of Equality, we have changed non-inclusive terminology where possible. Because changing terms in certain places can causing a breaking change, we maintain the existing terminology. So, you may continue to see the terms in

CLI commands and options, installation folders, configuration files. and other instances. For more information, see About Tableau Help.

Install on Linux

**To install the RMT Server:**

1. **Install the RMT Server:**

    1. Download the rpm or .deb RMT Server Installer and save it to a location that you can access from the machine where you plan to install the RMT Server.

    2. Login to the machine where you want the RMT Server installed as a user that has sudo access.

    3. Run the following command to install the RMT Server, where <version> is formatted as major-minor-maintenance:

        For RHEL like distribution including CentOS:

        ```
        sudo yum install <pathtormtserverinstaller>/Tabrmt-Master-x86_64-<version>.rpm
        ```

        For Ubuntu distributions:

        ```
        sudo apt install ./<pathtormtserverinstaller>/Tabrmt-Master-amd_64-<version>.deb
        ```

    This installs the package and the prerequisites including RabbitMQ, Erlang, and a PostgreSQL database. The PostgreSQL database is used to store usage data gathered from Tableau Server. It will then proceed to install the RMT Server.

2. **Initialize RMT Server:**

    You must explicitly accept the End User License Agreement (EULA) when you initialize RMT Server. You also have the option to specify non-default configurations. To initialize RMT Server with a default configuration, run this command :

```
sudo /opt/tableau/tabrmt/master/install-scripts/initialize-rmt-master --accepteula
```

The EULA can be found in the `/opt/tableau/tabrmt/master/docs` folder.

Beginning in version 2023.1 you can specify a custom Run As account to be used by RMT, as well as other configuration options. By default, RMT creates and uses an account called `rmt-master` to run under. To specify a custom Run As account to be used by RMT Server, include the `--unprivileged-user` option when you run the initialization script. For information about all the available switches for the `initialize-rmt-master` script, see RMT Server Initialization Script Options.

3. **Configure the RMT Server:**

    1. Run the following command as the `tabrmt-master` user:

        ```
        sudo su --login tabrmt-master
        ```

        ```
        rmtadmin master-setup [options]
        ```

        The configuration options can be supplied either through the command prompt, a configuration file. If you do not supply the options, the default values will be applied except for the administrator password. The administrator username will be set to admin and you will be prompted to provide the password.

        Example command including the required password parameter:

        ```
        rmtadmin master-setup --admin-username=<name of the administrator user> --admin-password=<administrator user password>
        ```

        The following table lists the required and some commonly used options to configure the RMT Server. For a full list of the configurations options, see rmtadmin Command Line Utility .

**Note:** Require HTTPS option ensures secure communications between the RMT Server and users. When you require HTTPS for communications, you must also select a mode for the certificate that should be used for these communications. The table below includes the various options. To learn more about these modes and certificates, see SSL Certificate Mode and Requirements

| Option | Required? | Default | Description |
|---|---|---|---|
| admin-password | Yes<br><br>Password can be supplied in the command line or provide a file with the password to use. If neither is provided, you will be prompted for the password. | n/a | The password for the administrator user. |
| admin-password-file | No<br><br>Password can be supplied in the command line or provide a file with the password to | n/a | The file where the password for the administrator user is stored.<br><br>**Note:** `tabrmt-master` user must have access to this file. |

| Option | Required? | Default | Description |
|---|---|---|---|
| | use. If neither is provided, you will be prompted for the password. | | |
| admin-username | No | admin | The username for the administrator user. |
| http-port | No | 80 | |
| require-https | No | True | Redirect http traffic to HTTPS. |
| https-certificate-mode | No | **"Default"**<br>Available options:<br>Default<br>Local | The type of certificate search to perform for the HTTPS certificate.<br>**Default:** This mode uses the default self-signed certificate supplied by the installer.<br>**Local:** Allows you to specify a file-based certificate in the */var/opt/tableau/tabrmt/master/config* folder. |
| https-certificate-local-name | No<br>Note: If not specified, the Resource Mon- | Null | The name of the HTTPS certificate file without the file extension. |

| Option | Required? | Default | Description |
|---|---|---|---|
| | itoring Tool is installed with a self-signed certificate and will use that certificate for HTTPS communications. | | |
| https-certificate-local-password | No | Null | The password to use for the HTTPS certificate. |
| https-certificate-local-password-file | No | Null | The path to the file containing the password to use for the HTTPS certificate. |

4. **Create an environment:**

    1. Run the following command to create an environment:

    ```
    rmtadmin create-env --name=<myenvironment> --api-user-name=<TableauServer API user name> --api-password=<password for the Tableau Server API user account>
    ```

    Configure the environment using the options available for this command. Here are some key configuration options to consider:

    - The Tableau Server REST API and the Tableau Server Repository configurations are used to communicate with Tableau Server. The Tableau Server Repository configuration is optional, but is a preferred method to

access Tableau Server.

- You have the option to configure secure encrypted connection when RMT connects to Tableau Server Repository. In order to use SSL connections between RMT and Tableau Server Repository database, Tableau Server must be configured to use SSL. For more information, see Configure SSL for Internal Postgres Communication.

The following table lists the some of the common options. To see a full list of options, see rmtadmin Command Line Utility .

| Option | Required? | Default | Description |
|---|---|---|---|
| --name | Yes | n/a | The name of the environment. |
| --gateway-url | Yes | n/a | URL used to access the Tableau Server gateway. |
| --version | Yes | n/a | Tableau Server version that this environment will be monitoring. |
| --api-username | No | Null | User name of the account used to connect to Tableau Server APIs. The user account should be a Tableau Server administrator with access to all Tableau Server sites. |
| --api-password | No<br><br>(If you specify the Tableau API user name, you | Null | Password of the Tableau Server API user account used to connect to Tableau Server APIs. |

| Option | Required? | Default | Description |
|---|---|---|---|
| | will either provide the password, or specify the file path and file that has the password) | | |
| --api-password-file | No | Null | The path to the file and the name of the file containing the password of the Tableau Server API user account. |
| --repository-server | Yes | Null | This is the server name for the PostgreSQL database that in installed with Tableau Server |
| --repository-port | Yes | Null | The port number of the Tableau Server Repository database. |
| --repository-username | Yes | Null | Username used to connect to PostgreSQL database installed with the Tableau Server Repository.<br><br>Resource Monitoring Tool accesses the Tableau Server Repository database directly for performance reasons. For this to work, access to the repository must be enabled, with a pass- |

| Option | Required? | Default | Description |
|---|---|---|---|
| | | | word set for the **readonly** database user. For details, see Enable access to the Tableau Server repository. |
| --repository-password | Yes | Null | Password for the user account used to connect to the PostgreSQL database that is installed with the Tableau Server .<br><br>Resource Monitoring Tool accesses the Tableau Server Repository database directly for performance reasons. For this to work, access to the repository must be enabled, with a password set for the **readonly** database user. For details, see Enable access to the Tableau Server repository. |
| --repository-password-file | No | Null | The path including the file name where the password for the user account used to connect to the PostgreSQL database that is installed with Tableau Server. |
| --repository-ssl-mode | No | Prefer | Tableau Server Repository SSL Mode:<br><br>**Prefer** SSL or **Require** SSL to configure SSL connections to |

| Option | Required? | Default | Description |
|---|---|---|---|
| | | | Tableau Repository.<br><br>**Disable** to never use SSL to make Tableau Server Repository connections. |
| --repository-ssl-thumbprint | No | Null | You can choose to either supply the thumbprint that was generated by Tableau Server, or copy the **server.crt** file to the Resource Monitoring Tool Server (RMT Server) machine. If you choose to copy the certificate file, you don't have to supply the thumbprint. For more information, see Configure Postgres SSL to Allow Direct Connections from Clients. |

2. Download the bootstrap file to a location that can be accessed from the Tableau Server nodes.

```
rmtadmin bootstrap-file --env=<myenvironment> --file-
name=<The absolute or relative path including the file
name>
```

5. **Optional step - only if not using SSD:** The Resource Monitoring Tool is optimized for SSD by default. If you are not using SSD hardware, run the command:

```
sudo /opt/tableau/tabrmt/master/tabrmt-master optimize --no-ssd
```

Install on Windows

**To install the RMT Server:**

1. **Run the RMT Server setup program:**

    1. Download the RMT Server installer and save it to a location that you can access from the machine where you plan to install the RMT Server.

    2. Open the command prompt as an administrator.

    3. Navigate to the location of the RMT Server installer and run the exe file using the following command

        ```
        Tabrmt-Master-64bit-<version>.exe /silent ACCEPTEULA=1
        ```

        **Note:** Use the /silent or /quiet switch to run the setup unattended and without displaying any UI or prompts.

        The default install folder is usually like this: *C:\Program Files\Tableau\Tableau Resource Monitoring Tool\master*. To provide a different install location run the following command:

        ```
        Tabrmt-Master-64bit-<version>.exe /silent ACCEPTEULA=1
        InstallFolder="D:\Tableau Resource Monitoring Tool\master"
        ```

        Full list of all the install command properties and switches can be found in this section below.

    This installs the package and the prerequisites including RabbitMQ, Erlang, and a PostgreSQL database. The PostgreSQL database is used to store usage data gathered from Tableau Server. It will then proceed to install the RMT Server.

2. **Configure the RMT Server:**

    1. Run the following command and provide the options:

        ```
        rmtadmin master-setup [options]
        ```

        The configuration options can be supplied either through the command prompt, a configuration file. If you do not supply the options, the default values will be

applied except for the administrator password. The administrator user name will be set to admin and you will be prompted to provide the password.

Example command including the required password parameter:

```
rmtadmin master-setup --admin-username=<name of the administrator user> --admin-password=<administrator user password>
```

The following table lists the required and some commonly used options used to configure the RMT Server. For a full list of the configurations options, see rmtadmin Command Line Utility .

**Note:** Require HTTPS option ensures secure communications between the RMT Server and users. When you require HTTPS for communications, you must also select a mode for the certificate that should be used for these communications. The table below includes the various options. To learn more about these modes and certificates, see Install the Tableau Resource Monitoring Tool

| Option | Required? | Default | Description |
|---|---|---|---|
| admin-password | Yes<br><br>Password can be supplied in the command line or provide a file with the password to | n/a | The password for the administrator user. |

| Option | Required? | Default | Description |
|---|---|---|---|
| | use. If neither is provided, you will be prompted for the password. | | |
| admin-password-file | No<br><br>Password can be supplied in the command line or provide a file with the password to use. If neither is provided, you will be prompted for the password. | n/a | The file where the password for the administrator user is stored. |
| admin-username | No | admin | The username for the administrator user. |
| http-port | No | 80 | |
| require-https | No | True | Redirect http traffic to |

| Option | Required? | Default | Description |
|---|---|---|---|
| | | | HTTPS. |
| https-certificate-mode | No | **Default**<br><br>Available options:<br>• Default<br>• Store<br>• Local | The type of certificate search to perform for the HTTPS certificate.<br><br>**Default:** This mode uses the default self-signed certificate supplied by the installer.<br><br>**Store:** This allows you to enter the thumbprint of a certificate in the Windows certificate store.<br><br>**Local:** Allows you to specify a file-based certificate *<installation directory>\config* folder. By default this is *C:\Program Files\Tableau\Tableau Resource Monitoring Tool\master\config*. |
| https-certificate-store-thumbprint | No | Null | The HTTPS certificate hash/thumbprint to search for in 'store' certificate mode. |
| https-certificate-local- | No | Null | The name of the HTTPS certificate file without the |

| Option | Required? | Default | Description |
|---|---|---|---|
| name | | Note: If not specified, the Resource Monitoring Tool is installed with a self-signed certificate and will use that certificate for HTTPS communications. | file extension. |
| https-certificate-local-password | No | Null | The password to use for the HTTPS certificate. |
| https-certificate-local-password-file | No | Null | The path to the file containing the password to use for the HTTPS certificate. |

3. **Create an environment:**

    1. Run the following command to create an environment:

        ```
        rmtadmin create-env --name=<myenvironment> --api-user-name=<TableauServer API user name> --api-password=<password for the Tableau Server API user account>
        ```

        Configure the environment using the options available for this command. Here are some key configuration options to consider:

        - The Tableau Server REST API and the Tableau Server Repository configurations are used to communicate with Tableau Server. The Tableau Server Repository configuration is optional, but is a preferred method to

access Tableau Server.

- You have the option to configure secure encrypted connection when RMT connects to Tableau Server Repository. In order to use SSL connections between RMT and Tableau Server Repository database, Tableau Server must be configured to use SSL. For more information, see Configure SSL for Internal Postgres Communication.

The following table lists the some of the common options. To see a full list of options, see rmtadmin Command Line Utility .

| Option | Required? | Default | Description |
|---|---|---|---|
| --name | Yes | n/a | The name of the environment. |
| --gateway-url | Yes | n/a | URL used to access the Tableau Server gateway. |
| --version | Yes | n/a | Tableau Server version that this environment will be monitoring. |
| --api-username | No | Null | User name of the account used to connect to Tableau Server APIs. The user account should be a Tableau Server administrator with access to all Tableau Server sites. |
| --api-password | No<br><br>(If you specify the Tableau API user name, you | Null | Password of the Tableau Server API user account used to connect to Tableau Server APIs. |

| Option | Required? | Default | Description |
|---|---|---|---|
| | will either provide the password, or specify the file path and file that has the password) | | |
| --api-password-file | No | Null | The path to the file and the name of the file containing the password of the Tableau Server API user account. |
| --repository-server | Yes | Null | This is the server name for the PostgreSQL database that in installed with Tableau Server |
| --repository-port | Yes | Null | The port number of the Tableau Server Repository database. |
| --repository-username | Yes | Null | Username used to connect to PostgreSQL database installed with the Tableau Server Repository.<br><br>Resource Monitoring Tool accesses the Tableau Server Repository database directly for performance reasons. For this to work, access to the repository must be enabled, with a pass- |

| Option | Required? | Default | Description |
|---|---|---|---|
| | | | word set for the **readonly** database user. For details, see Enable access to the Tableau Server repository. |
| --repository-password | Yes | Null | Password for the user account used to connect to the PostgreSQL database that is installed with the Tableau Server .<br><br>Resource Monitoring Tool accesses the Tableau Server Repository database directly for performance reasons. For this to work, access to the repository must be enabled, with a password set for the **readonly** database user. For details, see Enable access to the Tableau Server repository. |
| --repository-password-file | No | Null | The path including the file name where the password for the user account used to connect to the PostgreSQL database that is installed with Tableau Server. |
| --repository-ssl-mode | No | Prefer | Tableau Server Repository SSL Mode:<br><br>**Prefer** SSL or **Require** SSL to |

| Option | Required? | Default | Description |
|---|---|---|---|
| | | | configure SSL connections to Tableau Repository.<br><br>**Disable** to never use SSL to make Tableau Server Repository connections. |
| --repository-ssl-thumbprint | No | Null | You can choose to either supply the thumbprint that was generated by Tableau Server, or copy the **server.crt** file to the Resource Monitoring Tool Server(RMT Server) machine. If you choose to copy the certificate file, you don't have to supply the thumbprint. For more information, see Configure Postgres SSL to Allow Direct Connections from Clients. |

2. Download the bootstrap file to a location that can be accessed from the Tableau Server nodes.

```
rmtadmin bootstrap-file --env=<myenvironment> --file-
name=<The absolute or relative path including the file
name>
```

## Windows install properties and switches

**Switches:**

| Switch | Description | Comments |
|---|---|---|
| `/install \|` | Run Setup to either | Default is to install, displaying UI and all |

| Switch | Description | Comments |
|---|---|---|
| `/uninstall` | install or uninstall Resource Monitoring Tool. | prompts. If no directory is specified using the InstallFolder property on a fresh install, *C:\Program Files\Tableau\Tableau Resource Monitoring Tool\master* is assumed. If Resource Monitoring Tool is already installed, Setup will assume the same location as the current installation.<br><br>To completely remove Resource Monitoring Tool including the data directory, use, `/uninstall DELTEDATADIR=1` |
| `/passive` | Run Setup with minimal UI and no prompts. | |
| `/quiet \| /silent` | Run Setup in unattended, fully silent mode. No web interface or prompts are displayed. | Use either /quiet or /silent, not both. |
| `/norestart` | Run Setup without restarting Windows, even if a restart is necessary. | In certain rare cases, a restart cannot be suppressed, even when this option is used. This is most likely when an earlier system restart was skipped. For example, if restart was skipped during installation of other software. |
| `/log <log-file>` | Log information to the specified file and path. By default log files are created in %TEMP% with a naming convention of Tableau_Resource_Monitoring_ | If no file location is specified, the log file is written to the TEMP folder - *C:\Users\<username>\AppData\Local\Temp*. Check this log file for errors after installation.<br><br>For example: `<Setup file> /quiet /lo-` |

| Switch | Description | Comments |
|---|---|---|
| | Tool_<version_code>. | `g="C:\Tableau\Logs\RmtInstall` |

**Properties:**

| Property | Description | Comments |
|---|---|---|
| `InstallFolder-=<path\to\i-installation\directory>` | Install to the specified non-default install location. | Specifies the location to install RMT. If not used, RMT is installed to *C:\Program Files\Tableau\Tableau Resource Monitoring Tool\master*.<br>Example: `<Setup file> /silent InstallFolder-r="D:\Tableau\Tableau Resource Monitoring Tool\master"` |
| `ACCEPTEULA=1\|0` | Accept the End User License Agreement (EULA). Required for quiet, silent, and passive install | If not included when using /passive, /silent or /quiet, Setup fails silently. If included but set to 0, Setup fails. |

| Property | Description | Comments |
|---|---|---|
| | on both initial and additional nodes. 1 = true, accept the EULA, 0 = false, do not accept the EULA. | |

Who can do this

To install Resource Monitoring Tool, you must have all the following:

**Windows**

- Administrator permissions on the machine you are installing Resource Monitoring Tool.
- Tableau Server Administrator site role.
- Resource Monitoring Tool Administrator account.

**Linux**

- Full sudo access for the user account that is used to install the Agent.
- Resource Monitoring Tool Administrator account

Next Step

Install the Agent Using Command Line

## RMT Server Initialization Script Options

After installing the RMT Server you need to initialize the Server. By default the only required flag you must include when running the initialization script is `--accepteula`. Other options give you flexibility to customize the installation based on your environment and the security requirements of your enterprise.

--accepteula

Required.

Indicates you have read and accepted the terms of the End User License Agreement (EULA).

`-a <username>`

Optional.

Add the provided username to the appropriate groups, instead of the user running the initialize script. This gives the user access to the resources owned by the groups. This is not the same as the Run As user account.

Default: the user running the initialization script

`-f`

Optional.

Bypass warning messages or distribution version check.

`-h | -?`

Optional.

Displays the script's help text.

`-q`

Optional.

Quiet, suppress output except for errors and warnings.

`--debug`

Optional.

Print each command as it is run for debugging purposes. Produces extensive output.

`--default-group=<value>`

**Version:** Added in version 2023.1.0.

Optional.

Name of the group that allows authorization to access Tableau RMT Agent. If specified then `--unprivileged-user` must also be specified.

`---disable-account-creation`

**Version:** Added in version 2023.1.0.

Optional.

Accounts/groups, that do not exist, will not be created. If specified, then you must also specify the `--unprivileged-user` parameter and a combination of the `--default-group` and/or other `--rmt-<...>-group` parameters. The user ID and groups those parameters refer to must already exist.

`--rmt-authorized-group=<value>`

**Version:** Added in version 2023.1.0.

Optional.

Name of the group that owns the install base install directory and the `install_dir/-prerequisites` folder. If specified then `--unprivileged-user` must also be specified.

Default: "`rmtmasterapp`" or `--default-group` value

`--rmt-config-group=<value>`

**Version:** Added in version 2023.1.0.

Optional.

Name of the group that owns the `install_dir/master/config` directory. If specified then `--unprivileged-user` must also be specified.

Default: "`rmtmasterconfig`" or `--default-group` value

`--rmt-logs-group=<value>`

**Version:** Added in version 2023.1.0.

Optional.

Name of the group that owns the `install_dir/master/logs` directory. If specified then `--unprivileged-user` must also be specified.

Default: "`rmtmasterlogs`" or `--default-group` value

`--rmt-openssl-group=<value>`

**Version:** Added in version 2023.1.0.

Optional.

Name of the group that owns the `install_dir/prerequisites/openssl` directory.

Default: "`rmtopenssl`" or `--default-group` value

`--rmt-postgres-app-group=<value>`

**Version:** Added in version 2023.1.0.

Optional.

Name of the group that owns the `install_dir/prerequisites/postgresql13` directory.

Default: "`rmtpostgresapp`" or `--default-group` value

`--rmt-postgres-data-group=<value>`

**Version:** Added in version 2023.1.0.

Optional.

Name of the group that owns the install_dir/master/logs directory. If specified then `--unprivileged-user` must also be specified.

Default: "`rmtmasterlogs`" or `--default-group` value

`--rmt-rabbitmq-app-group=<value>`

**Version:** Added in version 2023.1.0.

Optional.

Name of the group that owns the `install_dir/prerequisites/rabbitmq` directory.

Default: "`rmtrabbitmqapp`" or `--default-group` value

`--rmt-rabbitmq-data-group=<value>`

**Version:** Added in version 2023.1.0.

Optional.

Name of the group that owns the `install_dir/data/rabbitmq` directory.

Default: "`rmtrabbitmqdata`" or `--default-group` value

`--unprivileged-user=<value>`

**Version:** Added in version 2023.1.0.

Optional.

Name of the unprivileged user account to run Tableau RMT Master. You cannot change the account after initializing RMT.

Default: "`tabrmt-master`"

Install the Agent Using Command Line

The Agent is a lightweight process that consumes minimal server resources and sends data to the Resource Monitoring Tool Server (RMT Server). Install the Resource Monitoring Tool Agent on each of your Tableau Server nodes. To install and register an Agent, download the Agent bootstrap configuration file and save it to a location that is accessible from the Resource Monitoring Tool Agent nodes.

This topic describes the steps you can use to install the Resource Monitoring Tool Agent using command line. Command line installation is supported on both Windows and Linux operating systems.

In an effort to align with our company values of Equality, we have changed non-inclusive terminology where possible. Because changing terms in certain places can causing a breaking change, we maintain the existing terminology. So, you may continue to see the terms in CLI commands and options, installation folders, configuration files. and other instances. For more information, see About Tableau Help.

Before you install

- Download the bootstrap file and save it to a location that is accessible to the nodes on which you are going to install RMT Agent. **Bootstrap files are only valid for 24 hours**

**after downloading. You will need to regenerate the bootstrap file if the one you are using is older than 24 hours.**

- Agent registration will need to communicate both through a https endpoint and RabbitMQ to complete. Make sure both ports 443 and 5672 are open for these communcations.

Install on Linux

**To install and configure the Agent:**

1. **Install:**

    1. Download the .rpm or .deb Agent Installer and save it to a location that you can access from the machine where you plan to install the Agent.

    2. Run the following command to install the Agent where <version> is formatted as major-minor-maintenance:

        For RHEL like distributions including CentOS:

        ```
        sudo yum install Tabrmt-Agent-x86_64-<version>.rpm
        ```

        For Ubuntu:

        ```
        sudo apt install Tabrmt-Agent-amd64-<version>.deb
        ```

2. Initialize RMT Agent:

    You must explicitly accept the End User License Agreement (EULA) when you initialize RMT Agent. You also have the option to specify non-default configurations. To initialize RMT Agent with a default configuration, run this command :

    ```
    sudo /opt/tableau/tabrmt/agent/install-scripts/initialize-rmt-agent --accepteula
    ```

    The EULA can be found in the `/opt/tableau/tabrmt/agent/docs` folder.

Beginning in version 2023.1 you can specify a custom Run As account to be used by RMT, as well as other configuration options. By default RMT creates and uses an account called `rmt-agent` to run under. To specify a custom Run As account to be used by RMT Agent, include the `--unprivileged-user` option when you run the initialization script. For information about all the available switches for the `initialize-rmt-agent` script, see RMT Agent Initialization Script Options.

3. **Register:**

    1. Log off and log on as the *tabrmt-agent* user so you can run rmtadmin commands which always require that you run as the *tabrmt-agent* user. Also,when you log on again, you create a new session in which group membership changes have taken effect.

        ```
        sudo su --login tabrmt-agent
        ```

    2. Run the following command and provide the path where the bootstrap file is located. Provide a description of the node where the Agent is being installed.

        ```
        rmtadmin register <bootstrap file path\file> --server-name-e=<Friendly name of machine> --server-description=<server description> --username=<name of the RMT admin user>
        ```

        You will be prompted for the password of the RMT admin user.

        > **Note:** The `tabrmt-agent` user defaults to run commands from the base working directory: /var/opt/tableau/tabrmt/agent, so you must specify the file path accordingly. For example, if you placed the bootstrap file in the /var/-opt/tableau/tabrmt/agent/bootstrap/ folder as recommended, the file path would be `/var/-opt/tableau/tabrmt/agent/bootstrap/<bootstrap_file_name>`.

The following table lists the configuration options used to register the Agent:

| Option | Required? | Default | Description |
|---|---|---|---|
| --bootstrap file | Yes | <none> | The location of the bootstrap file. |
| --username | Yes | <none> | This is typically the admin user you created during RMT Server installation. |
| --password | Yes | <none> | This is the password for the user account |
| --password-file | No<br><br>Password can be supplied in the command line or a file that contains the password. If neither is provided, you will be prompted for the password. | <none> | Path including the file name where the password is stored. |
| -- server-name | No | Host name of machine | Name of the computer that has the Agent Installed. If no option is provided, this field will default to the host name of the machine. |
| --server-description | No | <none> | Description of the computer that has |

| Option | Required? | Default | Description |
|---|---|---|---|
| | | | the Agent installed. If no option is provided, this field will remain blank. |

Install on Windows

**To install and configure the Agent:**

1. Download the bootstrap file to a location that can be accessed from the Tableau Server nodes.

   ```
   rmtadmin bootstrap-file --env=<myenvironment> --filename<The absolute or relative path including the file name>
   ```

2. Run the Agent setup program:

   1. Download the Agent installer and save it to a location that you can access from Tableau Server machines.

   2. Open the command prompt as an administrator.

   3. Navigate to the location of the Agent installer and run the **exe** file using the following command

      ```
      Tabrmt-Agent-64bit-<version>.exe /silent ACCEPTEULA=1
      ```

      **Note:** Use the /silent or /quiet switch to run the setup unattended and without displaying any UI or prompts.

      The default install folder is usually like this: *C:\Program Files\Tableau\Tableau Resource Monitoring Tool\agent*. To provide a different install location run the following command:

```
Tabrmt-Agent-64bit-<version>.exee /silent ACCEPTEULA=1
InstallFolder="D:\Tableau Resource Monitoring Tool\agent"
```

3. Register the Agent:

    1. Run the following command to register the Agent:

    ```
    rmtadmin register <bootstrap file path\file> --server-name-
    e=<Friendly name of machine> --server-description=<server
    description>
    ```

    The following table lists the configuration options used to register the Agent:

| Option | Required? | Default | Description |
|---|---|---|---|
| --bootstrap file | Yes | <none> | The location of the bootstrap file. |
| --username | Yes | <none> | This is typically the admin user you created during RMT Server installation. |
| --password | Yes | <none> | This is the password for the user account |
| --password-file | No<br><br>Password can be supplied in the command line or a file that contains the password. If neither is provided, you will be prompted for the password. | <none> | Path including the file name where the password is stored. |
| -- server- | No | Host name | Name of the com- |

| Option | Required? | Default | Description |
|---|---|---|---|
| name | | of machine | puter that has the Agent Installed. If no option is provided, this field will default to the host name of the machine. |
| -- server-description | No | <none> | Description of the computer that has the Agent installed. If no option is provided, this field will remain blank. |

## Windows install properties and switches

**Switches:**

| Switch | Description | Comments |
|---|---|---|
| `/passive` | Run Setup with minimal UI and no prompts. | |
| `/quiet \| /silent` | Run Setup in unattended, fully silent mode. No web interface or prompts are displayed. | Use either /quiet or /silent, not both. |

**Properties:**

| Property | Description | Comments |
|---|---|---|
| `InstallFolder=<path\to\i-` | Install | Specifies the location to |

| Property | Description | Comments |
|---|---|---|
| `nstallation\directory>` | to the specified non-default install location. | install RMT. If not used, RMT is installed to *C:\Program Files\Tableau\Tableau Resource Monitoring Tool\master*.<br><br>Example: `<Setup file> /silent InstallFolder="D:\Tableau\Tableau Resource Monitoring Tool\agent"` |
| `ACCEPTEULA=1\|0` | Accept the End User License Agreement (EULA). Required for quiet, silent, and pass- | If not included when using /passive, /silent or /quiet, Setup fails silently. If included but set to 0, Setup fails. |

| Property | Description | Comments |
|---|---|---|
| | ive install on both initial and additional nodes. 1 = true, accept the EULA, 0 = false, do not accept the EULA. | |

## Installing Agent on Multi-Node Tableau Server

Run the steps described above on each of the nodes of Tableau Server. On the web interface of the RMT Server you should be able to see all the nodes where the Agent is installed.

Who can do this

To install Resource Monitoring Tool, you must have all the following:

**Windows:**

- Administrator permissions on the machine you are installing Resource Monitoring Tool.
- Tableau Server Administrator site role.

**Linux:**

- Full sudo access for the user account that is used to install the Agent.

Next Step

Configure Tableau Resource Monitoring Tool

RMT Agent Initialization Script Options

After installing the RMT Agent you need to initialize the Agent. By default the only required flag you must include when running the initialization script is `--accepteula`. Other options give you flexibility to customize the installation based on your environment and the security requirements of your enterprise.

RMT Agent initialization options

--accepteula

Required.

Indicates you have read and accepted the terms of the End User License Agreement (EULA).

`-a <username>`

Optional.

Add the provided username to the appropriate groups, instead of the user running the initialize script. This gives the user access to the resources owned by the groups. This is not the same as the Run As user account.

Default: the user running the initialization script

`-f`

Optional.

Bypass warning messages or distribution version check.

`-h | -?`

Optional.

Displays the script's help text.

`-q`

Optional.

Quiet, suppress output except for errors and warnings.

`--debug`

Optional.

Print each command as it is run for debugging purposes. Produces extensive output.

`--default-group=<value>`

**Version:** Added in version 2023.1.0.

Optional.

Name of the group that allows authorization to access Tableau RMT Agent. If specified then `--unprivileged-user` must also be specified.

`---disable-account-creation`

**Version:** Added in version 2023.1.0.

Optional.

Accounts/groups, that do not exist, will not be created. If specified, then you must also specify the `--unprivileged-user` parameter and a combination of the `--default-group` and/or other `--rmt-<...>-group` parameters. The user ID and groups those parameters refer to must already exist.

`--rmt-authorized-group=<value>`

**Version:** Added in version 2023.1.0.

Optional.

Name of the group that owns the install base install directory and the `install_dir/-prerequisites` folder. If specified then `--unprivileged-user` must also be specified.

Default: "`rmtagentapp`" or `--default-group` value

`--rmt-config-group=<value>`

**Version:** Added in version 2023.1.0.

Optional.

Name of the group that owns the `install_dir/agent/config` directory. If specified then `--unprivileged-user` must also be specified.

Default: "`rmtagentconfig`" or `--default-group` value

`--rmt-logs-group=<value>`

**Version:** Added in version 2023.1.0.

Optional.

Name of the group that owns the `install_dir/agent/logs` directory. If specified then `--unprivileged-user` must also be specified.

Default: "`rmtagentlogs`" or `--default-group` value

`--unprivileged-user=<value>`

**Version:** Added in version 2023.1.0.

Optional.

Name of the unprivileged user account used to run Tableau RMT Agent. You cannot change the account after initializing RMT.

Default: "`tabrmt-agent`"

External Repository for Tableau Resource Monitoring Tool

The Tableau Resource Monitoring Tool uses a PostgreSQL database as its repository to gather and store Tableau Server monitoring data that is used to provide performance and usage information. This database is separate from the Tableau Server database.

Before the 2022.3 release, this PostgreSQL repository was automatically installed with the RMT Server, on the same machine as the RMT Server and this was the only option available. Starting in version 2022.3, you can reconfigure RMT Server to use an externally hosted PostgreSQL database instead of the locally installed database. When RMT Server is configured to use an externally hosted PostgreSQL database, we refer to it as the external repository.

The supported platform for hosting the external repository is an AWS RDS instance. Hosting the repository database externally allows you to manage the availability, backups, and disaster recovery of the repository component of the RMT Server.

With the addition of this option to configure an external repository, RMT Server can be configured in the following ways:

- **Continue to use the locally installed repository:** This means that the PostgreSQL database that is automatically installed with RMT Server on the same machine will be used as the repository for RMT Server, and no further changes are made to this configuration.

- **Configure RMT Server to use an external repository:** This means that the PostgreSQL database that RMT uses is hosted external to RMT Server. This requires making some configuration changes post installation. Currently only AWS RDS instances are supported as the hosting platform for PostgreSQL database.

In order to setup and manage the external repository, you should have a good understanding of the AWS RDS platform and PostgreSQL database. We recommend, you use the documentation on the AWS site for platform related instructions.

You will also need to know how to configure and manage the external repository configuration for Resource Monitoring Tool. This topic will provide you with that information in the sections below.

New installation of Resource Monitoring Tool

The instructions detailed in this section apply to a new installation of Resource Monitoring Tool. If you have an existing deployment of RMT, and want to move to an external repository configuration, see the Existing Resource Monitoring Tool installation  section of this topic.

When you install RMT Server, it automatically installs the repository database on the same machine as the RMT Server. The process to configure the external repository is a post install configuration where you will reconfigure RMT Server to use an externally hosted PostgreSQL database.

Use the following steps to install Resource Monitoring Tool and reconfigure RMT Server to use an external repository:

1. **Create the external repository:** Create an RDS instance to host the external repository with the following recommendations.
    - **Minimum recommended PostgreSQL instance specifications:**
        - db.m6g.2xlarge (8 vcpu, 32 GiB RAM)
        - SSD Storage with 500 GB disk space

- **Instance configuration values:**
  - Max Worker Processes: Total Logical Processors
  - Max Workers Per Gather: Min(Total Logical Processors / 2, 4)
  - Max Parallel Workers: Total Logical Processors
  - Max Parallel Maintenance Workers: Min(Total Logical Processors / 2, 4)
  - Shared Buffers: Total Memory / 4
  - Effective Cache Size: 75% of Total Memory
  - Maintenance Work Memory: Total Memory / 16 Linux, Max 2GB - 1MB in Windows
  - Wal Buffers: Derived from Shared Buffers, likely around 16 MB
  - Work Memory: Derived from Shared Buffers and Max Workers Per Gather

  To learn how to create and connect to a PostgreSQL DB instance on AWS, see this page on AWS documentation site.

2. **Install RMT:** Follow the instructions Install the RMT Server Using Command Line to Install RMT Server, but **skip the steps for creating an environment. You will do that later after configuring RMT Server to use the external repository**. **Note that this will initially install a local PostgreSQL database.**

3. **Test the connection to the external repository:** Test the connection to the new database using psql, a PostgreSQL administrative tool that is installed with the RMT Server;

   - Navigate to the 'bin' folder of the locally installed PostgreSQL installation directory.

     ```
     /var/opt/tableau/tabrmt/prerequisites/postgresql<version number>/bin
     ```

- Run the following command to test the connection. Substitute your own value below for **aws_rds_servername**, and provide the PostgreSQL password you created in AWS when prompted.

  ```
  psql -h <aws_rds_servername> -p 5432 -d postgres -U post-
  gres
  ```

  If you receive an error at this point and cannot connect successfully, review the parameter values in the command against the values from the AWS RDS console.

- Once the connection has been successfully established, you can close the psql session with the following command:

  ```
  \q
  ```

4. Run `rmtadmin master-setup` **to configure RMT Server to use the external repository**. Use the following command examples, and edit the command to reflect your Resource Monitoring Tool installation path, AWS RDS instance name, port number, and the RDS PostgreSQL admin user password:

   - Navigate to the Resource Monitoring Tool RMT Server installation directory:

     ```
     sudo /var/opt/tableau/tabrmt/master
     ```

   - Run the command to configure external repository:

     ```
     rmtadmin master-setup --db-config=external --db-server-
     r=<aws_rds_servername> --db-database=<aws_rds_database_
     name> --db-port=5432 --db-admin-username=postgres --db-
     admin-password=<postgres_user_password>
     ```

5. Now **create an environment** and download the bootstrap file:

- Run the following command to create and environment:

  ```
  rmtadmin create-env --name=<myenvironment> --api-user-
  name=<TableauServer API user name> --api-password=<password
  for the Tableau Server API user account>
  ```

- Download the bootstrap file to register Agents:

  ```
  rmtadmin bootstrap-file --env=<myenvironment> --file-
  name=<The absolute or relative path including the file
  name>
  ```

  The steps are described in full detail here: Install the RMT Server Using Command Line.

6. Follow the instructions Install the Agent Using Command Line to Install and register Agents on Tableau Server Nodes.

Existing Resource Monitoring Tool installation

In this release, to configure external repo, you will essentially have to start with a new installation of Tableau Resource Monitoring Tool using the steps described in the above section.

Upgrade best practices

Here are the general steps you need to follow if you want to upgrade Tableau Resource Monitoring Tool and migrate to an external repository at the same time:

**Migration with environment recreation:**

1. Upgrade RMT Server and all Agents to 2022.3 or later.
2. Steps through 2-4 are very similar to the steps you would take to do a new install - see New installation of Resource Monitoring Tool  above. This mainly involves:

   - Create an AWS PostgreSQL DB Instance.
   - Configure RMT Server to use the external repository.

- Recreate environments and re-register all the Agents.

3. Reconfigure any custom configurations.

**Note:** You will lose historical data and also need to reconfigure any custom configurations.

## Upgrading when the new version of RMT requires a major version PostgreSQL upgrade

When there is a change in the PostgreSQL major version requirement for Resource Monitoring Tool, it is a best practice to upgrade the external repository PostgreSQL version first before you upgrade Resource Monitoring Tool. More details are provided below. To see if you should upgrade your external repository PostgreSQL version, see the product compatibility table.

Use the following steps to upgrade RMT and the RDS instance when a PostgreSQL major version upgrade is required

1. Make a backup of your RDS instance. You will need this in case you need to roll back the upgrade. For more information, see Backing up and restoring an Amazon RDS DB instance topic on the AWS site.

2. Make a copy of the configuration file in the Resource Monitoring Tool directory. The configuration file is located at:

   ```
   /var/opt/tableau/tabrmt/master/config.json
   ```

3. Upgrade the RDS instance to the new version of PostgreSQL For more information, see Upgrading the PostgreSQL DB engine for Amazon RDS topic on the AWS site.

4. Upgrade RMT Server. If the upgrade including the database migration completes successfully, proceed to the next step. If the upgrade fails, see the instructions in this

section on how to recover and roll back the upgrade.

5. Upgrade all the Agents on Tableau Server nodes to the new RMT version. For more information, see Upgrading Resource Monitoring Tool.

### Recovering from a failed upgrade

1. Uninstall the upgraded RMT Server.
2. Restore the AWS RDS instance to the version previous to the upgrade. For more information, Backup up and restoring an Amazon RDS DB instance topic on the AWS site.
3. Replace the config file that you backed up prior to upgrade in the following location. You may have to create this folder as it might have been deleted during uninstall:

   ```
   /var/opt/tableau/tabrmt/master/config.json
   ```

4. Install RMT Server which installs a local repository.
5. Configure RMT Server to use the external repository:

   ```
   rmtadmin master-setup --db-config=external --db-server=<aws_
   rds_servername> --db-database=<aws_rds_database_name> --db-port-
   t=5432 --db-admin-username=postgres --db-admin-pass-
   word=<postgres_user_password>
   ```

## RMT and PostgreSQL version compatibility

This table lists RMT version 2022.3 and later only, since the external repository is only available from version 2022.3 and later.

| RMT Version | PostgreSQL Version shipped with RMT | Supported PostgreSQL Version for external repository |
|---|---|---|
| 2022.3 - | 13.7 | 13.7 |

| | | |
|---|---|---|
| 2024.2 | | |
| 2025.x | 15.6 | 15.6 |

Who can do this

To install Resource Monitoring Tool, you must have all the following:

- User account with full sudo access.
- Tableau Server Administrator site role.
- Resource Monitoring Tool Administrator account.

External Message Queue Service (RabbitMQ) for Tableau Resource Monitoring Tool

The Tableau Resource Monitoring Tool uses RabbitMQ as its message queue service to collect data from Agents and bring them to the RMT Server. This information in the queue is processed and eventually stored in the RMT repository (PostgreSQL database).

Before the 2022.3 release, the RabbitMQ message queue service was automatically installed with the RMT Server and this was the only configuration available. Starting in RMT version 2022.3, you can reconfigure RMT Server to use an externally hosted RabbitMQ service. When RMT Server is configured to use an externally hosted message queue service, we refer to it as the external message queue service.

With this new option added in version 2022.3, RMT Server can be configured in the following ways:

- **Continue to use the locally installed message queue service:** This means that RabbitMQ that is automatically installed with RMT Server on the same machine will be used as the message service for RMT Server, and no further changes are made to this configuration.
- **Configure RMT Server to use an external message queue service:** This means that RAbbitMQ that RMT uses is hosted external to RMT Server. Currently only AWS AMQ is supported as the hosting platform for RabbitMQ. Since all messages from the Agents go through RabbitMQ, by hosting this externally frees up resources from the machine where RMT Server is installed.

To setup and manage the external message queue service, you should have a good understanding of the AWS AMQ platform. We recommend reviewing the documentation on AWS site. You will also need to know how to configure and manage the external message queue service for RMT. This topic will provide you with that information in the sections below.

New installation of Resource Monitoring Tool

The instructions provided in this section apply to a new installation of Resource Monitoring Tool. If you have an existing installation, and want to move your local RabbitMQ to an externally hosted configuration, see the Existing installations of Tableau Resource Monitoring Tool section of this topic.

Use the following steps to install Tableau Resource monitoring tool and reconfigure RMT Server to use an external message queue service:

1. **Create Amazon AMQ for Rabbit MQ** to host the external message queue service with the following recommendations:

    - For engine type, use RabbitMQ engine. For the version of Rabbit MQ, see the Product compatibility section.
    - Use the same default version as the one used when RabbitMQ is installed locally. For more information, see the product compatibility table.
    - Use a single-Instance broker.
    - Instance specification: mq.m5.large, 2 vCPU/8 GiB RAM.
    - Create a RabbitMQ username/password.

    To learn more, see Working with Amazon MQ for Rabbit MQ on AWS documentation site.

2. **Test the connection from RMT Server** to the message broker by copying the RabbitMQ web console URL from the AWS MQ page, and paste it into a web browser on RMT Server. Log in via the username and password you created when you set up the

broker.

3. Follow the instructions in this topic to **install RMT Server**, but **skip the steps for creating an environment. You will do that later after configuring RMT Server to use the external repository**.

4. Run rmtadmin setup as follows to configure the external Rabbit MQ message queue service:

   ```
   rmtadmin master-setup --mq-config=external --mq-server=aws_amq_servername --mq-vhost='/' --mq-port=5671 --mq-username=aws_amq_username --mq-password='aws_amq_password' --mq-tls-certificate-host=aws_amq_servername
   ```

5. Now create an environment and download the bootstrap file.

   - Run the following command to create and environment: `rmtadmin create-env --name=<myenvironment> --api-username=<TableauServer API user name> --api-password=<password for the Tableau Server API user account>`

   - Download the bootstrap file to register Agents: `rmtadmin bootstrap-file --env=<myenvironment> --filename<The absolute or relative path including the file name>`

     The steps are described in full detail in the Install the RMT Server Using Command Line topic.

6. Re-register Agents on Tableau Server Nodes using the instructions in Install the Agent Using Command Line topic.

Existing installations of Tableau Resource Monitoring Tool

In this release, to configure external messaging service, you will essentially have to start with a new installation of Tableau Resource Monitoring Tool using the steps described in the above section.

Upgrade best practices

Here are the general steps you need to follow if you want to upgrade to a version 2022.3 or later and migrate to using an external message queue service at the same time.

**Migration with environment recreation:**

1. Upgrade RMT Server and all Agents to 2022.3 or later
2. Create an Amazon AMQ broker service.
3. Configure RMT Server to use the external message queue service
4. Recreate environments and re-register all the Agents
5. Recreate any custom configurations.

**Note:** You will lose some event and hardware processing data and you will also need to reconfigure the incident thresholds

## Upgrade steps with enabling TLS for RabbitMQ

Since the agents in versions earlier than 2022.3 have been communicating using unencrypted connection to the RabbitMQ message queue service, when upgrading to version 2022.3 or later, those agents need to be updated to use the new secure connection details. The steps to do this are as follows:

1. After completing the upgrade steps described in the above section, stop all agents by running the following command:

   ```
   rmtadmin stop --agent
   ```

2. Download the bootstrap file for the environment by running the following command:

   ```
   rmtadmin bootstrap-file --env<myenvironment> --filename <The absolute or relative path including the file name>
   ```

3. Run the following command on each of the machines where the Agent is installed:

```
rmtadmin rotate-mq-certificate <BOOTSTRAP_FILE> --username=<RMT
Server Username> --password-file=<RMT Server Password file
name>
```

4. Restart each Agent machine after successfully running the `rmtadmin rotate-mq-certificate` command.

Product Compatibility

This table lists RMT version 2022.3 and later only, since the external message queue is only available from version 2022.3 and later.

| RMT Version | RabbitMQ version shipped with RMT | Supoort RabbitMQ version for external message queue service |
|---|---|---|
| 22.3 | 3.10.5 | 3.10.5 |

Who can do this

To install Resource Monitoring Tool, you must have all the following:

- User account with full sudo access.
- Tableau Server Administrator site role.
- Resource Monitoring Tool Administrator account.

Tableau Resource Monitoring Tool Prerequisites - Licenses

Tableau Resource Monitoring Tool contains the following open source applications:

| RMT VERSION | OPENSSL VERSION | ERLANG VERSION | RABBITMQ VERSION | POSTGRESQL VERSION |
|---|---|---|---|---|
| 2022.1 | 1.1.1l | 24.1.2 | 3.9.7 | 13.3 |
| 2022.1.1 | 1.1.1n | 24.1.2 | 3.9.7 | 13.3 |
| 2022.1.5 | 1.1.1q | 24.3.4.2 | 3.10.5 | 13.6 |
| 2022.2 | 1.1.1l | 24.3.0 | 3.9.13 | 13.3 |
| 2022.3 - | 1.1.1q | 24.3.4.2 | 3.10.5 | 13.7 |

| RMT VERSION | OPENSSL VERSION | ERLANG VERSION | RABBITMQ VERSION | POSTGRESQL VERSION |
|---|---|---|---|---|
| 2023.1 | | | | |
| 2023.2 - 2024.3 | 1.1.1t | 24.3.4.10 | 3.10.20 | 13.7 |
| 2025.1 | 3.1.5.20240229235146 | 24.0 | 3.8.16 | 12.6 |

- **Erlang:** Copyright 2016 Industrial Erlang User Group, Apache 2.0. For more information, see the Erlang and Apache 2.0 sites.
- **RabbitMQ:** Copyright , MPL 2.0, Copyright (c) 2007-2021 VMware, Inc. or its affiliates. For more information, see Mozilla Public License site.

  Resource Monitoring Tool contains a single modified RabbitMQ source file, which is available upon request.
- **PostgreSQL:** Copyright Portions Copyright © 1996-2021, The PostgreSQL Global Development Group, Portions Copyright © 1994, The Regents of the University of California, PostgreSQL license. For more information, see PostgreSQL site.
- **OpenSSL:** Copyright (c) 1998-2019 The OpenSSL Project, Copyright (c) 1995-1998 Eric A. Young, Tim J. Hudson, OpenSSL license, double license under both the OpenSSL License and the original SSLeay license. For more information, see Open SSL License.

## Upgrading Resource Monitoring Tool

These instructions are for upgrading an existing installation of Tableau Resource Monitoring Tool.

In an effort to align with our company values of Equality, we have changed non-inclusive terminology where possible. Because changing terms in certain places can causing a breaking change, we maintain the existing terminology. So, you may continue to see the terms in CLI commands and options, installation folders, configuration files. and other instances. For more information, see About Tableau Help.

**Note:** The Resource Monitoring Tool performs an in-place upgrade, upgrading your current installation to the newer version. Do not uninstall your existing installation **before** upgrading.

Upgrade Notes

**Consider the following before you start the upgrade process:**

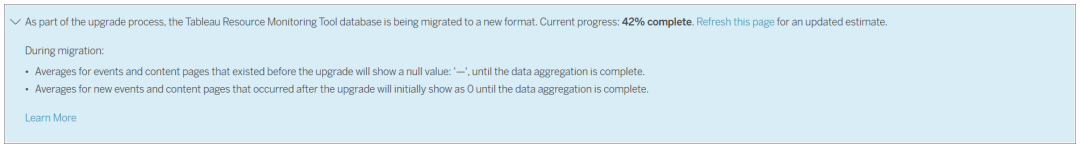
1. If you are planning to move to use an external repository (PostgreSQL) or external message queue service (RabbitMQ), make sure you review the upgrade best practices section in the following topics:
    - Upgrade best practices for external repository
    - Upgrade best practices for external message queue

2. Starting in version 2022.3, Tableau Resource Monitoring Tool has built-in encrypted communications between RMT Server and Agents. However, you will need to run `rmtadmin rotate-mq-certificates` on all the Agents to enable TLS. This applies to RabbitMQ that is configured locally on the same machine as RMT Server. For more details on how to do this, see **Upgrade steps with enabling TLS for RabbitMQ** below.

3. You may need to reboot the machine during an upgrade. This usually occurs if files are locked and cannot be updated by the installer. If necessary, you will be prompted by the installer. Because of this possibility, you may want to consider doing your upgrades during non-work hours.

4. Sometimes, the Resource Monitoring Tool will modify the database and in such cases, the upgrade process will include a database migration. In case of a database migration, you will see a message banner at the top of the RMT Server web page with a time estimate for completing the process. An example screen shot is shown below:

On expanding the banner you can review the details of the impact of the upgrade. Changes are unique to each release and the details shown are specific to the release.



5. The Resource Monitoring Tool is backward compatible with Tableau Server versions, but not forward compatible. This means the Resource Monitoring Tool version should be equal to or greater than the Tableau Server version you are monitoring.

   For compatibility reasons, Tableau recommends you upgrade the Resource Monitoring Tool first and then follow with a Tableau Server upgrade. For more information, see Product Compatibility with Tableau Server.

### How to Upgrade the Resource Monitoring Tool

We recommend you do an in-place upgrade of Resource Monitoring Tool. If you uninstall Resource Monitoring Tool and install a new version of the database, it may result in data corruption and you will be prompted to reinstall the previous version and re-do the upgrade process.

1. Log in to the Resource Monitoring Tool in a browser and confirm it is working before starting the upgrade.
2. Copy the new version of the RMT Server package to the RMT Server machine.
3. Copy the new version of the RMT Agent package to the machines where you have RMT Agents installed. RMT Agents are installed on Tableau Server nodes you are monitoring.
4. On each Tableau Server node running the RMT Agent service, switch to the tabrmtagent user and stop the RMT Agent service:

```
sudo su --login tabrmt-agent
rmtadmin stop
exit
```

5. Switch to the tabrmt-master user on the RMT Server and stop the RMT Server service using the following command:

   ```
   sudo su --login tabrmt-master
   rmtadmin stop
   exit
   ```

6. Wait until there are not any running processes with tabrmt in the name before continuing to the next step.

   Once the services have been stopped, it is best practice to check for any Resource Monitoring Tool processes that are running after the services have been stopped: Any with tabrmt-agent or tabrmt-master. This does not include PostgreSQL or RabbitMQ. You can check the status using the following command:

   ```
   rmtadmin status
   ```

7. Run the upgrade commands on the RMT Server. This will upgrade the existing version to the new version:

   **For RHEL-like distributions including CentOS:**

   ```
   sudo yum install <pathtomasterserverinstaller>/<tabrmt-master-setup-<version>-x86_64.rpm>
   ```

   ```
   sudo /opt/tableau/tabrmt/master/install-scripts/upgrade-rmt-master --accepteula
   ```

   **For Ubuntu distributions:**

   ```
   sudo apt install <pathtomasterserverinstaller>/<tabrmt-master-setup-<version>-amd_64.deb>
   ```

```
sudo /opt/tableau/tabrmt/master/install-scripts/upgrade-rmt-mas-
ter --accepteula
```

8. Once the RMT Server has been upgraded, upgrade all the RMT Agents by running the following command:

   **For RHEL-like distributions including CentOS:**

   ```
   sudo yum install <pathtoagentinstaller>/<tabrmt-agent-setup-
   <version>-x86_64.rpm>
   ```

   ```
   sudo /opt/tableau/tabrmt/agent/install-scripts/upgrade-rmt-
   agent --accepteula
   ```

   **For Ubuntu distributions:**

   ```
   sudo apt install <pathtoagentinstaller>/<tabrmt-agent-setup-
   <version>-amd_64.deb>
   ```

   ```
   sudo /opt/tableau/tabrmt/agent/install-scripts/upgrade-rmt-
   agent --accepteula
   ```

9. Confirm the RMT Server and Agents are running. Start the RMT Server and Agents if they do not automatically restart after the upgrade is complete.

10. To verify RMT Agents have been upgraded, log in to Resource Monitoring Tool in a browser and go to the **Admin** menu, select **Environments**, and click the **Edit Environment** icon to see the environment details. In the **Servers** tab, you can see the version of the RMT Agent. This can be useful to determine which RMT Agents have been upgraded when you have a multi-node Tableau Server cluster.

Upgrade steps with enabling TLS for RabbitMQ

Since the agents in versions earlier than 2022.3 have been communicating using unencrypted connection to the RabbitMQ message queue service, when upgrading to version 2022.3 or

later, those agents need to be updated to use the new secure connection details. The steps to do this are as follows:

1. After completing the upgrade steps described in the above section, stop all agents by running the following command:

   ```
   rmtadmin stop --agent
   ```

2. Download the bootstrap file for the environment by running the following command:

   ```
   rmtadmin bootstrap-file --env<myenvironment> --filename <The absolute or relative path including the file name>
   ```

3. Run the following command on each of the machines where the Agent is installed:

   ```
   rmtadmin rotate-mq-certificate <BOOTSTRAP_FILE> --username=<RMT Server Username> --password-file=<RMT Server Password file name>
   ```

4. Restart each Agent machine after successfully running the `rmtadmin rotate-mq-certificate` command.

Who can do this

To upgrade Resource Monitoring Tool, you will need to have the following permissions:

- User account with full sudo access.
- Tableau Server Administrator.
- Resource Monitoring Tool Administrator.

## Uninstalling Resource Monitoring Tool

There are two primary "uninstall" scenarios Resource Monitoring Tool supports:

- **Uninstall Resource Monitoring Tool:** Resource Monitoring Tool can be uninstalled using the `remove` command which removes each Tableau Resource Monitoring Tool service from the computer from which you are running the command. It also removes

data andResource Monitoring Tool user accounts and groups, but preserves configuration files, logs, and backup files, by moving them to a temporary directory under the `/opt/tableau/tabrmt/data` folder.

- **Obliterate Resource Monitoring Tool:** If you want to completely remove Resource Monitoring Tool from a computer, you can use a script provided by Tableau to remove Resource Monitoring Tool and all related files. *This removes all data as well as Resource Monitoring Tool components, so should only be done if you know you want to reset the computer to a pre-Tableau state.* You might need to do this if Technical Support recommends this step when troubleshooting an installation problem. Completely remove Resource Monitoring Tool without uninstalling any version first. The script will uninstall all existing versions found on the computer. If you have already uninstalled your existing version and now want to completely remove Tableau, you can find the script to do so in a temporary location.

Uninstall Resource Monitoring Tool using `remove`:

- For RHEL-like distributions including CentOS:

```
sudo yum remove tabrmt-master

sudo yum remove tabrmt-agent
```

- For Ubuntu distributions:

```
sudo apt remove tabrmt-master

sudo apt remove tabrmt-agent
```

Obliterate Resource Monitoring Tool using `tableau-rmt-obliterate` script:

If you run into issues when uninstalling using the `remove` command, you can use the obliterate script provided by Tableau to remove all of the installation files from your computer. By default, the obliterate script is located at `/opt/tableau/tabrmt/master/install-scripts/tableau-rmt-obliterate` on the RMT Server machine and `/op-`

`t/tableau/tabrmt/agent/install-scripts/tableau-rmt-obliterate` on Agent machines.

If you already attempted to uninstall Resource Monitoring Tool using the `remove` command, the obliterate script is automatically copied to: `/var/tmp/tableau-rmt-obliterate`

The information to run the script is described below:

1. As the root user, run the following command on the RMT Server machine to completely uninstall RMT Server:

   ```
   /var/tmp/tableau-rmt-obliterate -m -y -y -y
   ```

2. As the root user, run the following command on each Agent machine to completely uninstall Agents:

   ```
   /var/tmp/tableau-rmt-obliterate -a -y -y -y
   ```

You can force remove all the files, including the logs and backups, using the parameters:

`-y`

Required.

Removes Resource Monitoring Tool from this computer. Must be specified three times (`-y-y-y`) to confirm.

`-m`

Required to uninstall RMT Server.

Removes RMT Server.

`-a`

Required to uninstall Agent.

Removes Resource Monitoring Tool Agent if installed.

`-k`

Optional.

Does not copy backups to the `logs-temp` directory.

`-g`

Optional.

Does not copy logs to the logs to the `logs-temp` directory.

Who can do this

To uninstall Resource Monitoring Tool, you must have all the following:

- Administrator permissions on the machine you are installing Resource Monitoring Tool.
- Tableau Server Administrator site role.
- Resource Monitoring Tool Administrator account.

## Configure Tableau Resource Monitoring Tool

This section includes topics that provide information on how to configure Tableau Resource Monitoring Tool to suit your requirements.

### Resource Monitoring Tool Server Configuration

This topic describes the Resource Monitoring Tool Server (RMT Server) configuration options you can set using the web interface.

Post install setup configurations

You can update the configurations you specified during the setup.

Following are the two recommended ways to make configuration changes:

- **To do this using the web interface:** On the machine where RMT Server is installed, go to: *http://<hostname>/setup/server*.
- **To do this using command line**, use `rmtadmin master-setup` command with the `--skip-admin-creation` option to make sure you are not prompted to create the admin user post installation. For more information, see rmtadmin master-setup.

**Note:** Configuration values are saved in the configuration file. Changes can be made directly to this file, but it is advised to leverage the configuration options in the UI and through the `rmtadmin` command line utility. Changes to the config file will require a restart to be applied.

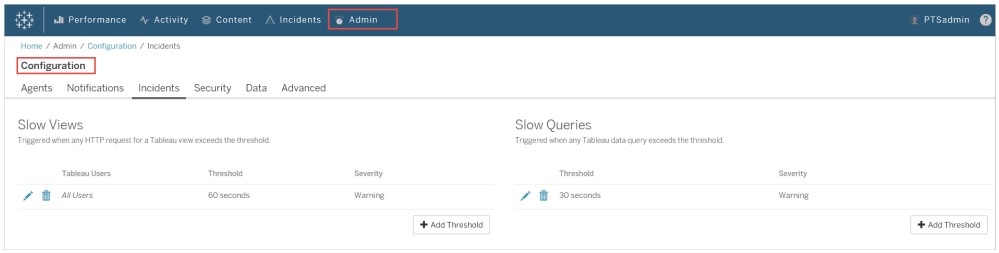
Here are some examples of the type of updates you might want to do after the initial setup.

- Changing SSL Configuration: The default configuration is set to false. You can change this configuration to require HTTPS. Use the rmtadmin master-setup command to update this setting.
- SSL Certificate Updates: You might have completed your initial RMT Server setup using the default certification mode for secure communications, and want to update the certification with your own certificate.
- Changes Ports: Sometimes you will need to use different port numbers than the default based on your network requirements. To learn more about ports and communications between the various components of Resource Monitoring Tool, see Tableau Resource Monitoring Tool Communication Ports.
- Update session expiration: If the user does not access the session for the set timeout period then the session will expire and they will need to log in again. By default, this is set to 240 minutes. You can also enable the **Sliding Expiration** option to reset the time out period when a session is accessed within the time out period.

> **Note:** Adding or removing a Tableau Server node: If you add a new node to the Tableau Server Cluster that you are monitoring using Resource Monitoring Tool, you will need to install and register this node. For more information, see Tableau Server Topology Changes.

To do this through command line, use `rmtadmin-master-setup` command. For more information, see rmtadmin Command Line Utility .

You can configure Resource Monitoring Tool by clicking on “Configuration” under the Admin menu. Configuration sections are divided by tabs. To do this using a configuration file, see RMT Server Configuration File.



Notifications

Notifications can be set at a global level and at the environment level.

You can choose how you want to receive your notifications- through email or Slack, or through both email and Slack.

**The following applies to both email and Slack notfications:**

Both email and Slack notifications can be set at a global level and at the environment level. To send any notifications, global configurations must be enabled, not just at the environment level. You can also configure different minimum severity levels at which to send notifications - they can be different for email and slack, they can also be different at global and environment levels.

Global configurations are applied to existing environments or any new environments created unless the environment is using custom thresholds.

## Slack notification settings

Slack notifications were introduced in Resource Monitoring Tool version 2022.1.

**Before** you set up Slack notifications in Resource Monitoring Tool, there is some initial setup you need to do in Slack. The full details are described in this Slack article, but here are the main things you will need to do:

1. Create a new or use an existing Slack workspace or app and make sure it is enabled to receive incoming webhooks.
2. Authorize a channel where the notifications should be posted.
3. Copy the Webhook URL that is generated for your workspace.

To set up Slack notification in the Resource Monitoring Tool:

1. From the **Admin** menu, select **Global Configuration**.
2. Under the **Notifications** tab, in the **Slack** section, use the toggle button at the top of the section to enable Slack notifications.
3. Configure the following settings:
    1. **Minimum Severity**: The minimum severity level at which you want to receive Slack notifications.
    2. **Webhook URL**: URL of the incoming webhooks for your Slack workspace. This URL is automatically generated when you enable incoming webhooks for your Slack workspace.
4. Test it using the **Send a Test Message** button to make sure your settings are valid and they work.

To specify the notifications for each environment:

1. From the **Admin** menu, select the environment that you want to modify and choose **Edit Environment**.
2. In the **Notifications** tab, choose **Custom** for configuration type to override the global settings.
3. Set the minimum severity and the Webhook URL.
4. Test it using the **Send a Test Message** button to make sure your settings are valid and they work.

## Email notifications

To set up email notification, start by configuring SMTP server settings at the global level. The SMTP server settings configured at the global level are applied automatically to all environments. You can customize certain settings like the minimum severity level and the sender and recipient emails for each environment.

Here are some technical details about how the TLS configuration works:

- RMT Server uses the STARTTLS SMTP option, which upgrades the SMTP connection to TLS after it has been initiated but before the mail content is sent. RMT does not support the REQUIRETLS SMTP option.
- RMT Server uses STARTTLS to encrypt mail in transit to the SMTP server. Whether or not the SMTP server stores the mail encrypted at rest is subject to the SMTP server configuration.

Before you can configure email notifications in the Resource Monitoring Tool, you must have an SMTP server set up and have the following pieces of information:

- **Name** of the SMTP server.
- If you are planning to use encrypted communications, make a note of the **TLS version** that the SMTP server accepts. Currently, **TLS 1.2 is required** by Resource Monitoring

Tool**and TLS 1.3 is supported**.

- The **certificate thumbprint** (optional).
- **Port number** for the SMTP server.
- **Username and password** (optional). Needed only if the SMTP server is configured to authenticate using a username and password.
- **Sender and recipient email addresses** that will be used to send and receive notifications.

**To specify the SMTP server settings in theResource Monitoring Tool:**

1. From the Admin menu, select **Global Configuration**.
2. In the **Notifications** tab in the **Email** section, select the toggle button at the top of the sections to enable email notifications.
    1. Configure the following SMTP server settings:
        1. **Server:** Provide the fully qualified DNS name of the SMTP server.
        2. **Encryption:** Specify whether you want the communications between RMT Server and the SMTP server encrypted. The option you choose will depend on the SMTP server configuration for encryption and your preference for using encrypted communications between RTM Server and the SMTP server.
            1. **Required:** Use this when your SMTP server is enabled to use encrypted communications and you want to make sure communications are always encrypted. When set to required, the connection will always be attempted using encryption. If the SMTP server is not enabled to use encryption, the RMT server will be unable to communicate with the SMTP server.

2. **Preferred:** Use this if you are not sure about the encryption settings of your SMTP server, but prefer that encrypted communications be used when possible. If the SMTP server is not enabled to use encryption, in this case, non-encrypted communication is used.

3. **Disabled:** Use this if your SMTP is not enabled to use encrypted communications. Communications between RMT Server and the SMTP server are not encrypted.

   > **Note:** If the SMTP server requires encryption, the connection will fail. If the SMTP server is enabled for encryption but does not require it, the connection will succeed.

4. **Options:** This determines how the SMTP server will be verified. You have the following options:

   1. Check Server identity: RMT will verify if the name of the certificate used matches the SMTP server name. If there is no match, the connection will fail.

   2. Trust all hosts: All certificate errors are ignored and overrides the Check Server identity. This should be used only if you are confident that the certificate that the RMT server using is from your server.

5. **TLS version:** The version of TLS that is supported by your SMTP server. There is a default version already selected, but you can select other versions. If multiple TLS versions are selected, the RMT server will use the most secure version compatible with RMT and the SMTP server. TLS version 1.3 requires Open SSL 1.1.1f. If you are planning to use TLS 1.3, make sure the machine where RMT Server is installed has Open SSL 1.1.1f.

6. **Certificate Thumbprint:** This is optional. The SHA1 certificate is used when provided and it must be valid and one that the SMTP server uses. A valid thumbprint will override other certificate errors like expiration dates and Server name mismatches.

7. **Port:** Port setting for the email server.

8. **Username:** Optional. The name of the account used to authenticate to the email server, if the SMTP server is configured with a username and password for authentication.

9. **Password:** Optional. The password for the account used to authenticate to the email server, if the SMTP server is configured with username and password for authentication.

10. **Minimum Severity:** The minimum severity level at which you want to receive email notifications. This will be applied to all environments unless modified at the environment level.

11. **Sender email:** The email address that is used to send the notifications. This will be applied to all environments unless modified at the environment level.

12. **Recipient email(s):** Email addresses of the people who should receive these notifications. This will be applied to all environments unless modified at the environment level.

13. **Test** it using the Send a Test Message button to ensure your settings are valid and can be used to successfully send an email notification.

**To customize the settings for an environment:**

1. From the **Admin** menu, select the environment that you want to modify and choose **Edit Environment**.

2. In the **Notifications** tab, choose **Custom** for configuration type to override the global settings.
3. Set the severity level, and sender and recipient email information.
4. Test it using the Send a Test Message button to make sure your settings are valid and you are able to send an email notification.

## Troubleshoot connection failures

Connection failures can happen due to various reasons, but here are some that could be caused due to configuration issues:

- **Encryption setting errors:** Happens if there is a mismatch of encryption settings between the RMT Server and the SMTP server. For example, if the RMT server is set to require encryption, but the SMTP server is not configured to use encryption. The reverse is also true. If the SMTP server requires encrypted communication and RMT Server is set to disable encryption, the connection will fail.
- **Certificate errors:** When using encrypted communications, things like certificate authority and match between certificate name and the SMTP server are considered unless you choose to explicitly **Trust all hosts** under **Options**.
- **TLS errors:** TLS version support is dependent on the Operating System (OS) on which the RMT Server is installed. Check to see if the version of TLS you selected is supported by the OS. TLS 1.2 is required, but TSL 1.3 is also supported. TLS 1.3 requires Open SSL 1.1.1f or greater. Make sure you have Open SSL 1.1.1f on the machine where RMT Server is installed.

Incident thresholds

Configure the global incident notification settings. These global thresholds apply to all environments by default unless overridden by the individual environments.

See Incidents for information on what incident options are available and how to configure them.

Security

Configure the security settings for Resource Monitoring Tool user accounts.

Data

By default, Resource Monitoring Tool stores two weeks of detailed activity data and ten years of aggregated reporting data.

**Data Retention:** Detailed activity data from your Tableau Server powers the dashboards and incidents for diagnosis of recent performance incidents. Due to the associated storage and processing requirements, this data is only stored for two weeks by default.

**Reporting Data:** Aggregated activity data from your Tableau Server is stored for reporting purposes (e.g., the Chargeback report). This data is compact and can easily be stored for many years of historical reporting.

Advanced

Allows configuration of the Resource Monitoring Tool diagnostic logging levels.

See the Log Files for more information about logging.

Who can do this

Resource Monitoring ToolAdministrator or a Resource Monitoring Tool user with **Server-/Environment Management** role.

RMT Server Configuration File

This topic describes the configuration options you can use using the configuration file. To do this using the web interface, see  Resource Monitoring Tool Server Configuration .

In an effort to align with our company values of Equality, we have changed non-inclusive terminology where possible. Because changing terms in certain places can causing a breaking change, we maintain the existing terminology. So, you may continue to see the terms in CLI commands and options, installation folders, configuration files. and other instances. For more information, see About Tableau Help.

The configuration file is located at `/var/opt/tableau/tabrmt/master/config.json`.

> **Note:** Configuration values are saved in the configuration file. Changes can be made directly to this file, but it is advised to leverage the configuration options in the UI and through the `rmtadmin` command line utility. Changes to the config file will require a restart to be applied.

You will need to restart the RMT Server after making changes to the configuration file.

Data Retention

By default the Resource Monitoring Tool stores two weeks of detail data and ten years of aggregated reporting data.

This is configurable. Here is an example snippet defining the data retention settings:

```
{
  "db":  {
    "cleanup":  {
      "afterDays":  14,
      "aggregate":  {
        "afterDays":  3650
      }
    }
  }
}
```

## SMTP Configuration

An example `config.json` snippet defining the SMTP information:

```
{
  "smtp":  {
    "server":  "localhost",
    "port":  25,
    "username":  "my-username",
```

```
    "password":  "my-password",
    "requireSSL":  true
  }
}
```

The full list of configuration values available in the `smtp` configuration section:

| Key | Data Type | Required? | Description |
|---|---|---|---|
| `server` | String | Optional | The SMTP server to use. Default value: `localhost` |
| `port` | Number | Optional | The SMTP server's port number. Default value: `25` |
| `username` | String | Optional | The username to use if authentication is required by the server. |
| `password` | String | Optional | The password to use if authentication is required by the server. |
| `requireSSL` | Boolean | Optional | `true` if your SMTP server requires SSL, otherwise `false`. Default value: `false` |

Notification Configuration

An example `config.json` snippet defining the notification information:

```
{
  "notifications":  {
    "email":  {
      "from":  "sender@domain.com",
      "to":  "recipient1@domain.com,recipient2@domain.com"
    }
```

```
    }
}
```

Global notification information (as shown above) can be overridden per environment in the `environments` section:

```
{
  "environments":  {
    "Environment1":  {
      "notifications":  {
        "email":  {
          "from":  "sender@domain.com",
          "to":  "recipient1@domain.com,recipient2@domain.com"
        }
      }
    }
  }
}
```

The full list of configuration values available in the `notifications.email` configuration section:

| Key | Data Type | Required? | Description |
|---|---|---|---|
| `from` | String | Required | The sender's email address. |
| `to` | String | Required | The recipient email address (es). Multiple addresses must be separated by commas or semi-colons. |
| `minimumIncidentSeverity` | String | Optional | The minimum incident severity at which emails |

| Key | Data Type | Required? | Description |
|---|---|---|---|
| | | | will be sent. Default value: `critical`. Also see Tableau Resource Monitoring Tool - Incidents. |

Histogram Configuration

The boundaries used to generate histograms in the web interface are configurable, using an array of values that represent each boundary.

The full list of configurable histograms in the `monitoring.histograms` section:

| Key | Data Type | Required? | Description |
|---|---|---|---|
| `viewLoadDuration` | Array of Numbers | Optional | The histogram boundaries for view loads. Values are in milliseconds. Default value: `[1000, 3000, 6000, 10000]` |
| `externalDataRequestDuration` | Array of Numbers | Optional | The histogram boundaries for external data requests. Values are in milliseconds. Default value: `[1000,` |

| Key | Data Type | Required? | Description |
|---|---|---|---|
| | | | `3000, 6000, 10000]` |
| `backgroundTaskDuration` | Array of Numbers | Optional | The histogram boundaries for background tasks. Values are in milliseconds. Default value: `[60000, 300000, 600000, 1800000]` |

As an example, to use the following histogram buckets for everything at a global level:

- ≤ 1 second
- > 1 second and ≤ 10 seconds
- > 10 seconds and ≤ 30 seconds
- > 30 seconds

The configuration would look like:

```
{
  "monitoring":  {
    "histograms":  {
      "viewLoadDuration":  [1000,  10000,  30000],
      "externalDataRequestDuration":  [1000,  10000,  30000],
      "backgroundTaskDuration":    [1000,  10000,  30000]
    }
  }
}
```

Histogram boundaries can also be set per environment. As an example, for an environment whose identifier is “staging-environment” to use the following view histogram buckets:

- ≤ 2.5 seconds
- > 2.5 seconds and ≤ 5 seconds
- > 5 seconds and ≤ 30 seconds
- > 30 seconds and ≤ 1 minute
- > 1 minute and ≤ 10 minutes
- > 10 minutes

The configuration would look like:

```
{
  "environments":  {
    "staging-environment":  {
      "monitoring":  {
        "histograms":  {
          "viewLoadDuration":  [2500,  5000,  30000,  60000,
600000]
        }
      }
    }
  }
}
```

The “staging-environment” would fall back to the global histogram configuration for background tasks.

Minimum TLS Version

By default, RMT will use a secure version of TLS to encrypt traffic. The default minimum version is 1.2, but if you have specific security requirements that mandate that older versions of TLS be disabled, you can modify the `server.minimumTlsVersion` section of the configuration file to enforce a minimum TLS version, as shown in the example snippet below where the minimum version is set to 1.3. The list of valid values for `minimumTlsVersion` are defined in SslProtocols from .Net Core.

```
"server":  {
  "url":  "https://rmtserver:443",
  "https":  {
    "enforce":  true,
```

```
    "certificate":  {
      "mode":  Default,
      "local":  {
        "name":  null,
        "password":  null
       },
      "store":  {
        "certificateThumbprint":  ""}
     },
     "minimumTlsVersion":  "Tls13"
   },
```

## Incident Configuration

See Incidents for information on what incident options are available and how to configure them.

## RMT ServerLogging

See Tableau Resource Monitoring Tool Log Files.

Agent

The agent service's configuration file is located at `/var/-opt/tableau/tabrmt/master/config.json`

You will need to restart the agent service after making changes to the config file.

## Tableau Server Detection

In almost all situations agents will automatically detect the Tableau Server installation and no configuration is needed beyond the standard agent setup process. If desired, you can however manually configure the Tableau Server information through the `config.json` file.

An example `config.json` snippet defining the Tableau Server information needed to run the agent:

```
{
  "agent":  {
    "tableauServer":  {
      "override":  true,
      "productVersion":  2021.4,
      "applicationDirectory":  "/var/opt/tableau/tableau_
server/2021.4"
    }
  }
}
```

The full list of configuration values available in the `agent.tableauServer` configuration section:

| Key | Data Type | Required? | Description |
|---|---|---|---|
| `applicationDirectory` | String | Required | The Tableau Server application root directory. |
| `dataDirectory` | String | Optional | The directory to get Tableau Server data files. |
| `override` | Boolean | Optional | `true` to have the configuration values take precedent over any automatically detected values. `false` to have the configuration values act as a fallback to the automatically detected values. |
| `productVersion` | Number | Required | The version num- |

| Key | Data Type | Required? | Description |
|---|---|---|---|
| | | | ber of the Tableau Server. |

## Agent Logging

See Tableau Resource Monitoring Tool Log Files.

Common

Common configuration values are available in both RMT Server and Agent applications. See application-specific sections for guidance on locating the configuration file.

You will need to restart the application service after making changes to the config file.

Encrypted Messaging

To enable encrypted messaging, the RabbitMQ server must be first configured to allow TLS. See the Encrypted Data Collection administrator guide for more details.

When configuring the RMT Server or Agent(s) for encrypted messaging:

- Both the `enabled` flag and the `certificateHostName` must be configured for encryption to be enabled.
- The `certificateHostName` variable MUST match the canonical name (CN=) on the server certificate or the connection will fail.
- The `port` setting in the `mq` section will likely need to be changed based on the TLS port you configured RabbitMQ.

```
{
  "mq":  {
    "port":  5671,
    "tls":  {
      "enabled":  true,
      "certificateHostName":  "foo"
    }
  }
}
```

The full list of configuration values available in the `mq.tls` configuration section:

| Key | Data Type | Required? | Description |
|---|---|---|---|
| `enabled` | Boolean | Optional | `true` enables TLS encryption for messaging connections. `false` uses unencrypted connections for messaging. Default value: `false` |
| `certificateHostName` | String | Optional | `certificateHostName` MUST match the canonical name (CN=) of the server certificate or the connection will fail. Default value: `""` |

Who can do this

Resource Monitoring Tool Administrator or a Resource Monitoring Tool user with **Server-/Environment Management** role.

rmtadmin Command Line Utility

Resource Monitoring Tool includes a command line interface, `rmtadmin.cmd`, located in the installation folder. The default installation folder is:

- RMT Server `/var/opt/tableau/tabrmt/master/`.
- Agent: `/var/opt/tableau/tabrmt/agent/`.

  `rmtadmin` is included in both the **RMT Server** and **Agent** installations. Some commands may vary based on whether you are using the RMT Server or Agent `rmtadmin` command line utility. E.g., the `users` command only works from the *RMT Server*. The `ziplogs` command is available everywhere but only includes the log files from the application the command is run on.

**Note:** You must run these commands as the `tabrmt-master` user:

```
sudo su --login tabrmt-master
```

Here are the commands that can be used with the `rmtadmin` command line:

**Note:** The `rmtadmin` commands use both positional parameters and options.
The positional parameters should be specified using only the values. You don't need to specify the actual keyword. The option keyword and the value should be specified using an equal sign.
Example:

```
rmtadmin <command> <positional parameter value> --<option keyword>=<value>
```

- rmtadmin add-user
- rmtadmin agents
- rmtadmin bootstrap-file
- rmtadmin cleanup
- rmtadmin create-admin-user
- rmtadmin create-env
- rmtadmin delete-env
- rmtadmin data-access
- rmtadmin delete-env-data
- rmtadmin delete-server
- rmtadmin delete-server-data
- rmtadmin delete-user
- rmtadmin deregister-agent
- rmtadmin environments
- rmtadmin get
- rmtadmin get-user
- rmtadmin help
- rmtadmin master-setup
- rmtadmin passwd
- rmtadmin query

- rmtadmin register
- rmtadmin restart
- rmtadmin rotate-mq-certificate
- rmtadmin rotate-mq-certificates
- rmtadmin servers
- rmtadmin set
- rmtadmin start
- rmtadmin stop
- rmtadmin status
- rmtadmin test-env
- rmtadmin update-baseline
- rmtadmin update-env
- rmtadmin users
- rmtadmin version
- rmtadmin ziplogs

*In an effort to align with our company values of Equality, we have changed non-inclusive terminology where possible. Because changing terms in certain places can cause a breaking change, we maintain the existing terminology. So, you may continue to see the terms in CLI commands and options, installation folders, configuration files, and other instances. For more information, see About Tableau Help.*

rmtadmin add-user

**Note:** Added in version 2024.2.

Creates a user account with the given user name if one does not exist.

**This command only works on the RMT Server.**

## Synopsis

```
rmtadmin add-user [options][global option]
```

## Options

`--username`

The username for the new user account to be added.

`--auth-mode`

The Authentication mode for the new user account. The value can be `Local` or `Delegated`.

`--password`

The password for the user account. Only required if the auth-mode is `Local`.

`--password-file`

The path to the file containing the password for the user account. You can use this if you do not want to type in the password directly and have the password stored in a file that can be accessed. Only required if the auth-mode is Local.

Roles

`--download-log-bundles`

Optional. Grants the user the privilege to download log bundles.

`--download-tds-files`

Optional. Grants the user the privilege to download TDS files.

`--generate-chargeback-report`

Optional. Grants the user the privilege to generate chargeback report.

`--environment-management`

Optional. Grants the user the privilege to manage environment.

`--user-management`

Optional. Grants the user the privilege to manage users.

`--webhook-management`

Optional. Grants the user the privilege to manage webhook.

**Example:**

```
rmtadmin add-user --username=<username> --password=<password> --
auth-mode=<Local|Delegated> --download-log-bundles=[T|F] --down-
load-tds-files=[T|F] --generate-chargeback-report=[T|F] --envir-
onment-management=[T|F] --user-management=[T|F] --webhook-
management=[T|F]
```

**Note:** Local Authentication mode is disabled if the DisableLocalAuthentication configuration key is set to true.

rmtadmin agents

**Note:** Added in version 2021.2

Lists all the registered Agents on Tableau Server nodes for all environments.

This is useful to see where the Resource Monitoring Tool Agent is installed on Tableau Server.

**This command only works on the RMT Server.**

## Synopsis

```
rmtadmin agents [options][global option]
```

## Options

`--env`

Optional: Use this option to see the list of Agents for the specific environment. This is the system generated identifier. You can find this by going to **Admin** > **Environments** > **Edit Environment**. On this page, in the **Environment Details** section, you will see the identifier for the environment.

`--keys`

Optional: includes the agent key in the output.

**Example:** `rmtadmin agents --env=<myenvironmentidentifier> --keys`

rmtadmin bootstrap-file

**Note:** Added in version 2021.2

Creates and saves the bootstrap file used to register Agents on Tableau Server nodes.

Bootstrap file will be created and saved to the specified absolute path or relative path. Relative paths are resolved to the current working directory.

**This command only works on the RMT Server.**

## Synopsis

```
rmtadmin bootstrap-file [options][global option]
```

## Options

`--env`

Required. This is the system generated identifier. You can find this by going to **Admin > Environments > Edit Environment**. On this page, in the **Environment Details** section, you will see the identifier for the environment.
The Agent on a Tableau Server node can only registered to one environment at a time.

`--filename`

Optional. The absolute or relative path including the file name. The relative paths are resolved to the current working directory. If not specified, the default output filename is used.

`--force`

Optional. Overwrites the existing file with the same name.

**Example:** `rmtadmin bootstrap-file --env=<myenvironmentidentifier>`

rmtadmin cleanup

**Note:** Added in version 2021.2

Deletes the log files that are older than a certain number of days. By default it deletes log files older than 31 days.

**This command on both RMT Server and Agent.**

**Note:** If the Resource Monitoring Tool processes are running, the active log files will not be cleaned up by the command. If you want to be sure that all files are deleted, you will need to stop RMT using the rmtadmin_stop command and then run cleanup using the fol-

lowing command, `rmtadmin cleanup --log-files-retention=0`, and then restart the processes using the rmtadmin_start command.

## Synopsis

```
rmtadmin cleanup [option][global option]
```

## Option

`--log-files-retention`

Optional. Deletes the log files older than the specified number of days.

**Example:**`rmtadmin cleanup --log-files-retention=<number of days>`

rmtadmin create-admin-user

**Version:** Added in version 2022.1

Creates an initial admin user if no other users exist.

**Note:** Beginning in version 2023.1 you can create multiple admin users.

**This command on only RMT Server.**

## Synopsis

```
rmtadmin create-admin-user [options][global option]
```

## Options

`--username`

Optional. The username for the admin user account. Defaults to "admin" if not specified.

`--password`

Required. The password for the admin user account.

`--password-file`

Optional. The path to the file containing the password for the admin user account. You can use this if you do not want to type in the password directly and have the password stored in a file that can be accessed.

**Example:**`rmtadmin create-admin-user --username<admin user name> --password <password for the admin user account>`

rmtadmin create-env

**Note:** Added in version 2021.2

Creates a new environment.

**This command only works on the RMT Server.**

## Synopsis

```
rmtadmin create-env [options][global option]
```

## Options

| Option | Required? | Default | Description |
|---|---|---|---|
| --name | Yes | n/a | The name of the environment. |
| --gateway-url | Yes | n/a | URL used to access the Tableau Server gateway. |
| --version | Yes | n/a | Tableau Server version that this environment will be monitoring. |

| Option | Required? | Default | Description |
|---|---|---|---|
| --non-inter-active | No | Interactive prompts are enabled by default. | Disables all interactive prompts. |
| --no-test | No | API and Repository connection testing is enabled by default. | Disables testing API and repository connections. |
| --api-username | No | Null | User name of the account used to connect to Tableau Server APIs. The user account should be a Tableau Server administrator with access to all Tableau Server sites. |
| --api-password | No<br><br>(If you specify the Tableau API user name, you will either provide the password, or specify the file path and file that has the password) | Null | Password of the Tableau Server API user account used to connect to Tableau Server APIs. |
| --api-password-file | No | Null | The path to the file and the name of the file containing the password of the Tableau Server API user account. |

| Option | Required? | Default | Description |
|---|---|---|---|
| --repository-server | Yes | Null | This is the server name for the PostgreSQL database that in installed with Tableau Server. |
| --repository-database | Yes | Null | This is the name of the PostgreSQL database that is installed with Tableau Server. |
| --repository-port | Yes | Null | The port number of the Tableau Server Repository database. |
| --repository-username | Yes | Null | Username used to connect to PostgreSQL database installed with the Tableau Server Repository.<br><br>Resource Monitoring Tool accesses the Tableau Server Repository database directly for performance reasons. For this to work, access to the repository must be enabled, with a password set for the **readonly** database user. For details, see Enable access to the Tableau Server repository. |
| --repository-password | Yes | Null | Password for the user account used to connect to the PostgreSQL database that is installed with the Tableau Server .<br><br>Resource Monitoring Tool accesses the Tableau Server Repository database directly for performance reas- |

| Option | Required? | Default | Description |
|---|---|---|---|
| | | | ons. For this to work, access to the repository must be enabled, with a password set for the **readonly** database user. For details, see Enable access to the Tableau Server repository. |
| --repository-password-file | No, but required if you are not providing the password in command prompt or in a script directly. | Null | The path including the file name where the password for the user account used to connect to the PostgreSQL database that is installed with Tableau Server. |
| --repository-ssl-mode | No | Prefer | Tableau Server Repository SSL Mode:<br><br>**Prefer** SSL or **Require** SSL to configure SSL connections to Tableau Repository.<br><br>**Disable** to never use SSL to make Tableau Server Repository connections. |
| --repository-ssl-thumbprint | No | Null | When configuring Tableau Server PostgreSQL to allow direct connections, Tableau Server creates a certificate and keys. You can choose to either supply the thumbprint for the certificate that was generated by Tableau Server, or |

| Option | Required? | Default | Description |
|---|---|---|---|
| | | | copy the **server.crt** file to the Resource Monitoring Tool Server machine. If you choose to copy the certificate file, you don't have to supply the thumbprint. For more information, see Configure Postgres SSL to Allow Direct Connections from Clients. |

**Example:**`rmtadmin create-env --name=<myenvironment> --api-user-name=<TableauServer API user name> --api-password=<password for the Tableau Server API user account> --gateway-url <Tableau Server Gateway URL> --version <Tableau Server version>`

rmtadmin data-access

**Note:** Added in version 2022.3

Enables or disables access to PostgreSQL database. Note: Access to PostgreSQL database is required starting in version 2022.3 for Resource Monitoring Toolto successfully gather all monitoring data from Tableau Server.

**This command only works on the RMT Server**

**Note:** The PostgreSQL database must be restarted for this configuration to take effect.

## Synopsis

```
rmtadmin data-access [positional parameter][options] [global option]
```

## Positional Parameter

`mode`

Required. The mode that should be used for remote data access to PostgreSQL database. The values should be one of: *None*, *ReadOnly*, *Admin*. When set to *None*, the data access is disabled. ReadOnly, and Admin specify which user account to use to access the database..

## Options

`--`

**Example:**

```
rmtadmin data-access ReadOnly
```

```
rmtadmin restart --db
```

rmtadmin delete-env

**Note:** Added in version 2021.2

Deletes a specific environment and all data that has been collected for that environment. It also removes the connection and topology information about the Tableau Server that the environment is monitoring and deregisters all the Resource Monitoring Tool Agents.

**This command only works on the RMT Server.**

## Synopsis

```
rmtadmin delete-env [positional parameter][options] [global option]
```

## Positional Parameter

`env`

Required. This is the system generated identifier. This is the system generated identifier. You can find this by going to **Admin** > **Environments > Edit Environment**. On this page, in the **Environment Details** section, you will see the identifier for the environment.

## Options

`--confirm`

Optional. Confirm that you want to delete the environment. If you do not provide this option, you will be prompted to confirm.

`--skip-agent-disconnect`

Optional. Skips disconnecting the Agent and continues with deregistering the Agent. Use this option if you think the Agent is inaccessible - For example, if the Tableau Server node has been removed or if the Agent has been uninstalled on that node.

**Example:**`rmtadmin delete-env <myenvironmentidentifier>`

rmtadmin delete-env-data

Permanently deletes all Tableau Server related data collected for a specific environment. Environment configuration, Tableau Server information, and Agent registration will not be removed.

This is useful for clearing all the existing data in an environment without removing the environment itself. After deleting the existing data, new data sent by the Agents will continue to be processed.

**This command only works on the RMT Server.**

## Synopsis

```
rmtadmin delete-env-data [positional parameter][option][global
option]
```

## Positional Parameter

`env`

The identifier of the environment for which the data should be deleted. This is the system generated identifier. You can find this by going to **Admin** > **Environments > Edit Environment**. On this page, in the **Environment Details** section, you will see the identifier for the environment.

## Option

`--confirm`

Optional. Confirm that you want to delete the environment data. If you do not provide this option, you will be prompted to confirm.

**Example:** `rmtadmin delete-env-data <myenvironmentidentifier>`

rmtadmin delete-server

**Note:** Added in version 2021.2

Deletes the configuration information of the Tableau Server node from the environment, deregisters the Agent on that node, and deletes all monitoring data collected specific to that node.

**This command only works on the RMT Server.**

## Synopsis

```
rmtadmin delete-server [options][global option]
```

## Options

`--env`

Required. The identifier of the environment that the Tableau Server node is connected to. This is the system generated identifier. You can find this by going to **Admin** > **Environments > Edit Environment**. On this page, in the **Environment Details** section, you will see the identifier for the environment.

`--hostname`

Required to delete information about on or more connected to the environment and if **--all** is not specified.

This is the machine name of the Tableau Server node. Use commas to separate multiple values if specifying more than one host name.

`--all`

Optional, but required if **--hostname** is not specified.

Deletes the information for all the Tableau Server nodes connected to the environment.

`--skip-agent-disconnect`

Optional. Skips disconnecting the Agent and continues with deregistering the Agent. Use this option if the Agent is inaccessible- For example, if the node has been removed from Tableau Server or if the Agent has been uninstalled on that node.

`--confirm`

Confirm that you want to delete all the information about the Tableau Server node. If you do not provide this option, you will be prompted to confirm.

**Example:**`rmtadmin delete-server --hostname=<machine name of the Tableau Server node>`

rmtadmin delete-server-data

**Note:** Added in version 2021.2

Deletes the data collected from one or more Tableau Server nodes. Data removed only pertains to the nodes that are specified. If you specify *all*, then all the data collected from all the nodes will be deleted. Environment configuration, Tableau Server information, and Agent registrations will not be deleted.

**This command only works on the RMT Server.**

## Synopsis

```
rmtadmin delete-server-data [options][global option]
```

## Options

`--env`

Required. The identifier of the environment that the Tableau Server node is connected to. This is the system generated identifier. You can find this by going to **Admin** > **Environments > Edit Environment**. On this page, in the **Environment Details** section, you will see the identifier for the environment.

`--hostname`

Required to delete information about on or more connected to the environment and if **--all** is not specified.

This is the machine name of the Tableau Server node. Use commas to separate multiple values if specifying more than one host name.

`--all`

Optional, but required if **--hostname** is not specified.

Deletes the monitoring data for all the Tableau Server nodes connected to the environment.

`--confirm`

Confirm that you want to delete all the monitoring data from the Tableau Server nodes. If you do not provide this option, you will be prompted to confirm.

**Example:** `rmtadmin delete-server-data --all`

rmtadmin delete-user

**Note:** Added in version 2024.2.

Deletes the user account with the given username if one exists.

**This command only works on the RMT Server.**

## Synopsis

```
rmtadmin delete-user [options][global option]
```

## Options

`--username`

The username for the user account to be deleted

**Example:**

```
rmtadmin delete-user --username=<username>
```

rmtadmin deregister

**Note:** Added in version 2021.2

Deregisters the Agent from the environment. Monitoring data from this node will no longer be collected. Existing data will remain and not be deleted.

**This command only works when run on the RMT Agent. Run this on the Agent you want to deregister.**

## Synopsis

```
rmtadmin deregister [options]
```

## Options

`--confirm`

Optional. Confirm that you want to deregister the Agent. This bypasses the confirmation prompt.

`--ignore-master-errors`

Optional. Ignores any errors that occur while communicating with the RTM Server during this process.

**Example:** `rmtadmin deregister --confirm`

rmtadmin deregister-agent

**Note:** Added in version 2021.2

Deregisters the specified Agent from the environment. Monitoring data from this node will no longer be collected. Existing data will remain and not be deleted.

**This command only works when run on the RMT Server.**

## Synopsis

```
rmtadmin deregister-agent [options][global option]
```

## Options

`--env`

Required if **--key** is not specified.

This is identifier of the environment where the Agent is currently registered. This is the system generated identifier. This is the system generated identifier. You can find this by going to **Admin** > **Environments > Edit Environment**. On this page, in the **Environment Details** section, you will see the identifier for the environment.

`--key`

Optional if **--env** is specified.

This is the Agent key. Use commas to separate multiple values. You can get the key values by running the rmtadmin agents command.

`--hostname`

Optional. Machine name of the Tableau Server node where the Agent is installed. Use commas to separate multiple values.

`--all`

Optional. Use this option to deregister Agents on all the nodes.

`--ignore-agent-errors`

Optional. Ignores any errors that occur if unable to connect with the Agents during this process.

`--skip-agent-disconnect`

Optional. Skips disconnecting the Agent and continues with jderegistering the Agent. Use this option if you think the Agent is inaccessible - For example, if the node has been removed from Tableau Server or if the Agent has been uninstalled on that node.

`--confirm`

Optional. Confirm that you want to deregister the Agents. If you do not provide this option, you will be prompted to confirm.

**Example:** `rmtadmin deregister-agent --env=<myenvironmentidentifier> --all`

rmtadmin environments

**Note:** Added in version 2021.2

Lists all the environments on the Resource Monitoring Tool Server.

**This command only works on the RMT Server.**

## Synopsis

```
rmtadmin environments [global option]
```

rmtadmin get

Gets the value of a specified configuration key.

**This command can be used both on the RMT Server and Agent.**

## Synopsis

```
rmtadmin get <config.key> [global option]
```

## Positional Parameter

`key`

Name of the configuration key.

**Example:** `rmtadmin get db:database`

## Supported configuration keys

| Key | Data Type | Applies To | DEFAULT | Description |
|---|---|---|---|---|
| `auth:disableLocalAuthentication` | Boolean | RMT Server | FALSE | If TRUE, creating user with authentication mode as local is not permitted. Added in version 2024.2 |
| `auth:disableUserManagementUI` | Boolean | RMT Server | FALSE | If set to TRUE, user management from UI is not permitted. Added in version 2024.2 |

| Key | Data Type | Applies To | DEFAULT | Description |
|---|---|---|---|---|
| db:database | String | RMT Server | tabrmtdb | Name of the PostgreSQL database that RMT uses. |
| db:readOnlyUsername | String | RMT Server | readonly | Username of a PostgreSQL user account which has only read-only access to the RMT data. |
| db:readOnlyPassword | String | RMT Server | Generated by the installer program. | Password of the PostgreSQL read-only user. |
| monitoring:antiDomainLockoutEnabled | Boolean | RMT Server | TRUE | When set to TRUE (the default), the anti domain lockout feature is enabled. Added in version 2025.1.1. |

| Key | Data Type | Applies To | DEFAULT | Description |
|---|---|---|---|---|
| | | | | This feature allows you to configure RMT to stop attempting to sign in before the domain is locked. |
| `monitoring:antiDomainLockoutTimeSeconds` | Integer | RMT Server | 600 | The time duration for which all the attempts to Tableau server will be throttled before attempting the connection again. Added in version 2025.1.1. |
| `monitoring:antiDomainMaxFailedLoginAttempts` | Integer | RMT Server | 3 | The threshold of consecutive unsuccessful login attempts to |

| Key | Data Type | Applies To | DEFAULT | Description |
|---|---|---|---|---|
| | | | | Tableau Server for anti domain lockout to be activated. Added in version 2025.1.1. |
| `mq:tls:certificateHostName` | String | RMT Server and Agent | n/a | Host name in the certificate to use when connecting to RabbitMQ via TLS. |
| `mq:tls:enabled` | Boolean | RMT Server and Agent | FALSE | Enable/disable TLS connection to RabbitMQ. |
| `mq:port` | Integer | RMT Server and Agent | 5672 | RabbitMQ host port number. |
| `mq:virtualHost` | String | RMT Server and Agent | tabrmt | Connection to the RMT Server or Agent. For Agent, you |

| Key | Data Type | Applies To | DEFAULT | Description |
|---|---|---|---|---|
| | | | | can modify this setting by registering the Agent with a bootstrap file. For the RMT Server, the value is managed by the installer. |
| `server.web.run` | Boolean | Agent | TRUE | Enable or disable the Agent's web interface. |

Use the set command to change the current configuration value.

rmtadmin get-user

**Note:** Added in version 2024.2.

Lists the user account details for the given username if the user account exists. Details include username, authentication mode, and role privileges.

**This command only works on the RMT Server.**

## Synopsis

```
rmtadmin get-user [options][global option]
```

## Options

`--username`

The username for the user account.

**Example:**

```
rmtadmin get-user --username=<username>
```

rmtadmin help

Shows general help about the command line interface and the available commands.

**This command can be used both on the RMT Server and Agent.**

## Synopsis

```
rmtadmin help
```

Show help and usage information for a specific command:

**This command can be used both on the RMT Server and Agent.**

```
 rmtadmin help [command]
```

rmtadmin master-setup

Configures the RMT Server with specified options. Used both during install and post installation configurations.

## Synopsis

```
rmtadmin master-setup [options][global option]
```

The configuration options are listed below:

| Option | Required? | Default | Description |
|---|---|---|---|
| --admin-password | Yes (Required for initial installation only)<br><br>Password can be supplied in the command line or provide a file with the password to use. If neither is provided, you will be prompted for the password. | n/a | The password for the administrator user. |
| --admin-password-file | Yes (Required for initial installation only)<br><br>Password can be supplied in the command line or provide a file with the password to use. If neither is provided, you will be prompted for the password. | n/a | The password for the administrator user. |
| --admin-username | No | admin | The username for the administrator user. |
| --skip-admin-creation<br><br>**Added:** version 2020.4.0<br><br>**Retired:** version | No<br><br>This option must be and only used when you making configuration updates | False | Skip creating the administrator user and password. |

| Option | Required? | Default | Description |
|---|---|---|---|
| 2022.3.0 | post installation.<br><br>In versions where this option is valid (2020.4.0 - 2022.2.x), if not used during post installation configuration updates, the command will fail and no updates will be made.<br><br>In versions 2022.3.0 and later, the command will create the admin where necessary. | | |
| --http-port | No | 80 | |
| --require-https | No | False | Redirect http traffic to HTTPS. |
| --https-certificate-mode | No | 'Default'<br><br>Available options:<br><br>• Default<br>• Store (Windows only)<br>• Local | The type of certificate search to perform for the HTTPS certificate.<br><br>**Default:** This mode uses the default self-signed certificate supplied by the installer. |

| Option | Required? | Default | Description |
|---|---|---|---|
| | | | **Store:** This allows you to enter the thumbprint of a certificate in the Windows certificate store.<br><br>**Local:** Allows you to specify a file-based certificate in the **config** folder. |
| --https-certificate-store-thumbprint | No | Null | The HTTPS certificate hash/thumbprint to search for in 'store' certificate mode. |
| --https-certificate-local-name | No | Null<br><br>Note: If not specified, the Resource Monitoring Tool is installed with a self-signed certificate and will use that certificate for HTTPS communications. | The name of the HTTPS certificate file. |
| --https-certificate-local-password | No | Null | The password to use for the HTTPS certificate. |
| --https-certificate- | No | Null | The path to the file con- |

| Option | Required? | Default | Description |
|---|---|---|---|
| local-password-file | | | taining the password to use for the HTTPS certificate. |
| --confirm | No | Prompt for confirmation. | Confirms the restart of the RMT Server. |
| --host | No<br><br>**Note**: We don't recommended changing this value. | Current configuration value or machine name. | The preferred URL for accessing the Resource Monitoring Tool server. The server will listen to all the IPs regardless of the host name. |
| --db-config=external | No | None.<br>This is only used when the repository is configured external to RMT Server. | Use this to configure RMT Server to use an external repository.<br>You do not need to specify this if you want the PostgreSQL database to be installed locally. |
| --db-server | No | Current configuration value or installer default. | This is the server name for the PostgreSQL database that in installed with the Resource Monitoring Tool.<br><br>If you are using an external repository hosted on AWS RDS, this should be the RDS |

| Option | Required? | Default | Description |
|---|---|---|---|
| | | | instance name. |
| --db-ssl-mode<br><br>Version: Added in version 2023.1.0 | No | `Prefer` | This determines the SSL/TLS encryption for the connection to the PostgreSQL database that in installed with the Resource Monitoring Tool.<br><br>Options are `Prefer` (the default), `VerifyCA`, and `VerifyFull`. For details, see the Npgsql documentation. |
| --db-port | No | Current configuration value or installer default. | Port number for the database server. |
| --db-username | No | Current configuration value or installer default. | Username used to connect to PostgreSQL database installed with the Resource Monitoring Tool.<br><br>If you are using an external repository hosted on AWS RDS, this should be "postgres". |
| --db-password | No | Current con- | Password for the user |

| Option | Required? | Default | Description |
|---|---|---|---|
| | | figuration value or installer default. | account used to connect to the PostgreSQL database that is installed with the Resource Monitoring Tool.<br><br>If you are using an external repository hosted on AWS RDS, this is the user password you created when creating the RDS instance. |
| --mq-config=external | No | None<br>This option in only specified when the messaging service is hosted external to RMT Server. | This options configures RMT Server to use an external Rabbit MQ messaging service. |
| --mq-server | No | Current configuration value or installer default. | The name of the message queue server. |
| --mq-port | No | Current configuration value or installer default. | The message queue port. |
| --mq-vhost | No | Current configuration value or installer default. | The message queue virtual host. |
| --mq-username | No | Current configuration value or | The user name used to connect to the mes- |

| Option | Required? | Default | Description |
|---|---|---|---|
| | | installer default. | sage queue. |
| --mq-password | No | Current configuration value or installer default. | The password for the user account used connect to the message queue. |
| --mq-enable-tls | No | Current configuration value or **false**. | Requires TLS connection to connect to the message queue. |
| --mq-tls-certificate-host | No | Current configuration value or **null**. | The canonical name of the message queue server. This must match the name on the certificate. |
| --password-salt | No | Random | A global salt to use to hash the password.<br><br>This applies to the local user accounts created in the Resource Monitoring Tool. |
| --password-min-length | No | Current configuration value or **10**. | The minimum length for the password.<br><br>This applies to the local user accounts created in the Resource Monitoring Tool. |
| --password-min-numeric | No | Current configuration value or **1**. | The minimum required numeric characters in |

| Option | Required? | Default | Description |
|---|---|---|---|
| | | | the password.<br><br>This applies to the local user accounts created in the Resource Monitoring Tool. |
| --password-min-special | No | Current configuration value or **1**. | The minimum required special characters in the password.<br><br>This applies to the local user accounts created in the Resource Monitoring Tool. |
| --password-min-latin | No | Current configuration value or **5**. | The minimum required latin characters in the password.<br><br>This applies to the local user accounts created in the Resource Monitoring Tool. |
| --password-require-mixed-case | No | Current configuration value or **true**. | Requires mixed case characters in passwords.<br><br>This applies to the local user accounts created in the Resource Monitoring Tool. |

| Option | Required? | Default | Description |
|---|---|---|---|
| --auth-timeout-minutes | No | Current configuration value or **240**. | The number of minutes before the user authentication expires for the session. |
| --auth-sliding-expiration | No | Current configuration or **true**. | Whether or not to reset the authentication timeout period with user activity. |

**Examples:**

**To specify the admin password:** `rmtadmin master-setup --admin-password=<password> --skip-admin-creation`

**To update the port post install:** `rmtadmin master-setup --http-port=8000 --skip-admin-creation`

rmtadmin passwd

Resets the password for a specific Resource Monitoring Tool user account.

**This command works only on the RMT Server.**

## Synopsis

```
rmtadmin passwd [positional parameter][global option]
```

## Positional Parameter

`username`

Name of the user that you want to change the password for.

**Example:** `rmtadmin passwd <username>`

rmtadmin query

Executes a raw SQL query against the Resource Monitoring Tool database and saves the results to an output file.

**This command works only on the RMT Server.**

## Synopsis

```
rmtadmin query [positional parameter][options] [global option]
```

## Positional Parameter

`sql`

SQL command text to run. You can provide multiple SQL commands. To use a file with the SQL commands, use **@** as a prefix to the name of the file.

## Options

`--outfile=VALUE`

Name of the zip file you want to output the query results. Default is *queryresults.zip*

`--force`

Overwrites the existing file.

`--timeout=VALUE`

timeout for the query. Specify this in seconds

`--commit`

Commits any changes made by the SQL command to the database. By default, the SQL command is run as a transaction, but is rolled back at completion.

**Example:** `rmtadmin query <SQLCommand> --outfile=<path and the output file name>`

rmtadmin register

**Note:** Added in version 2020.2

Registers the Agent using a bootstrap file. The bootstrap file can be downloaded using the rmtadmin bootstrap-file command.

**This command is can only be used on the Agent and should be run on the machine where you want to install the Agent.**

## Synopsis

```
rmtadmin register [options][positional parameter] [global option]
```

## Positional Parameter

`bootstrap`

The file path including the name of the bootstrap file.

## Options

`--username`

Required. Name of the admin user created during the RMT Server installation.

`--password`

Required. Password for the user account.

`--password-file`

Path including the file name that contains the password information. Password can be supplied in the command line or a file that contains the password. If neither is provided, you will be prompted for the password.

`--server-name`

Name of the node where Agent is being installed. It defaults to the machine name if no name is specified.

`--server-description`

Custom description for the Server.

**Example:** `rmtadmin register <bootstrap file name and path> --server-name=<server name>`

rmtadmin restart

Restarts the Resource Monitoring Tool applications. When run from the machine where RMT Server is installed, it restarts the RMT Server application. When run on a node where the Agent is installed, it restarts just the Agent application on that particular node.

**This command can be run from both the RMT Server and Agent.**

## Synopsis

```
rmtadmin restart [options] [global option]
```

## Options

If no option is specified, the command acts as though `-all` is used:

**RMT Server:**

`--all`

Restarts all services.

`--master`

Restarts the RMT Server.

`--mq`

Restarts the message queue service.

`--db`

Restarts the database service.

**Agent:**

`--agent`

Restarts the Agent service running on the machine.

**Example:** `rmtadmin restart --db`

rmtadmin rotate-mq-certificate

Rotates the Agent message queue client certificate on the agent machine. Run this command after running `rmtadmin rotate-mq-certificate` on the Server machine.

**This command must be run from the RMT Agent.**

## Synopsis

```
rmtadmin rotate-mq-certificate [options] [positional parameter]
```

## Positional Parameter

`bootstrap`

The file path including the name of the bootstrap file.

## Options

`--username`

Required. The username for the master server.

`--password`

Required. Password for the master server user account.

`--password-file`

Path including the file name that contains the master server password information. Password can be supplied in the command line or a file that contains the password. If neither is provided, you will be prompted for the password.

`--confirm-restart`

Confirms service restart and bypasses confirmation prompt.

rmtadmin rotate-mq-certificates

Rotates message queue server and client certificates on the Server machine.

**This command must be run from the RMT Server.**

## Synopsis

```
rmtadmin rotate-mq-certificates [options]
```

## Options

`--confirm-restart`

Confirms service restart and bypasses confirmation prompt.

rmtadmin servers

**Note:** Added in version 2021.2

Lists all the Tableau Server nodes across all environments or a specific environment.

**This command only works on the RMT Server.**

## Synopsis

```
rmtadmin servers [positional parameter][global option]
```

## Positional Parameter

`env`

Optional. Specify the identifier of the environment to get a list of Tableau Server nodes registered in that environment. This is the system generated identifier. You can find this by going to **Admin** > **Environments > Edit Environment**. On this page, in the **Environment Details** section, you will see the identifier for the environment.

rmtadmin set

Sets the value of a specified configuration key.

**This command works both on the RMT Server and Agent.**

## Synopsis

```
rmtadmin set [positional parameter] [global option]
```

## Positional Parameters

`key`

The configuration key you want to change the value for.

`value`

The new value you want to use.

**Example:** `rmtadmin set mq:port <port number>` where `mq:port` is the key and the `<port number>` is the value.

## Supported configuration keys

| Key | Data Type | Applies To | DEFAULT | Description |
|---|---|---|---|---|
| `auth:disableLocalAuthentication` | Boolean | RMT Server | FALSE | On setting this to true, creating user with authentication mode as local is not permitted. Added in version 2024.2 |

| Key | Data Type | Applies To | DEFAULT | Description |
|---|---|---|---|---|
| auth:disableUserManagementUI | Boolean | RMT Server | FALSE | On setting this to true, user management from UI is not permitted. Added in version 2024.2 |
| monitoring:antiDomainLockoutEnabled | Boolean | RMT Server | TRUE | When set to TRUE (the default), the anti domain lockout feature is enabled. Added in version 2025.1.1. |
| monitoring:antiDomainLockoutTimeSeconds | Integer | RMT Server | 600 | The time duration for which all the attempts to Tableau server will be throttled before attempting the connection again. Added in ver- |

| Key | Data Type | Applies To | DEFAULT | Description |
|---|---|---|---|---|
| | | | | sion 2025.1.1. |
| `monitoring:antiDomainMaxFailedLoginAttempts` | Integer | RMT Server | 3 | The threshold of consecutive unsuccessful login attempts to Tableau Server for anti domain lockout to be activated. Added in version 2025.1.1. |
| `mq:tls:certificateHostName` | String | RMT Server and Agent | n/a | Host name in the certificate to use when connecting to RabbitMQ via TLS |
| `mq:tls:enabled` | Boolean | RMT Server and Agent | FALSE | Enable/disable TLS connection to RabbitMQ |
| `mq:port` | Integer | RMT Server and Agent | 5672 | RabbitMQ host port number. |

| Key | Data Type | Applies To | DEFAULT | Description |
|---|---|---|---|---|
| `server.web.run` | Boolean | Agent | TRUE | Enable or disable the Agent's web interface. |

## Options

`--backup`

Creates a backup of the configuration file before making changes.

Use the get command to view the current configuration value.

rmtadmin start

Starts the Resource Monitoring Tool services. When this is run on the RMT Server, it will start the RMT Server only. When run on an Agent, it will start the Agent on the machine you are running the command from.

**This command works both on the RMT Server and Agent**

## Synopsis

```
rmtadmin start [options] [global option]
```

## Options

At least one option must be specified:

**RMT Server:**

`--all`

Starts all services.

`--master`

Starts the RMT Server.

`--mq`

Starts the message queue service.

`--db`

Starts the database service.

**Agent:**

`--agent`

Starts the Agent service running on the machine.

**Example:** `rmtadmin start --all`

rmtadmin status

Checks the status of the application and running services on the machine you are running this command on. For RMT Server, the status report confirms that the RMT Server is connected to the database and message queue. For Agents, the status report confirms that the agent is connected to the RMT Server.

**This command can be run both on the RMT Server and the Agent.**

This command returns the following:

- Application status (running or not)
- License status
- MQ connection
- Queue details
- Memory used
- Disk space used
- Tableau server version on machine
- Process topology of Tableau Server that is stored in Agent config file.

Beginning with version 2024.2.0, when run on the RMT Server, the command returns:

- Disk space usage warning if messaging tables in the local database are using more space than the warning threshold (4 GB). For more information, see Troubleshoot Messaging Tables Disk Usage Warnings

## Synopsis

```
rmtadmin status [global option]
```

rmtadmin stop

Stops the Resource Monitoring Tool services. When this command is run on the RMT Server, it will only stop the RMT Server. When run on a machine where Agent is installed, it will only stop the Agent on that machine.

**This command can be run both on the RMT Server and the Agent.**

## Synopsis

```
rmtadmin stop [options] [global option]
```

## Options

At least one option must be specified:

**RMT Server:**

`--all`

Stops all services.

`--master`

Stops the RMT Server.

`--mq`

Stops the message queue service.

`--db`

Stops the database service.

**Agent:**

`--agent`

Stops the Agent service running on the machine.

**Example:** `rmtadmin stop --db`

rmtadmin test-env

**Note:** Added in version 2021.2

Tests the various connection points between Resource Monitoring Tool and Tableau Server. This includes testing Tableau Server Repository connection, Tableau Server API connections, and Advanced Management capabilities.

**This command only works on the RMT Server.**

## Synopsis

```
rmtadmin test-env [positional parameter][global option]
```

## Positional Parameter

`--env`

Optional. The identifier of the environment that the Resource Monitoring Tool is monitoringThis is the system generated identifier. You can find this by going to **Admin** > **Environments > Edit Environment**. On this page, in the **Environment Details** section, you will see the identifier for the environment.

`--force`

Optional. Use this option to update the baseline immediately even if enough data is not available. By default the command will wait for 50 successful loads to calculate the baseline

rmtadmin update-baseline

**Note:** Added in version 2021.4

Updates the baseline for all view loads. Baseline is the 95th percentile of 50 successful initial load times for a view.

**This command only works on the RMT Server.**

## Synopsis

```
rmtadmin update-baseline [options][global option]
```

## Options

`env`

Required. This is the system generated identifier. You can find this by going to **Admin > Environments > Edit Environment**. On this page, in the **Environment Details** section, you will see the identifier for the environment.

rmtadmin update-env

**Note:** Added in version 2021.2

Updates the environment settings.

**This command only works on the RMT Server.**

## Synopsis

```
rmtadmin update-env [options][global option]
```

## Options

| Option | Required? | Description |
|---|---|---|
| --non-inter-active | No | Disables all interactive prompts. |
| --no-test | No | Disables testing API and repository connections. |
| --name | Yes | The name of the environment. |
| --id | No | Identifier of the environment used in web interface URLs.<br><br>This is the system generated iden- |

| Option | Required? | Description |
|---|---|---|
| | | tifier. You can find this by going to **Admin** > **Environments > Edit Environment**. On this page, in the **Environment Details** section, you will see the identifier for the environment. |
| --gateway-url | No | URL used to access the Tableau Server gateway. |
| --version | No | Tableau Server version that this environment will be monitoring. |
| --api-username | No | User name of the account used to connect to Tableau Server APIs. The user account should be a Tableau Server administrator with access to all Tableau Server sites. |
| --api-password | No | Password of the Tableau Server API user account used to connect to Tableau Server APIs. |
| --api-password-file | No | The path to the file containing the password of the Tableau Server API user account. |
| --repository-server | No | This is the server name for the PostgreSQL database that in installed with the Resource Monitoring Tool. |
| --repository-port | No | The port number of the Tableau Server Repository database. |
| --repository- | No | Username used to connect to Post- |

| Option | Required? | Description |
|---|---|---|
| username | | greSQL database installed with the Tableau Server Repository.<br><br>Resource Monitoring Tool accesses the Tableau Server Repository database directly for performance reasons. For this to work, access to the repository must be enabled, with a password set for the **readonly** database user. For details, see Enable access to the Tableau Server repository. |
| --repository-password | No | Password for the user account used to connect to the PostgreSQL database that is installed with the Tableau Server .<br><br>Resource Monitoring Tool accesses the Tableau Server Repository database directly for performance reasons. For this to work, access to the repository must be enabled, with a password set for the **readonly** database user. For details, see Enable access to the Tableau Server repository. |
| --repository-password | No | The path including the file name where the password for the user account used to connect to the PostgreSQL database that is installed |

| Option | Required? | Description |
|---|---|---|
| | | with Tableau Server. |
| --repository-ssl-mode | No | Tableau Server Repository SSL Mode:<br><br>**Prefer** SSL or **Require** SSL to configure SSL connections to Tableau Repository.<br><br>**Disable** to never use SSL to make Tableau Server Repository connections. |
| --repository-ssl-thumbprint | No | When configuring Tableau Server PostgreSQL to allow direct connections, Tableau Server creates a certificate and keys. You can choose to either supply the thumbprint for the certificate that was generated by Tableau Server, or copy the **server.crt** file to the Resource Monitoring Tool Server machine. If you choose to copy the certificate file, you don't have to supply the thumbprint. For more information, see Configure Postgres SSL to Allow Direct Connections from Clients. |

**Example:** `rmtadmin update-env --name=<new name>`

rmtadmin users

Shows a list of the Resource Monitoring Tool user accounts.

**This command works only on the RMT Server.**

## Synopsis

```
rmtadmin users
```

rmtadmin version

Shows the current version information for the RMT Server when run on the RMT Sever machine. It shows the current version information of the Agent installed on the machine that you are running the command from.

**This command can be run both on the RMT Server and the Agent.**

## Synopsis

```
rmtadmin version
```

rmtadmin ziplogs

Creates a ZIP archive file containing the Resource Monitoring Tool log files.

**This command works both on the RMT Server and Agent but only includes the log files from the application the command is run on.**

## Synopsis

```
rmtadmin ziplogs [positional parameter] [option] [global option]
```

## Positional Parameter

```
filename
```

Name of the output zip file. Defaults to log.zip if no name is provided.

## Option

`--force`

Overwrites the existing file.

**Example:** `rmtadmin ziplogs <zip file name> --force`

Global Option

--help

Shows the help for the command.

Tableau Resource Monitoring Tool Communication Ports

This article lists the communication ports the Tableau Resource Monitoring Tool uses, the default port configuration, and how to change these ports when your network requirements needs them to be different than what is set by default.

RMT Server

You can change or update the port information using:

- rmtadmin master-setup command
- Web interface: From the machine where RMT Server is installed, go to: `http://-localhost/setup/server`

## RMT Server Communications

Ports used: 9001, 443, and 80

- Setup initially defaults to port 9001, but changes the default to 80 after initial configuration.

- The SSL self signed certificate on initial installation is for port 443. RMT Server listens on port 80 by default and will attempt to forward traffic to 443 for SSL. Any user specified certificate will also be for port 443.
    - The certificates are used during user traffic to the RMT Server and when the Agent is registered using the Web interface.
    - We generally do not recommend changing port 443. If however, you need to change this due to your environment restrictions, you will need to explicitly list the port number when connecting to RMT Server. If you are registering the Agent using the web interface, you must explicitly specify the port number to connect to the RMT Server.
- Port 80 is used for non SSL traffic and can be changed either during initial setup or post installation.
- The RMT Server will reach out directly to the Tableau Server gateway for REST API calls.
- The RMT Server will reach out directly to the Tableau Server repository to query information if PostgreSQL info is supplied (optional). For information about configuring SSL between RMT server and the Tableau Server repository, see Pre-Installation Checklist - Tableau Resource Monitoring Tool.

## RabbitMQ

RabbitMQ is the component (message queue) used to broker information between Agents and the RMT Server.

Ports used: 5671, 5672

- RabbitMQ is installed and listens to port 5671 (TLS), 5672 (non-TLS).
- TLS communication for RabbitMQ is enabled by default.

## PostgreSQL Database

Ports used: 5555

- PostgreSQL database is installed and listens to port 5555. This cannot be changed.
- PostgreSQL has an `admin` user that is used by the Resource Monitoring Tool. The `readonly` user is used to connect to the Resource Monitoring Tool PostgreSQL database in .tds files downloaded from the Resource Monitoring Tool web interface. For more information about downloading the .tds files, see Explore Monitoring Data Using Tableau Data Source Files.
- PostgreSQL requires SCRAM-SHA-256 authentication. For more information, see Explore Monitoring Data Using Tableau Data Source Files.

Agent

Ports used: 9002, 443, 5672

- During installation, the Agent installer open a web browser that is only used for registration that listens on port 9002.
- If Agent registration is done using the web interface, the registration process uses port 443. If the registration is done using the command line, the registration process goes through RabbitMQ and uses port 5672.

Tableau Resource Monitoring Tool Response Headers

This article describes how to set custom response headers in Tableau Resource Monitoring Tool. The ability to do this was added in August 2024 maintenance releases of RMT.

**Important:** Changes to response headers can break RMT. If you make updates to headers, test afterward to confirm that RMT is working as it should.

Viewing and updating response headers

You can view and change response headers using `rmtadmin get` and `rmtadmin set` commands.

To view a list of currently set response headers, run this command:

```
rmtadmin get server.web.responseheaders
```

To set or change a response header:

```
rmtadmin set server.web.responseheader.<some header>
```

This sets the value for the given header.

Headers are a string of the complete header and any key-value pairs. For example, this sets the keep alive timeout and max values:

```
rmtadmin set server.web.responseheader.keep_alive "Keep-Alive:
timeout=5, max=997"
```

## Invalid headers

RMT allows you to set invalid response headers. If the response header you specify is not a valid one, RMT will warn you but allow you to set the value. It is your responsibility to verify that RMT is working properly after updating response headers.

Test RMT after making *any changes* to the response headers.

Manage Users

When you install Resource Monitoring Tool, you create an admin user during configuration. That user has permissions to perform all tasks on the RMT Server. You can later add other users and specify which tasks they are able to perform related to RMT.

Add a local user

To add users to RMT, click the **Admin** menu and select **Users** (this option may not be available if you have not configured an environment).

To add a new user in Resource Monitoring Tool:

1. From the **Admin** menu, select **Users**.
2. Click **New User**.
3. Provide a user name, password, and apply the server roles.
4. Click **Save**.

Add a delegated user

Beginning in version 2023.1 users can be authenticated using their domain account credentials rather than using a separate password stored locally in RMT. When a user configured for delegated authentication signs into RMT, RMT passes the user and the password they entered to the computer operating system (OS) for verification.

To add a new, delegated user in Resource Monitoring Tool:

1. From the **Admin** menu, select **Users**.
2. Click **New User**. The default is a local user.
3. Select **Operating System (Delegated)**.
4. Provide a **Username**.

   Be sure to type *just* the user name. Do not include any domain.

   When signing into RMT, the user will provide their standard network password and the OS will verify this.
5. Select the server roles the user should have. For more details about server roles, see below.
6. Click **Save**.

Change user authentication

With version 2023.1.0 or later you can change an existing user from one auth type to another. To change an existing user's authentication:

1. Click the Edit icon.
2. Select the **Authentication Mode** you want:
    - If you are changing to **Operating System (Delegated)** mode, you only need to enter the username (without domain). The user will provide their own password at sign in. And existing password stored in RMT is deleted and cannot be restored.
    - If you are changing to **RMT (Local)** mode, you need to enter a username and password. These are stored locally by RMT.
3. Confirm the **Server Roles** selected for the user.
4. Click **Save** to save your changes.

Server Roles in Tableau Resource Monitoring Tool

The Tableau Resource Monitoring Tool has various server roles that you can assign to a user to give them permissions to perform certain tasks.

The following table lists the available roles and what each roles allows the user to do:

| Server Roles | Role Description |
|---|---|
| Download Log Bundles | Download log files. |
| Download TDS Files | Download **.tds** files. |
| Generate Chargeback Reports | Create chargeback reports. |
| Server/Environment Management | Has permissions to update all configurations. |
| User Management | Create and edit users. |
| Webhook Management | Manage Slack notification settings. |

## Troubleshoot authentication issues

For details on how to troubleshoot user sign in and authentication issues, see Troubleshoot User Authentication.

Tableau Resource Monitoring Tool - Incidents

Incidents are reported for events that are unusual and may require human attention. Incidents can be configured for a variety of events either at a global level or can be customized for each environment.

To see current incidents reported for an environment, after selecting an environment, from the **Incidents** menu, select **All Incidents** to see a list of all incidents logged and reported.

You may also receive a notification through email or Slack depending on your settings for notifications. To learn more about how notifications work, see Notifications.

You can generally categorize incidents into two types:.

1. Incidents that are set by default and cannot be changed. We will refer to these as "**system-defined incidents**".
2. Incidents that can be configured by you. We will refer to these as "**configurable incident**s".

All incidents have an incident severity level. The severity level is something that is specifically defined. For system-defined incidents, Resource Monitoring Tool sets the severity levels, and for configurable incidents, you set the severity level depending on what is right for your environment.

Here is the list of severity levels:

| Severity Level | Key | Description |
|---|---|---|
| Info | `information` | When you wish to be informed of an incident that does not cause service distruption. |
| Warning | `warning` | Incidents causing possible service disruptions. |
| Critical | `critical` | Incidents causing major service disruption or the service is down entirely. |

System-defined incidents

The following is a list of system incidents that are set by default and cannot be changed.

| Incident | Incident Level | Description |
|---|---|---|
| Agent Down | `warning` | An incident is logged and reported when either one or more Agents are down, and the RMT Server is unable to communicate with the Agent. |
| Agent Unli-censed | `critical` | This can happen if Tableau Server is not properly licensed to use Tableau Resource Monitoring Tool, or due to connection issues. For more information on the possible causes, see Agent Incidents |
| Environment Down | `critical` | An incident is logged and reported when Tableau Server is offline. |

Configurable incidents

These incidents can be configured based on your environment characteristics and organizational priorities. Following are the events that you can configure severity levels and, or thresholds. The links provide more details on what you can configure for each of the events.

- Extract Failure Incidents
- Hardware Incidents: Includes CPU and memory usage, memory availability, disk space, and disk queue length.
- Hyper Spooling Incidents
- Slow Query Incidents
- Slow Views Incidents

To configure incidents at the global level:

1. From the **Admin** menu, select Global Configuration.
2. In the **Incidents** tab, configure the threshold and severity levels for the incidents.

Global configurations are applied to existing environments or any new environments created unless the environment is using custom thresholds.

Environment Down Incidents

*Environment Down* incidents will be logged as critical when we detect that your Tableau Server is offline. Following are couple of use cases where Tableau Server is considered off-line by Tableau Resource Monitoring Tool:

- Resource Monitoring Tool is unable to get a response from Tableau Server. Resource Monitoring Tool will retry three times before the incident is logged.
- If Resource Monitoring Tool detects that a process is down across all the nodes, an environment down incident will be logged.

Resource Monitoring Tool polls Tableau Server's `http://{Tableau-ServerUrl}/admin/systeminfo.xml` page every 30 seconds (by default) to check the status. If the 30 second polling interval is not sufficient, increase the interval to 60 seconds. If the status is offline, or does not reply within the set value for three consecutive polling intervals then a critical incident is created.

> **Note:** The polling interval cannot be set using the rmtadmin set command. This setting can only be changed by editing the config.json file."

An example `config.json` snippet is below:

```
{
  "background":  {
   "run":true,
   "loglevel":"Information",
    "pollRates":  {
      "processStatus":  30000
      }
    }
}
```

| Key | Data Type | Required? | Description |
|---|---|---|---|
| `processStatus` | Number | Optional | The amount of time in milliseconds to pause between Tableau Server status polling. |

# Who can do this

Resource Monitoring Tool Administrator or a Resource Monitoring Tool user with **Server-/Environment Management** role.

Agent Incidents

Agents Unlicensed (critical)

Incompatible Agent Version (critical)

Agent Message Queue Credential Rotation Failure (critical)

Agent Down (warning)

In an effort to align with our company values of Equality, we have changed non-inclusive terminology where possible. Because changing terms in certain places can causing a breaking change, we maintain the existing terminology. So, you may continue to see the terms in CLI commands and options, installation folders, configuration files. and other instances. For more information, see About Tableau Help.

# Agents Unlicensed

**Agents Unlicensed** incidents will be logged as critical when we detect that your Tableau Server has not been properly licensed to use Tableau Resource Monitoring Tool.

To monitor a Tableau Server using the Resource Monitoring Tool your Tableau Server must be licensed with the Tableau Advanced Management.

Agents will no longer collect data in the unlicensed state and send to the RMT Server. You can however, continue to see the data that was previously collected when the environment was properly licensed.

To resolve this issue, license Tableau Server with Advanced Management. For more information, see About Tableau Advanced Management on Tableau Server.

> **Note:** It may take up to an hour after adding a valid license to Tableau Server, for the incident to be cleared.

There are other possible causes that can cause an **Agents Unlicensed** incident:

- Tableau Server API credentials may not be correct. In the environment configuration page, verify that the username and password are correct and that the account used has the Server Administrator role on Tableau Server.
- Unable to connect to Tableau Server REST API. Make sure that REST API is enabled on Tableau Server and that Tableau Server is running.

  To resolve the REST API connectivity issue, from the **Admin** menu, select **Environments**, click **Edit Environment** on the environment you want to modify, and in the **Environment Details** tab, click the **Test Connection** button in the **Tableau Server REST API** section on the right side of the page.
- The RMT Server was unable to connect to Tableau Server, likely due to a network connectivity or similar issue.

# Incompatible Agent Version

Agent incompatible incidents will be logged as critical when one or more Agents in the environment are on a version that is not compatible with the RMT Server version.

To resolve the issue, you need to make sure that the Agent is on a version that is compatible with the current RMT Server version.

Use one of the following to resolve this issue:

We recommend that the RMT Server and all Agents be on the same version.

- If the Agent is on a version that is earlier than the minimum compatible version, then you must upgrade the Agent to at least the minimum compatible version that is listed in the incident report.
- If the Agent is on a version that is later than the RMT Server version, we recommend that you upgrade the RMT Server to that same later version as well. You may need to upgrade other Agents depending on the version that they are currently on.

## Upgrading Agents:

Use the following steps to upgrade the Agent:

1. Copy the Agent package to the machines where you have Agents installed. Agents are installed on Tableau Server nodes that you are monitoring. The Agent should be on the same version as the RMT Server or use a version that is compatible with the RMT Server version. The incident details provides the minimum compatible version.

2. Stop the Resource Monitoring Tool Agent service on all Tableau Server nodes using the following command:

   ```
   rmtadmin stop --agent
   ```

3. Upgrade all the Agents by running the following command:

   **For RHEL like distributions including CentOS:**

   ```
   sudo yum install <pathtoagentinstaller>/<tabrmt-agent-setup-<version>-x86_64.rpm>
   ```

   ```
   sudo /opt/tableau/tabrmt/agent/install-scripts/upgrade-rmt-agent --accepteula
   ```

**For Ubuntu and Debian distributions:**

**If you are upgrading from version 2020.4 to 2020.4.1 or later:**

```
touch /tmp/tabrmt-agent-upgrading.txt && sudo apt install <tab-rmt-agent-setup-<version>-amd_64.deb>
```

```
sudo /opt/tableau/tabrmt/agent/install-scripts/upgrade-rmt-agent --accepteula
```

**Note:** The touch command is only required when upgrading from 2020.4. If you do not run the touch command before installing the package, your existing version of the Resource Monitoring Tool will be uninstalled before upgrading.

**If you are upgrading from version 2020.4.1 to 2020.4.2 or later:**

```
sudo apt install <pathtoagentinstaller>/<tabrmt-agent-setup-<version>-amd_64.deb>
```

```
sudo /opt/tableau/tabrmt/agent/install-scripts/upgrade-rmt-agent --accepteula
```

4. Confirm that the Agent is running and has been upgraded. You can view Agent registration status by navigating to **Admin** -> **Environments** -> **Edit the Environment** -> **servers** tab to see a full list of Tableau Server nodes and the status of the Agent.

## Upgrading RMT Server

Upgrade the RMT Server if one or more Agents are on a later version.

Use the following steps to upgrade RMT Server:

1. Copy the new version of the RMT Server package to the machine where RMT Server is installed.
2. Stop the Resource Monitoring Tool on the RMT server using the following command:

```
rmtadmin stop --master
```

3. Stop the Resource Monitoring Tool Agents on all Tableau Server Nodes using the following command:

   ```
   rmtadmin stop --agent
   ```

4. Once the services have been stopped, it is best practice to check for any Resource Monitoring Tool processes that are running after the services have been stopped: Any with tabrmt-agent or tabrmt-master. This does not include PostgreSQL or RabbitMQ. You can check the status using the following command:

   ```
   rmtadmin status
   ```

5. Run the upgrade commands on the RMT Server. This will upgrade the existing version to the new version:

   **For RHEL like distributions including CentOS:**

   ```
   sudo yum install <pathtomasterserverinstaller>/<tabrmt-master-setup-<version>-x86_64.rpm>
   ```

   ```
   sudo /opt/tableau/tabrmt/master/install-scripts/upgrade-rmt-master --accepteula
   ```

   **For Ubuntu and Debian distributions:**

   **If you are upgrading from version 2020.4 to 2020.4.1 or later:**

   ```
   touch /tmp/tabrmt-master-upgrading.txt && sudo apt install <tabrmt-master-setup-<version>-amd_64.deb>
   ```

   ```
   sudo /opt/tableau/tabrmt/master/install-scripts/upgrade-rmt-master --accepteula
   ```

   **Note:** The touch command is only required when upgrading from 2020.4. If you do not run the touch command before installing the package, your existing version of the Resource Monitoring Tool will be uninstalled before upgrading.

**If you are upgrading from version 2020.4.1 to 2020.4.2 or later:**

```
sudo apt install <pathtomasterserverinstaller>/<tabrmt-master-setup-<version>-amd_64.deb>
```

```
sudo /opt/tableau/tabrmt/master/install-scripts/upgrade-rmt-master --accepteula
```

6. Confirm that the Agent and RMT Server are running. Start the Agent and RMT Server if they do not automatically restart after the upgrade is complete.

# Agent Message Queue Credential Rotation Failure

Starting in version 2021.3, as a security best practice, the credentials for connections between Agent and Rabbit MQ must be unique to that Agent. The unique credentials are created during a new installation or updated when upgrading to 2021.3.

During upgrade, if there are network issues, the credential update process can fail, resulting in a critical incident report. This, however, does not interrupt the upgrade process and the upgrade process will continue. After upgrade is complete, the Resource Monitoring tool will retry daily to create the unique credentials. A critical incident report is created for the initial failure and every subsequently failed retry. During this time, Agent will continue to work using the previous credentials until new credentials have been created.

The issue might resolve by itself, but if it persists, do the following:

- Verify that the Agents can connect to RMT Server.
- Check for firewall issues between Agent and RMT Server.

# Agent Down

Agent Down incidents will be logged as warning when the Tableau Resource Monitoring Tool is unable to communicate with the Agents on Tableau Server.

Use the following steps to troubleshoot this issue:

1. Make sure that the hardware that hosts the Agents is running and available to communicate with the RMT Server.
2. Make sure that the Agent service is successfully registered, and is running. You can view Agent registration status by navigating to **Admin** -> **Environments** -> **Edit the Environment** -> **servers** tab to see a full list of Tableau Server nodes and the status of the Agent.

## Agent polling and incident creation times

- Agent sends a *heartbeat message* to the Resource Monitoring Tool server every 5 minutes.
- The Resource Monitoring Tool server checks to see if the most recent *heartbeat message* from Agent is less than 15 minutes old.
    - If the latest *heartbeat message* received from the Agent is less than 15 minutes old, then the Agent is considered to be online and no incident is created, and any existing **Agent Down** incidents are cleared.
    - If the latest *heartbeat message* received from Agent is more than 15 minutes old, then it is considered to be the first failed attempt. Every minute thereafter, a check is done, two more times. If after three attempts (first attempt and two retries) there is still no recent heartbeat message, then an **Agent Down** incident is created.

> **Note:** Based on the polling interval described above, it takes about 17 (15+1+1) minutes for an **Agent down** incident to be created after the Agent is offline.

# Who can do this

Resource Monitoring Tool Administrator or a Resource Monitoring Tool user with **Server-/Environment Management** role.

Extract Failure Incidents

*Extract Failure* incidents will be logged as a warning when there is an extract failure in Tableau.

# Who can do this

Resource Monitoring Tool Administrator or a Resource Monitoring Tool user with **Server-/Environment Management** role.

Hardware Incidents

**Hardware** incidents monitor the server itself. These can be used to help identify server issues that may affect Tableau Server's performance.

You can set thresholds for the following issues:

- CPU Usage
- Available Memory
- Memory Usage
- Free Disk Space

The following incidents are configured by default when you install a new Tableau Resource Monitoring Tool:

- When the available disk space falls below 10 GB for 10 minutes or more a warning incident is logged, and when available disk falls below 5 GB for 10 minutes or more, a critical incident is logged.
- When available memory falls below 8 GB for over 10 minutes, a warning incident is logged.
- When the CPU usage for the entire server is 80% or more for 5 minutes, a warning incident is logged.

**Note:** Memory related incidents are configured in binary multiples of bytes.

**You can configure thresholds using the RMT Server web interface or by updating the configuration file `config.json`.**

# Use the RMT Server web interface

To set the thresholds for hardware incidents, under the **Admin** menu, select **Configuration**, and go to the **Incidents** tab.

For **CPU Usage**, set the following:

To set the thresholds for hardware incidents, under the **Admin** menu, select **Configuration**, and go to the **Incidents** tab.

| Key | Required? | Description |
|---|---|---|
| **Severity** | Required | See Incident Severity Level. |
| **Process** | Required | The threshold applies to the entire Tableau Server or for a single process as specified. |
| **Start Threshold** | Required | The CPU usage must surpass the value specified before an incident is created and monitored. Set the percent and the duration for this threshold. |
| **End Threshold** | Optional | The CPU usage that must fall below the value specified before an incident is considered resolved. |

For **Available Memory**, set the following:

| Key | Required? | Description |
|---|---|---|
| **Severity** | Required | See Incident Severity Level. |
| **Start** | Required | The available memory must fall below the value specified |

| Key | Required? | Description |
|---|---|---|
| **Threshold** | | before an incident is created and monitored. Set the percent and the duration for this threshold. |
| **End Threshold** | Optional | The available memory must be above the value specified before an incident is considered resolved. |

For **Memory Usage**, set the following:

| Key | Required? | Description |
|---|---|---|
| **Severity** | Required | See Incident Severity Level. |
| **Process** | Required | The threshold applies to the entire Tableau Server or for a single process as specified. |
| **Start Threshold** | Required | The memory usage must be equal to the value specified before an incident is created and monitored. Set the percent and the duration for this threshold. |
| **End Threshold** | Optional | The memory usage must be below the value specified before an incident is considered resolved. |

For **Free Disk Space**, set the following:

| Key | Required? | Description |
|---|---|---|
| **Severity** | Required | See Incident Severity Level. |
| **Start Threshold** | Required | The free disk space must fall below the value specified before an incident is created and monitored. Set the percent and the duration for this threshold. |
| **End Threshold** | Optional | The free disk space must be above the value specified before an incident is considered resolved. |

For **Disk Queue Length**, set the following:

| Key | Required? | Description |
|---|---|---|
| **Severity** | Required | See Incident Severity Level. |
| **Start Threshold** | Required | The disk queue length must be equal to the value specified before an incident is created and monitored. Set the percent and the duration for this threshold. |
| **End Threshold** | Optional | The disk queue length must be below the value specified before an incident is considered resolved. |

# Use the configuration file (config.json)

An example `config.json` snipped defining two hardware incidents:

```
{
 "monitoring":  {
    "incidents":  {
      "triggers":  [
        {
          "counter":  "DiskSpaceAvailableKB",
          "severity":  "warning",
          "threshold":  1048576
        },
        {
          "counter":  "ProcessorTimePercent",
          "severity":  "warning",
          "threshold":  0.95,
          "thresholdDuration":  300000,
          "endThreshold":  0.90,
          "endThresholdDuration":  5000
        }
      ]
    }
  }
}
```

- The **DiskSpaceAvailableKB** incident will trigger a warning once the available disk space falls below 10 GB.
- The **ProcessorTimePercent** incident will trigger a warning once the CPU has had at least 95% utilization for over 5 minutes. The incident will be considered resolved once the CPU is below 90% utilization for 5 seconds.

The default settings may or may not meet your requirements, and can be changed based on your environment. As an example, for an environment whose identifier was “staging-environment” to trigger a warning when the available disk space falls below 2 GBs, the configuration would look like:

```
{
  "environments":  {
    "staging-environment":  {
     "monitoring":  {
        "incidents":  {
          "triggers":  [
            {
              "counter":  "DiskSpaceAvailableKB",
              "severity":  "warning",
              "threshold":  2097152
            }
          ]
        }
      }
    }
  }
}
```

| Key | Data Type | Required? | Description |
|---|---|---|---|
| `counter` | String | Required | The identifier for the hardware incident to monitor. available options are:<br>• `ProcessorTimePercent`<br>• `DiskSpaceAvailableKB` |

| Key | Data Type | Required? | Description |
|---|---|---|---|
| | | | • `DiskQueueTotalLength`<br>• `MemoryAvailableKB`<br>• `MemoryCommittedKB` |
| `severity` | String | Optional | See Incident Severity Level. Default value: `Warning` |
| `threshold` | Number | Required | The threshold that must be surpassed before an incident is monitored. |
| `thresholdDuration` | Number | Optional | The amount of time in milliseconds to monitor the situation before triggering an incident. If not specified, an incident will be triggered as soon as the `threshold` is reached. |
| `endThreshold` | Number | Optional | The threshold that must be surpassed before an incident is considered resolved. |
| endThresholdDuration | Number | Optional | The amount of time in milliseconds to monitor the situation before completing the incident. If not specified, an incident will be resolved as soon as the `endThreshold` is reached. If `endThreshold` is not defined, then `threshold` is used. |

# Who can do this

Resource Monitoring Tool Administrator or a Resource Monitoring Tool user with **Server-/Environment Management** role.

Hyper Spooling Incidents

*Hyper Spooling* incidents will be logged as a warning when Hyper queries are spooled to disk. Typically, this happens when there is not enough available memory and the Tableau Server Data Engine process shifts to spooling by temporarily writing to disk. The Tableau Server Data Engine topic describes this in more detail in the memory usage section.

# Who can do this

Resource Monitoring Tool Administrator or a Resource Monitoring Tool user with **Server-/Environment Management** role.

Slow Query Incidents

*Slow Query* incidents are triggered when any data query takes too long to complete. By default, a Slow Query incident will trigger a warning if any data query takes at least 30 seconds to execute.

**You can configure thresholds using the RMT Server web interface or by updating the configuration file `config.json`.**

# Use the RMT Server web interface

To set the thresholds for slow query incidents, under the **Admin** menu, select **Configuration**, and go the **Incidents** tab.

| Key | Required? | Description |
|---|---|---|
| **Severity** | Required | See Incident Severity Level. |
| **Duration** | Required | The minimum duration for a query to be considered slow. Values are in seconds. |

# Use the configuration file (config.json)

An example `config.json` snippet defining a Slow Query incident:

```
{
 "monitoring":  {
    "incidents":  {
      "triggers":  [
        {
          "counter":  "DataQueryDuration",
          "severity":  "critical",
          "threshold":  45000
        }
      ]
    }
  }
}
```

This Slow Query incident will trigger if a data query takes at least 45 seconds to execute.

Incidents can be configured per environment. As an example, for an environment whose identifier was “staging-environment” to trigger a warning when a data query takes longer than 30 seconds to execute, the configuration would look like:

```
{
  "environments":  {
    "staging-environment":  {
     "monitoring":  {
       "incidents":  {
          "triggers":  [
            {
              "counter":  "DataQueryDuration",
              "severity":  "warning",
              "threshold":  30000
            }
          ]
        }
      }
```

```
      }
    }
}
```

| Key | Data Type | Required? | Description |
|---|---|---|---|
| `counter` | String | Required | Slow Query incidents use the `DataQueryDuration` identifier. |
| `severity` | String | Optional | See Incident Severity Level. Default value: `Warning` |
| `threshold` | Number | Required | The minimum duration for a query to be considered slow. Values are in milliseconds. |

# Who can do this

Resource Monitoring ToolAdministrator or a Resource Monitoring Tool user with **Server/Environment Management** role.

Slow Views Incidents

*Slow View* incidents are triggered when any view request takes too long to load.

By default, a slow view incident will trigger a warning if any view request takes at least 1 minute to load.

# Configure Slow View Incident Thresholds

To set the thresholds for slow view incidents, under the **Admin** menu, select **Configuration**, and go the **Incidents** tab.

| Key | Required? | Description |
|---|---|---|
| **Severity** | Required | See Incident Severity Level. |
| **Duration** | Required | The minimum duration for a query to be considered slow. Values are in seconds. |
| **Tableau Users** | Required | This threshold is can be either applied to specific users when they make view requests or for all users. Default is **All Users**. |
| **Content** | Required | Content includes workbooks and views. This threshold can be applied to a single view or all views. If a workbook is specified, the threshold would be applied to all the views in that workbook. To specify a view, use the share URL. For more information, see How View URLs are structured.<br>You can also exclude certain views or workbooks by specifying exceptions.<br><br>Default is **All Views** |

Only one incident is created per view request. The Resource Monitoring Tool evaluates all of the incident triggers, and if multiple triggers match a specific view request, then the triggers are ranked in order of priority and specificity. The highest ranking trigger is used to create the incident.

For example, a trigger with a severity of critical is ranked higher than a severity of warning.

Encrypted Data Collection

To make sure the data collection from Tableau Server to Tableau Resource Monitoring Tool is encrypted, communications between RMT Server and Agents, and connections to Tableau Server Repository have to be enabled to use encrypted messaging.

For versions 2022.3 and later

- If RabbitMQ is installed on the same machine as the RMT Server (local configuration), Tableau Resource Monitoring Tool has built-in encrypted communications between

RMT Server and agents. There is no set up required for encryption between RabbitMQ and RMT Server.

- If RabbitMQ is hosted external to RMT Server (external configuration), you must follow the same steps as described in the For versions 2022.2 and earlier section in this topic

You still need to enable and configure encrypted communications to Tableau Server repository database in both cases stated above.

Tableau Repository SSL Configuration

1. Make sure Tableau Server is configured to use SSL connections for internal Postgres connections. For more information, see Configure SSL for Internal Postgres Communication. The Resource Monitoring Toolallows you to use either the certificate file or thumbprint for the SSL connections. If you plan to use the certificate file, copy the certificate file generated by Tableau Server for internal Postgres SSL connections, to the machine where you plan to install the RMT Server. For more information, see Configure Postgres SSL to Allow Direct Connections from Clients.

2. On the RMT Server web interface, from the Admin menus, select Environments. Click on the edit environment icon.

   In the **Tableau Repository Configuration** section:

   1. In the **SSL Mode** drop down box, select **Prefer SSL** or **Require SSL** to configure SSL connections to Tableau Repository. Choosing **Disable** means SSL will never be used to make Tableau Server Repository connections.

      In the **Prefer SSL** mode, the Resource Monitoring Tool will use SSL in the first attempt, and if that fails the subsequently attempts a non-encrypted connection.

      In the **Require SSL** mode, if the SSL connection fails, the connections to Tableau Server Repository will fail entirely. In this case, Tableau Server REST API connections will be used to communicate with Tableau Server.

   2. You can choose to either supply the thumbprint that was generated by Tableau Server, or copy the **server.crt** file to the Resource Monitoring Tool Master Server machine. If you choose to copy the certificate file, you don't have to sup-

ply the thumbprint. For more information, see Configure Postgres SSL to Allow Direct Connections from Clients.

For versions 2022.2 and earlier

Encrypted communication between the Agent(s) and RMT Server is possible by performing the following:

- Configuring RabbitMQ with SSL/TLS certificates.
- Configuring the RMT Server and agent(s) to enable encrypted messaging.
- Configuring encrypted connections to Tableau Repository.

RabbitMQ Setup

For details on RabbitMQ server setup please reference RabbitMQ's documentation for TLS Setup.

Tableau Resource Monitoring Tool Setup

After RabbitMQ has been configured for TLS all client applications: the Tableau Resource Monitoring Tool RMT Server and all Agents will need to be configured to enable encrypted messaging. Do the following on the RMT Server web interface:

1. On the machine where RMT Server is installed, go to: *http://<hostname>/setup/server*.
2. In the Message Queue section, check the Enable TLS check box, and provide the Certificate Host Name.
3. Update the port information if needed.

When configuring the RMT Server and agent(s) for encrypted messaging:

- Both the `enabled` flag and the `certificateHostName` must be configured for encryption to be enabled.
- The `certificateHostName` variable must match the canonical name (CN=) on the server certificate or the connection will fail.
- The `port` number will likely need to be changed based on the TLS port you configured on RabbitMQ.

**Note:** If the Agents were already registered before SSL was configured, then you must re-register the agent. To do this, download the new bootstrap file and re-register the Agent using the new bootstrap file. For more information on re-registering the Agent, see Re-registering an Agent.

Who can do this

To configure encrypted data collection you must be both a Tableau Server Administrator and a Resource Monitoring Tool administrator.

Hardware Changes to RMT Server - Tuning PostgreSQL Database

Sometimes you may need to upgrade or change hardware on the machine where RMT Server is installed. Whenever you make any hardware changes, specifically to memory and CPU, it would be beneficial to tune the underlying PostgreSQL database that is installed with the RMT Server.

When you install RMTr Server, the setup program configures the PostgreSQL database to optimize the use of available hardware on the machine. Example optimizations include managing the buffer and cache size. When you change the hardware on your machine, it may affect the performance.

Use the following steps to make sure the configuration is updated to reflect the change in hardware:

1. Connect to the RMT Server as a user with complete sudo access.
2. Navigate to the "master" directory and run the following command:

   ```
   sudo /opt/tableau/tabrmt/master/tabrmt-master optimize
   ```

   You should see a message that indicates that the configuration file has been updated. It will also state that a restart of the PostgreSQL service is required for the changes to take effect. The updates to the configuration file does not require downtime of the server.

3. Restart the PostgreSQL database. You can do this during off-work hours when the Resource Monitoring Tool is not in use.

### Tableau Server Topology Changes

This article will help you understand what you need to do when you make certain topology changes to Tableau Server. The changes include: adding or removing a node, adding or removing a process from a node, and changing the number of processes on a node.

#### Adding a Node

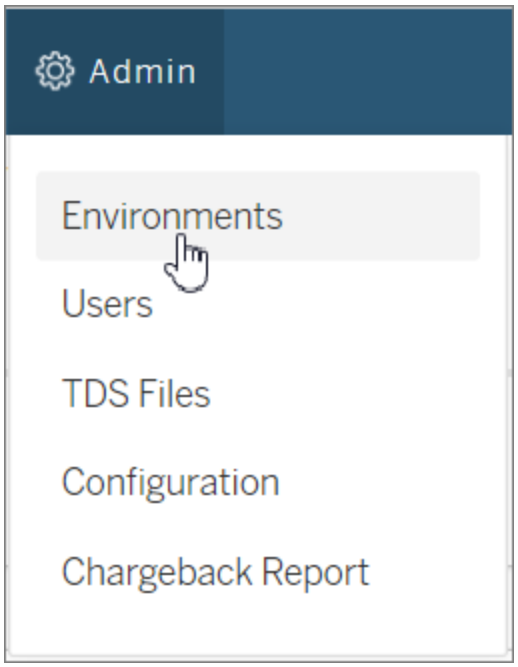
When you add a new node to Tableau Server, you must install the agent on this node. For more information on installing Agent on Tableau Server cluster, see Install the Tableau Resource Monitoring Tool. Until you install the agent, information about this node will not be included in the reports.

#### Removing a Node

When you remove an existing node from Tableau Server cluster, you must update the environment on the RMT Server.

**Use the following steps to update the environment:**

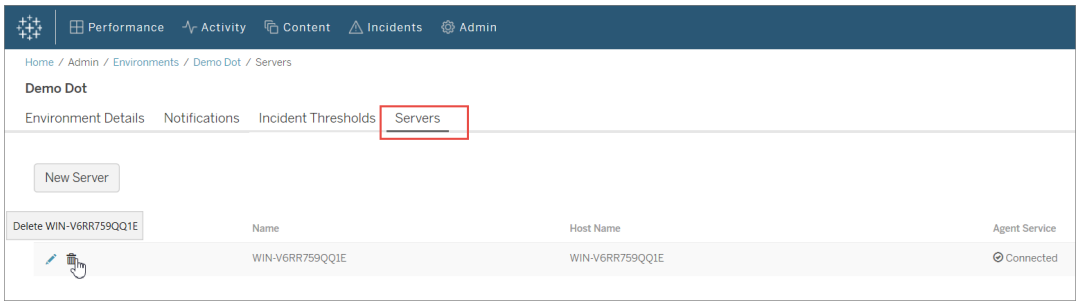
1. Log into the RMT Server web interface.
2. From the **Admin** menu, choose **Environments**. Select the environment that should reflect this change.



3. Choose **Edit Environment**. This opens more detailed information about the environment.

4. From the **Servers** tab, select the node that was removed from Tableau Server, and choose **Delete**.

> Note: The host name should match the name or the IP address of the node.



### Re-registering an Agent

There can be situations when you might want to re-register an Agent. One such use case might be when you want to point one node or the entire Tableau Cluster to a different environment. Another example might be if you had to re-image a Tableau Server node and need to install and re-register the Agent. Use the following instructions to re-register the Agent.

1. On the RMT Server web interface, navigate to **Admin** -> **Environments**. Select the environment. From the **Servers** tab, click delete to completely remove the Agent registration for this node on this environment. This also removes historical monitoring data that has been collected on this node. Use this for scenarios where you are ok with losing the history. For example, if you planning to point this node to a new environment, it might be acceptable to remove the historical data and start fresh.

> **Note:** In the RMT Server web interface, each node in a Tableau Server is referred to as a **Server**. The entire Tableau Server constitutes an environment. For more information, see Concepts

### Who can do this

To make topology changes, you must be both a Tableau Server Administrator and a Resource Monitoring Tool Administrator.

Tableau Resource Monitoring Tool Log Files

Log Files

Tableau Resource Monitoring Tool includes many components. Each component maintains its own set of log files.

By default, 31 log files with a max file size of 1 GB each will be retained in each set. Excess log files beyond that will be deleted automatically.

**Note:** In an effort to align with our company values of Equality, we have changed non-inclusive terminology where possible. Because changing terms in certain places can causing a breaking change, we maintain the existing terminology. So, you may continue to see the terms in CLI commands and options, installation folders, configuration files. and other instances. For more information, see About Tableau Help.

## Components

| **Component**<br><br>**For additional information about services installed with RMT, see Resource Monitoring Tool (RMT) Services.** | **Log File Location**<br><br>`/var/opt/tableau/tabrmt/master/logs` | **Description** |
|---|---|---|
| Backgrounder | `background\YYYYMMDD-pts.log` | Logs generated by the general background processor. |
| Director | `director\YYYYMMDD-pts.log` | Logs generated by the director background pro- |

| Component<br><br>**For additional information about services installed with RMT, see Resource Monitoring Tool (RMT) Services.** | Log File Location<br><br>`/var/opt/tableau/tabrmt/master/logs` | Description |
|---|---|---|
| | | cessor. |
| Host | `host\YYYYMMDD.log` | Logs generated by the host. |
| Web Server | `web\YYYYMMDD-pts.log` | Logs generated by the web server. |
| RabbitMQ (Message Broker) | `rabbitmq/*.log` | Logs generated by RabbbitMQ |
| PostgreSQL (local data repository) | `pgsql/*.log and *.csv` | Logs generated by the local PostgreSQL database. |

For advanced troubleshooting, verbose logging can also be enabled for more internal activities. These activity logs are stored in the associated component's log directory.

| Activity | Log File Location | Description |
|---|---|---|
| Database | `logs\*\YYYYMMDD-ef.log` | Logs of internal database queries. By default, only errors are written to this log. Enable by changing |

| Activity | Log File Location | Description |
|---|---|---|
| | | `db.logLevel` to `Debug` or higher. |
| Message Queue | `logs\*\YYYYMMDD-mq.log` | Logs of internal message queue communication. By default, this log will not be generated. Enable by changing `mq.logLevel` to `Debug` or higher. |

Log Level Configuration

Resource Monitoring Tool log levels can be adjusted in the following ways:

- Resource Monitoring Tool web interface: From the Admin menu, navigate to Configuration and select the Advanced tab. You can set the log levels and also specify if you want to include database queries and message queue communications.

  Logging levels you can set using the web interface:

  | Level |
  |---|
  | Default: Includes Information, Warning, Error, and Critical levels |
  | Verbose: Includes Information, Warning, Error, Critical (everything in the default) and Debug levels |

- Settings in the `config.json` files. Log levels are configured independently for each component. The default config file paths are below. This may vary depending on your installation folder.

| Install | Default Location |
|---|---|
| • Tableau Resource Monitoring Tool | `/var/opt/tableau/tabrmt/master/config.json` |
| Tableau Resource Monitoring Tool Agent | `/var/opt/tableau/tabrmt/agent/config.json` |

Logging levels that can be configured using the configuration file:

| Level |
|---|
| Trace |
| Debug |
| Information |
| Warning |
| Error |
| Critical |
| None |

Below is a snippet demonstrating some default log level settings:

```
{
  "db":  {
    "logLevel":  "Error"
  },
  "mq":  {
    "logLevel":  "Warning"
  },
  "server":  {
    "background":  {
      "logLevel":  "Information"
```

```
    },
    "director":  {
      "logLevel":  "Information"
    },
    "web":  {
      "logLevel":  "Information"
    }
  }
}
```

## Sending Log Files to Tableau Customer Support

If you are working with Tableau Support and they ask you to send log files, zip the files up before you send them.

1. Connect to RMT Server and each server that has the Resource Monitoring ToolAgent installed.
2. Open a command prompt and run: `rmtadmin ziplogs <output file path>`, to create a ZIP archive of the log files.

   For more information on sending log files to Tableau, see the Tableau Knowledge Base.

**Note:** Installation log files are located at `/var/tmp/`.

Who can do this

Resource Monitoring Tool Administrator or a Resource Monitoring Tool user with **Server-/Environment Management** role.

Tableau Log Files

Tableau Resource Monitoring Tool agents monitor the Tableau log files in near real time and send log messages to the RMT Server for processing and reporting.

Below is a list of the specific Tableau log files that are monitored.

All directory paths are relative to the Tableau Server data directory. By default, this is located at: `/var/opt/tableau/tabrmt/data/tabsvc`

| Directory | File Name |
|---|---|
| `logs\backgrounder` | `backgrounder-*.log` |
| `logs\httpd` | `*.log` |
| `logs\vizportal` | `vizportal-*.log` |
| `logs\dataserver` | `dataserver_*.txt` |
| `logs\vizqlserver` | `vizqlserver_*.txt` |

Upgrading Tableau

When upgrading a Tableau Server installation that is monitored by Tableau Resource Monitoring Tool, there are a few additional steps that need to be followed.

Ensure Resource Monitoring Tool supports the new Tableau version

Before upgrading Tableau, you'll want to make sure that the version of Resource Monitoring Tool you have installed supports the version of Tableau that you are upgrading to.

The quickest way to check is to log in to the Resource Monitoring Tool web interface and navigate to the **Admin** | **Environments** screen. Edit the environment you are upgrading and check the **Tableau Version** drop down for the version you are upgrading to.

Stop Agents

Resource Monitoring Tool agents should be stopped while you upgrade Tableau Server. Follow these steps on each machine in your Tableau Server cluster:

Run the following command as the `tabrmt-master` user:

```
sudo su --login tabrmt-master
```

```
rmtadmin stop --agent
```

Upgrade Tableau

Follow the normal process for upgrading Tableau Server. This process is outlined in the Tableau Server documentation.

Update Tableau Version in Resource Monitoring Tool

1. Log in to the Resource Monitoring Tool web interface.
2. Go to **Admin** | **Environments**
3. Edit the environment you upgraded.
4. Modify the **Tableau Version** to match

Restart Agents

After the upgrade is complete you are ready to restart the Resource Monitoring Tool agents. Follow these steps on each machine in your Tableau Server cluster:

Run the following command as the `tabrmt-master` user:

```
sudo su --login tabrmt-master

rmtadmin restart --agent
```

Who can do this

To upgrade Resource Monitoring Tool, you must have all the following:

- Full sudo access for the user on machine you are installing Resource Monitoring Tool.
- Tableau Server Administrator site role.
- Resource Monitoring Tool Administrator account.

## Monitor Tableau Server Performance

Tableau Resource Monitoring Tool is used to monitor and analyze Tableau Server health and performance. Performance, usage and hardware metrics are collected through the Agents installed on the Tableau Server nodes and sent to the RMT Server. The aggregated and analyzed data is then displayed in the form or charts and views on the web interface of the RMT Server.

The web interface of the RMT Server has built-in charts and views that you can use to identify what is causing slow load times, extract failures, and other critical issues. For more information, see Monitor Tableau Server Performance with Tableau Resource Monitoring Tool.

You can also download the data that is used to create the pre-built charts and explore it further. For more information, see Explore Monitoring Data Using Tableau Data Source Files.

Monitor Tableau Server Performance with Tableau Resource Monitoring Tool

Tableau Resource Monitoring Tool makes it easy to detect and resolve health and performance problems within your Tableau Server environments. One instance of the Resource Monitoring Tool can provide a single unified interface for administrators to monitor multiple Tableau Servers.

The Resource Monitoring Tool consists of two components:

- Agent, which collects resource usage and performance recording of interactions on Tableau Server.
- RMT Server, which aggregates and displays this performance data in the form of charts on a web interface.

The Resource Monitoring Tool may not be able to provide information for Tableau Server process that are external:

- External Repository: The process status is not monitored and not included in the chartss
- External File Store: The process status is not monitored and the extract file size information is not tracked. The extract failure and time taken to complete is still available.
- External Gateway: The process status is not monitored and not included in the charts.

Pre-built Charts

The web interface of the RMT Server has built-in dashboards and charts that can be used to identify performance bottlenecks and issues. These built-in charts and metrics can be found on the **Performance**, **Activity**, and **Content** pages. You can also set up alerts (called **incidents** ) to report outliers or unusual behavior based on thresholds that you configure.

Here is a full list of capabilities that the Resource Monitoring Tool offers to help with monitoring your Tableau Server:

| Capability | Component | Where to find it on RMT Server |
|---|---|---|
| Configuring Incidents/Alerts | • Hardware resources at Tableau Server node and process level.<br>• View load times.<br>• Query times.<br>• Tableau Server node down events. | **Admin** -> **Environments** ->**Edit Environment** -> **Incidents** or **Notifications** tabs.<br>• Use the **Incidents** tab to configure incident thresholds.<br>• Use the **Notifications** tab to configure when and how you want to receive notifications. |
| Hardware Resources | • CPU<br>• Memory<br>• Disk<br>• Network | For a high level view, go to **Performance** -> **Select environment** ->**Environment**<br>For a more detailed view, go to **Performance** -> **Select environment** -> **Servers** |
| Tableau Server Usage | • Concurrent users<br>• Aggregated view load times across the server<br>• Background tasks<br>  • Duration, state, and detailed errors for failed tasks.<br>  • Log snippets for failed tasks.<br>• Query details<br>  • Duration, state, and | Most of this information is on the **Environment** tab of the performance dashboard.<br>**Performance** -> **Select environment** ->**Environment**<br>To see query details, go to **Activity** -> **Data Queries** and select a query for more details.<br>To see log information, go to **Activity** -> and make a selection from the list to see more details. |

| Capability | Component | Where to find it on RMT Server |
| --- | --- | --- |
| | query text for long-running or expensive queries.<br>• Log information for:<br>  • Individual view load times.<br>  • VizQL session information.<br>  • Duration of events during view loads.<br>  • Query text, load time, and number of rows returned<br>  • Background tasks and run times. | |

Custom Charts

You can also download the data that is used to create the pre-built charts and explore it further in Tableau. For more information, see Explore Monitoring Data Using Tableau Data Source Files.

Who can do this

Any Resource Monitoring Tool user can view the charts.

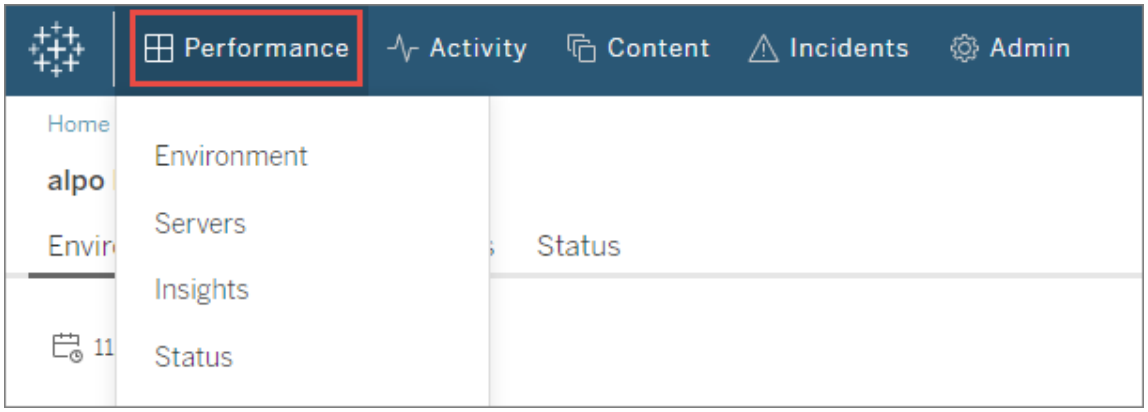
Tableau Resource Monitoring Tool Performance Charts

The Tableau Resource Monitoring Tool includes dashboards that help you monitor and analyze various performance metrics like hardware resource usage, user activity, and the status of

Tableau Server processes. They can be useful in identifying performance bottlenecks and the overall health of your Tableau Server.

This topic describes the information on the charts on the **Performance** page. The performance page provides a dashboard view of the overall health of the Tableau Server and includes the following tabs:

1. **Environment:** A dashboard of the performance metrics specific to the environment you selected.
2. **Servers:** Focuses on the hardware resource metrics.
3. **Insights:** Highlights the slowest views and the longest extract refreshes.
4. **Status:** Tableau Server processes status. Information about each process on the nodes whether they are active, busy, or down. This is similar to what you might see on the Tableau Server Settings page.



# Environment Tab

The charts on the environment tab give you an all-up view of the health of the Tableau Server.

- The left side of the page has resource-related metrics: Performance, Tableau Processes, and Background Tasks.
- The right side charts focus on the user activity and the impact: Concurrent Users, Slow View Load Requests, and Total View Load Requests.

**Navigation Tips:**

At the top left corner of the page, you can select a time line that is applied to all the charts on

this page. You can also select a time range by selecting a part of a specific chart (range selection).
- When you make a range selection in the hardware performance and background task charts, the time line acts as a filter for all the charts on this tab.
- When you make a range selection in the slow view load, and user activity charts, you will be automatically be navigated to the Activity page which provides more details for the selected time range.

## Performance Chart

The information on this chart shows you the overall health and usage of the hardware resources for each Tableau Server node. The hardware resources included in this chart are CPU, memory, disk queue, and network.

> **Note:** Network information is not available and not currently supported for Tableau Server running on Linux.

## Tableau Processes Chart

Use this chart to get more details about a specific node and the processes running on that node. **Starting in 2021.4**, almost all Tableau Server processes are tracked with a few exceptions like cluster controller and process that are configured external to Tableau Server cluster, like the External Repository, External File Store, and Independent Gateway. This chart allows you to identify the processes that are driving CPU or memory utilization on a particular node. The chart is dynamically updated to highlight the top ten processes that are using the most resources on a node for the selected time period.

> **Note:** Some Tableau Server sub-processes like tabprotosrv, postgres, and gateway, are not capturedby RMT Server and can cause apparent discrepancies between the Performance chart and the sum of all the values from the Tableau Processes chart.

## Background Tasks Chart

The chart is an overview of the volume of background tasks, categorized by the task type. Use the toggle button to see the total number of tasks, the median duration of those tasks, and a histogram that shows you the run-time for the selected time period. This can be a quick way to drill down to see which tasks are taking a long time to run.

## Concurrent Users Chart

This chart shows you the number of users that have been sending requests in the time period that is selected.

> **Note:** When you select a portion of this chart, it automatically takes you to the related activity page and shows you the information for that specific time period.

## Slow View Load Requests Chart

This chart uses a **baseline** that is established for each view and is then uses it to compare the time it takes to render that view to determine if the view is taking longer than expected.

**In version 2021.4**, the baseline is established by calculating the median value of the first 10 times a specific workbook is rendered successfully.

**In version 2021.4.1** and later, the baseline is established by calculating the 95th percentile of 50 times a specific workbook is rendered successfully.

Once the baseline is established, every time that same workbook is rendered in the future, the time taken for a workbook to load is then compared to its baseline. Depending on whether the time taken to render the view falls within the expected range or at varying degrees outside of the expected range, they are categorized as follows:

- **Normal:** <=2x baseline
- **Long:** >=2x baseline

- **Very Long:** >=4x baseline
- **Failed**: Failed to load or resulted in an error

This baseline and the comparisons only apply to initial rendering of the view. It does apply to subsequent actions like filter selections. Also, when you publish a new version of the workbook, it triggers a recalculation of the baseline.

> **Note:** When you select a portion of this chart, it automatically takes you to the related activity page and shows you the information for that specific time period.

For a detailed walk through on how to use this chart and investigate performance with view rendering, see Investigating Slow View Load Requests.

### Total View Load Requests Chart

This chart gives you an overall feel for how many views have been rendered over a period of time. This chart is useful to assess the scope of the impact of a particular incident.

> **Note:** When you select a portion of this chart, it automatically takes you to the related activity page and shows you the information for that specific time period.

## Server Tab

The charts on this tab provide a more detailed view of the **Performance** chart on the **Environment** tab.

# Insights Tab

## Slowest Views

This chart shows the slowest views ordered by average view load duration. The orange dot indicator represents that view's longest load duration. The time period that is represented here is the full range of data that is available, default is 2 weeks.

## Longest Extract Refreshes

This chart shows the slowest Refresh Extract tasks ordered by duration. Both data source extracts and workbook extracts are considered. They can be distinguished by the icon next to their name. The time period that is represented here is the full range of data that is available, default is 2 weeks.

# Status Tab

This tab lists the Tableau Server processes and their status on each node of the Tableau Server Cluster. This does not include Tableau Server processes that are configured external to Tableau Server cluster like External Repository, External File Store, and Independent Gateway.

# Who can do this

Any Resource Monitoring Tool user can view the charts.

# Related Topics

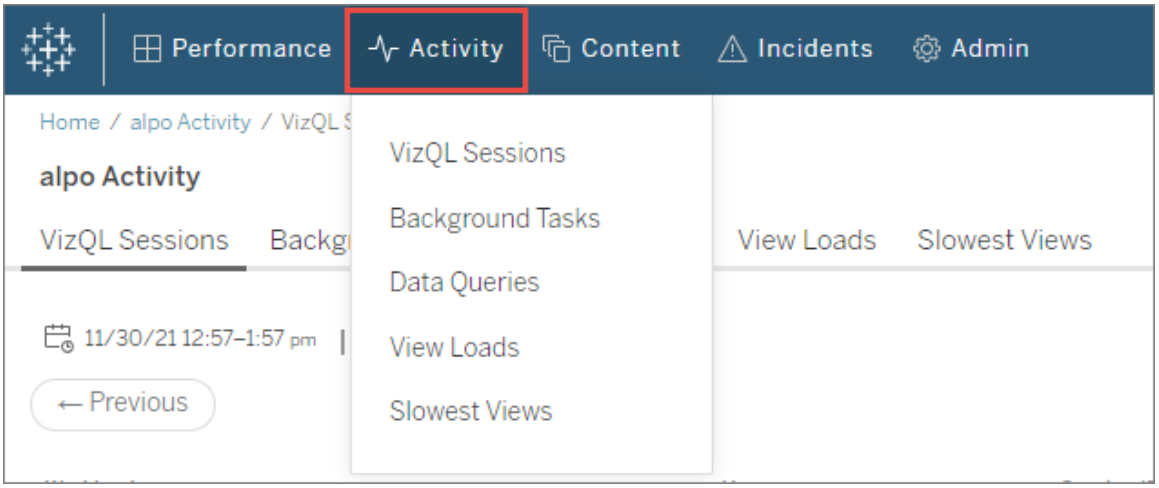
Tableau Resource Monitoring Tool Activity Pages

The Tableau Resource Monitoring Tool includes dashboards that help you monitor and analyze various performance metrics like hardware resource usage, user activity, and the status of Tableau Server processes. They can be useful in identifying performance bottlenecks and the overall health of your Tableau Server.

This topic describes the information on the **Activity** page. The activity page provides the next level of detail to what is seen on the charts on the **Performance** page. The filter selections on either of these dashboards are carried over to the other so you can see corresponding information as you are trying to identify any performance issues.

The activity page includes detailed information about the following:

- VizQL Sessions
- Background Tasks
- Data Queries
- View Loads
- Slowest Views



# VizQL Sessions

Shows you a list of all the VizQL sessions in the selected time range. A VizQL session is a set of interactions that a user has with a workbook on Tableau Server.

Click a session ID to see a summary chart and more details such as the requests made during the session, request duration, and related workbook sessions. You can also see any related data queries, incidents that have been reported, and the environment activity filtered to the same time period as the VizQL session's time frame.

# Background Tasks

Shows you a list of all the background tasks in the selected time range.

Click the start time of the task to see more details about the background task including a summary that shows you a comparison of the time it took to complete the task versus the average duration of time taken to complete similar tasks. You can also see any related incidents that have been reported and the overall environment activity during the time this task was run.

Click the site name to see more information about the site including the number of workbooks, views, and VizQL sessions for each project on that site.

# Data Queries

Shows you a list of all the data queries during the selected time range.

Click on a query to see query performance details, the full query text, and the connection details.

# View Loads

Shows you the list of rendered views in the selected time range.

The **Load Time Severity Category** filter allows you to filter views are taking much more time to load than normally expected. This uses the same baseline concept and comparisons used on the **Slow View Load Request** Chart. The baseline is established by calculating the median value of the first 10 times a specific workbook is rendered. Once the baseline is estab-

lished, every time that same workbook is rendered in the future, the time taken for a workbook to load is then compared to its own baseline.

The categories for the load time severity are as follows:

- **Normal:** <=2x baseline
- **Long:** >=2x baseline
- **Very Long:** >=4x baseline
- **Failed:** Failed to load or resulted in an error
- **Processing:** The baseline calculation is in process and is not yet established.

# Slow Views

Shows you the list of all views that have taken the longest time in descending order. This list is based on average load duration time rather than a comparison against a baseline. You can narrow this list by filtering by duration, publisher, site or a specific view.

- Click on the view to see more details about the load times You can also see any related incidents that have been reported and the overall environment activity during the time this task was run.
- Click on the workbook to see more details about a specific workbook.

# Who can do this

Any Resource Monitoring Tool user can view the charts.

# Related Topics

- Monitor Tableau Server Performance with Tableau Resource Monitoring Tool
- Tableau Resource Monitoring Tool Performance Charts
- Tableau Resource Monitoring Tool Content Pages

Tableau Resource Monitoring Tool Content Pages

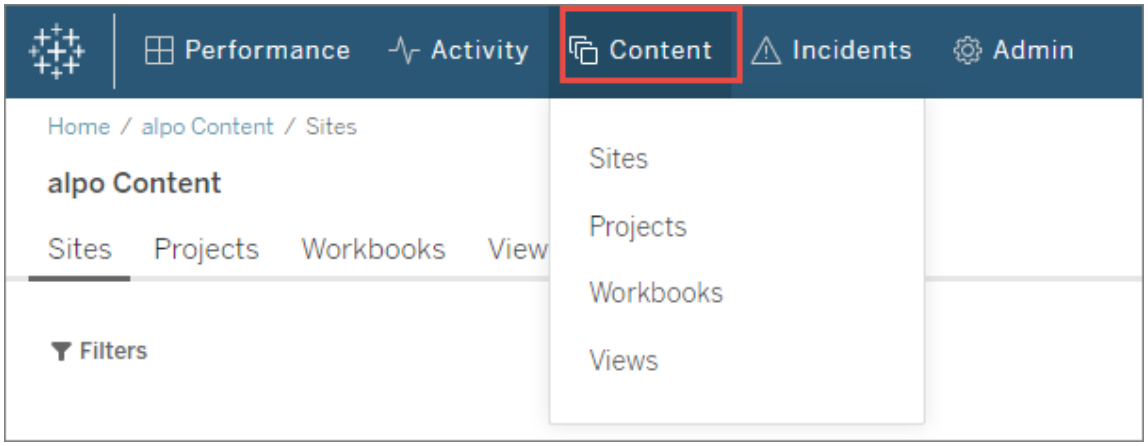
The Tableau Resource Monitoring Tool includes dashboards that help you monitor and analyze various performance metrics like hardware resource usage, user activity, and the status of Tableau Server processes. They can be useful in identifying performance bottlenecks and the overall health of your Tableau Server.

This topic describes the information on the charts on the **Content** page. This page is the main way to look at the details for a specific content item. It is a useful place to start when you need to investigate performance for a specific workbook or a view.

The content page includes detailed information about the following:

- Tableau Sites
- Projects in each Tableau Site
- Workbooks
- Views

You can see performance metrics for the VizQL sessions, data queries related to a project, workbook, or a view. You can also see any related incidents specific to workbooks or views.



# Sites

Shows you a list of sites on your Tableau Server environment including the total number of projects, workbooks, and VizQL sessions.

# Projects

Shows you a list of all the projects on a site. Click on the project to see a list of all the workbooks, views, and related VizQL sessions, and data queries.

# Workbooks

Shows you a list of all the workbooks on a site. Click on a workbook to see the load times, VizQL session information, related data queries, and any reported incidents specific to this workbook.

# Views

Shows you a list of all the Views on a site. Click on view to see the load times for the view, VizQL session information, related data queries, and any reported incidents specific to the view.

# Who can do this

Any Resource Monitoring Tool user can view the charts.

# Related Topics

Investigating Slow View Load Requests

The **Slow View Load Requests** chart on the performance page is a useful metric to understand the performance of views and the resulting impact on user interactions on Tableau Server.

The Slow View Load Requests chart shows when views are rendering more slowly than normal on Tableau Server. To do this, the chart uses a **baseline** that is established for each view and is then uses it to compare the time it takes to render that view to determine if the view is taking longer than expected.

**In version 2021.4**, the baseline is established by calculating the median value of the first 10 times a specific workbook is rendered successfully.

**In version 2021.4.1** and later, the baseline is established by calculating the 95th percentile of 50 times a specific workbook is rendered successfully.

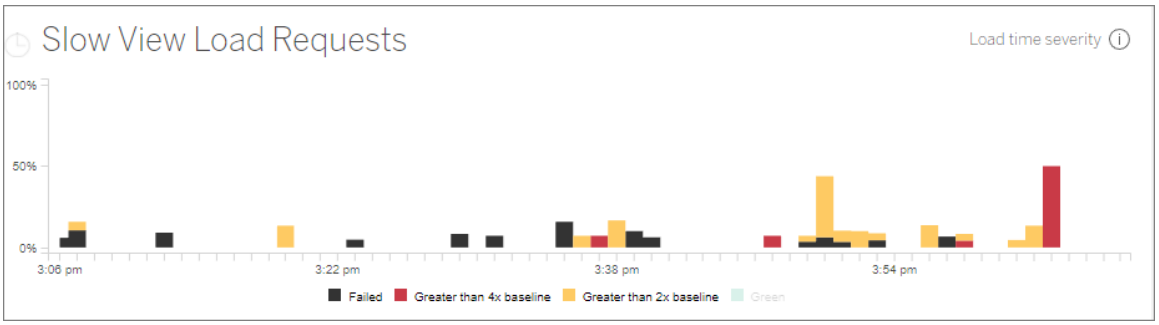
Once the baseline is established, every time that same workbook is rendered in the future, the time taken for a workbook to load is then compared to its baseline. Depending on whether the time taken to render the view falls within the expected range or at varying degrees outside of the expected range, they are categorized as follows:

- **Normal:** <=2x baseline
- **Long:** >=2x baseline
- **Very Long:** >=4x baseline
- **Failed:** Failed to load or resulted in an error

**Note**: This baseline and the comparisons only apply to initial rendering of the view. It does apply to subsequent actions like filter selections. Also, when you publish a new version of the workbook, it triggers a recalculation of the baseline.

The chart shows the percentage of view loads that are outside of the normal range for the selected time range. So, if you see yellow (Long) or red (Very Long) spikes on this chart, that is the first indication that there is likely a problem.

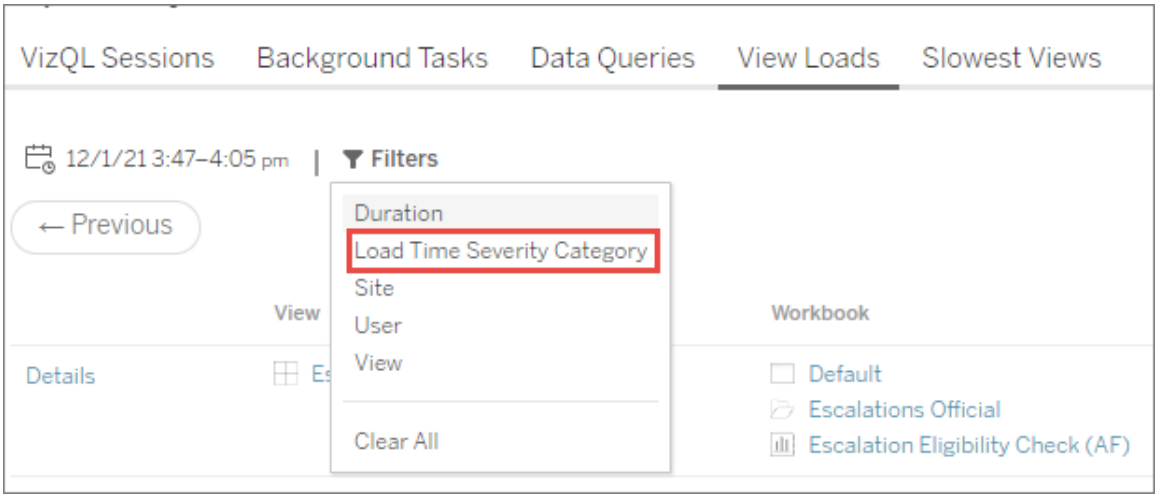
**Tip:** Selecting the “Past 48 hours” time range might be a good place to start as it will give you some context on activity in the past versus current.



The **Concurrent Users** and the **Total View Load Requests** charts on the same page can be used to see the scope of the impact resulting from slow view loads in the same time range. You can also use the **Tableau Processes** chart to identify any correlations between the slow view load performance and resource usage - like for example, you might see high VizQL Server resource usage on specific nodes during the same time that you are seeing spikes in the **Slow View Load Requests** chart.

If you see a spike in the slow view load request chart, you can then start to drill down further to identify what might be causing the issue - whether the problem is due to a single view or a much broader issue. To do this, within the **Slow View Load Requests** chart, select a range to include a large portion of the slow views. This will take you to the **View Loads** activity page, showing you view load requests for the same time frame.

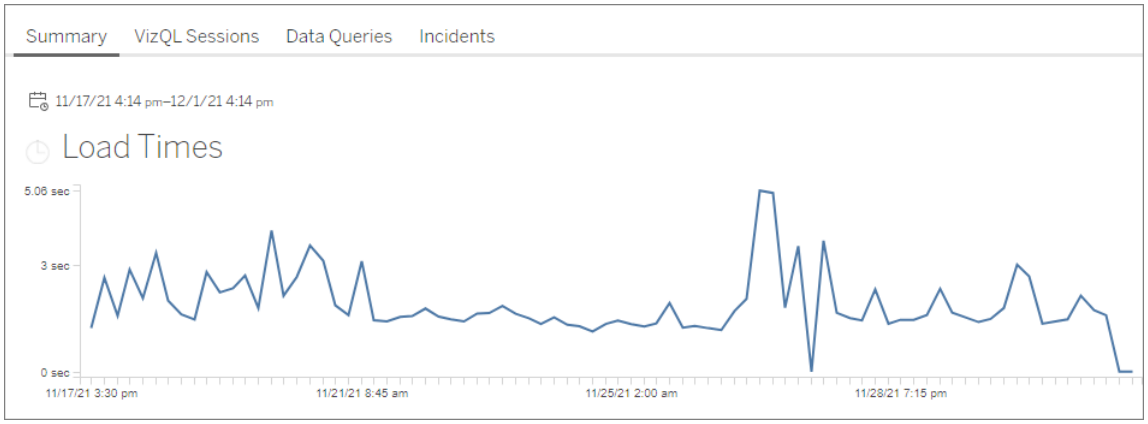
Filter by **Load Time Severity Category** and select the appropriate category for the view loads you want to investigate.



The list should indicate which views might have caused the chart results and can be understood in the following ways:

**Multiple views:** If the list shows multiple views, this is likely a broader issue with Tableau Server. Go back to the performance page, and take a look at the **Performance**, and **Tableau Server Processes** chart to investigate the resource usage. The **Status** tab on the performance page will show the status of the processes whether they are active, busy, or down. Look for the VizQL Server, Data Server, and the Data Engine processes on this list.

**Same view:** If the list is mostly one single view, this could mean that there is an issue with that view or workbook. Further investigation might be needed to see what might be causing the problem. Click on the **view name** in the list to see more information about load times, related data queries, and VizQL sessions.



**Important!** On the **Load Times** chart, if the average load time is consistent even when adjusting the date range to span just before and after the spike began, it means that the baseline calculation was likely created when view loads were heavily cached, causing subsequent view loads to be considered 'slow'. This scenario does not reflect an issue with Tableau Server or the view. If this is the case, you can trigger a recalculation of the baseline by publishing a new version of the workbook.

Here are some resources to help with performance troubleshooting for a specific view:

- Optimize Workbook Performance
- Record and Analyze Workbook Performance

# Who can do this

Any Resource Monitoring Tool user can view the charts.

Tools used in Data Collection

Below is a list of the specific classes used to collect monitoring data :

| Class | Command | Monitoring Category |
|---|---|---|
| `LinuxSystemCpuCollector` | top | CPU |
| `LinuxProcessPerformanceCollector` | top | Process |
| `LinuxSystemMemoryCollector` | free | Memory |
| `LinuxDiskQueueLengthCollector` | iostat | Disk |
| `LinuxDiskUsageCollector` | df | Disk |

Explore Monitoring Data Using Tableau Data Source Files

The Tableau Resource Monitoring Tool includes built-in charts that you can use to monitor and analyze Tableau Server health and performance. The data Tableau Resource Monitoring Tool leverages can be downloaded as Tableau data source (.tds) files for exploration within Tableau Desktop. You can download the .tds files from the **Admin** menu using the Resource Monitoring Tool web interface. This methods works for both local and external repository configurations.

The following is a list of Tableau data source (.tds) files you can download:

- **Background Tasks**: Includes information about scheduled backgrounder tasks like extract refreshes, subscriptions, and flows.
- **Data Queries**: Information about all queries executed by Tableau Server.
- **Gateway Requests**: HTTP requests handled by Tableau Server including VizQL Server session details.
- **Incidents**: Incidents recorded by the Resource Monitoring Tool .
- **Server Performance**: Tableau Server hardware and process information that is gathered by the Resource Monitoring Tool.
- **Tableau Entities**: Information about the Tableau Server sites, projects, workbooks, and views gathered by the Resource Monitoring Tool.

Requirements

- Encryption used is SCRAM-SHA-256 which is supported by Tableau Desktop 2020.4 and later.

Enable access to the Resource Monitoring Tool PostgreSQL database

The Tableau data source (.tds) file contains a connection to the Resource Monitoring Tool PostgreSQL database. Before you can connect to a downloaded .tds file, you need to enable access for the `readonly` user to the Resource Monitoring Tool PostgreSQL database. Once the `readonly` user has access, you can then use the `readonly` username and password to

connect to the Resource Monitoring Tool PostgresSQL database from the .tds file in Tableau Desktop.

## Resource Monitoring Tool versions 2022.3 and later:

### Resource Monitoring Tool with local repository:

1. On the RMT Server machine, enable access to the Resource Monitoring Tool PostgreSQL database for the `readonly` user:

   ```
   rmtadmin data-access ReadOnly
   ```

2. Restart the Resource Monitoring Tool PostgreSQL database for the configuration change to take effect:

   ```
   rmtadmin restart --db
   ```

3. Retrieve the password for the `readonly` user:

   ```
   rmtadmin get db.readOnlyPassword
   ```

### Resource Monitoring Tool with external repository:

You must configure the RDS instance to allow access from Tableau Desktop. Retrieve the username and password for the Resource Monitoring Tool PostgreSQL database and use it to download .tds files. For more information see the documentation on AWS site.

## Resource Monitoring Tool versions 2022.2 and earlier:

1. Open the `postgresql.conf` file. By default, the file is located at: `/var/-opt/tableau/tabrmt/data/postgresql<version>`

2. Update `Listen_addresses = 'localhost'` to `Listen_addresses = '*'`.

   **Note:** You must remove the '`#`' from this line.

3. Open the `pg_hba.conf` file. This file is also located in the same directory as the `postresql.conf` file. By default the file is located at: `/var/-opt/tableau/tabrmt/data/postgresql<version>`

4. Add the following to the end of the `pg_hba.conf` file and then save the file:

   ```
   host all all 0.0.0.0/0 scram-sha-256

   host all all ::/0 scram-sha-256
   ```

5. Restart the Resource Monitoring Tool PostgreSQL database for the configuration changes to take effect:

   ```
   rmtadmin restart --db
   ```

6. Retrieve the password for the `readonly` user:

   ```
   rmtadmin get db.readOnlyPassword
   ```

Connect to the RMT .tds files from Tableau Desktop

After access to the Resource Monitoring Tool PostgreSQL database has been enabled for the `readonly` user, you can then connect to the downloaded .tds files from Tableau Desktop.

1. In Tableau Desktop, go to **File > Open** and select the .tds file downloaded from the Resource Monitoring Tool web interface.

   > **Note**: You might need to install the PostgreSQL database drivers. You can download drivers from www.tableau.com/support/drivers.

   If Tableau Desktop does not automatically connect to the Resource Monitoring Tool Postgres database after opening the .tds file, you might need to manually enter the `readonly` username and password into the edit connection window in Tableau Desktop.

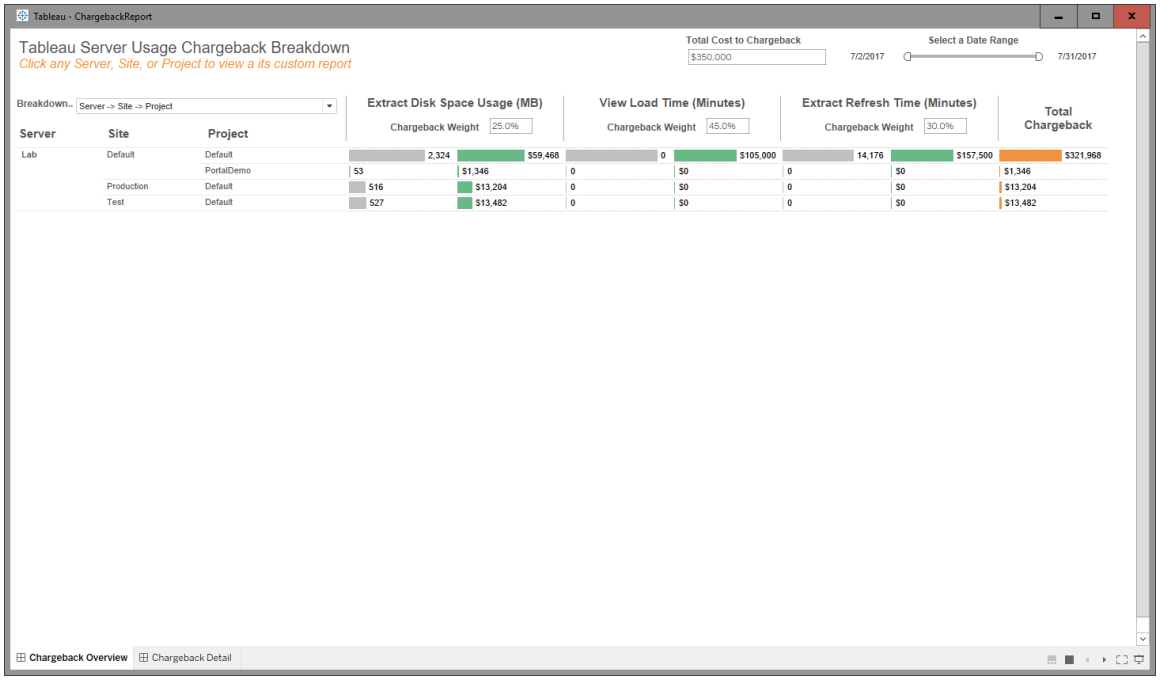
Who can do this

Resource Monitoring Tool Administrator or a Resource Monitoring Tool user with **Download TDS Files** server role.

Chargeback Reports

Chargeback reports show usage on a per-project or per-site basis and are available for allowed users through the **Admin** menu. The report is generated as a Tableau workbook using a generated extract, allowing you to modify the report or reuse the extract as needed.

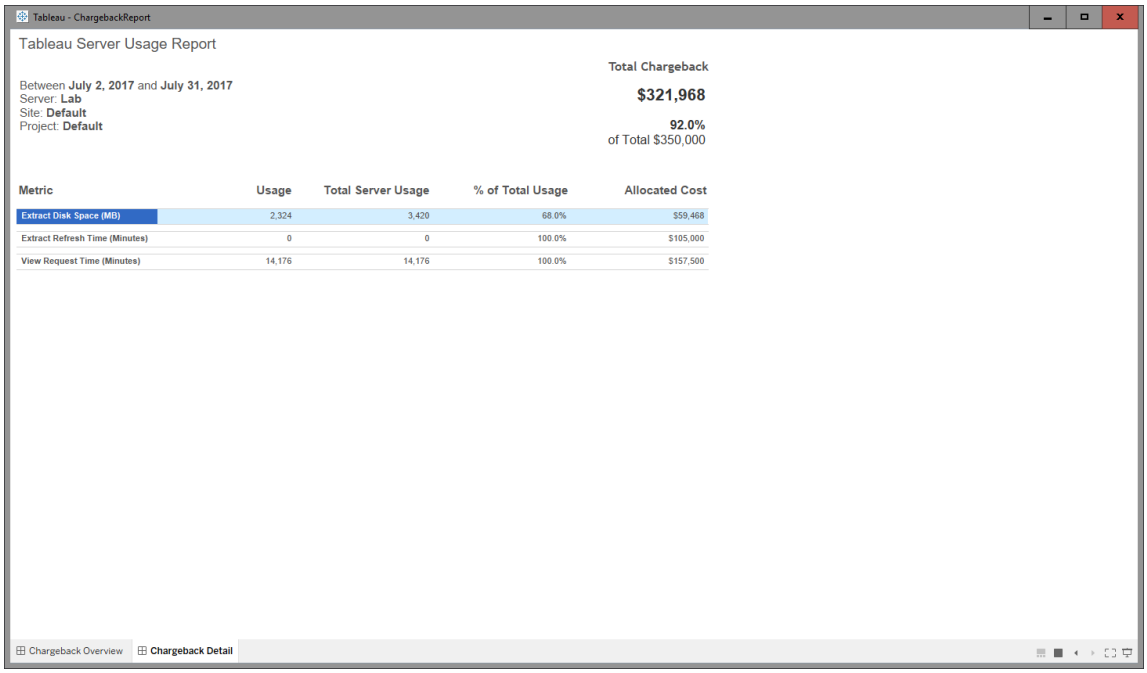
The **Chargeback Overview** worksheet shows a breakdown of various metrics based on site and/or project:



Overview

Dollar amounts can be customized using the total cost field, and by adjusting the cost weights for each metric.

Clicking on a project or site navigates to a customized invoice-style detail report for that project/site:



Detail

Security

User access is controlled through the **Generate Chargeback Reports** server role.

Data Generation

Data for the chargeback report is aggregated at the daily level, with the following metrics included in the data set:

| Metric | Description |
|---|---|
| Extract File Usage | The size, in Kilobytes, of extract files is collected once per day. For the default report this is simply totaled across the time period for ratio/comparison purposes between projects/sites. |
| Extract Query Duration | The length of time, in milliseconds, that queries running against extract files ran, totaled per day. |

| Metric | Description |
|---|---|
| Extract Refresh Task Duration | The length of time, in milliseconds, that extract refresh background tasks ran, totaled per day. |
| Query Duration | The length of time, in milliseconds, that queries ran, totaled per day. This includes both extract and non-extract queries. |
| View Request Duration | The length of time, in milliseconds, that requests to render views ran, totaled per day. This includes the duration of any data queries that blocked view rendering. |

## Who can do this

Resource Monitoring Tool Administrator or a Resource Monitoring Tool user with **Server-/Environment Management** role.

## Troubleshoot Tableau Resource Monitoring Tool Issues

This section includes articles that describe troubleshooting steps and tips. If you have any questions or encounter other issues not described here, contact Tableau customer support.

Troubleshoot Missing Hardware Performance Data

Processor (CPU) usage, memory usage, disk queue, and network performance stats are considered hardware performance data in the Tableau Resource Monitoring Tool. The most common places to see this data are:

- On the **Environment Overview** dashboard in the Performance and Tableau Processes charts
- On the **Servers** dashboard

This data is reported in near-real-time by the Resource Monitoring Tool agent processes running on each of your Tableau Server machines.

If these charts show no data for an extended period of time, this may be due to the following reasons:

1. Tableau Server is not licensed correctly. This may be due to missing Advanced Management capabilities. Make sure Tableau Server has the required license. For more information on Advanced Management, see About Tableau Advanced Management on Tableau Server.
2. Connectivity issues between Agent and Tableau Server. Use the steps below to troubleshoot and isolate these issues.

Step 1: Check the Agent connection status

First, check that the Agents are currently connected to the Resource Monitoring Tool. The Agents send a regular heartbeat message to the RMT Server to indicate their connection status.

1. Log in to the Resource Monitoring Tool as an administrator.
2. Navigate to the **Admin** > **Environments** page.
3. Click the Edit link for the environment that is missing performance data.
4. Locate the **Servers** list and ensure that each server shows the Agent Service as **Connected**. You can hover over the **Connected** status for a timestamp of when the last heartbeat message was received.

Step 2: Ensure the Agent is running

If the Agent shows as **Disconnected** in the Resource Monitoring Tool, then the Agent's Windows service may not be running.

1. Connect to the machine the agent is running on.
2. Ensure that the Tableau Resource Monitoring Tool Agent Windows service is running.

Step 3: Ensure the Agent is configured correctly

If the agent shows as **Disconnected** in the Resource Monitoring Tool, but the service is running, then the agent may not be able to reach the Resource Monitoring Tool's message queue.

1. Connect to the machine the agent is running on.
2. Navigate to the agent's installation folder. For example: `/opt/tableau/tabrmt/agent`
3. Run the *rmtadmin status* command.

The *rmtadmin status* command will test the agent's connectivity to the message queue and the Resource Monitoring Tool's RMT Server.

Step 4: Restart the Agent

In some cases, the Agent may be running and all status indicators show success but the agent continues to not send hardware performance data. This is a known issue that can result from transient connectivity errors between the Agent and the message queue. For example, when restarting the message queue server or during brief network interruptions.

To ensure this isn't the case, restart the Agent and wait a few minutes to confirm whether the performance data is working again.

1. Connect to the machine the Agent is running on.
2. Restart the Tableau Resource Monitoring Tool Agent Windows service.
3. Ensure the service starts successfully.
4. Wait at least 10 minutes and then log in to Resource Monitoring Tool and check Servers dashboard to see if any hardware performance data has been received.

Step 5: Verify Run As account configuration

Ensure the run-as accounts for the agents are configured to use the same run-as account that Tableau Server uses to connect to Tableau Server and get the performance and CPU data. It must be the same account that Tableau Server is configured with. Make sure this account has permissions to access Tableau Server logs.

Step 6: Contact Support

If, after following the above steps the issue is still not resolved, please contact support.

The support team will need a copy of the Resource Monitoring Tool log files from the RMT Server and from each of the agents that are having connection issues. For more information

on how to collect log files and sending them to Tableau customer support, see Sending Log Files to Tableau Customer Support.

Who can do this

Resource Monitoring Tool Administrators.

Troubleshoot RMT Server Service Interruptions

You may be experiencing service interruptions due to RMT Server stopping on a regular basis. This is most likely because Resource Monitoring Tool has been configured with service accounts that do not conform to your internal IT policies. Many IT departments employ automation tools that will revoke privileges on accounts that are deemed non-compliant with their standards, and are the cause for the service interruptions.

**Temporary solution:** Restart RMT Server by running `rmtadmin start -master`.

**Long term solution:** You can either configure the Resource Monitoring Tool to run under an account that is compliant with your internal governance policies (recommended), or alternatively, work with your IT department to obtain an exception from the policy.

Who can do this

You need to be a Administrator on the machine and be a Resource Monitoring Tool Administrator in order to make configuration and database changes.

Troubleshoot Unknown Status of Tableau Server Processes

Under certain conditions you might see that the status of a Tableau Server process as reported as **Unknown**. This is often due to a change in the process configuration in Tableau Server which has not yet been updated in Tableau Resource Monitoring Tool.

**Note:** After updating any configuration, it may take a few minutes for the status reported by the Resource Monitoring Tool to refresh. By default, the Resource Monitoring Tool

checks the Tableau Server status every 15 seconds but it may be longer if you configured it to check less frequently.

Use the following troubleshooting steps to resolve this issue:

Step 1: Check Tableau Server Environment Settings

The Resource Monitoring Tool connects to Tableau Server for monitoring and data collection. If the Tableau Server is upgraded, or the Tableau Server credentials expire then Resource Monitoring Tool will not be able to monitor it as expected.

To confirm that theResource Monitoring Tool is able to connect to your Tableau Server:

1. Go to **Admin** > **Environments list** page.
2. Edit the environment that is having the issue.
3. Confirm that the selected Tableau Server version is correct. When you upgrade your Tableau Server you may need to update the version in the Resource Monitoring Tool.
4. Test the Tableau Server REST API connection using the “Test Connection” button.

   Optionally, test the Tableau Repository connection using the “Test Connection” button.

Step 2: Update Tableau Server Machines and Processes

To correctly monitor a Tableau Server, the Resource Monitoring Tool needs to be configured with a complete record of your Tableau Server machine names and process ports. This information is automatically gathered when creating a new environment but may need manually updated if the Tableau Server configuration is changed.

1. Go to the **Admin** > **Environments** page.
2. Edit the environment that is having the issue.
3. Confirm that the list of **Servers** contains your initial node/gateway Tableau Server machine as well as all additional node machines.
4. Follow the steps below to confirm that each server is configured correctly.

Step 3: Update Machine Name

1. Open this Tableau Server URL: *http://<your TableauServer URL>/admin/systeminfo.xml*.
2. Compare and update the Resource Monitoring Tool configuration with this page to ensure it is up-to-date:
    - Update the server's Host Name to exactly match the <machine name="{HOST NAME}" /> attribute value.

Step 4: Contact Support

If, after following the above steps the issue is still not resolved, contact Tableau customer support.

VizQL Session details page says the VizQL process is unknown

HTTP requests for a Tableau view are linked to the VizQL process (the actual VizQL PID) that last locked the request's VizQL session ID.

In some cases we may not be able to find a matching VizQL process (PID) and in these cases you will see a message on the view session details page that the VizQL process is unknown.

This can happen in a few rare cases:

- The Tableau cluster has been modified with the addition of a new VizQL worker instance.
- Tableau adjusting the VizQL process's port number to avoid a conflict with another process.

If this happens, sign in to the Resource Monitoring Tool and navigate to the environment admin screen. You'll want to check the process definitions for your servers. Ensure that VizQL processes are defined on the expected servers and with the correct port numbers.

Who can do this

To troubleshoot Tableau Server processes issues, you need to be both a Tableau Server Administrator and a Resource Monitoring Tool Administrator.

## Troubleshoot User Authentication

When a Resource Management Tool user is unable to sign in to RMT, there are a few different reasons why this might happen. Your troubleshooting steps depend on what version of RMT you are using, and what kind of authentication the user is configured for.

### Troubleshoot RMT user authentication issues

When a user is unable to sign into Resource Management Tool, troubleshoot the problem by verifing the following:

- Is the user name they are entering added as a user in RMT?
- What type of authentication does the user have in RMT?
    - **Local:** If the user has local auth, reset the password and give them the new one.
    - **Delegated** (Version 2023.1.0 and later)**:**
        - If the user has delegated auth, make sure their user name is correctly entered into RMT. It should not include the domain either before or after the user name:
            - Correct: `<username>`
            - Incorrect: `<subnet.network>\<username>` or `<username@<subnet>.<network>`
        - Have the user confirm their credentials by signing into another system that uses their domain credentials.
        - Make sure the user is not locked out due to excessive failed sign in attempts (this is not something RMT handles; they'll need to work with their IT help desk on this).

**Note:** Beginning with version 2025.1.1 we added anti-domain lockout configuration which allows you to set a threshold of consecutive failed sign in attempts before RMT stops attempting to sign in. This is designed to give you flexibility to configure RMT to stop trying to sign in, and avoid domain lockouts due to too many failed attempts. For more information, see: Supported configuration keys

### Using logs to troubleshoot authentication problems

Logs for authentication issues can be found at: `\[Install Directory]\master\logs\web\tabrmt_YYYMMDD.log`.

Error strings to look for:

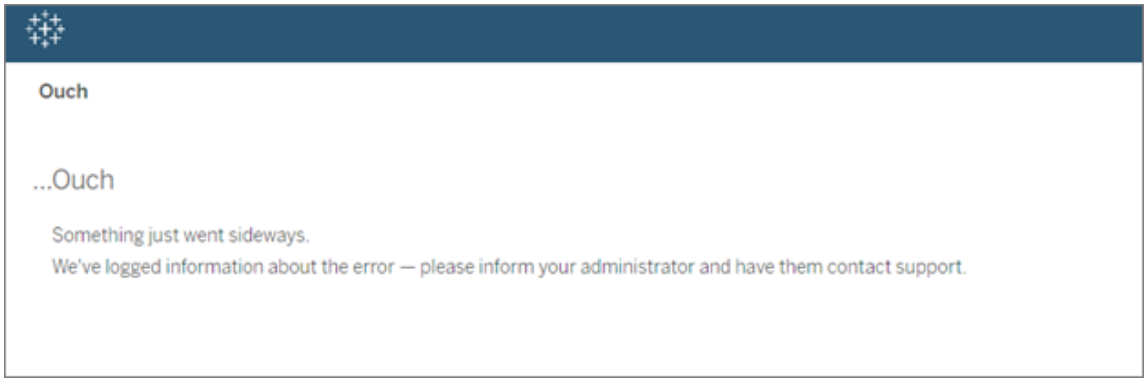
- "Invalid password for user" - A user entered the valid username, mapped to an RMT user assigned Local authentication, but provided an invalid password.
- "User failed to provide the correct password" - A user entered the correct username, mapped to an RMT user assigned delegated authentication, but provided an invalid password.
- "Executing action method \"T-ableau.PowerTools.Server.Master.Web.Controllers.AuthenticationController.Login" - A sign in attempt is being made.

Who can do this

You need to be a Administrator on the machine and be a Resource Monitoring Tool Administrator in order to troubleshoot user authentication issues.

Troubleshoot Web Interface Timeouts

When you try to navigate to the Tableau Resource Monitoring Tool web interface, you see the following error:



This can happen when the load time takes longer than the default 30 seconds threshold. The load time can be affected by the following:

- The size of the underlying PostgreSQL database.
- If RMT is connected to Tableau Server environments that push the current scale that RMT can support, this may also have an effect on the load times.

- Port conflict. Make sure the port Resource Monitoring Tool is using is not in conflict with the ports that Tableau Server is using.

To resolve this issue you can either change the data retention time period or change the threshold to greater than 30 seconds.

**To change the data retention time period, use the following steps:**

1. Navigate to the Configuration UI as described in this topic.
2. Navigate to the Data tab.

   There are two types of Data Configurations:

   - Data retention that is set to 2 weeks by default. It includes detailed activity data and the data displayed in the charts.
   - Reporting data that is set to 10 year time period by default. It includes aggregated historical data and data used for chargeback reports.
3. Tableau recommends changing the data retention time period to 1 week.

To change the timeout threshold, use the following steps:

1. Log into the machine where the RMT Server is installed.
2. Find the "master" configuration file. The file when installed in the default location can be found at:

   ```
   /var/opt/tableau/tabrmt/master/config.json
   ```
3. Add or change the key: **db:timeoutSeconds**

If you need to reduce the size of the PostgreSQL database immediately, Use the rmtadmin command line utility to delete the data. For more information, see rmtadmin Command Line Utility .

Who can do this

You need to be a Administrator on the machine and be a Resource Monitoring Tool Administrator in order to make configuration and database changes.

Troubleshoot Messaging Tables Disk Usage Warnings

In rare situations you may see a disk space usage warning at the command line after running the `rmtadmin status` command:

```
Internal RMT messaging tables total disk usage is now: <nn.nn> KB.
```

A message displays when disk space reaches or exceeds the warning threshold of 4 GB.

The database usually cleans up unnecessary tables automatically, but if this warning displays, take the following steps to clean up the tables manually:

1. Stop RMT Server:

   ```
   rmtadmin stop
   ```

2. Start the database service:

   ```
   rmtadmin start --db
   ```

3. Clean up the unnecessary tables:

   ```
   rmtadmin query "DROP SCHEMA hangfire CASCADE;" --outfile=drop_
   hangfire_schema_output.zip --commit
   ```

4. Start RMT Server:

   ```
   rmtadmin start
   ```

Who can do this

You need to be a Resource Monitoring Tool Administrator in order to run the necessary commands.

## About Tableau Content Migration Tool

This set of articles guides you through setting up, using, and maintaining the Tableau Content Migration Tool.

> **Note**: The Tableau Content Migration Tool is not recommended for migrations when moving from Tableau Server to Tableau Cloud. To migrate from Tableau Server to Tableau Cloud, use the Tableau Migration SDK. For Tableau Content Migration Tool recommended use cases, see Tableau Content Migration Tool Use Cases

## What is Content Migration Tool?

The Content Migration Tool provides an easy way to copy or migrate content between Tableau Server sites. You can do this between sites on a single Tableau Server installation, or if you have user-based licensing, between sites on separate installations (for example, between a development instance of Tableau Server and a production installation). The Content Migration Tool user interface walks you through the steps necessary to build a "migration plan" that you can use once or as a template for multiple migrations.

Before migrating content, we recommend reviewing the Content Governance section in Tableau Blueprint.

## Help and Support

If you have problems that you cannot solve with this documentation, contact Tableau Technical Support.

## Getting Started with Tableau Content Migration Tool

This article will help you get started with the Tableau Content Migration Tool. It contains links to other articles about information you need to prepare before installing the Content Migration Tool, and steps to design a migration plan and upgrade existing installations.

Pre-installation

Installation requirements

The Content Migration Tool can only be installed on Windows operating systems. Before installing, you must be able to connect to the Tableau source site (the site you are migrating

from) and the destination site (the site you are migrating to) from the computer where Content Migration Tool is installed. Both the source and destination sites must have a valid Advanced Management license. For more information about installing and upgrading Content Migration Tool, see Install Tableau Content Migration Tool.

Compatibility with Tableau Server

The Content Migration Tool supports content migration for Tableau Server versions 2019.3 and later.

The table lists compatible versions of Tableau Server based on the installed version of Content Migration Tool.

| CMT Version | Tableau Server Version |
|---|---|
| 2025.2x | 2023.3x - 2025.1.x |
| 2025.1x | 2023.3x - 2025.1.x |
| 2024.3x | 2022.3x - 2024.2.x |
| 2024.2x | 2022.3x - 2024.2.x |
| 2024.1x | 2022.1x - 2024.1.x |
| 2023.3.x | 2021.4.x - 2023.3.x |
| 2023.2.x | 2021.3.x - 2023.2.x |
| 2023.1.x | 2021.2.x - 2023.1.x |
| 2022.4.x | 2021.1.x - 2022.4.x |
| 2022.3.x | 2020.4.x - 2022.3.x |
| 2022.2.x | 2020.3.x - 2022.2.x |
| 2022.1.x | 2020.2.x - 2022.1.x |
| 2021.4.x | 2020.1.x - 2021.4.x |

| CMT Version | Tableau Server Version |
|---|---|
| 2021.3.x | 2019.4.x - 2021.3.x |
| 2021.2.x | 2019.3.x - 2021.2.x |
| 2021.1.x | 2019.3.x - 2021.1.x |
| 2020.4.x | 2019.3.x - 2020.4.x |
| 2020.3.x | 2019.3.x - 2020.3.x |

### Compatibility with Tableau Cloud

Content Migration Tool version 2022.2.1 and later support content migration for all Tableau Cloud deployments. We recommend installing the most recent version from the Tableau Advanced Management downloads page to take advantage of the latest features and fixes.

### Compatibility with Tableau content

The Content Migration Tool supports migrating workbooks and published data sources saved in the eight most recent versions of Tableau. While you can migrate existing data sources, only data sources that use the connection types in the table below can be changed and modified during migration. For more information, see Data Source Transformations in Migration Plans: Workbooks and Migration Plans: Published Data Sources.

| | | |
|---|---|---|
| Actian Matrix | Google Drive | Pivotal Greenplum Database |
| Actian Vectorwise | HortonWorks Hadoop Hive | PostgreSQL |
| Amazon Athena | HP Vertica | Progress OpenEdge |
| Amazon Aurora | IBM DB2 | Salesforce |
| Amazon EMR | IBM Netezza | SAP HANA |
| Amazon Redshift | Map R Hadoop Hive | SAP Sybase ASE |
| Apache Drill | Microsoft Access | SAP Sybase IQ |

| | | |
|---|---|---|
| Aster Database | Microsoft Analysis Services | Snowflake |
| Box | Microsoft Excel | Spark SQL |
| Cloudera Hadoop | Microsoft Excel Direct | Statistical File |
| Delimited Text File | Microsoft OneDrive | Tableau Extract |
| EXASOL | Microsoft SQL Server | Tableau Published Data Source |
| Firebird | MySQL | Teradata |
| Google Analytics | OData | Text File |
| Google BigQuery | Oracle | Web Data Connector |
| Google Cloud SQL | Oracle Essbase | Other Databases (ODBC) |

Post-installation

Limitations when migrating content

Before you start, make sure you understand the limitations when migrating content using the Content Migration Tool. For more information, see Migration Limitations.

Create a migration plan

The Content Migration Tool walks you through migrating content across projects on a single site, to a new site on the same Tableau Server instance, and to sites that exist on different Tableau Server instances. The plan you create can be saved and used again for future migrations. For more information, see Migration Plan Overview.

## Install Tableau Content Migration Tool

Installing Tableau Content Migration Tool is straightforward and easy.

### Installation requirements

The Content Migration Tool tool is run from a Windows computer and can connect to Tableau Cloud sites and Tableau Server 19.3 and later with a valid Advanced Management license. For more information about compatible versions, see Getting Started with Tableau Content Migration Tool.

The computer that you install Content Migration Tool on must meet the requirements below:

- Microsoft Windows 10 or newer (x64)
- Intel Core i3 or AMD Ryzen 3 (Dual Core)
- 4 GB memory or larger
- Can connect to the source and destination sites. Both sites must have a valid Advanced Management license to migrate content.
- 2 GB HDD or larger. The drive where the `\temp` folder resides must have enough disk space to hold a copy of all content being migrated in a single migration. All content is stored locally on the disk and deleted when the migration is complete.
- Have enough free disk space to hold the application and its logs.

In addition, confirm that the REST API is enabled on Tableau Server (this is the default). Use the `tsm configuration get -k api.server.enabled` command to confirm this. A return value of `true` means the REST API is enabled. To enable the REST API, use the `tsm configuration set` command. For more information, see api.server.enabled.

### Install Content Migration Tool

To install the Content Migration Tool:

1. Download the Content Migration Tool installer (`Tabcmt-64bit-<version>.exe`) for your version of Tableau Server from the Tableau Advanced Management downloads page.
2. Run the Content Migration Tool Setup program.

> **Note:** Running the Content Migration Tool Setup program overwrites the previous version.

3. After reading the EULA, select **I agree to the license terms and conditions**, and click **Install**.
4. If the User Account Control dialog opens, click **Yes** to allow the installer to make changes.

Upgrade Content Migration Tool

Upgrading to the latest version of Content Migration Tool ensures that you can take advantage of the latest features and fixes included with each new version.

**Important:**

- Running the Content Migration Tool Setup program overwrites the previous version.
- Content Migration Tool doesn't support side-by-side installation of previous versions.

To upgrade Content Migration Tool:

1. Log on to the machine where Content Migration Tool is installed. If there are instances of Content Migration Tool open, save your migration plan and exit the application.
2. Follow the steps listed in Install Content Migration Tool to download the latest installer and complete the upgrade.

Install Content Migration Tool from the command line

You can install Content Migration Tool from the command line if you're a local administrator on the machine.

Install switches

Specify one or more switches in the command line for the installer. For example:

```
Tabcmt-64bit-2022-3-0.exe /quiet /norestart
```

| Switch | Description | Comments |
|---|---|---|
| `/install` \| `/repair` \| `/uninstall` \| `/layout` "<dir- | Run Setup to either install, repair, or uninstall Content Migration Tool, or with `/layout`, | Default is to install, displaying UI and all prompts. If no directory is specified on a fresh install, `C:\Program Files\Tableau\Tableau Content Migra-` |

| | | |
|---|---|---|
| `ectory>"` | create a complete local copy of the installation bundle in the directory specified. | `tion Tool` is assumed. If Content Migration Tool is already installed, Setup assumes the same location as the current installation. |
| `/passive` | Run Setup with minimal UI and no prompts. | Content Migration Tool doesn't start automatically when installed in `/passive` mode. To start Content Migration Tool, open the application manually. |
| `/quiet` \| `/silent` | Run Setup in unattended, fully silent mode. No UI or prompts are displayed. | Content Migration Tool doesn't start automatically when installed in `/silent` or `/quiet` mode. To start Content Migration Tool, open the application manually.<br><br>**Note:** Use either `/silent` or `/quiet`, not both. |
| `/norestart` | Run Setup without restarting Windows, even if a restart is necessary. | **Note:** In certain rare cases, a restart cannot be suppressed, even when this option is used. This is most likely when an earlier system restart was skipped, for example, during installation of other software. |

Who can do this

A user with Administrator access on the machine.

## Using Tableau Content Migration Tool

The following steps are designed to guide you through using the Tableau Content Migration Tool:

- Migration Plan Overview
  - Migration Plans: Sites
  - Migration Plans: Source Projects
  - Migration Plans: Workbooks
  - Migration Plans: Published Data Sources
  - Migration Plans: Permissions and Ownership
  - Migration Plans: Migration Scripts
  - Migration Plans: Plan Options
- Using the Tableau Content Migration Tool Console Runner

## Tableau Content Migration Tool Use Cases

Tableau Content Migration Tool as the name suggests, is primarily used for moving Tableau Server content from one site to another. However, there are many features in the tool that makes it ideal for accomplishing several tasks related to content migration and maintenance.

> **Note:** In many of the use cases we use the term migration to describe moving content from one environment, site, or project to another. However, technically the Content Migration Tool copies content and does not automatically delete or archive the original or source content.

The information below describes some common use cases where you can leverage the Content Migration Tool.

Content promotion

You can use the Content Migration Tool to create content for development sites and then perform routine migrations to promote content to staging or production environments.

**Use the following steps to promote content to production environments:**

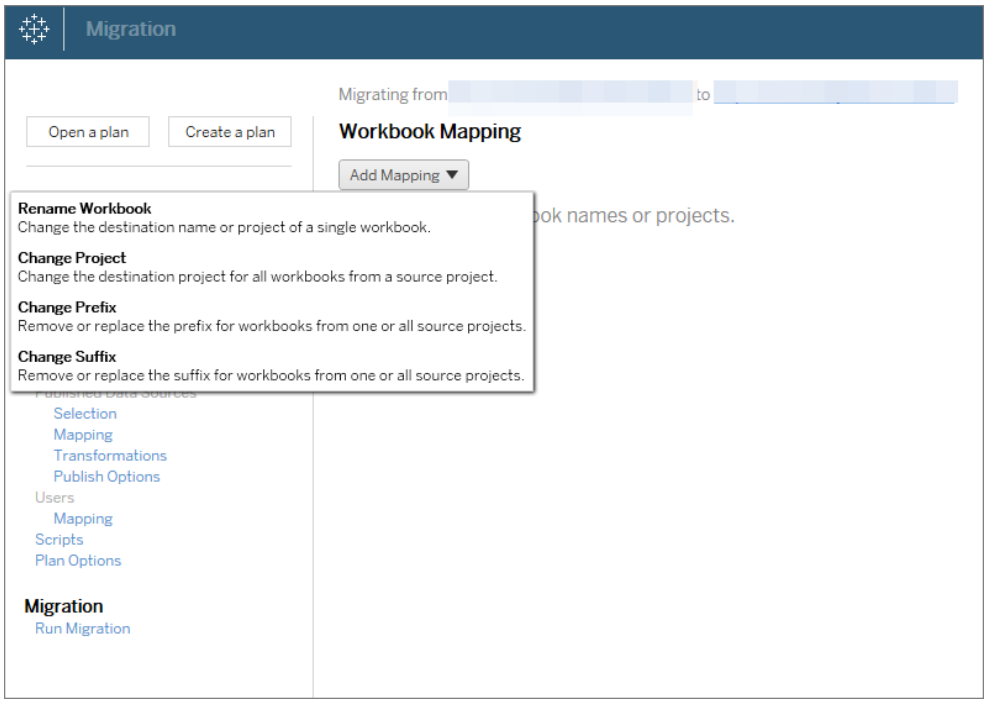
1. **Create a plan** and select the site used for development as the source and the staging or production site as the destination. For more information, see Create a Plan in Migration Plan Overview topic.

   When migrating your workbooks between two projects on the same site, your sign-in credentials for the source and destination may be similar or identical. In this scenario, we recommend using personal access tokens for a more reusable connection. For more information, see Personal Access Tokens.

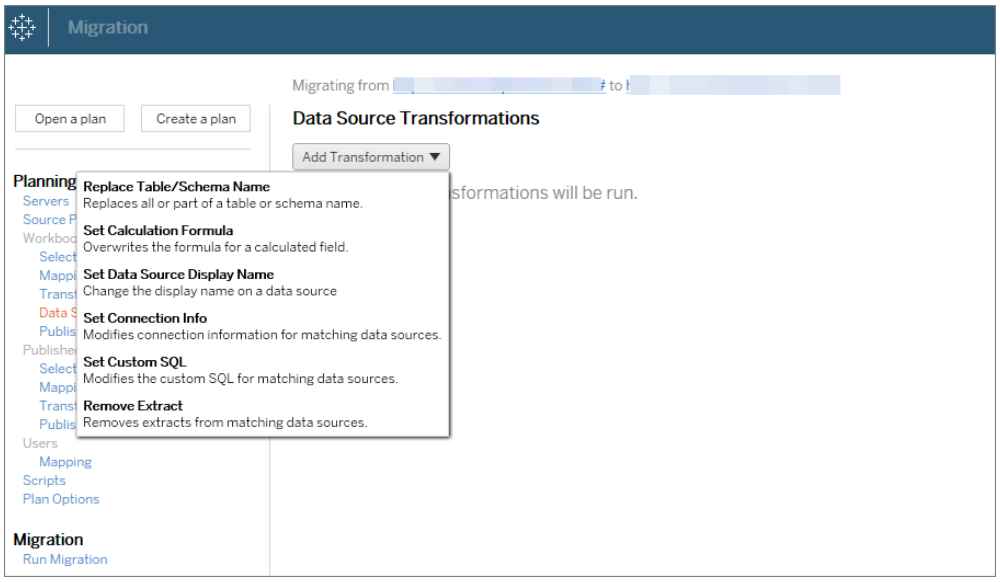
2. **Select the content** you want to migrate from your source site. You can select entire projects, specific workbooks and data sources, and user permissions. For more information, see Planning in Migration Plan Overview topic.

3. If you need to make any **changes or transformations** to the content during this migration, you can configure that in the plan as well. This is referred to as **Mapping**. The types of mapping you can make include:

   - **Changes to workbooks:** Includes renaming workbooks and changing the destination project. For a full list of workbook transformations, see Migration Plans: Workbooks.



- **Changes to data sources:** Includes replacing table or schema names, settings calculation formulas, and setting connection information. For a full list of data source transformations, see Migration Plans: Workbooks (embedded data sources) and Migration Plans: Published Data Sources (published data sources).



- **Changes to Users:** Includes domain, user, and group name changes in the destination.

4. When you are ready, click **Run Migration** to end the Planning phase and prepare to run your plan.

5. **To schedule** this to run regularly, you can script this as a job using the Content Migration Tool Runner and schedule it. For more information on using the Content Migration Tool Runner, see Using the Tableau Content Migration Tool Console Runner.

Tailoring content for customers

When working in a consulting scenario, you can customize content for each of your customers using the Content Migration Tool. Each workbook functions as a template for your migration plan, allowing you to apply styling (text, images, etc.) and replace data sources for specific customers.

**Use the following steps to customize content for your customers:**

1. **Create a plan** and select the production site as the source and the customer site as the destination. For more information, see Create a Plan in Migration Plan Overview topic.

2. **In the Workbooks** step of the Migration Plan, use workbook mappings and transformations to customize your content. Below are two examples of frequently used transformations. For a full list of workbook transformations, see Migration Plans: Workbooks.

    - To personalize content, you can use the **Replace Image** and **Replace Text** transformations to update the workbook with a customer's company name and logo.

    - When it comes to data sources, you can use the **Replace Table/Schema Name** or **Set Custom SQL** transformations to modify content for your customer.

3. **Verify and run** the plan. When you are ready, click **Run Migration** to end the Planning phase and prepare to run your plan.

Environment migration

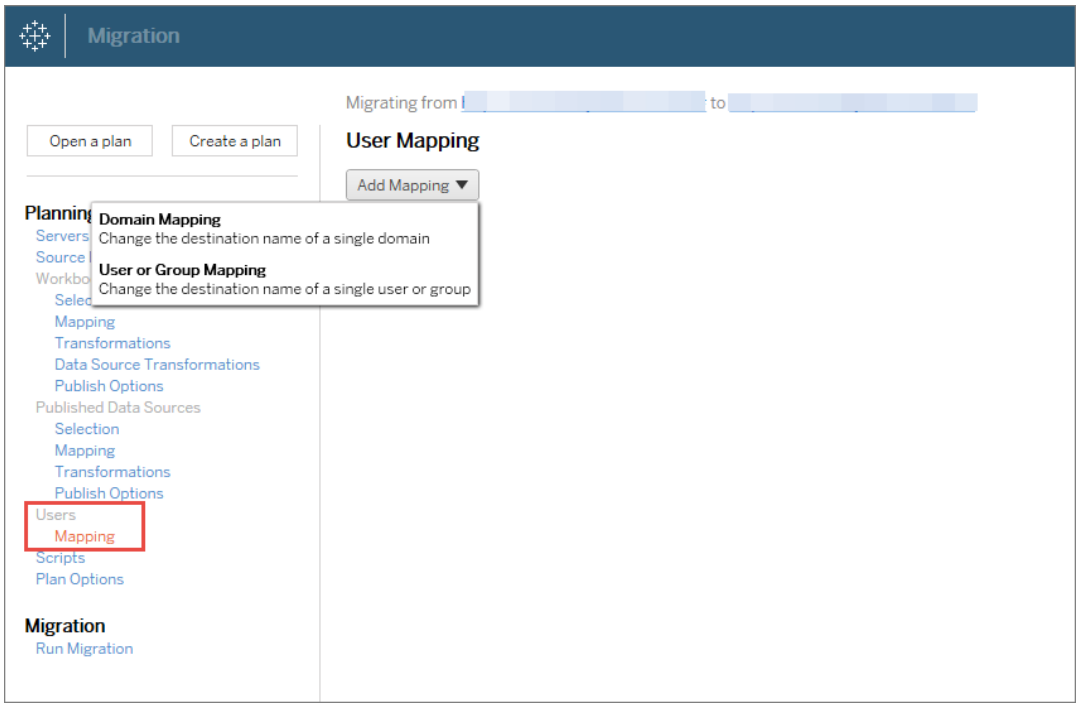
You can use the Content Migration Tool to migrate content between Tableau Server environments.

**Use the following steps to migrate content between Tableau deployments:**

1. **Create a plan** and **select the site** you want to migrate from as your source. For more information, see Create a Plan in Migration Plan Overview topic.

2. **Select the content** you want to migrate from your source site. You can select entire projects, specific workbooks and data sources, and user permissions.

3. **Create user permissions mappings** to customize and secure content. For more information, see Migration Plans: Permissions and Ownership.



4. **Verify and run** the plan. When you are ready, click **Run Migration** to end the Planning phase and prepare to run your plan.

**Tips**

- Before you perform an environment migration, make sure you understand the Migration Limitations when using the Content Migration Tool.
- You can migrate your content in stages, test and validate content iteratively before final migration is complete. There is no server downtime when you use this method of migration. It can be a replacement for Site import/export.
- Content Migration Tool migration does not handle embedded credentials, subscriptions, and custom views. These will have to be migrated manually.

External content sharing

You can use the Content Migration Tool to share internal content with external collaborators, without allowing access to your site. This keeps your data secure and allows you to publish only select workbooks and data sources. Once content has been shared, collaborators sign in

to their Tableau Server site to view and make changes, without affecting content stored on your internal server.

Before you continue, make sure the content you share is compatible between the internal (source) and external (destination) sites. The external site should be running the same version of Tableau as the internal site or later. For more information about compatibility, see Make Workbooks Compatible Between Versions in Tableau Desktop help.

**Use the following steps to share content externally:**

1. **Work with** the external site administrator to determine a user account that has publishing rights on the site. You will use this user account to create the migration plan. For more information, see Set Users' Site Roles and Permissions.

2. **Prepare internal content**. As a best practice, we recommend separating content on the internal server to a project, with locked permissions and strict governance rules. Workbooks and data sources should be clearly labeled to indicate the content is for external use. For more information, see Use Projects to Manage Content Access.

   > **Note:** Content shared with external sites must use data extracts unless the data source is publicly accessible. For information about creating extracts and replacing data sources, see Extract Your Data and Replace Data Sources in Tableau Desktop help.

   If you have implemented row level security, those data sources must be updated to reflect user filters and other details for the external site. For more information about row level security, see Restrict Access at the Data Row Level in Tableau Desktop help.

3. **Create a plan** and select the internal site as the source and the external site as the destination. For more information, see Create a Plan in Migration Plan Overview topic.

4. **Select the content** you want to share with the external site. You can select entire projects, specific workbooks and data sources, and user permissions.

5. **Verify and run** the plan. When you are ready, click **Run Migration** to end the Planning phase and prepare to run your plan.

### Validating database migrations

This use case is when you intend to validate content after a migration of the underlying databases. One example of database migration is moving from SQL Server to Snowflake. CMT can help you validate the content built from both data sources is the same before you finalize your migration, but it cannot perform the actual database migration.

**Use the following steps to validate database migrations:**

1. **Create a plan** and select the Tableau site to use as your source. In this example, we describe a migration between projects on the same Tableau site, so select the same site for your destination. For more information, see Create a Plan in Migration Plan Overview topic.
2. **Configure the migration** to copy your content to a new project. Let's call the **source** project as **Project A**, and the new or the **destination** project as **Project B**.

    - Changes to workbooks: Create a workbook mapping to change Project A to Project B. For a full list of workbook transformations, see Migration Plans: Workbooks.

    - Changes to data sources: Create a data source mapping to change the Project A to Project B. For a full list of data source transformations, see Migration Plans: Published Data Sources.

3. **Verify and run** the plan. When you are ready, click **Run Migration** to end the Planning phase and prepare to run your plan.

4. **Update the content** in **Project B** with the new database connections or replace the data sources. This needs to be done manually by authoring.

5. **Test each workbook** in **Project A** with the copy in **Project B** and review for any inconsistencies in the data due to the change in data source.

6. Once you have confirmed everything is working as expected, **overwrite the content** in Project A with the updated content in Project B.

> **Note:** If the content already exists in the destination project and you do not select the **Overwrite Newer Workbooks** and **Overwrite Newer Data Sources** publish options, the content will not be copied to the destination project.

Geographical content migration

If you are maintaining a geographically distributed, multi-site environment, you will need some of this content to be shared and accessible across all the servers. This use case describes how to migrate content between servers in different geographies. The server can be in the same country or across continents.

**Best Practices:**
- We recommend prioritizing the content that you most need. Content Migration Tool shouldn't be used to copy entire server environments to multiple geographies.
- We recommend migrating content in one direction only meaning Primary to Secondary. Here we use the term Primary to indicate the source site and Secondary to indicate the destination. You can have one or more destination by creating multiple migration plans.

**Use the following steps to migrate between Tableau Server that are distributed in different geographies:**

1. **Create a plan** and select the Primary site as the source and the secondary site as the destination. For more information, see Create a Plan in Migration Plan Overview topic.

2. **Select content** that you want to share between the Primary and Secondary.

3. **Verify and run** the plan. When you are ready, click **Run Migration** to end the Planning phase and prepare to run your plan.

4. **To schedule** this to run on regularly, you can script this as a job using the Content Migration Tool Runner and schedule it. For more information on using the Content Migration Tool Runner, see, Using the Tableau Content Migration Tool Console Runner.

5. **Review the content** on the source **periodically** to determine if new items should be added to the migration plan.

Consolidate sites

If you need to combine the content of multiple sites into a single site (if, for example, organizational restructuring has changed how your sites should be arranged), you can use the Content Migration Tool to do this.

> **Note:** Before consolidating sites, make sure you understand the limitations when migrating content using the Content Migration Tool. For more information, see Migration Limitations.

Use the following steps to copy all the workbooks and data sources from one site to another:

1. Create a plan and select the site you want to consolidate as the source. For more information, see Create a Plan in Migration Plan Overview topic.

2. On the Source Projects page, select **All Projects** and click **Next**.

   If a project with the same name exists on the destination site, the content will be migrated to the same folder.

3. On the Project Options page, select your preferences for the destination site and click **Next**.

If the content already exists in the destination project and you do not select the overwrite option, the content will not be copied to the destination project.

4. On the Workbook Selection screen, select **All Workbooks**.
5. (Optional) If you are copying published data sources:
    - From the left navigation menu, under Published Data Sources, click **Selection**.
    - Select **All Data Sources**.
6. Click **Run Migration** and review the migration plan. When you're ready, click **Run** at the bottom of the screen to run the migration.

Repeat these steps until you've consolidated all sites. For more information, see Planning in Migration Plan Overview topic.

Maintenance tasks

You can use the Content Migration Tool to perform a variety of maintenance tasks.

Tagging stale content

Using the Content Migration Tool, you can manage archiving stale content. For example, you can build a plan that runs on a regular schedule that can automatically pick up content tagged as Stale Content and move it to an Archive project. After a certain amount of time, the content in this project can be purged from the system. For more information see, Migration Plans: Workbooks.

Restoring content

You can use the Content Migration Tool to restore content removed (accidentally or purposefully) from the production Tableau Server with content from a backup server. The restoration process is simple and does not require downtime, compared to restoring with a backup file.

**Use the following steps to restore content from a backup server:**

1. **Create a plan** and select the backup Tableau Server as the source and the production server as the destination. For more information, see Create a Plan in Migration Plan Overview topic.
2. **Select the content** you want to restore from the backup Tableau Server.
3. **Verify and run** the plan. When you are ready, click **Run Migration** to end the Planning phase and prepare to run your plan.
4. **Review the content** on the production server.

Partial backup

Once you have a backup Tableau Server environment, you can use the Content Migration Tool to transfer new content from production to the backup Tableau Server. If you have not configured a backup Tableau Server environment, see the Disaster Recovery for Tableau Server whitepaper for more information.

**Notes:**
- Before you perform a partial backup, make sure you understand the Migration Limitations when using the Content Migration Tool.You may still need to periodically perform a full backup and restore to backup all Tableau Server content. For more information, see Perform a Full Backup and Restore of Tableau Server.
- The Content Migration Tool shouldn't be used to perform your first backup.

**Use the following steps to perform a partial backup of your content:**

1. **Create a plan** and select the backup Tableau Server as the source and the production server as the destination. For more information, see Create a Plan in Migration Plan Overview topic.
2. **Select the content** you want to backup. You can select entire projects, specific workbooks and data sources, and user permissions. To migrate only new content, make sure

the publish options **Overwrite Newer Workbooks** and **Overwrite Newer Data Sources** are not selected. For more information, see Migration Plans: Workbooks.

3. **Verify and run** the plan. When you are ready, click **Run Migration** to end the Planning phase and prepare to run your plan.

4. **To schedule** this to run on a regular basis, you can script this as a job using the Content Migration Tool Runner and schedule it. For more information on using the Content Migration Tool Runner, see Using the Tableau Content Migration Tool Console Runner.

## Migration Plan Overview

Tableau Content Migration Tool creates a streamlined process for migrating Tableau content between sites and projects. The easy-to-follow plan can be audited, is repeatable, and works via a batch process so any number of workbooks and data sources can be migrated in a simple and efficient process.

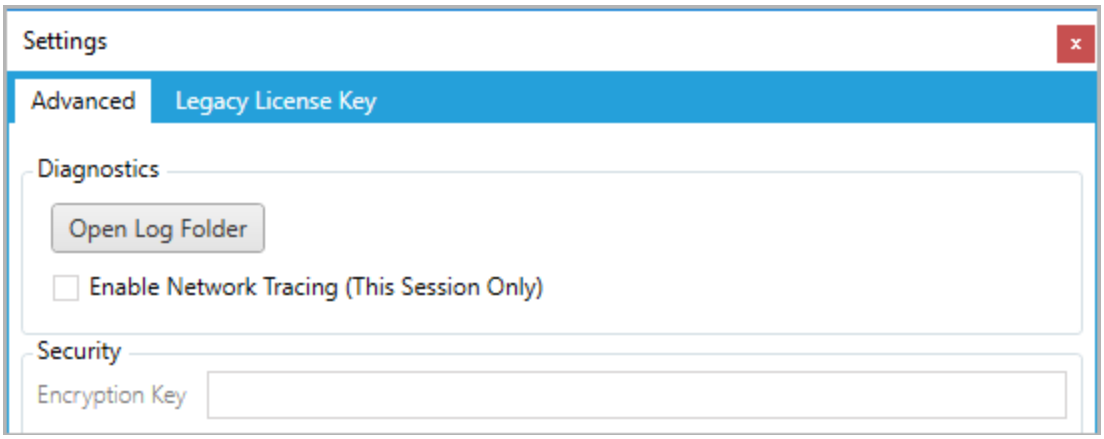
The Content Migration Tool will display contextual tips to walk you through creating or editing a migration plan. Once you select the source and destination sites, a summary of your migration will be displayed at the top of the screen as follows:

### Limitations when migrating content

Before you start, make sure you understand the limitations when migrating content using the Content Migration Tool. For more information, see Migration Limitations.

### Encryption keys

Each migration plan file is generated with an encryption key unique to the application that created the plan. Encryption keys can be shared if the migration plan needs to be run through an application that did not originally generate the file. When sharing encryption keys, you will need to overwrite the existing key in the application to run the migration plan. To view your encryption key, select **Help** > **Settings**.



If you will be using the Content Migration Tool Console Runner for migration plans, you must specify the encryption key using the `tabcmt-runner encryption` command before running the plan. For more information, see Using the Tableau Content Migration Tool Console Runner.

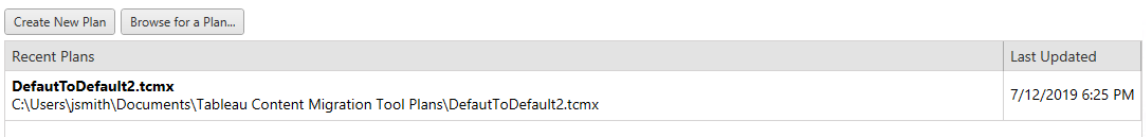
Migration process

Step 1: Start

The core of the migration process is creating a plan, which you can save and re-use for future migrations or modify and update as needed. The first step is choosing whether to create a new plan, or select a previously saved plan.

To create a new plan, click **Create New Plan**. If you already created a migration plan and want to use it, click **Browse for a Plan**.

By default, all of your saved migration plans will be stored in the `Tableau Content Migration Tool Plans` folder in your My Documents folder. All migration plans are saved with a `.tcmx` extension, with recently accessed plans listed separately to make them easy to select:



You can select a recently accessed plan and duplicate it to modify the plan and save it as a new plan. Select the plan you want to copy and click **Duplicate**.

Step 2: Planning

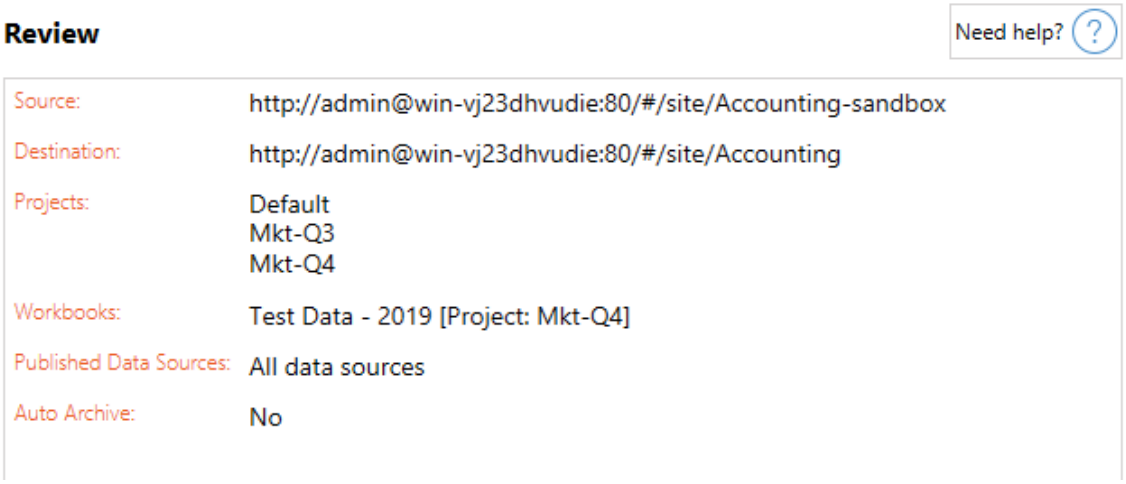
The Content Migration Tool guides you through building or editing your migration plan in six steps.

Click on each step for detailed instructions:

- Migration Plans: Sites
- Migration Plans: Source Projects
- Migration Plans: Workbooks
- Migration Plans: Published Data Sources
- Migration Plans: Permissions and Ownership
- Migration Plans: Migration Scripts
- Migration Plans: Plan Options

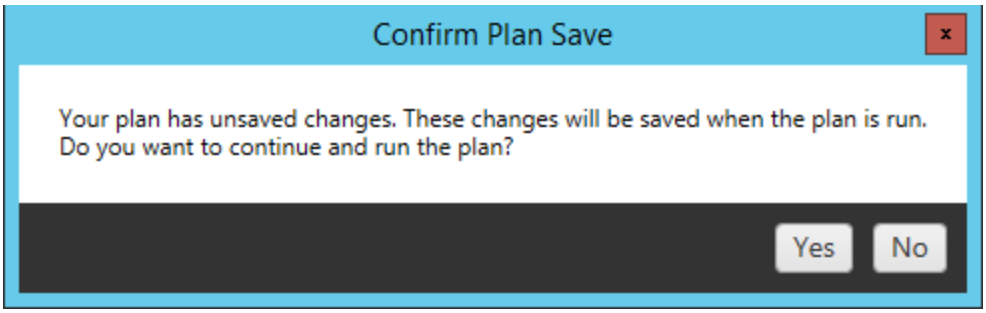
Step 3: Migration

Once you have completed your plan, you are now ready to run the batch process for migration. When you reach the final step of the migration, a plan summary displays for your verification:



If you want to change any aspects of your plan, you can click on a section in the left sidebar to go directly to that phase. When you are ready, click **Run** to begin your migration.

When you click **Run**, the migration tool will prompt you about any unsaved elements of your plan. By default, any unsaved elements will be saved when you click **Yes**. Remember you can always keep your previous plan without making any changes by duplicating it during the Start phase of the migration process.

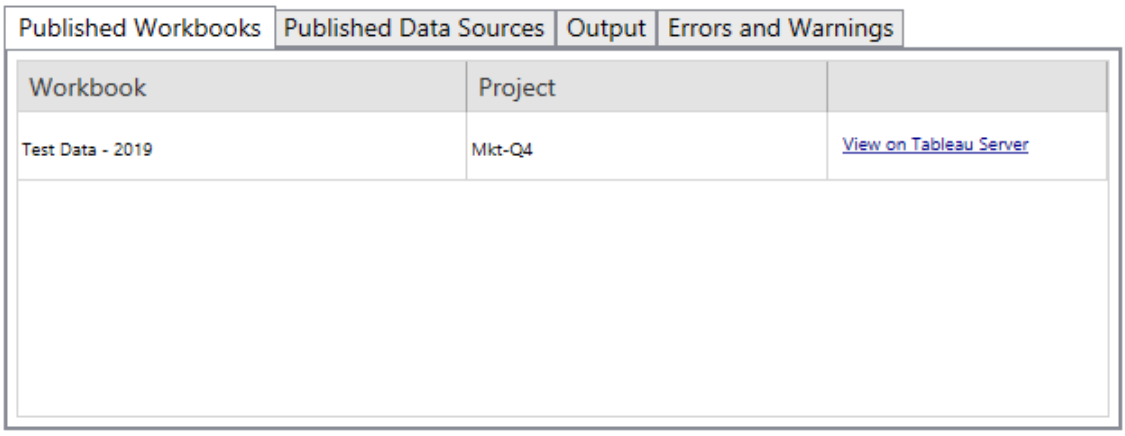


Your migration plan will run and a status bar displays for the overall plan progress and each workbook being sent to the destination server.

When the plan finishes running, you can click the tabs at the bottom of the screen for more information about the migration.

## Published workbooks

**Published Workbooks** details the newly published workbooks and the projects where they were migrated.

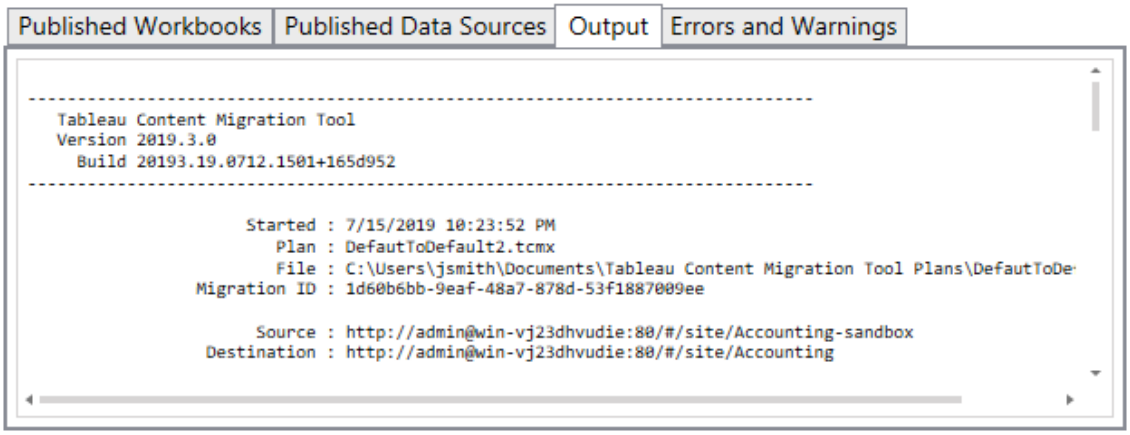


## Published data sources

**Published Data Sources** details the newly published data sources and the projects where they were migrated.

## Output

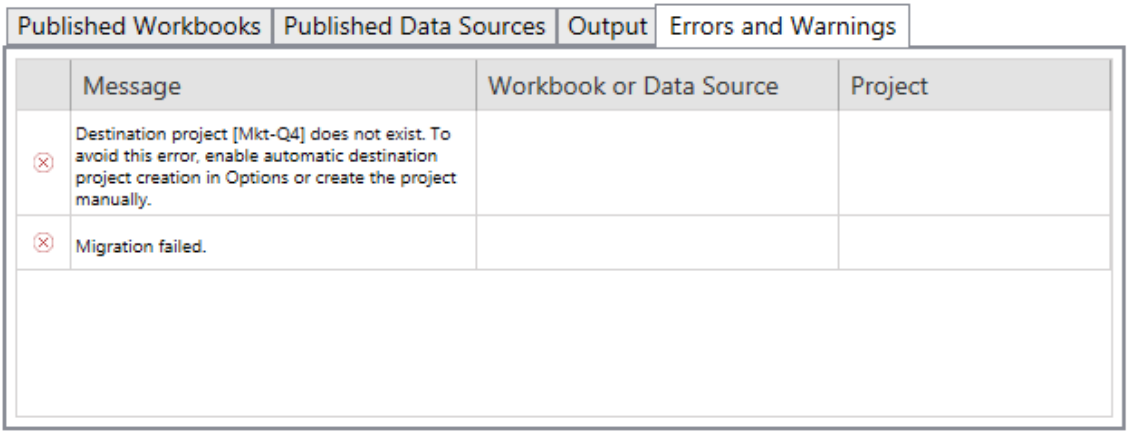
The **Output** tab details the migration log of your plan.



You can save this log by clicking **Save Log**.

## Errors and warnings

The **Errors and Warnings** tab highlights any problems that occurred during the migration.



You can correct these and rerun your plan. When you have completed your migration and saved your plan, click **Done** to finish.

Who can do this

Tableau site user with an Explorer role or higher. To migrate content, you must have **View** and **Download/Save a Copy** capabilities for workbooks on the source site and **View** and **Publish** capabilities for target projects on the destination site. For more information, see Permissions.

Migration Limitations

There are certain limitations to migrations when using the Tableau Content Migration Tool. Before creating your migration plan, review the sections below to learn about version compatibility and content that will not be migrated.

Compatibility with Tableau content

The Content Migration Tool supports migrating workbooks and published data sources saved in the eight most recent versions of Tableau. Workbooks and published data sources saved before version 2018.1.x are not supported by CMT. For more information, see Getting Started with Tableau Content Migration Tool.

Migrating content to previous Tableau versions can fail if the content includes features or formats not recognized by the previous version. The Content Migration Tool will tell you if incompatibilities are found, and the migration will fail.

Configurations

The following configurations are not migrated to the destination site when using the Content Migration Tool.

- Users
- Groups
- Site settings (custom logos, view recommendations, etc.)

## Data connections

While you can migrate existing data sources, only data sources that use the connection types in the table below can be changed and modified during migration. For more information, see Data Source Transformations in Migration Plans: Workbooks and Migration Plans: Published Data Sources.

| | | |
|---|---|---|
| Actian Matrix | Google Drive | Pivotal Greenplum Database |
| Actian Vectorwise | HortonWorks Hadoop Hive | PostgreSQL |
| Amazon Athena | HP Vertica | Progress OpenEdge |
| Amazon Aurora | IBM DB2 | Salesforce |
| Amazon EMR | IBM Netezza | SAP HANA |
| Amazon Redshift | Map R Hadoop Hive | SAP Sybase ASE |
| Apache Drill | Microsoft Access | SAP Sybase IQ |
| Aster Database | Microsoft Analysis Services | Snowflake |
| Box | Microsoft Excel | Spark SQL |
| Cloudera Hadoop | Microsoft Excel Direct | Statistical File |
| Delimited Text File | Microsoft OneDrive | Tableau Extracts |
| EXASOL | Microsoft SQL Server | Tableau Server Data Sources |
| Firebird | MySQL | Teradata |
| Google Analytics | OData | Text File |
| Google BigQuery | Oracle | Web Data Connector |
| Google Cloud SQL | Oracle Essbase | Other Databases (ODBC) |

Unsupported content

The following content is not migrated to the destination site when using the Content Migration Tool and will require additional configuration.

| Content | Action required |
| --- | --- |
| Ask Data lenses | Users must recreate Ask Data lenses on the destination site. For more information, see Create Lenses that Focus Ask Data for Specific Audiences. |
| Collections | Users must recreate collections on the destination site. For more information, see Collections in Tableau Desktop help. |
| Comments | Users must re-add comments to views on the destination site. For more information, see Comment on Views in Tableau Desktop help. |
| Custom views | Users must recreate custom views on the destination site. For more information, see Use Custom Views in Tableau Desktop help. |
| Data roles | Users must recreate data roles on the destination site. For more information see Use Data Roles to Validate your Data in Tableau Prep Builder help. |
| Data source certifications | If you have the following site roles and capabilities, you can certify data sources on the destination site.<br>• Site Administrator Creator<br>• Creator or Explorer (can publish) with Project Leader capability on the project containing the data source<br>For more information, see Use Certification to Help Users Find Trusted Data. |
| Data-driven alerts | Users must recreate data-driven alerts for dashboards and views on the destination site. After data-driven alerts are created, anyone with access to the view can add themselves to existing alerts. |

| | |
|---|---|
| | For more information, see Send Data-Driven Alerts from Tableau Cloud or Tableau Server in Tableau Desktop help. |
| Descriptions for workbooks and data sources | If you own the content item or have the appropriate permissions, you can edit the item's description on the destination site. For more information, see Add or edit descriptions in Tableau Desktop help. |
| Embedded credentials | For security purposes, Tableau Server removes embedded credentials from data sources during the download process.<br>• To include embedded credentials when migrating from Tableau Server to Tableau Cloud, use the Migrate Embedded Credentials for Workbooks and Migrate Embedded Credentials for Data Source publish options. For more information, see Migrate Workbooks and Data Sources with Embedded Credentials.<br>• To include embedded credentials when publishing to Tableau Server sites, use the Set Connection Info data source transformation. For more information, see Migration Plans: Published Data Sources.<br>**Note:** CMT does not support embedded credential migration for OAuth connections. To migrate OAuth credentials, use the Set Connection Info data source transformation. |
| External assets | Customized attributes for external assets are not migrated to the destination site. For example, tags, certifications, data quality warnings, descriptions, permissions, user contacts, tables, and columns must be recreated. For more information, see Manage Permissions for External Assets. |
| Extract refresh schedules | Extract refresh schedules cannot be migrated to Tableau Cloud destination sites. To refresh data on Tableau Cloud, you can run extract refreshes manually or create new extract refresh schedules. For more |

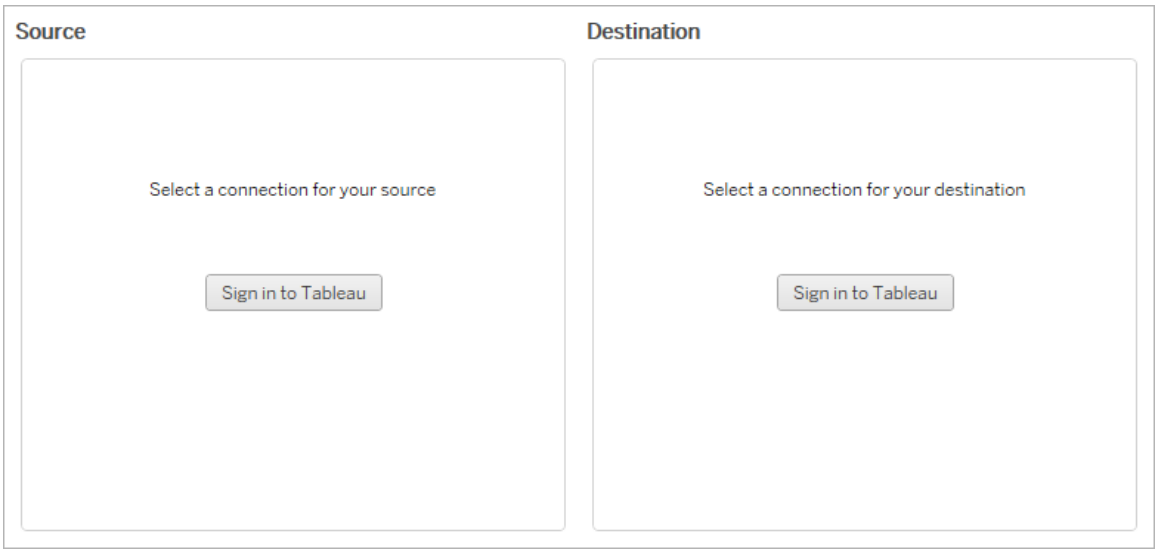
| | |
|---|---|
| | information, see Schedule Refreshes on Tableau Cloud. |
| Favorites | Users must reselect their favorite content on the destination site. For more information, see Mark Favorites in Tableau Desktop help. |
| Flows | To run flows on a schedule, users must republish flows to the destination site with Tableau Prep. For more information, see Publish a Flow to Tableau Server or Tableau Cloud in Tableau Prep help. |
| Incremental extract refreshes | Incremental extract refreshes are changed to full extract refreshes on the destination site. Users must reconfigure incremental refreshes in Tableau Desktop and publish extracts to the destination site after migration. For more information, see Refresh Extracts in Tableau Desktop help. |
| Metrics | The historical values for metrics are removed from views, and users must recreate metrics on the destination site. For more information, see Create and Troubleshoot Metrics (Retired). The legacy Metrics feature was retired in February 2024 for Tableau Cloud and in Tableau Server version 2024.2. For more information, see Create and Troubleshoot Metrics (Retired). |
| Revision history | To migrate previous versions of workbooks to the destination site, users must download the versions they wish to keep and republish the workbook to the destination site. For more information see Work with Content Revisions in Tableau Desktop help. |
| Subscriptions | Users must resubscribe to views and workbooks on the destination site. For more information, see Create a Subscription to a View or Workbook. |
| Thumbnails for workbooks and views | Workbooks and views that are migrated using the Content Migration Tool will retain their original thumbnails, even if the migration plan includes transformations that result in the views being rendered differently (for example, if data connections change).<br><br>To update thumbnails, edit the workbook or view on the destination site |

| | |
|---|---|
| | and re-save it. For more information, see Edit Tableau Views on the Web in Tableau Desktop help. |
| Virtual connections | Users must recreate virtual connections on the destination site. For more information, see Create a Virtual Connection. |

Migration Plans: Sites

The first step when creating a migration plan in the Tableau Content Migration Tool is to sign in to the source and destination sites.

In the Sites section of the planning phase, you'll sign in to the source and destination sites. The permissions of the user credentials you use govern the sites and projects you see when creating a migration plan. You can only migrate content that the user has access to.



Required permissions and licenses

The user account(s) used to sign in to the source and destination sites must have an Explorer role or higher, and the following permissions for the content you want to migrate:

- View
- Download Workbook/Save a Copy
- Optional: Administrator (to select workbooks, to access a user list)

Both the source and destination sites must have Advanced Management capacities. For more information, see About Tableau Advanced Management on Tableau Server.

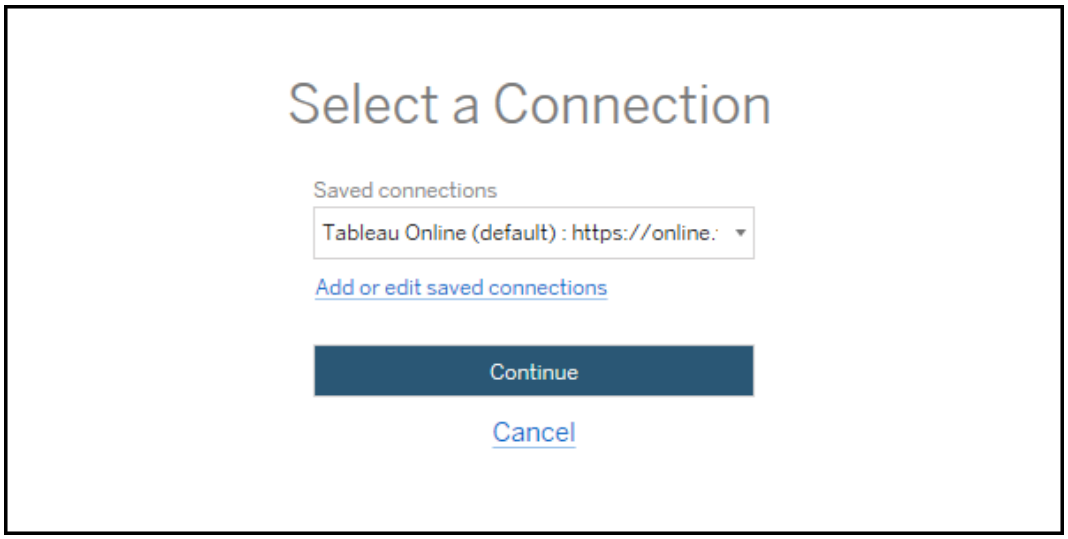
Step 1: Source

Here is the starting point of the migration. Sign in to Tableau Server , then select your *site* to use as the source. Sites are independent silos of workbooks, data, and user lists created within Tableau to group related content for selected users. You can only migrate content from one site at a time.

## Sign in to the source site

Use the steps below to sign in to Tableau Cloud or Tableau Server. For more information about signing in to Tableau Cloud with Single Sign-On and Tableau with MFA, see Sign In to Tableau Cloud.

1. Click **Sign in to Tableau**.
2. In the **Select a Connection** dialog window, select a saved connection and click **Continue**.



If no connections are available, click **Add or edit saved connections** to add a new connection. For more information, see Saved connections.

3. Enter your username and password, and click **Sign In**.

   If your server is configured for SAML or Single Sign-On, you are redirected to the Identity Provider sign-in page to complete the authentication process.

4. Select the site you want to use.

To change the source server or update your site selection, click **Select a different source**.

Step 2: Destination

Repeat the sign-in process for the destination site (the site you are migrating content to).

If you are migrating your workbooks between two projects on the same Tableau site, your sign-in credentials for the source and destination site will be identical (including the server URL and site name).

Saved connections

Using saved connections allow you to quickly sign in to the source and destination sites by creating a reusable connection. When adding a saved connection, you must specify the preferred sign-in method for your site.

As of 2021.2, the Content Migration Tool supports the following sign-in methods:

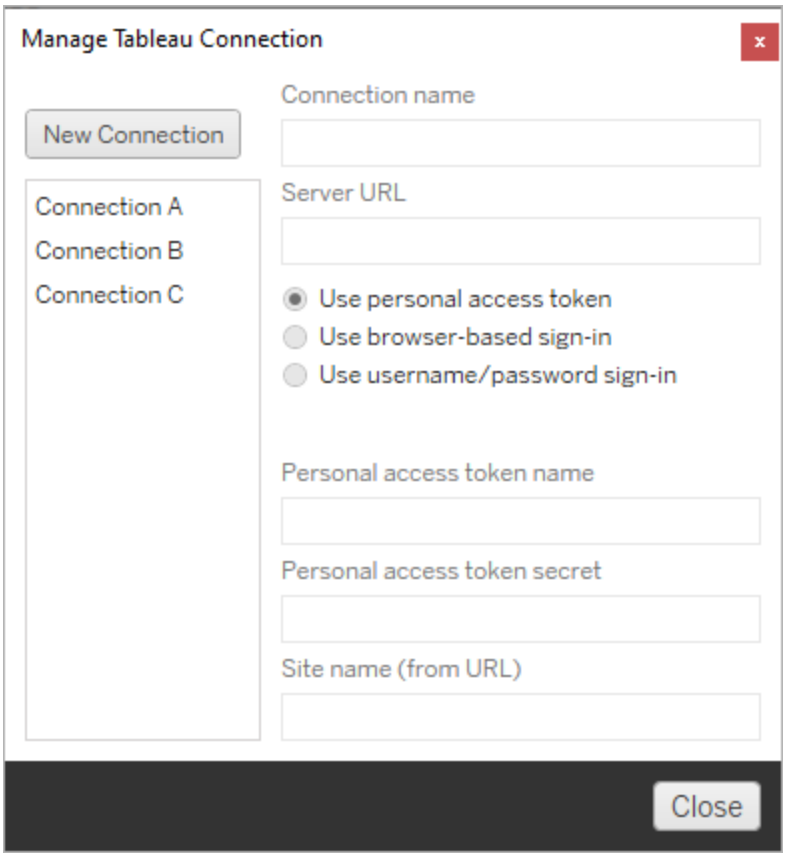
- **Personal access tokens:** Allows users to create long-lived authentication tokens for improved security, auditing, and automation of migration plans. Personal access tokens

let users sign in without requiring interactive login in the Content Migration Tool. For more information, see Personal Access Tokens.

- **Browser-based sign-in:** Users enter their credentials and complete authentication through an embedded web browser. This option may be similar to how you usually authenticate to Tableau.
- **Username and password sign-in:** Users authenticate through the Content Migration Tool instead of an embedded browser window. This option passes credentials to the server using Tableau REST APIs. You can use username and password sign-in to authenticate to migration plans created before version 2020.3 and when troubleshooting issues that prevent the use of browser-based sign-in.

## Add or edit saved connections

A link to **Add or edit saved connections** is displayed at the bottom of the Content Migration Tool, and when signing in to the source and destination sites. Clicking this link will open the **Manage Tableau Connections** window.



Use the steps below to add a saved connection:

1. On the **Manage Tableau Connections** window, click **New Connection**, or select an existing connection to make changes.
2. Enter a **Connection Name** (name to describe your server) and the **Server URL**.

   If you don't include a prefix for the Server URL, the Content Migration Tool will use `http://`.
3. Select the sign-in method for your connection.

   If you're using personal access tokens, see Add saved connections with personal access tokens.
4. Click **Save**.

After you create a saved connection, it's listed in the Select a Connection window next time you sign in to the source and destination sites.

## Add saved connections with personal access tokens

Adding a saved connection with a personal access token requires more information than other sign-in methods. You will need to create a new personal access token on the source and destination sites to begin. Personal access tokens should not be shared between applications. For more information, see Personal Access Tokens.

## Creating personal access tokens

1. In a web browser, sign in to your Tableau site.
2. At the top of the page, click your profile image or initials, and then select **My Account Settings**.
3. Under **Personal Access Tokens**, enter a descriptive name for your token in the **Token Name** field, and then click **Create new token**.
4. In the resulting window, click **Copy to clipboard** and then close the window.
5. Paste the token secret to a file. Store the file in a safe location.

## Adding personal access tokens

1. In the Content Migration Tool, click **Add or edit saved connections**.
2. On the **Manage Tableau Connections** window, enter a **Connection name** and the **Server URL**.

If you are connecting to Tableau Cloud, you must enter the full pod URL of your site. For example, `https://10ay.online.tableau.com`. Your pod is shown in the first portion of the site URL after signing in to Tableau Cloud.

3. Enter the **Personal access token name** and **Personal access token secret**, obtained when creating a personal access token in the previous section.

4. In the **Site name** field, enter the site name as it appears in the URL, without spaces. This is different than the friendly site name. For example, “Site A” would be “sitea” in a browser URL.

5. Click **Save**.

Step 3: Continue to the next step

After successfully signing in to both source and destination sites, click **Next** to continue to the Migration Plans: Source Projects section of the planning phase.

Who can do this

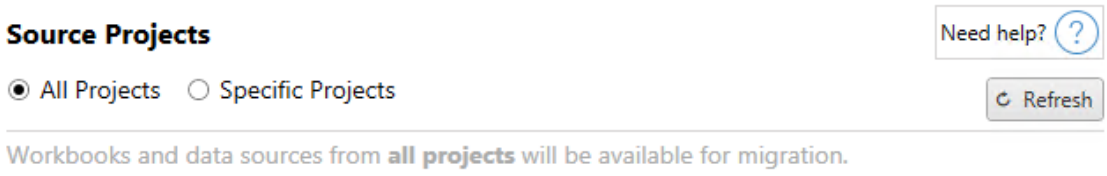
Tableau site user with an Explorer role or higher. To migrate content, you must have **View** and **Download/Save a Copy** capabilities for workbooks on the source site and **View** and **Publish** capabilities for target projects on the destination site. For more information, see Permissions.

Migration Plans: Source Projects

The next step in creating a migration plan in the Tableau Content Migration Tool is to select the source projects. Source projects are the projects the workbooks and published data sources will be migrated from. The projects you choose determine which workbooks are available to migrate in the next step of the migration plan.

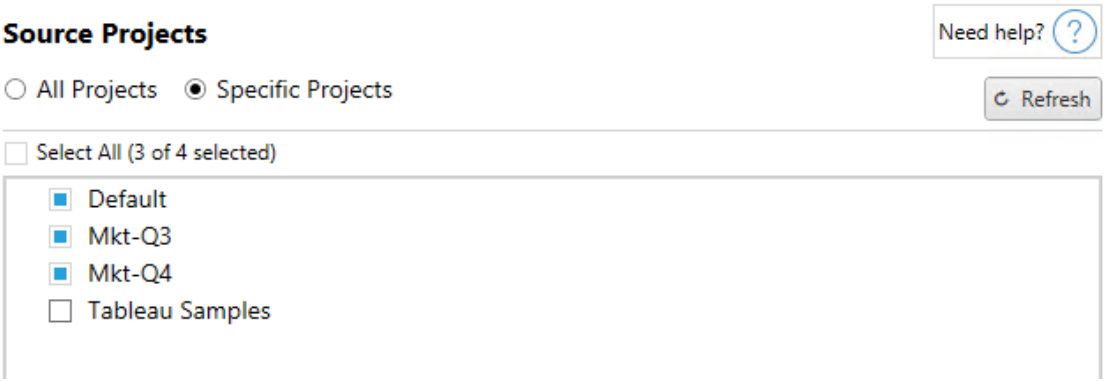
Step 1: Select your source project

There are two options when selecting source projects, **All Projects**, and **Specific Projects**:

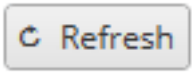


The **All Projects** option selects all projects from the source site you specified in the Servers step. The **Specific Projects** option allows you to select specific projects from the source site.

**Note:** Source projects must contain workbooks or data sources. Content Migration Tool will not migrate empty projects.

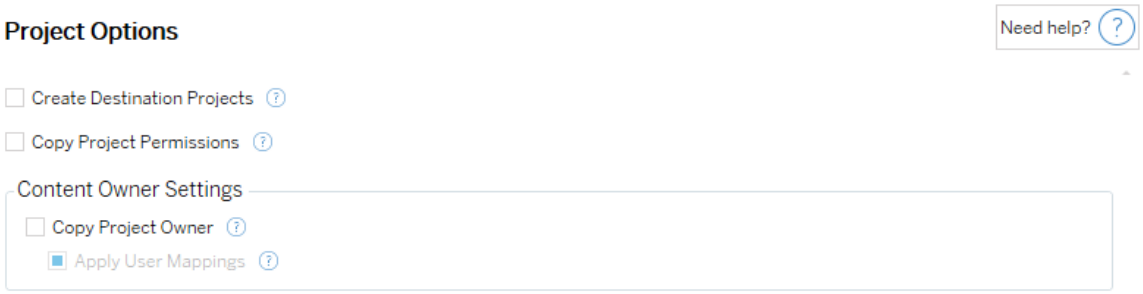


You can select each project individually or use the **Select All** button and then clear selections for the projects you don't want to include. If you make any changes on the source site while on this step, you can use the **Refresh** button to update the projects list.



Step 2: Select project options

Once the source projects are selected, select which project options to apply for the destination location. There are options to create projects that don't exist, in addition to copying project permissions and ownership from the source location. To assign new content ownership based on user mappings, select **Apply User Mappings**.



- **Create Destination Projects**: Automatically create projects that don't exist in the destination location. Content Migration Tool will not create destination projects if the source project is empty or no workbooks or data sources are selected. By default, attempts to migrate to a non-existent project will result in a failed migration.
- **Copy Project Permissions**: Copy source project permissions as closely as possible.
- **Copy Project Owner**: Copy project ownership settings from the source location to assign the project owner.
- **Apply User Mappings**: Apply user mappings to assign content ownership of projects in the destination location. Content ownership won't be applied if the destination project already exists. For more information, see Migration Plans: Permissions and Ownership.

Step 3: Continue to the next step

After selecting the source projects, click **Next** to continue to the Migration Plans: Workbooks section of the planning phase. If you are migrating workbooks between two projects on the same Tableau site, you'll choose your destination project in the next section.

Who can do this

Tableau site user with an Explorer role or higher. To migrate content, you must have **View** and **Download/Save a Copy** capabilities for workbooks on the source site and **View** and **Publish** capabilities for target projects on the destination site. For more information, see Permissions.

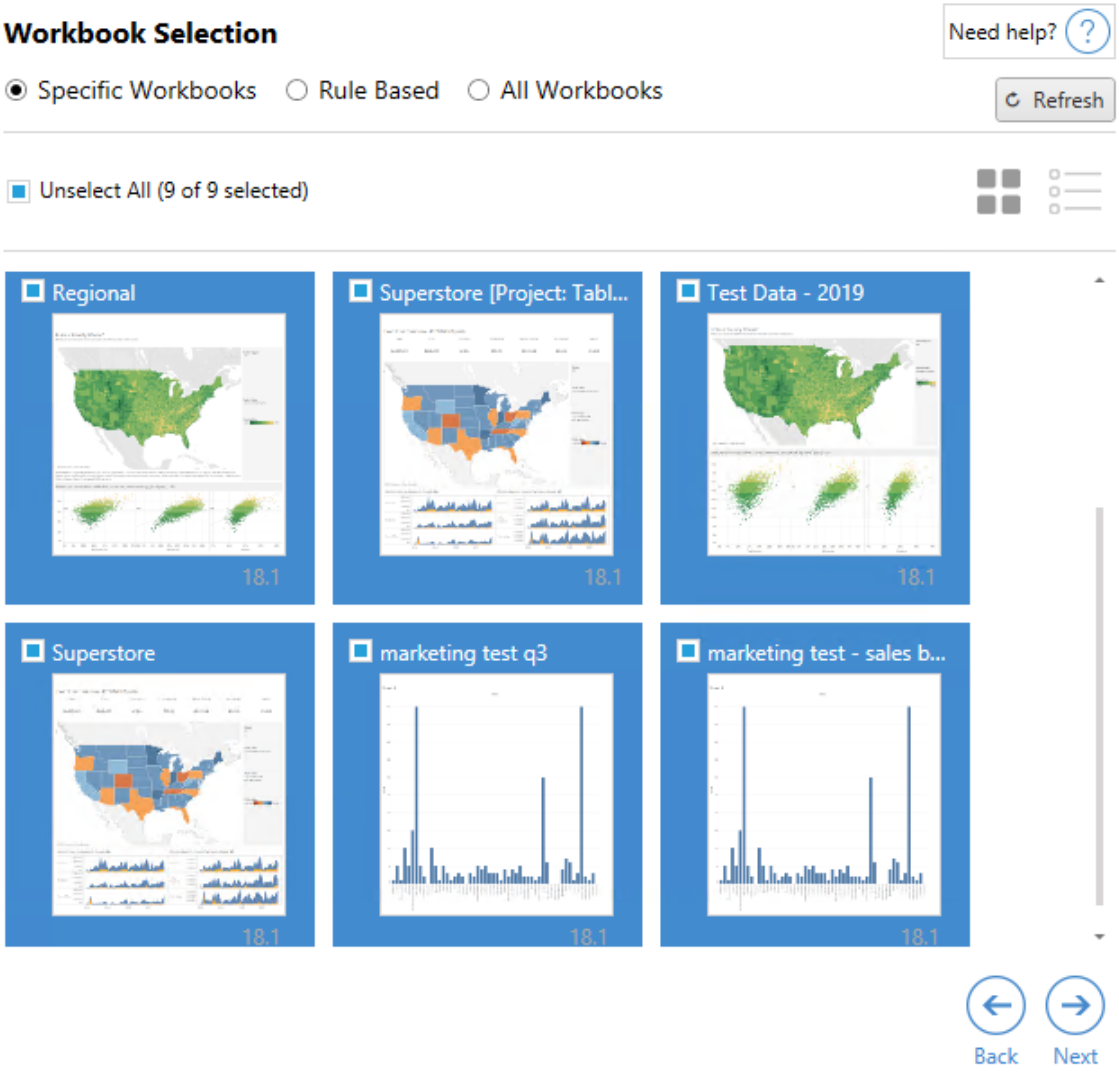
Migration Plans: Workbooks

You have successfully signed in to your source and destination sites and selected projects. The next step is to prepare your workbooks for migration.

> **Note:** If your workbooks or data sources include extracts, be sure you read and understand the information in Migrate Workbooks and Data Sources with Extracts.

Step 1: Workbook selection

All of the workbooks in the source site and selected projects appear on the **Workbook Selection** screen.



If you make any changes to the workbooks in the source site while on this step, you can click **Refresh** to update the workbook listings. There are several different ways to select these workbooks.

## Specific workbooks selection

There are three buttons in the **Specific** section. Any choices from the Basic section will immediately include the specifically selected workbook in the migration plan. Alternately, you can individually select specific workbooks by clicking on each one.

### Select all

The **Select All** button will select or clear selection of all the workbooks in the site. If additional workbooks are added to the site after the plan is saved, they will not be automatically added the next time the plan is used.

### Display:

Thumbnails

The default view shows your workbooks in thumbnail previews to help you differentiate each of them. In this view, mousing over the thumbnail will show previews of the other worksheets and dashboards within that workbook.

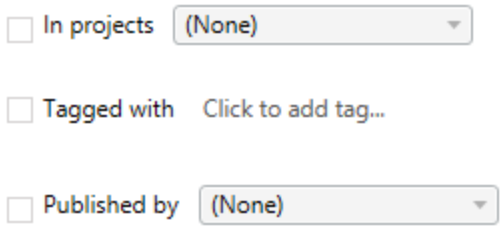
List

The list view is a more succinct listing that also provides additional information, including Workbook Name, Project, Tableau Version, and Last Modified.

Clicking on any of the column headers will sort the workbooks appropriately. Also, mousing over any of the workbooks will also provide a floating preview of the worksheets and dashboards within that workbook. List view is particularly useful if you have a large amount of workbooks in a site.

## Rule Based selection

You can use **Rule Based** selection to choose workbooks based on specific criteria. Rule-based options will create workbook selection criteria to be used when the migration plan is run. Be aware that selecting "all" in any of the **Rule Based** options is different than the **Specific Workbooks** selection. A rule-based "all" selection will always include all workbooks, so any newly added workbooks are included in future migrations.



The **Rule Based** radio button allows you to select workbooks by using the following options:

### Workbooks in projects

This menu allows you to select workbooks from specific projects.

### Workbooks tagged with

This menu allows you to select workbooks by their tags.

### Workbooks published by

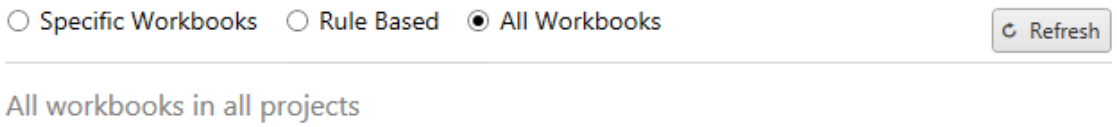
This menu allows you to select workbooks by their author.

With each option, you can select individually or multiple by clicking on the option next to each entry. All selected workbooks will appear in the **Selection Description** box.

## All Workbooks selection

The last option is to select the **All Workbooks** radio button, which selects all workbooks in all projects in the site.

Using the **All Workbooks** radio button is different than selecting all of the workbooks using the **Specific Workbook** method because it will use every workbook in the source site each time the migration plan is used in the future.

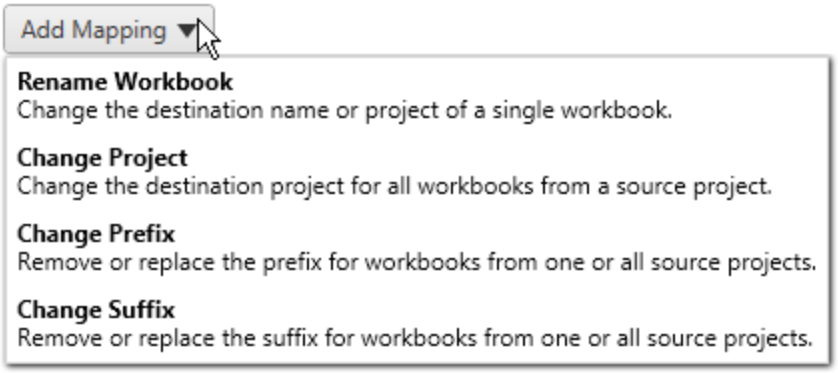


When you're satisfied with your workbook selections, click **Next**.

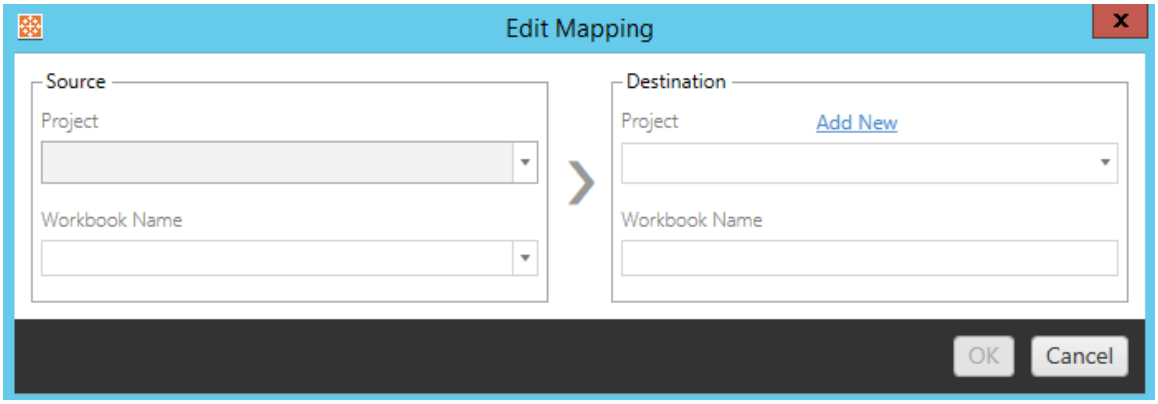
Step 2: Workbook mapping

You can now map your selected workbooks from the source file to the destination file. Mapping allows you to rename source workbooks as they are migrated and choose different destinations. You can also add mapping to change the project, prefix, or suffix for the workbooks as well. Projects can be added to the Destination in this section as well.

If you make no changes here, then the selected workbooks will simply be migrated with the same name and into the same project as the source. If you have not defined projects in your destination site, then they will be migrated into the Default project. To add workbook mapping click the **Add Mapping** button. The following options will appear in the mapping area.

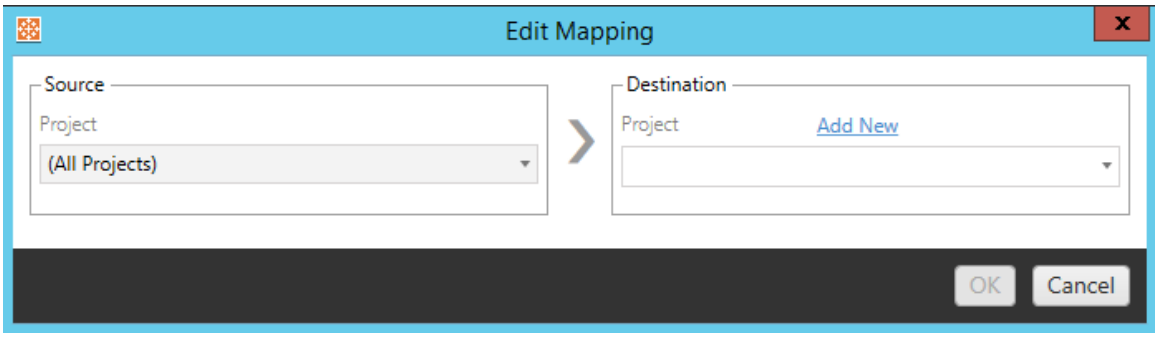


## Rename workbook



This transformation allows you to filter by the **Source** project and select the desired workbook (s) to rename. In the **Destination** field, select which project you would like the workbook to be directed to and enter the desired name.

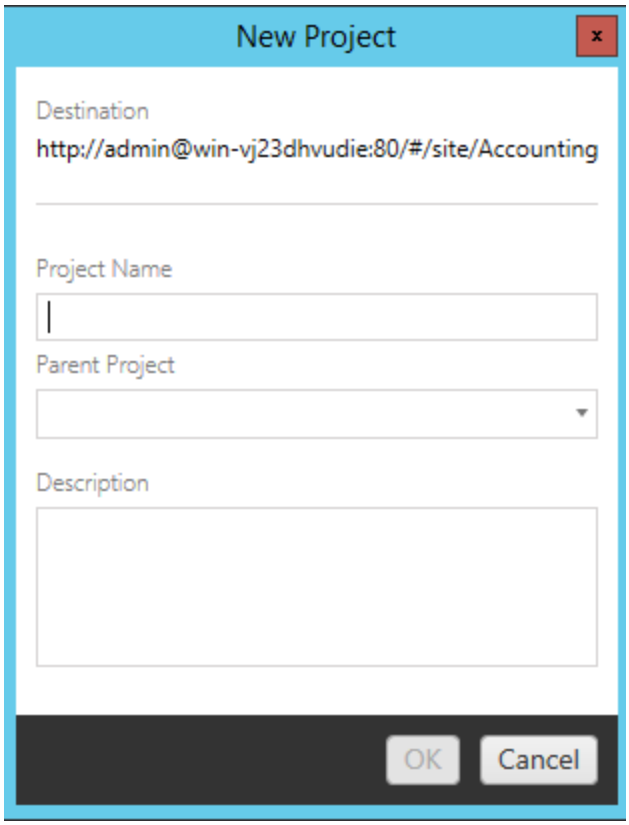
## Change project



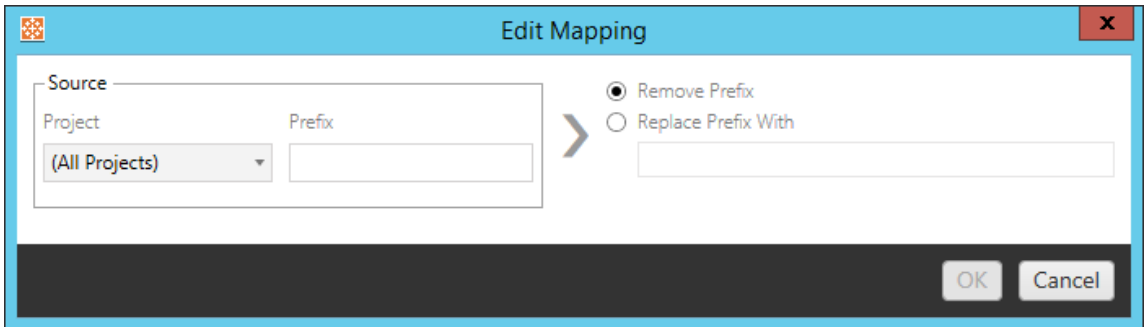
By default, the workbooks are migrated to the same project in the destination. This mapping allows you to change the destination project for all workbooks from a source project.

## Add project

When renaming the workbook or changing the project, the **Add New** option allows you to create a destination project without having to sign in to the destination site and create the project manually. You can create both projects and nested projects using the **Add New** dialog box.



## Change prefix



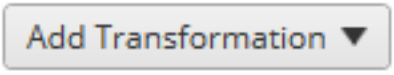
This allows you to remove or replace the prefix for workbooks from one or all source projects.

## Change suffix

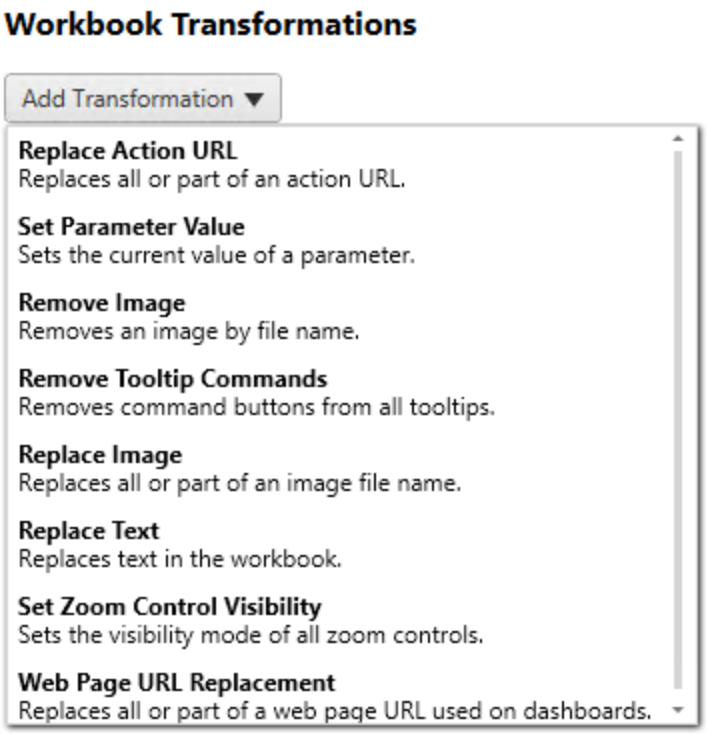
Like the prefix mapping, you can remove or replace the suffix for workbooks from one or all source projects.

Step 3: Workbook transformations

You can change and modify your workbooks by using the Transformation step.

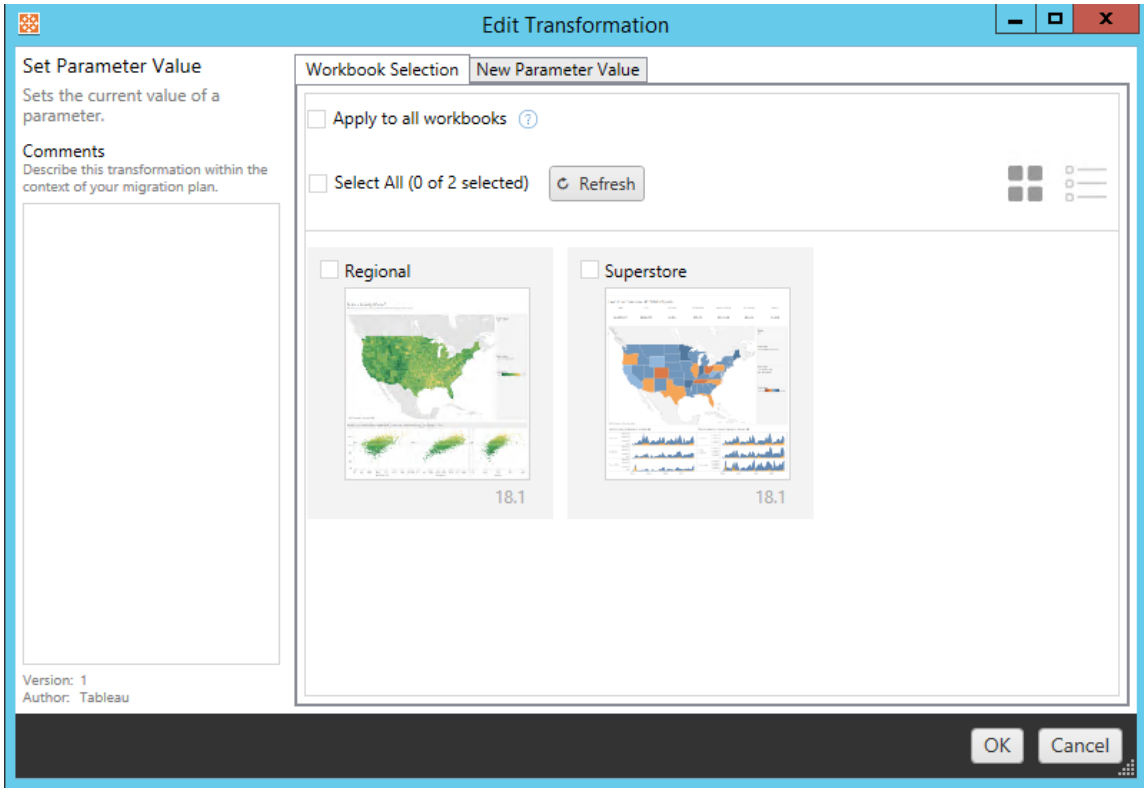


Transformations modify your workbooks in a specified manner. Additional transformations can be included via plug-ins or will be added in future versions of the application. Click on the **Add Transformation** drop-down menu to see the selection of Transformations currently available.

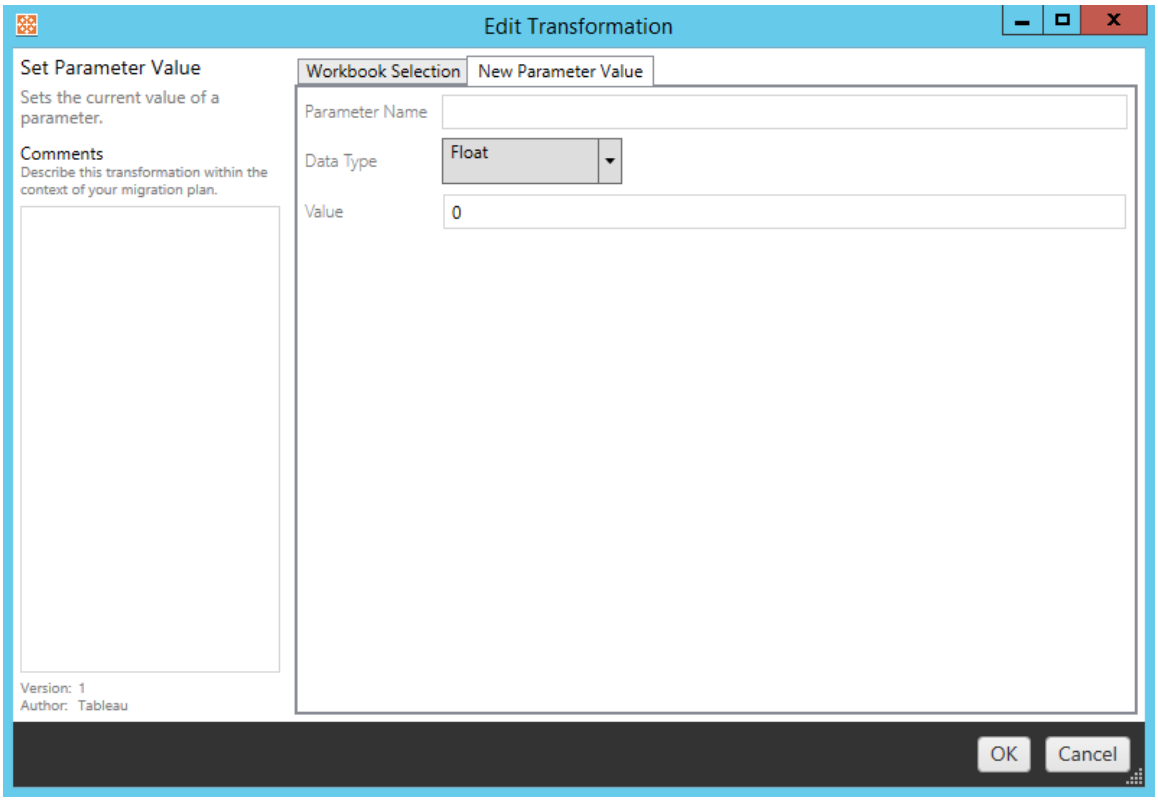


Selecting any of the transformations will bring up the Edit Transformation window, which will allow you to customize it to your selected workbooks. All transformations will be completed in the order that they are listed from top to bottom.

For all of the different types of transformations, there are two basic steps. The first step is to make your selection for the transformation. In this case, select the workbook(s) you want to transform. The selection area is similar to the Workbook Selection section of the Planning phase with all of the features of the Basic selection radio button: **Select/Unselect All**, **Refresh**, **Thumbnail** Display, and **List** Display. At the top of the list, you can select **Select All** workbooks, which is an option to automatically select all workbooks for future transformations. You can also **Refresh** the workbook display window to reflect any changes or updates to the source site.



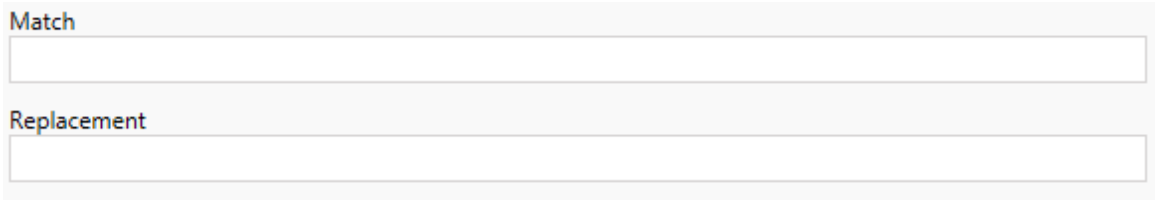
The second step is to use the options tab to enter the specific selections for whichever transformation you select.



Each of the workbook transformations have different values to be entered on the options tab, and the tab will have different names, depending on the transformation you're editing:

## Replace URL action

Replace part or all of a URL action inside the workbook using this transformation. On the options tab, enter the text to be matched and its replacement value. The replacement functionality is intended for URL actions and doesn't check the entire workbook XML.



### Example:

URL: `www.exampledev.com`

Match: `dev`

Replacement: `Prod`

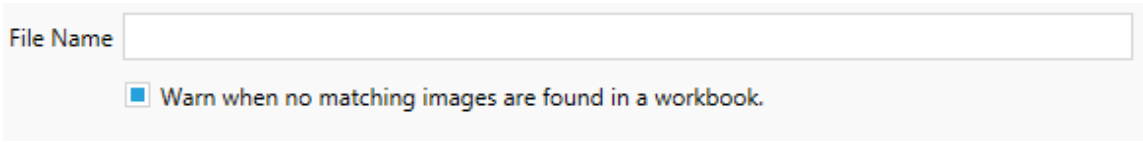
Result: `www.exampleProd.com`

## Set parameter value

Define a new parameter. On the options tab, enter the name of the Parameter, the data type from the drop-down menu, and the value.

## Remove images

Remove any images (such as a watermark) in the selected workbooks by entering in the file name on the options tab. There is an additional check box to receive a warning during migration if no image is found.

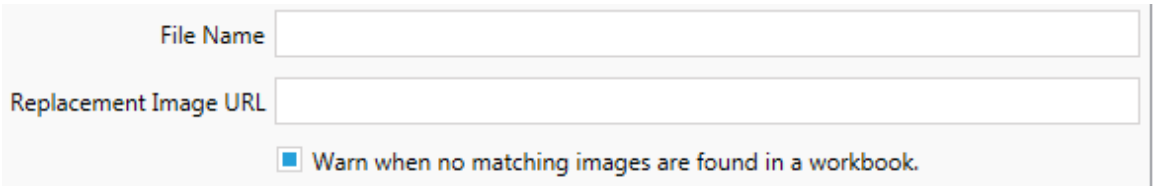


## Remove tooltip commands

Remove all of the tooltip commands from the selected workbooks. There are no additional options to define for this transformation.

## Replace images

Replace images embedded in the selected workbooks. On the options tab, enter the file name of the current image and the replacement image. You can replace images using a local file path or URL.



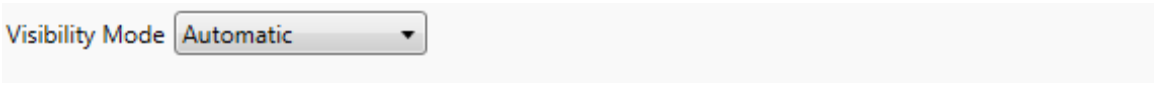
### Example:

File Name: `image.png`

Replacement Image URL: `https://www.exampledev.com/replacementImage.png`

## Zoom control visibility

Set the visibility mode from the drop-down menu: **Automatic**, **Show on Hover**, or Hide on the options tab.



## Web page URL replacement

Replace part or all of a web page URL used on dashboards using this transformation. On the options tab, enter the text that should be matched and its replacement value.

### Example:

URL: `www.exampledev.com`

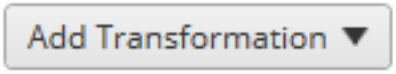
Match: `dev`

Replacement: `Prod`

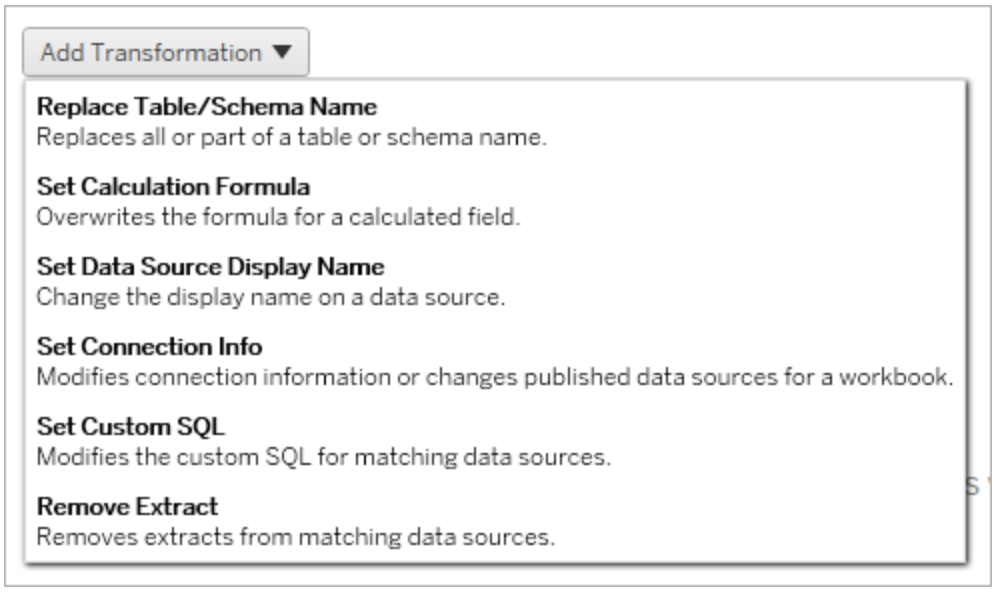
Result: `www.exampleProd.com`

Step 4: Data source transformations

The next step in planning your workbooks for your enterprise migration are your data source transformations. It is similar in function to the Workbook Transformations step. These are for data sources that are packaged within the workbooks. Published data sources are handled in a different step in the process.

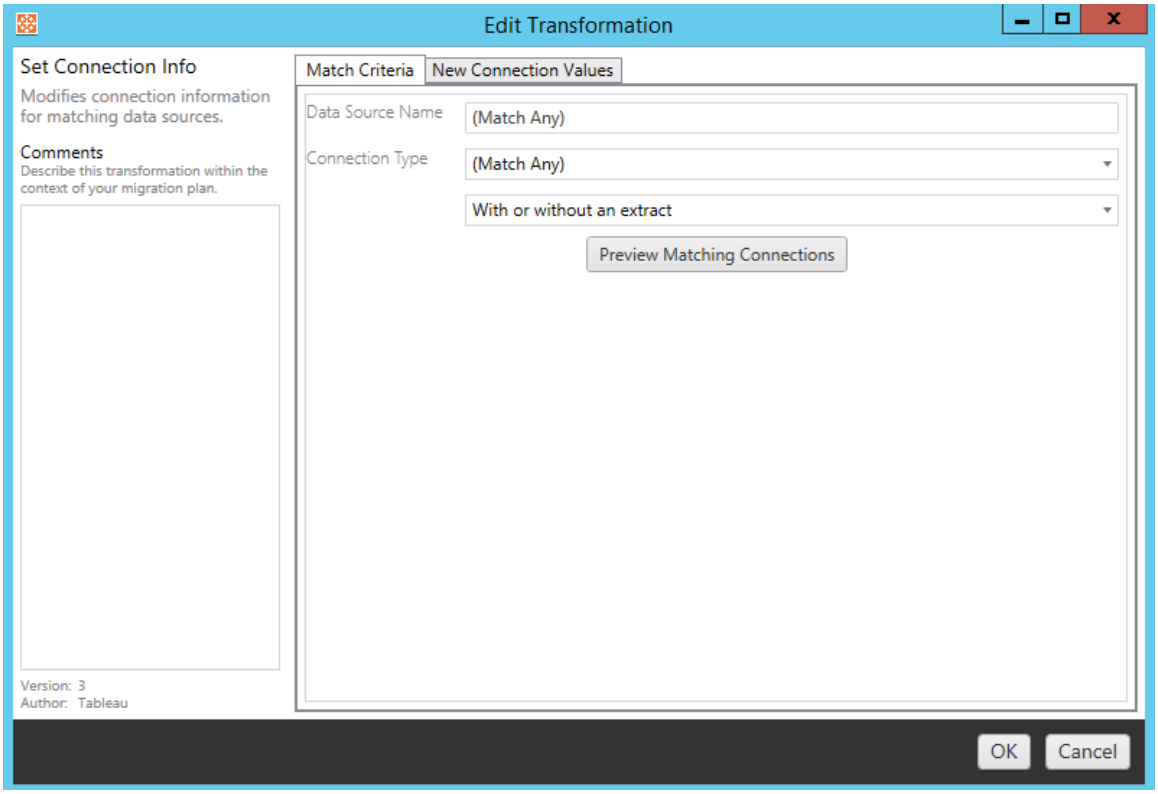


Click on the **Add Transformation** drop-down menu and the following options will appear:

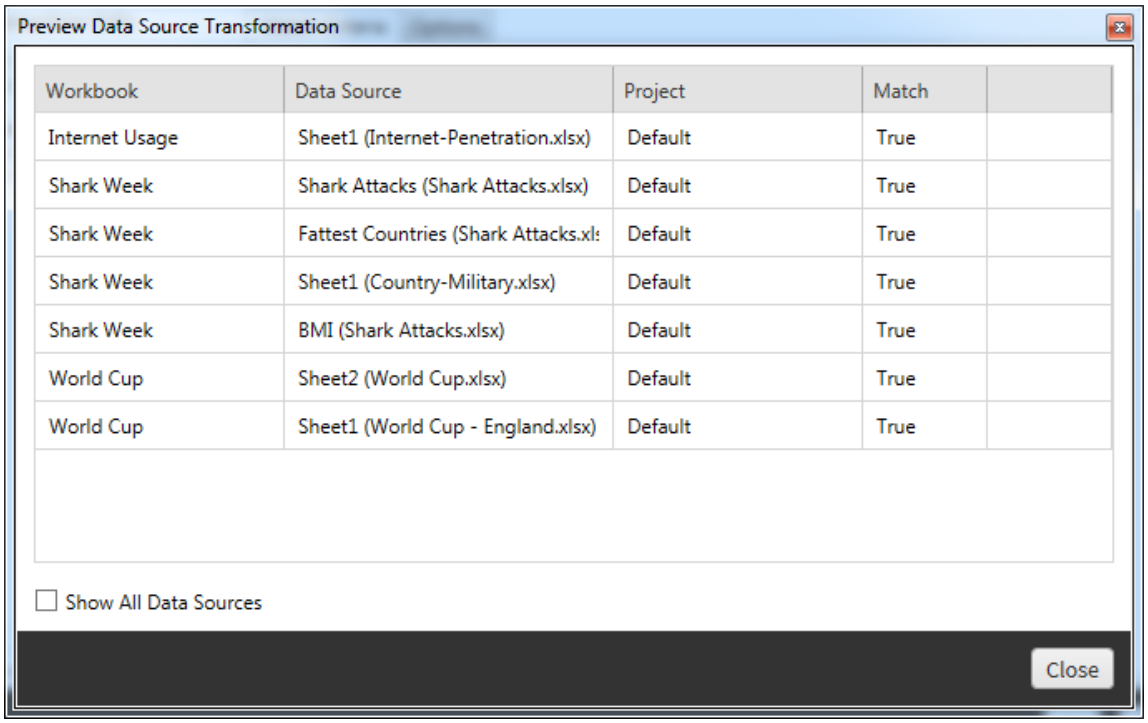


Selecting any of the data source transformations will bring up the Edit Transformation window, which will allow you to customize it to your selected data sources. All transformations will be completed in the order that they are listed from top to bottom.

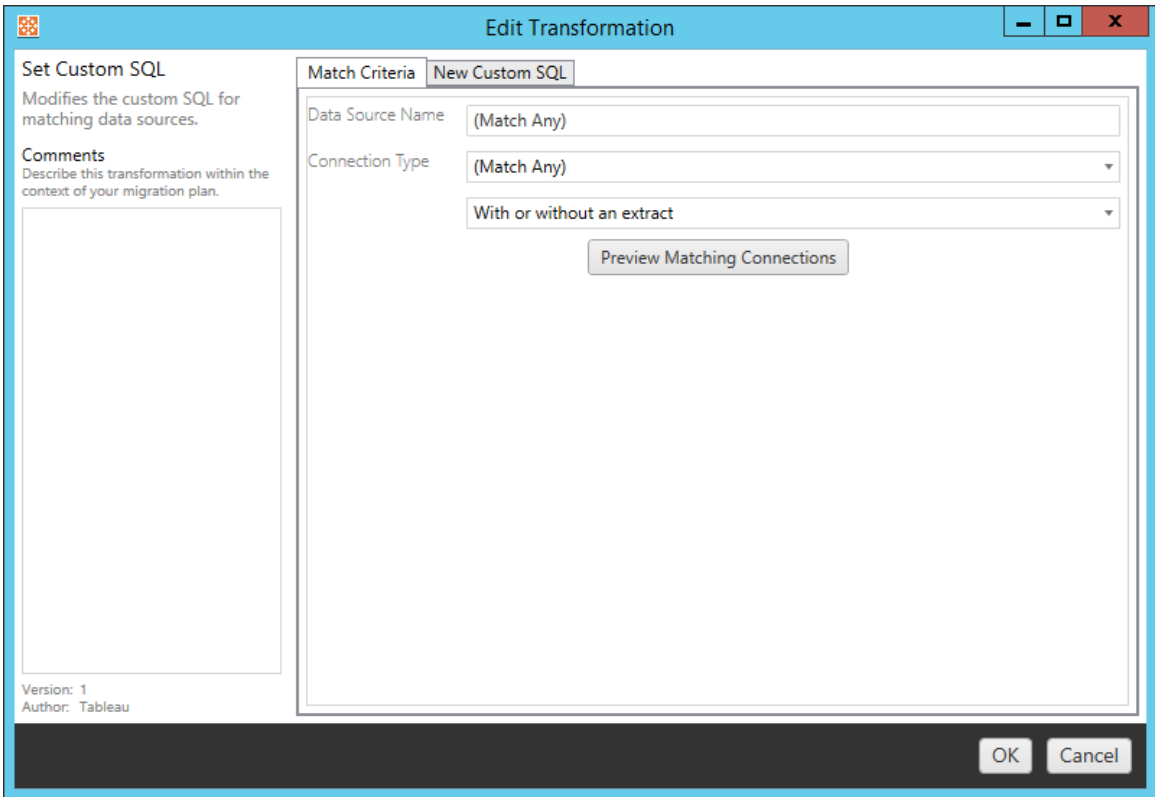
For all of the different types of data source transformations, there are two basic steps. The first step is to enter in the match criteria for the desired data source. Depending on which connection type you select, more fields will appear on the **Match Criteria** tab.



Click on the **Preview Source Connections** to find any connections that match the criteria entered.



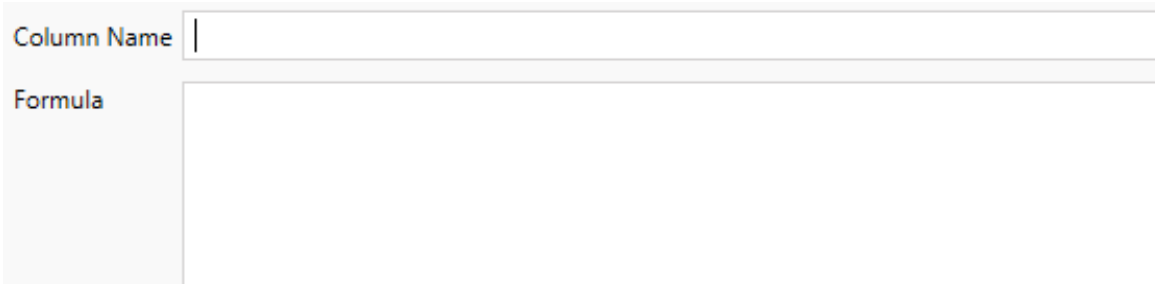
The second step is to use the options tab to enter the specific selections for whichever transformation you select.



Each of the data source transformations have different values to be entered on the options tab:

## Set calculation formula

On the options tab, you can replace the calculation for a column.



## Set connection info

On the **New Connection Values** tab, enter the authentication method and connection details for the new data source. Depending on which connection type you select, more fields will appear.

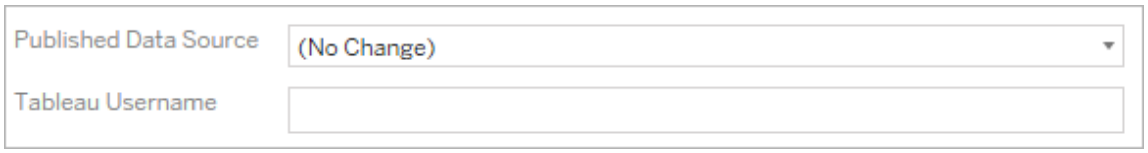
**Change published data sources with CMT**

As of version 2022.1, select the **Tableau Server (Published Data Source)** connection type to change the published data source for a workbook. This can reduce the manual steps required when migrating workbooks between Tableau environments, for example, promoting content from development to production.

To change the published data source, select a data source from the drop-down menu and enter the **Tableau Username** for authentication. The user must exist on the destination site and have the Connect capability for the published data source.

- For file-based data sources, users will access the workbook and see data based on permissions of the specified Tableau user.
- For all other data sources, users are prompted for their own database credentials when the view or workbook loads.

If Tableau Username isn't specified, only users with the Connect capability can see data in the workbook.



## Set custom SQL

On the **New Custom SQL** tab, enter the name of the custom SQL query you want to modify for **Match Query Name**. The query name must match the custom SQL query name from the physical layer of the data source. If these names don't match, the transformation will fail. For more information about data modeling and the physical layer, see The Tableau Data Model.

After entering the query name, enter the desired **Custom SQL** in the text field. Be aware that custom SQL can negatively impact the performance of your workbooks if improperly used.

## Remove extract

There is no options tab for this transformation, simply enter in the **Match Criteria** information and the extract will be removed during migration.

In addition, on each of the transformations you can enter notes in the **Comments** section on the left-hand side of the **Edit Transformation** window.

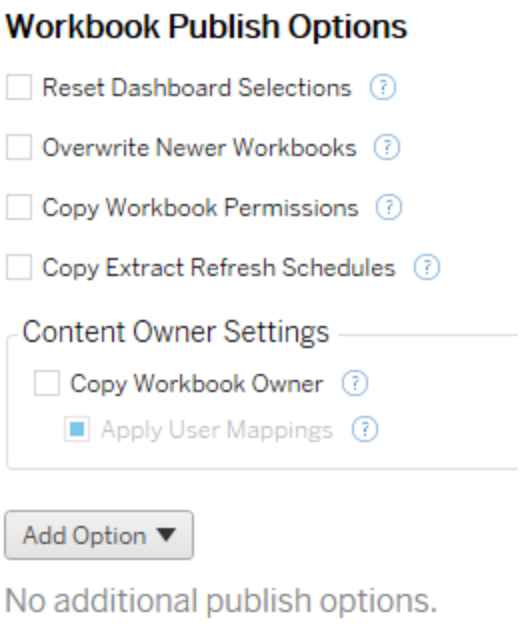
## Apply saved credentials

Deprecated in version 2022.3. Use the Set Connection Info data source transformation instead.

On the options tab, enter the **Tableau Username** and corresponding **Saved Credentials Username** for the data connection. You can only apply saved credentials for existing data connections on the Account Settings page of your Tableau site. For more information, see Manage Saved Credentials for Data Connections.

Step 5: Publish options

The final step in the Workbooks phase is to select publish options and create transformations for tags, extract refresh schedules, and permissions.



## Reset dashboard selections

This option deselects all objects on dashboards.

## Overwrite newer workbooks

If checked, a workbook will be migrated even if it will overwrite a workbook that has been created at the same time or more recently than the moved workbook

## Copy workbook permissions

When selected, the migration tool will attempt to match source workbook permissions as closely as possible.

## Copy extract refresh schedules

When selected, the migration tool will attempt to set the destination workbook extract refresh schedule(s) to schedules matching the source's name.

**Note:** Extract refresh schedules cannot be created in Tableau Cloud. This option is not available if the destination is a Tableau Cloud site. For more information, see Migration Limitations.

### Copy embedded credentials for workbooks

Copy the embedded credentials for data sources embedded in workbooks. Only available when migrating from Tableau Server to Tableau Cloud sites. For more information, see Migrate Workbooks and Data Sources with Embedded Credentials.

**Note:** CMT does not support embedded credential migration for OAuth connections. To migrate OAuth credentials to the destination site, use the Set Connection Info data source transformation.

### Copy workbook owner

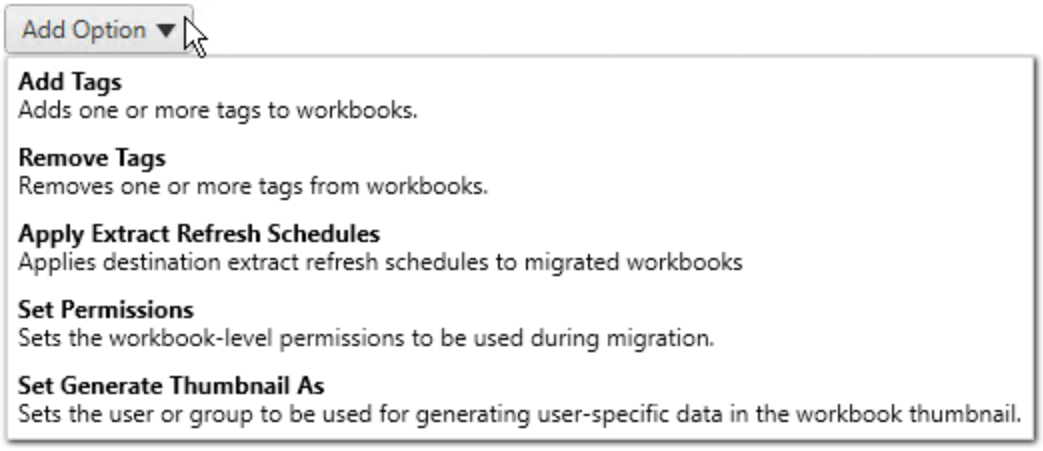
Copy workbook owner settings from the source location to assign the workbook owner. If unselected, the Content Migration Tool user is given ownership of the workbook in the destination location.

### Apply user mappings

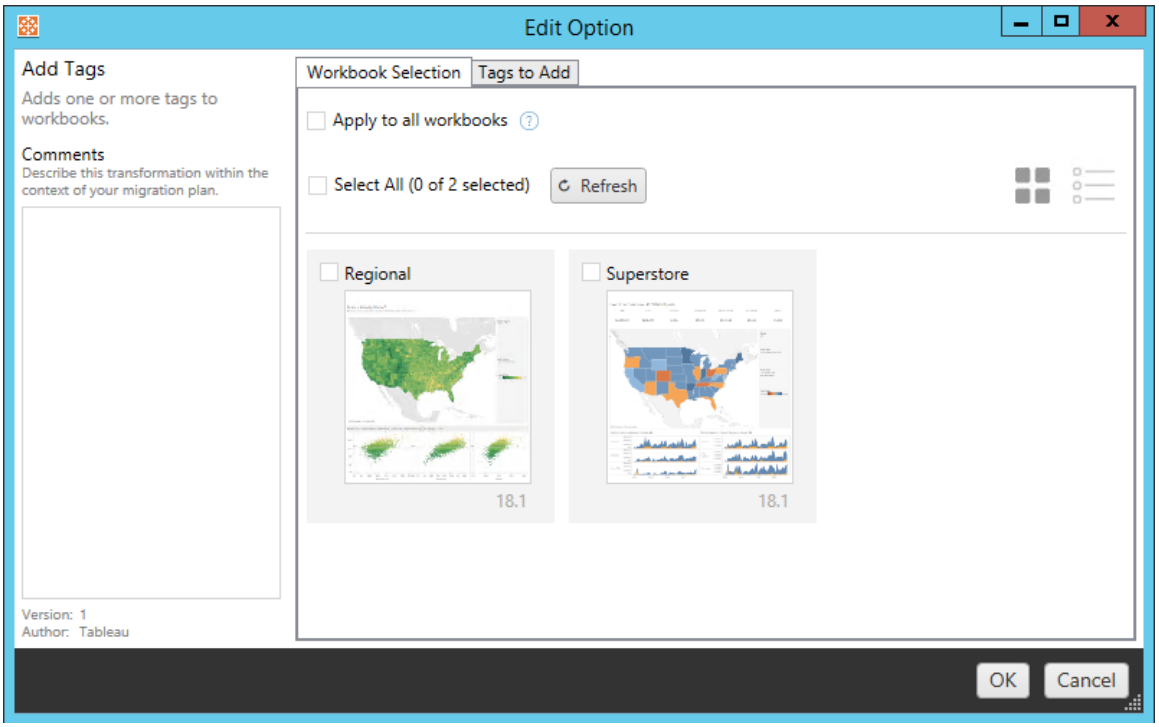
Apply user mappings to assign content ownership. Select this option if there are differences in username syntax in the destination location. For more information, see Migration Plans: Permissions and Ownership.

## Add option

Click on the **Add Option** drop-down menu for the different types of transformations you can add:



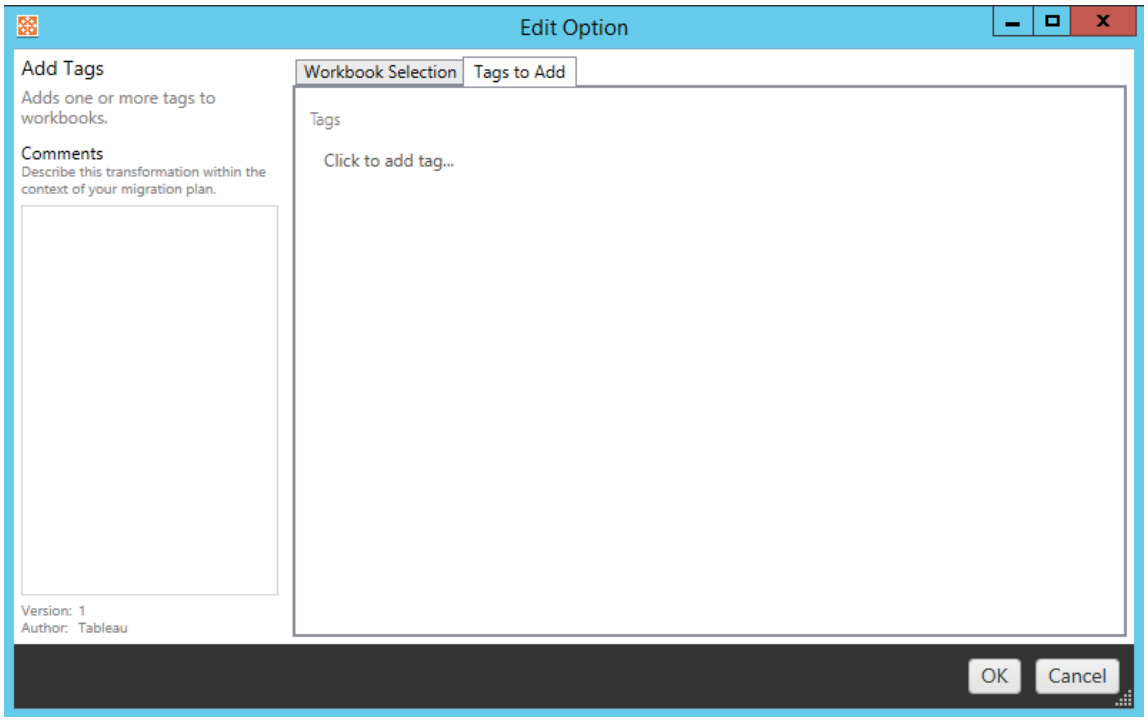
For all of the different types of transformations, there are two basic steps. The first step is to make your selection for the transformation. In this case, select the workbook(s) you want to transform. The selection area is similar to the Workbook Selection section of the Planning phase with all of the features of the Basic selection radio button: **Select/Unselect All**, **Refresh**, **Thumbnail Display**, and **List Display**. At the top of the list, you can select **Select All** workbooks, which is an option to automatically select all workbooks for future transformations. You can also **Refresh** the workbook display window to reflect any changes or updates to the source site.



The second step is to use the options tab to enter the specific selections for whichever transformation you select. **Note:** The options tab will have different names, depending on which transformation you are editing.

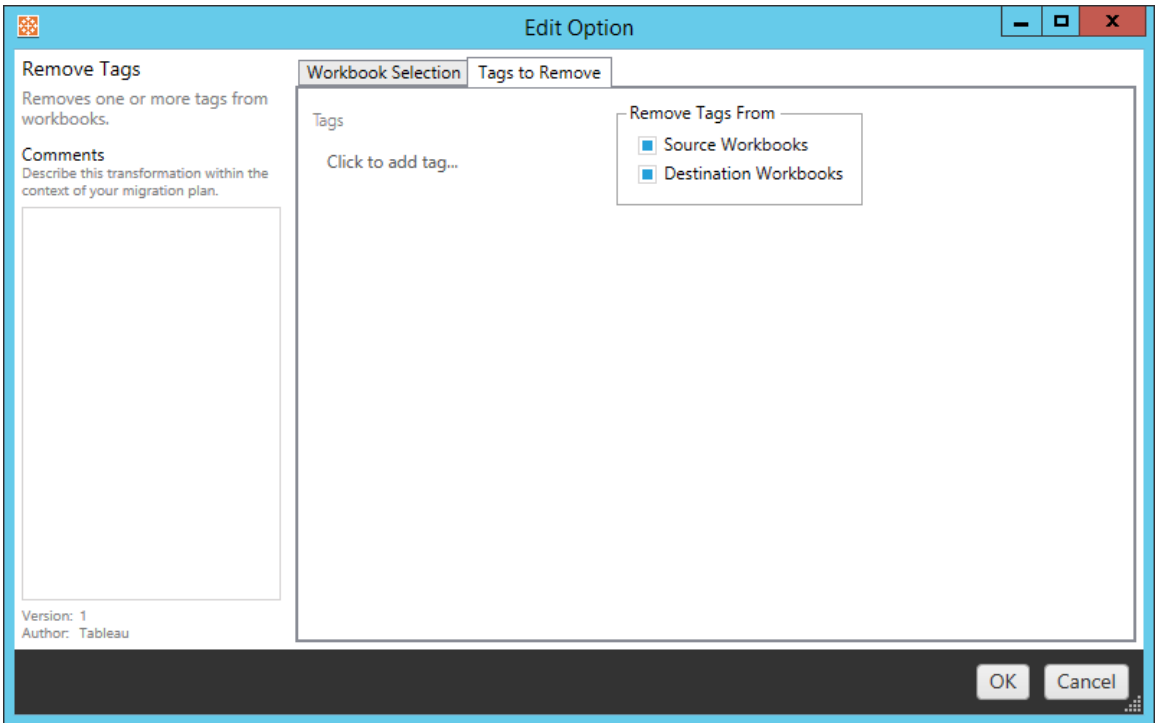
## Add tags

This allows you to add one or more tags to the workbook. If you hover your mouse over a previously entered tag, a blue “X” will appear to allow deletion.



## Remove tags

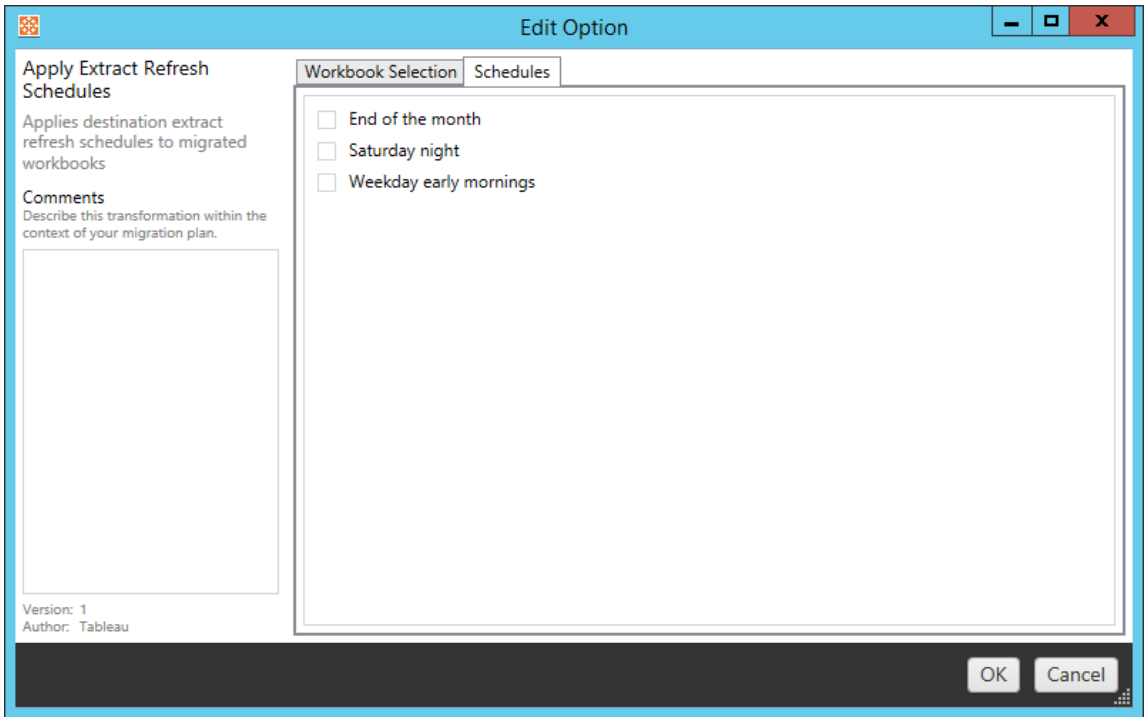
This allows you to add one or more tags to the workbook. If you hover your mouse over a previously entered tag, a blue “X” will appear to allow deletion. You can also choose to remove the tag from the source or destination workbooks.



## Apply extract refresh schedules

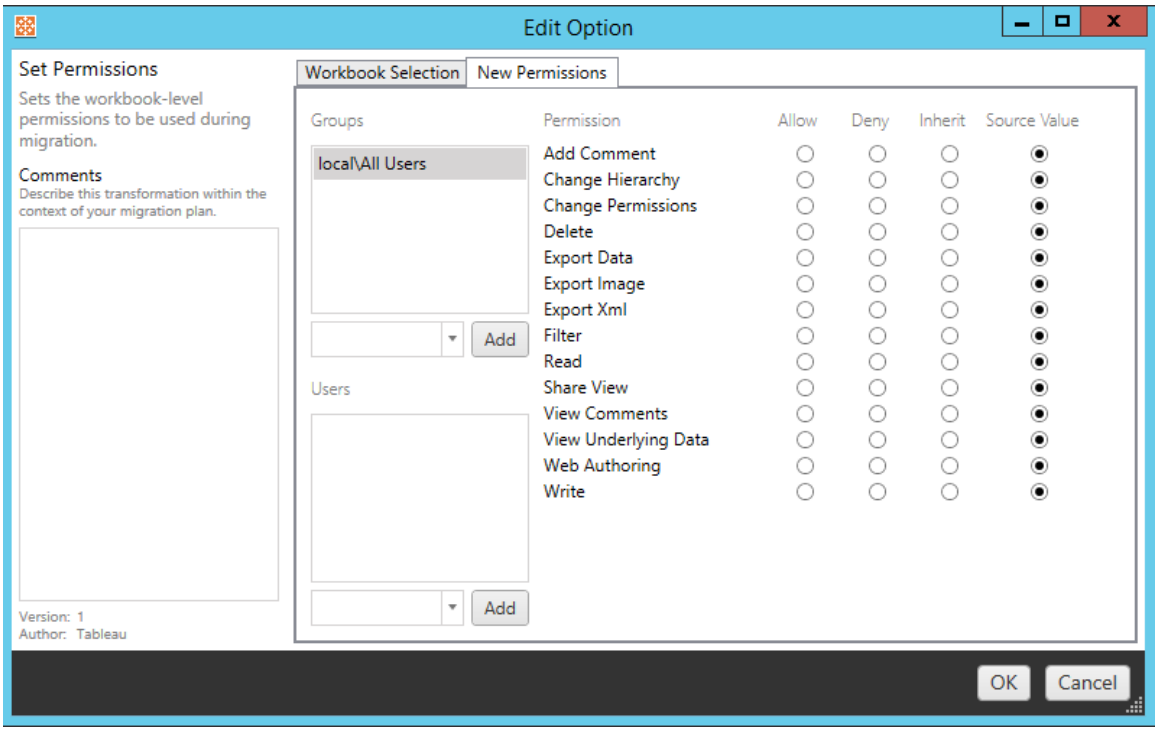
Here you can apply destination extract refresh schedules to migrated workbooks. The list of schedules generated are from the destination.

> **Note:** Extract refresh schedules cannot be created in Tableau Cloud. This option is not available if the destination is a Tableau Cloud site. For more information, see Migration Limitations.



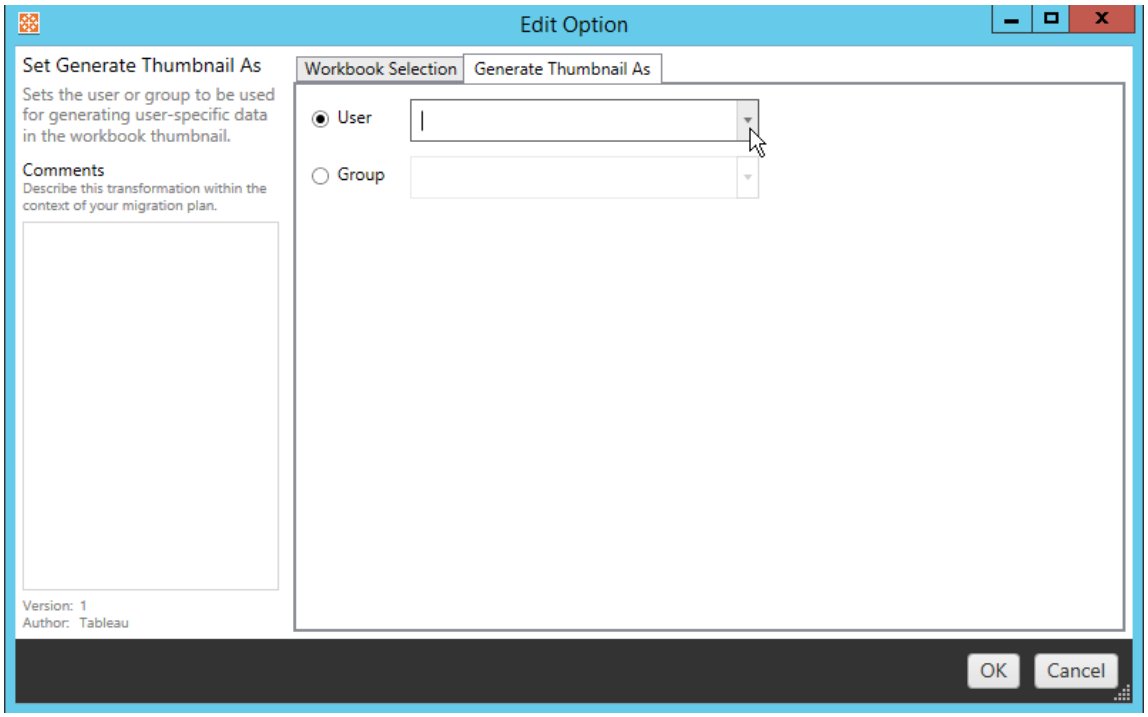
## Set permissions

This transformation is to edit the permissions for the selected workbooks. Enter in a Group or User and then click **Add**. Adjust the permissions as desired. The four different options are to **Allow** the permission, **Deny** the permission, **Inherit**, or to keep the **Source Value**.



## Set **Generate Thumbnail As**

This allows you to set the **User** or **Group** to be used for generating user-specific data in the workbook thumbnail after being migrated. Each option has a drop down to select the desired user or group.



Step 6: Continue to the next step

After selecting your workbooks and preferences, click **Next** to continue to the Migration Plans: Published Data Sources section of the planning phase.

Who can do this

Tableau site user with an Explorer role or higher. To migrate content, you must have **View** and **Download/Save a Copy** capabilities for workbooks on the source site and **View** and **Publish** capabilities for target projects on the destination site. For more information, see Permissions.

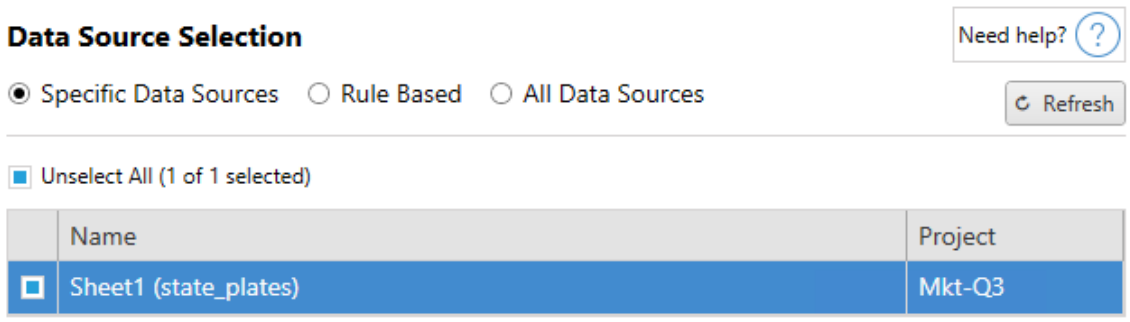
Migration Plans: Published Data Sources

The next step of creating a migration plan in the Tableau Content Migration Tool is to select, map, and add any transformations to your published data sources. The process is very similar to the Workbooks step of the planning phase, particularly the data source mapping step.

> **Note:** If your workbooks or data sources include extracts, be sure you read and understand the information in Migrate Workbooks and Data Sources with Extracts.

Step 1: Selection

Starting the Published Data Sources phase of the migration plan, you'll select any data sources you want to include in the migration plan:

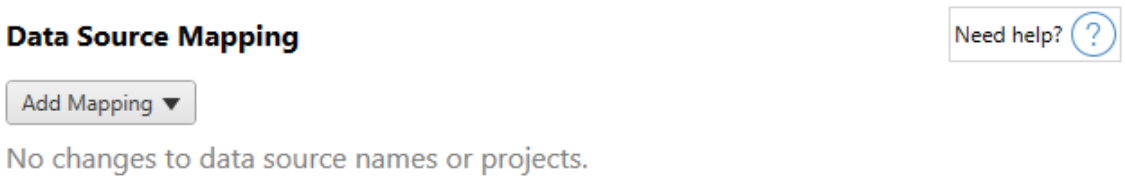


The data sources will only be selected at the moment of migration. You have two methods of selection. Use **Specific Data Sources** to choose one or more published data sources. Click **Refresh** to reload the list of published data sources available.

The second option is **All Data Sources**, which selects every data source in the source site.

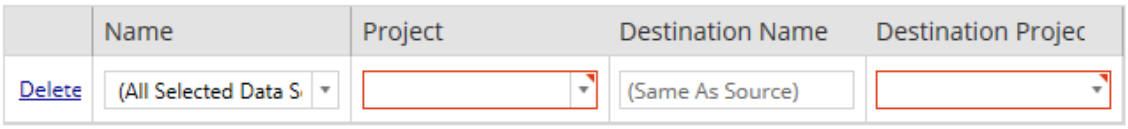
Step 2: Mapping

The next step is to map your source data sources to the new destination. This is similar in functionality to mapping workbooks.



If you make no changes here, then the selected data sources will simply be deployed with the

same name and project as the source. To add data source mapping click **Add Mapping**. The following options will appear in the mapping area.



The entry has the following options:

## Delete

Clicking the **Delete** link will delete this mapping entry.

## Name

Use the **Name** menu to select the data source you wish to map. You can select **(All Selected Data Sources)** to choose all of the data sources.

## Project

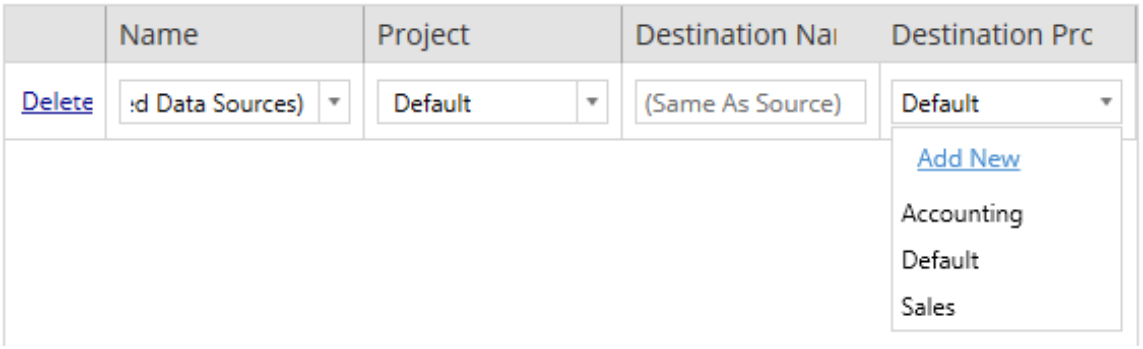
The **Project** is the project of the associated data source names.

## Destination Name

By default, the Content Migration Tool will use the same **Destination Name(Same As Source)**, keeping the original name in the Source file, but you can type in a new name here for the destination folder.

## Destination Project

If your destination projects have already been created on your site, you can choose which project to place your migrated workbooks or click **Add New** to create a new project. You can create different project destinations for individual data sources.

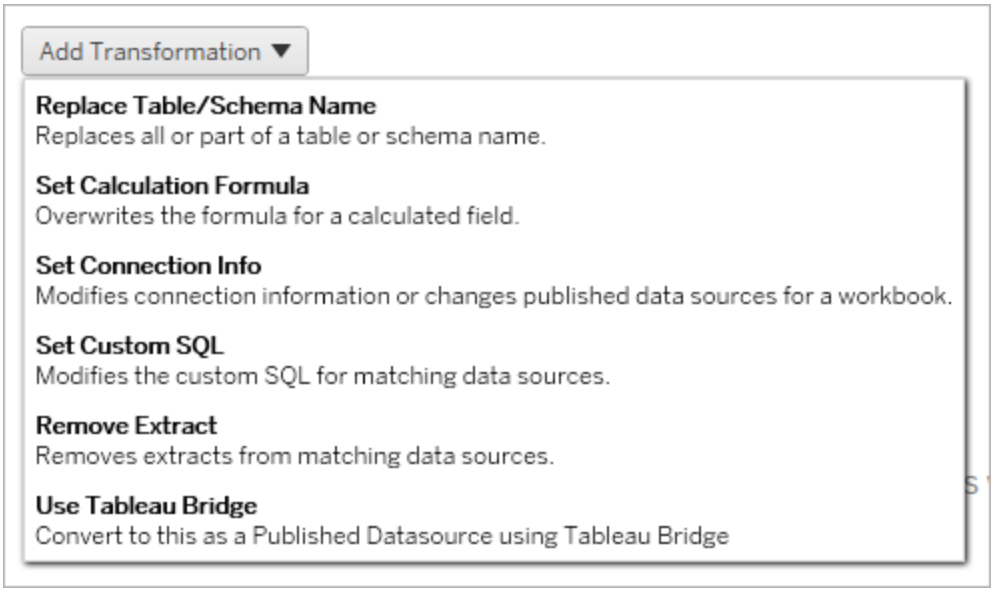


In most situations if multiple mapping entries exist for a single data source, a validation error will be displayed and must be fixed to continue. There is one important exception to this – a data source may match both a specific selection and a project-wide mapping entry. In this instance, the more specific entry will be used.

When you have completed all of the data source mapping necessary, click **Next** to continue.

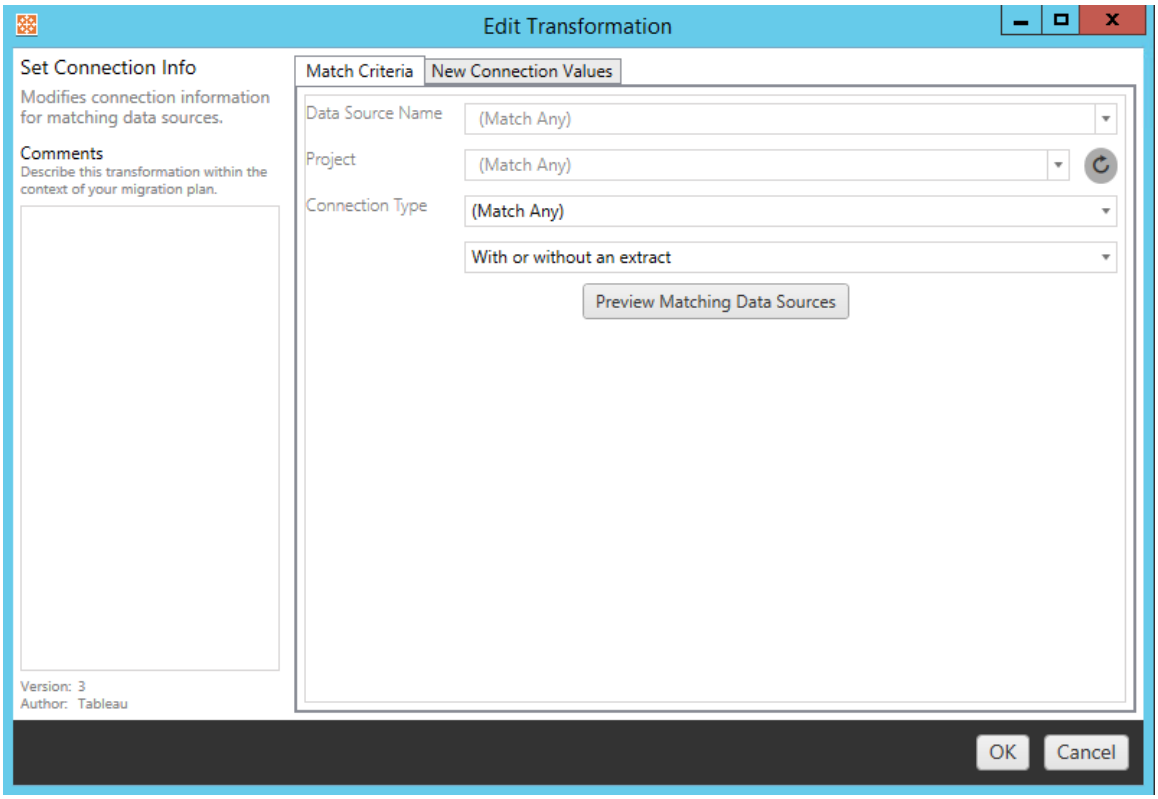
Step 3: Data source transformations

You can modify your data sources by using the transformation option. Click **Add Transformation** to see the list of transformations available.



Selecting any of the data source transformations opens the **Edit Transformation** window. Use this to customize your selected data sources. Transformations are executed in the order they are listed, from top to bottom.

For most data source transformations, there are two basic steps. The first step is to enter in the **Match Criteria** for the desired data source. Depending on which connection type you select, more fields will appear on the **Match Criteria** tab.



The second step depends on which transformation type you are adding. Each of the data source transformations have different values to be entered on the second tab.

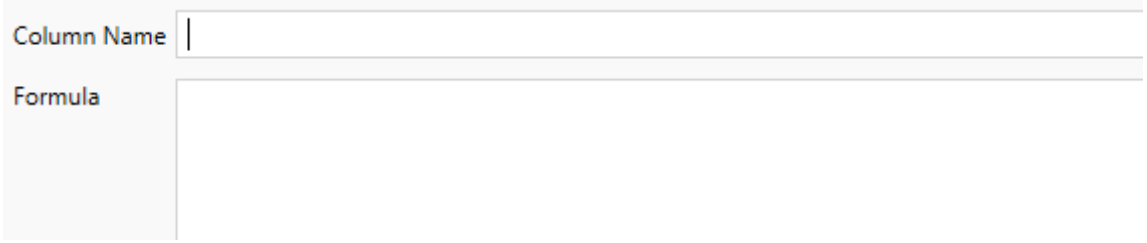
You can add notes in the **Comments** section on the left side of the **Edit Transformation** window for each of the transformations you add.

## Replace Table/Schema Name

On the **Options** tab, you can replace all or part of a table or schema name.

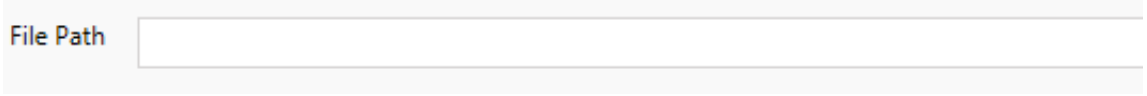
## Set Calculation Formula

On the **New Calculation Formula** tab, you can replace the calculation for a column.



## Set Connection Info

On the **New Connection Values** tab, enter the authentication method and connection details for the new data source. Depending on which connection type you select, more fields will appear.



## Set Custom SQL

On the **New Custom SQL** tab, enter the name of the custom SQL query you want to modify for **Match Query Name**. The query name must match the custom SQL query name from the physical layer of the data source. If these names don't match, the transformation will fail. For more information about data modeling and the physical layer, see The Tableau Data Model.

After entering the query name, enter the desired **Custom SQL** in the text field. Be aware that custom SQL can negatively impact the performance of your workbooks if improperly used.

## Remove Extract

There is no **Options** tab for this transformation. Type the **Match Criteria** information and the extract will be removed during migration.

## Use Tableau Bridge

There is no **Options** tab for this transformation. Type the **Match Criteria** information and data sources that are within a private network (inaccessible to the public internet) will be allowed to refresh using Tableau Bridge.

The destination Tableau Cloud site must have Tableau Bridge configured before migrating data sources. For information about Tableau Bridge, see Use Tableau Bridge in Tableau Cloud help. After the migration, data sources will need to be assigned a refresh schedule through Tableau Cloud.

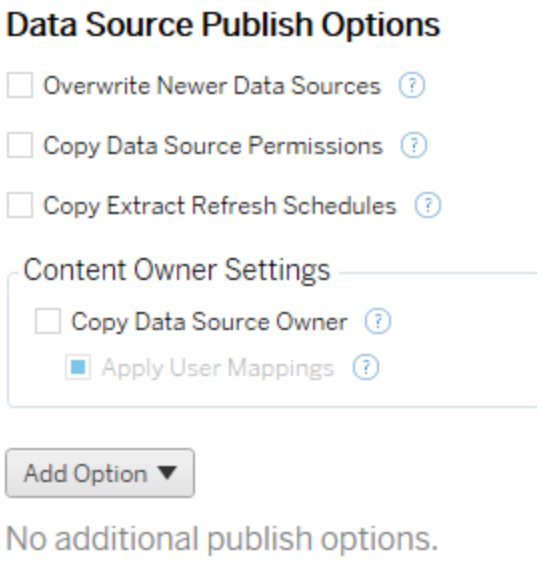
## Apply Saved Credentials

Deprecated in version 2022.3. Use the Set Connection Info data source transformation instead.

On the options tab, enter the **Tableau Username** and corresponding **Saved Credentials Username** for the data connection. You can only apply saved credentials for existing data connections on the Account Settings page of your Tableau site. For more information, see Manage Saved Credentials for Data Connections.

Step 4: Publish options

The final step in the Published Data Source phase is to create transformations for permissions and tags and finalize the publish options specific to the data sources.



## Overwrite Newer Data Sources

If selected, a data source will be published even if it will overwrite a data source that has been updated more recently.

## Copy Data Source Permissions

When selected, the migration tool will attempt to match source published data source permissions as closely as possible.

## Copy Extract Refresh Schedules

When selected, the migration tool will attempt to set the destination data source extract refresh schedule to schedules matching the source's name.

> **Note:** Extract refresh schedules cannot be created in Tableau Cloud. This option is not available if the destination is a Tableau Cloud site. For more information, see Migration Limitations.

### Copy Embedded Credentials for Data Sources

Copy the embedded credentials for published data sources. Only available when migrating from Tableau Server to Tableau Cloud sites. For more information, see Migrate Workbooks and Data Sources with Embedded Credentials.

> **Note:** CMT does not support embedded credential migration for OAuth connections. To migrate OAuth credentials to the destination site, use the Set Connection Info data source transformation.

### Copy Data Source Owner

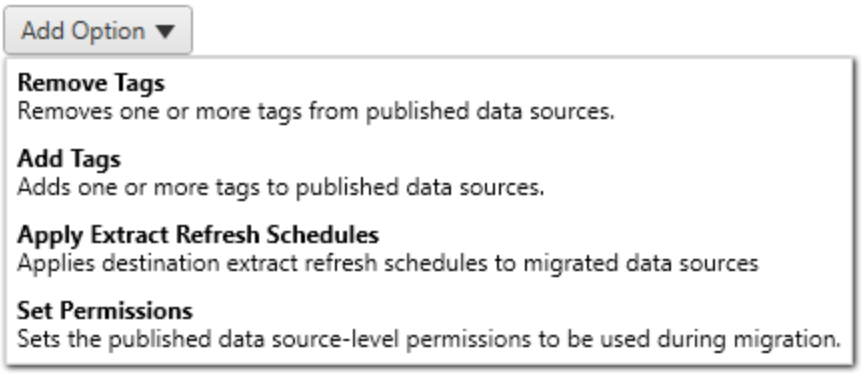
Copy data source owner settings from the source location to assign the data source owner. If unselected, the Content Migration Tool user is given ownership of the data source in the destination location.

### Apply User Mappings

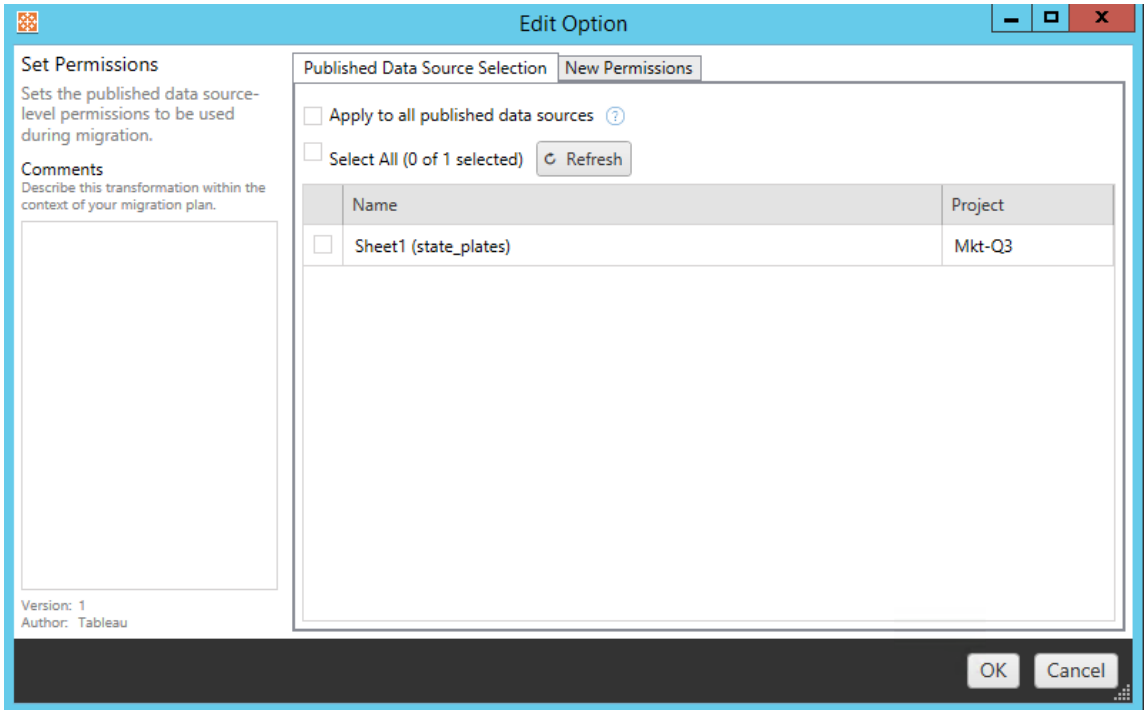
Apply user mappings to assign content ownership. Select this option if there are differences in username syntax in the destination location. For more information, see Migration Plans: Permissions and Ownership.

## Add Options

Click on the **Add Option** drop-down menu for the different types of transformations you can add:



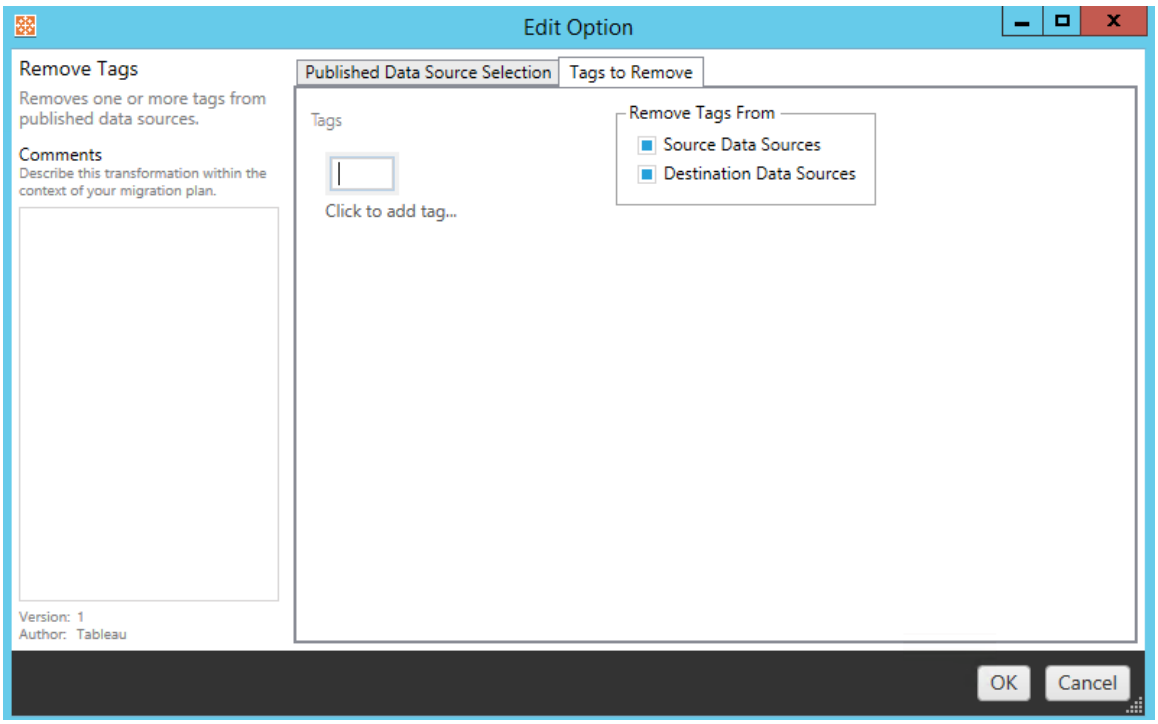
For all of the different types of transformations, there are two basic steps. The first step is to make your selection for the transformation. In this case, select the data source(s) you want to transform. At the top of the list, you can select **Apply to all published data sources**, which is an option to automatically select all data sources for future transformations. You can also **Refresh** the data source display window to reflect any changes or updates to the source site.



The second step is to enter the specific selections for the transformation you select.

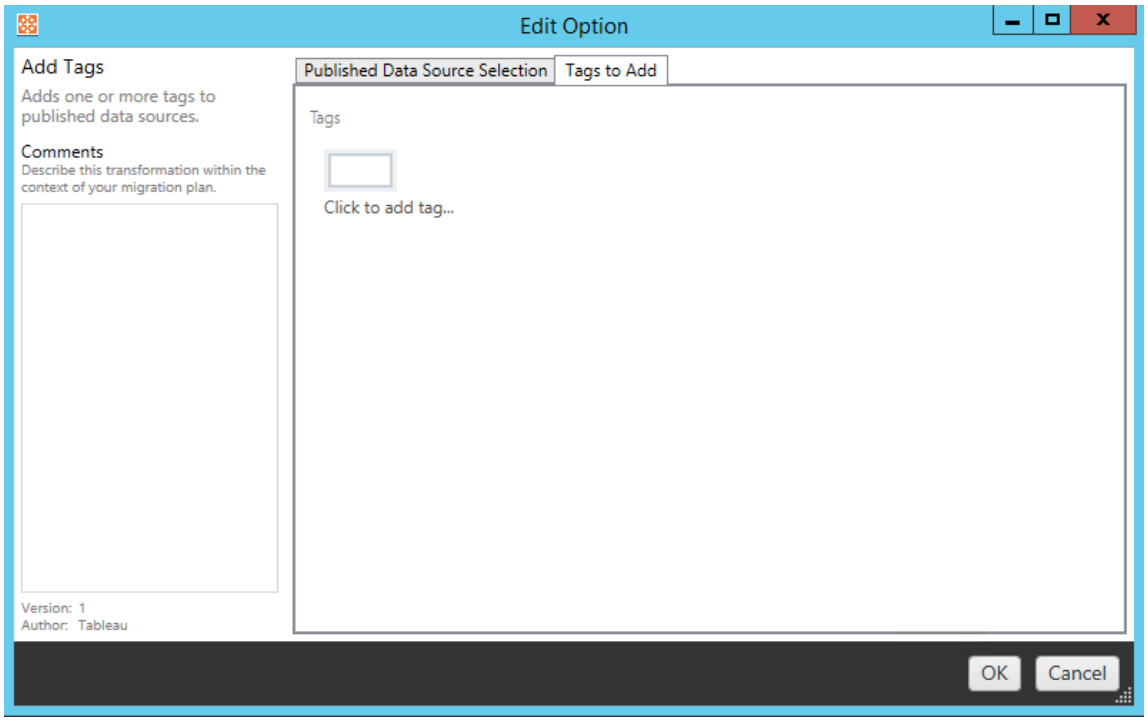
## Remove Tags

Once the data sources you would like to remove tags from are selected, enter any tags you want to remove by entering them into the field at the bottom and click **Add**. From this screen, you can also select to remove from the source or destination data sources. If you want to remove a previously entered tag, click on it and press the delete key.



## Add Tags

After selecting the data sources desired, enter any tags you want to assign by entering them into the field at the bottom and click **Add**. If you want to remove a tag, click on it and press the delete key.

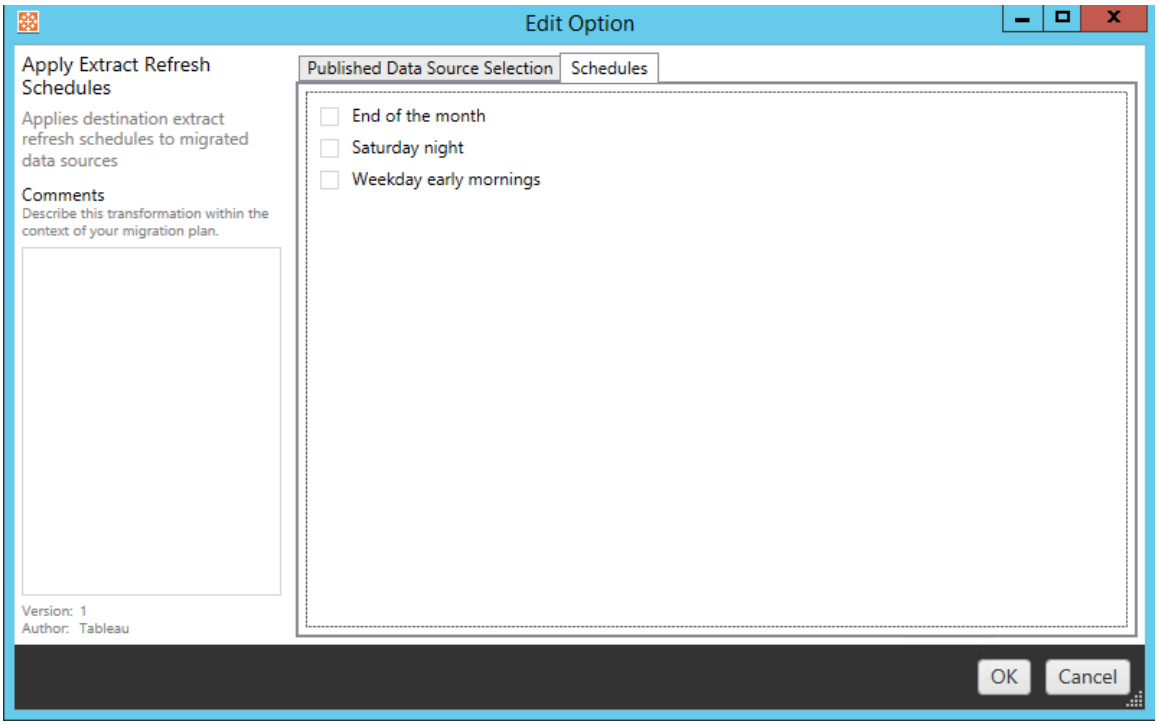


In addition, on each of the transformations you can enter notes in the **Comments** section on the left-hand side of the Edit Transformation window.

## Apply Extract Refresh Schedules

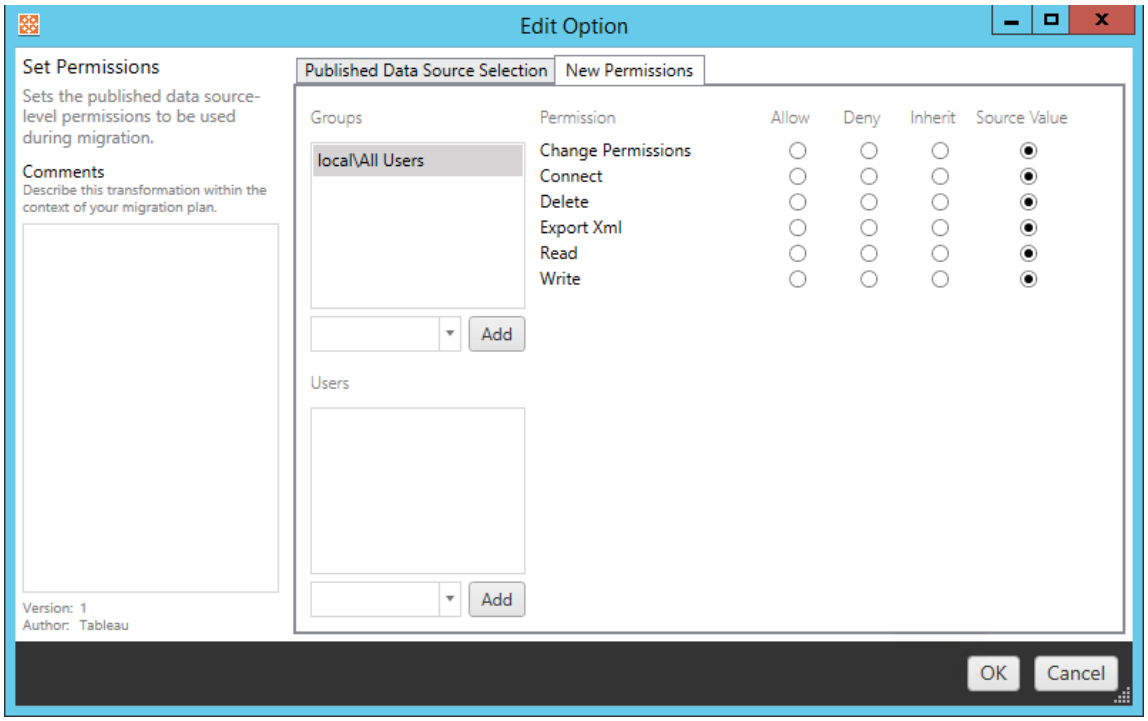
This transformation applies destination extract refresh schedules to migrated data sources. The list of schedules generated are from the destination.

> **Note:** Extract refresh schedules cannot be created in Tableau Cloud. This option is not available if the destination is a Tableau Cloud site. For more information, see Migration Limitations.



## Set Permissions

The last type of transformation is to edit the permissions for the selected data sources. Enter in a Group or User and click **Add**. Adjust the permissions as desired. The four different options are to **Allow** the permission, **Deny** the permission, **Inherit**, or to keep the **Source Value**.



Step 5: Continue to the next step

When you are ready, click **Next** to continue to the Migration Plans: Permissions and Ownership section of the planning phase.

Who can do this

Tableau site user with an Explorer role or higher. To migrate content, you must have **View** and **Download/Save a Copy** capabilities for workbooks on the source site and **View** and **Publish** capabilities for target projects on the destination site. For more information, see Permissions.

Migration Plans: Permissions and Ownership

The Content Migration Tool allows you to replicate workbook and data source permissions to Tableau environments in different network domains or have differences in username or group syntax. You can create user permissions mappings to customize and secure content after it has been published to the destination location. Mappings are applied if **Copy Project Per-**

**missions**, **Copy Workbook Permissions**, or **Copy Data Source Permissions** have been selected earlier in the planning phase, along with **Apply User Mappings**.

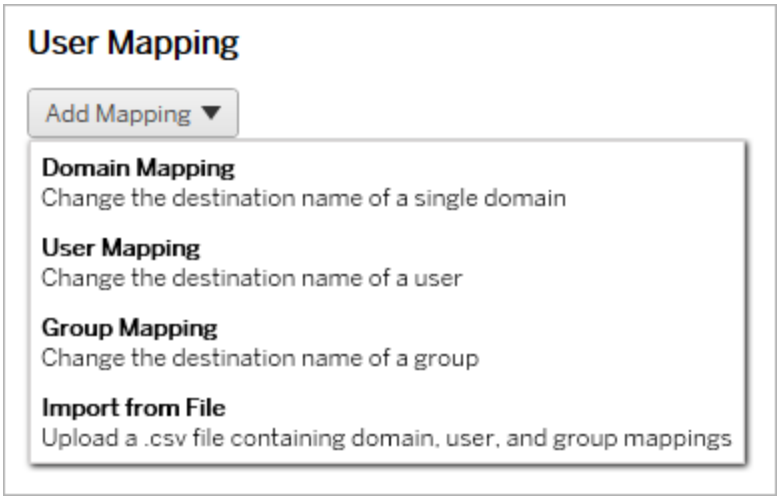
For more information, see Migration Plans: Source Projects, Migration Plans: Workbooks, and Migration Plans: Published Data Sources.

Mapping limitations

- Content Migration Tool will stop the migration process if it fails to find the mapped user or group in the destination location. Subsequent user or group permissions mappings are not checked after the first failure, and the plan must be run again.
- Content Migration Tool cannot replicate permissions if the source content has permissions for multiple users and groups with identical names. This only occurs when there are duplicate user or group names sourced from separate domains.

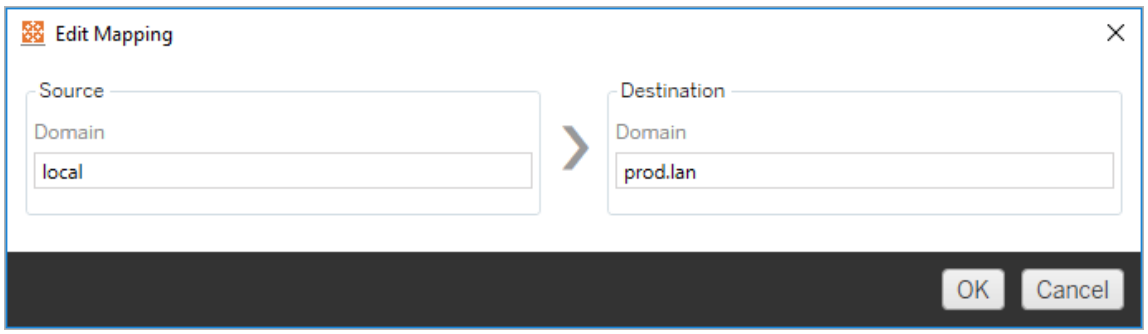
Step 1: Add mapping

To add user permissions mapping, click **Add Mapping** and select whether to change the name of a domain, user, group or to import mappings from a comma-separated values (CSV) file. If Content Migration Tool is unable to match a permission in the destination location, the source content will not be migrated.



## Domain Mapping

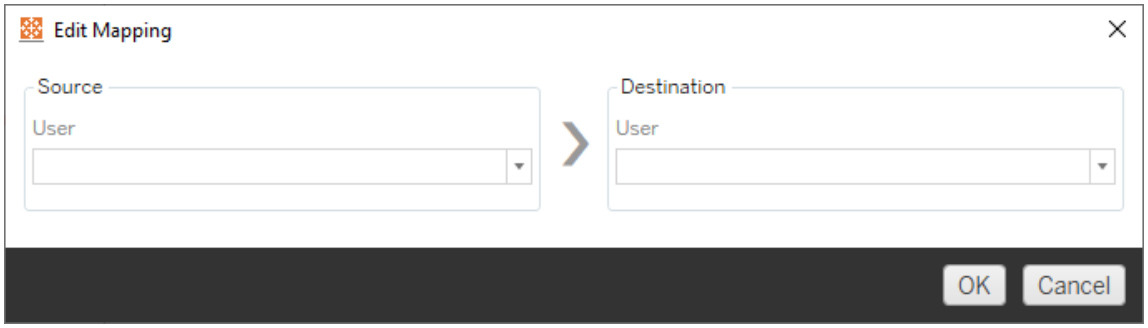
Domain permissions mapping applies to all users and groups in the destination location. If you are unsure about the source or destination domain, you can check the user and group pages on your Tableau site. If local user provisioning has been selected, the domain must be specified as `local`.



## User Mapping

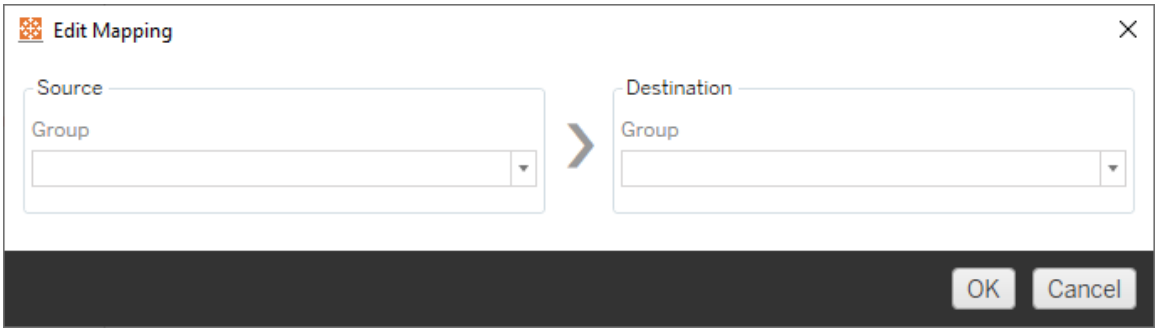
User permissions mapping automatically populates a list of users from the source and destination locations using the syntax `domain\user`. You cannot enter and save the names of users that don't exist.

**Note:** When migrating between projects on the same site, the destination location and list of users will be the same. You can use mappings to update content ownership from `User_A` to `User_B` on the site.



## Group Mapping

Group permissions mapping automatically populates a list of users from the source and destination locations using the syntax `domain\group`. You cannot enter and save the names of groups that don't exist.



Import mappings from a CSV file

Starting in version 2021.4, you can import a CSV file containing domain, user, and group mappings to quickly prepare your data for migration. Importing mappings can reduce the manual steps required to run a migration plan by allowing you to create and edit your mappings in bulk outside of Content Migration Tool. To import mappings, select **Import from File** from the Add Mapping menu.

## CSV file format requirements

When you create a CSV file to import mappings, make sure that the file meets the following requirements:

- The file does not include column headings. Tableau assumes that every line represents a mapping.
- The file contains three comma-separated values per row: mapping type, source domain/user/group, and destination domain/user/group.
- Include the domain for user names and groups if the server uses Active Directory authentication or "local" if a local identity store is used.

You must specify "domain," "user," or "group" for mapping type, as shown in the following table. The source and destination columns provide example syntax for Active Directory and a local identity store. Actual values in the CSV file will vary depending on your organization.

| Mapping Type | Source | Destination |
|---|---|---|
| domain | <domain> | <domain> |
| user | <domain>\<user name><br>local\<user name> | <domain>\<user name><br>local\<user name> |
| group | <domain>\<group name><br>local\<group name> | <domain>\<group name><br>local\<group name> |

## Import user permissions mappings

To import user permissions mappings in the Content Migration Tool:

1. Click **Add Mapping** and select **Import from File**.
2. In the dialogue window, click **Export CSV** to export a .csv file containing all users and groups from the source site. Edit the resulting file in a text editor to add mappings for the destination site.

   If you already have a mapping file, skip to step 3.

   > **Note:** The exported CSV file doesn't include domains from the source site. Domains must be added manually to the CSV to create domain mappings.

3. Click **Import Mappings** and select the mapping file you want to import.

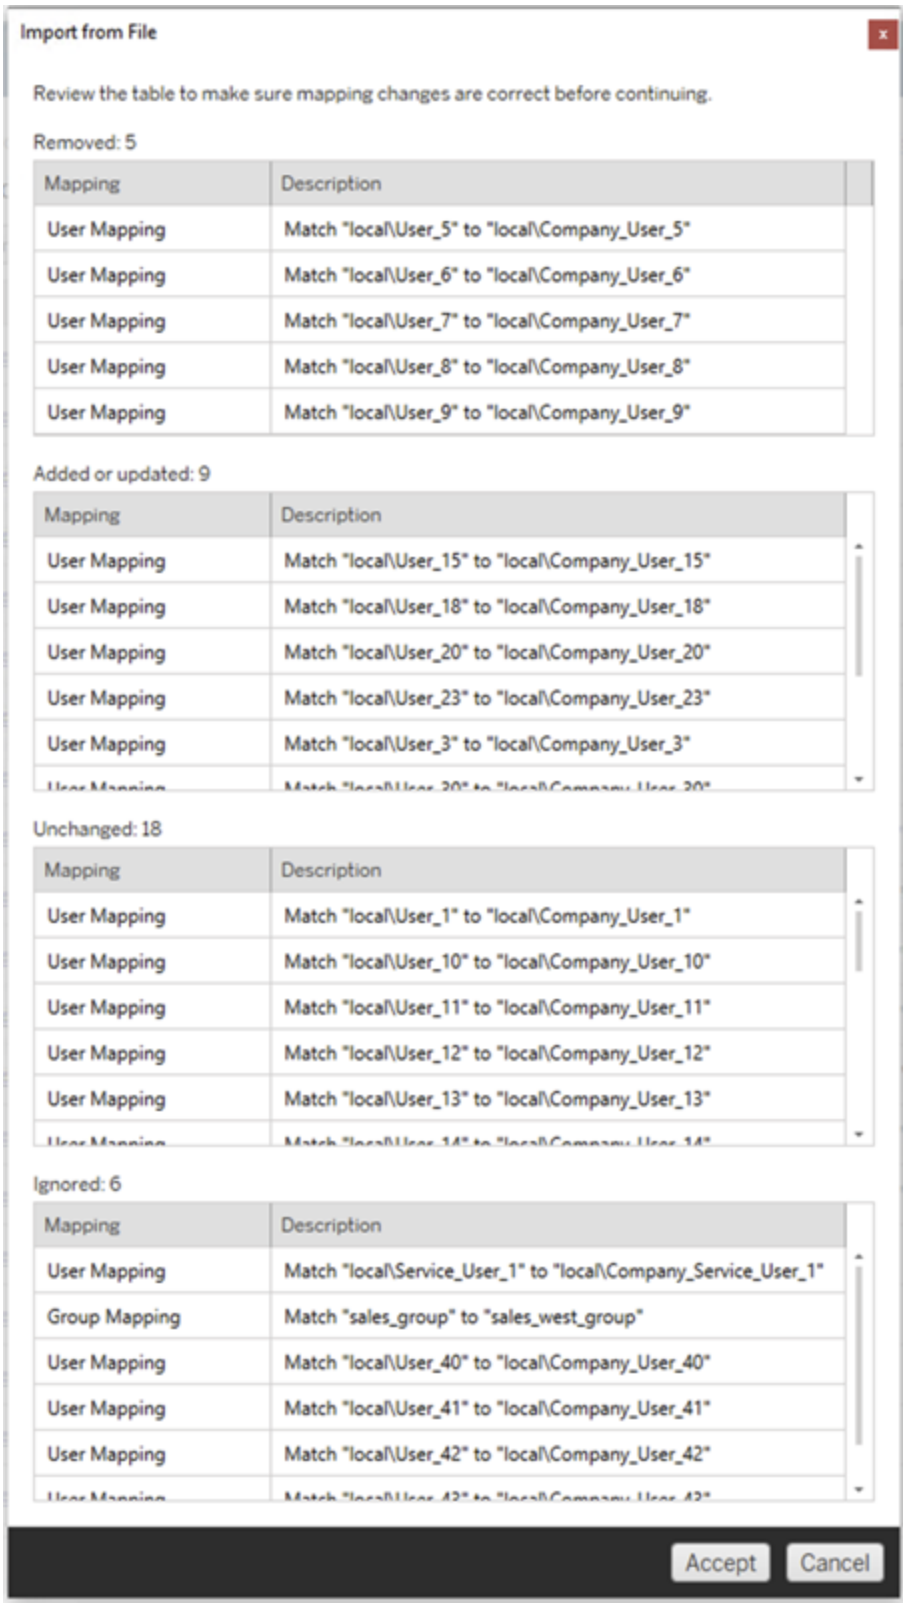
Content Migration Tool will validate the mappings for errors when importing the file. If errors are detected, you must fix each error in the CSV file and then import it again.

## CSV import example

The following example shows a CSV file that contains multiple mapping types.

```
user,local\hwilson,companyx.lan\henry.wilson
user,local\jjohnson,companyx.lan\janna.johnson
user,local\mkim,companyx.lan\michele.kim
user,local\fsuzuki,companyx.lan\fred.suzuki
user,local\awang,companyx.lan\alan.wang
user,local\snguyen,companyx.lan\susan.nguyen
user,local\lrodriguez,companyx.lan\laura.rodriguez
user,local\agarcia,companyx.lan\ashley.garcia
group,local\All Users,companyx.lan\All Users
group,local\Finance Team,companyx.lan\Finance Group
domain,dev.mycompany,prod.mycompany
```

A preview window is displayed while importing the CSV that shows mappings removed, added or updated, unchanged, and ignored. Review that the mapping changes are correct and click **Accept**.



Import from File
Review the table to make sure mapping changes are correct before continuing.
Removed: 5
Mapping

Match "local\User_10" to "local\Company_User_10"
User Mapping
Match "local\User_11" to "local\Company_User_11"
User Mapping
Match "local\User_12" to "local\Company_User_12"
User Mapping
Match "local\User_13" to "local\Company_User_13"
Ignored: 6
Mapping
Description
User Mapping
Match "local\Service_User_1" to "local\Company_Service_User_1"
Group Mapping
Match "sales_group" to "sales_west_group"
User Mapping
Match "local\User_40" to "local\Company_User_40"
User Mapping
Match "local\User_41" to "local\Company_User_41"
User Mapping
Match "local\User_42" to "local\Company_User_42"
Accept
Cancel

Once the mappings are imported successfully, you can edit, delete, or change the mapping order as described in Step 2.

Step 2: Change mapping order

After a permissions mapping is created, you can change the order using the **Up** or **Down** options to determine when it will be handled during the migration. When a domain, user, or group is handled in a permissions mapping, any subsequent permissions mappings for the source domain, user, or group will be ignored.

In the example below, permissions for `User_A` are mapped to `User_B`. Content Migration Tool will ignore the second permissions mapping because `User_A` has already been handled.

| | Mapping | Description |
|---|---|---|
| Edit Delete Up Down | User Mapping | Match "local\User_A" to "local\User_B" |
| Edit Delete Up Down | User Mapping | Match "local\User_A" to "local\User_C" |

In the example below, the first permissions mapping associates the domain for all users to `prod`. Content Migration Tool will ignore the second permissions mapping because the domain for `User_A` has already been handled.

| | Mapping | Description |
|---|---|---|
| Edit Delete Up Down | Domain Mapping | Match "local" to "prod" |
| Edit Delete Up Down | User Mapping | Match "User_A" to "dev\User_B" |

Step 3: Continue to next step

When you are ready, click **Next** to continue to the Migration Plans: Migration Scripts section of the planning phase.

Who can do this

Tableau site user with an Explorer role or higher. To migrate content, you must have **View** and **Download/Save a Copy** capabilities for workbooks on the source site and **View** and **Publish**

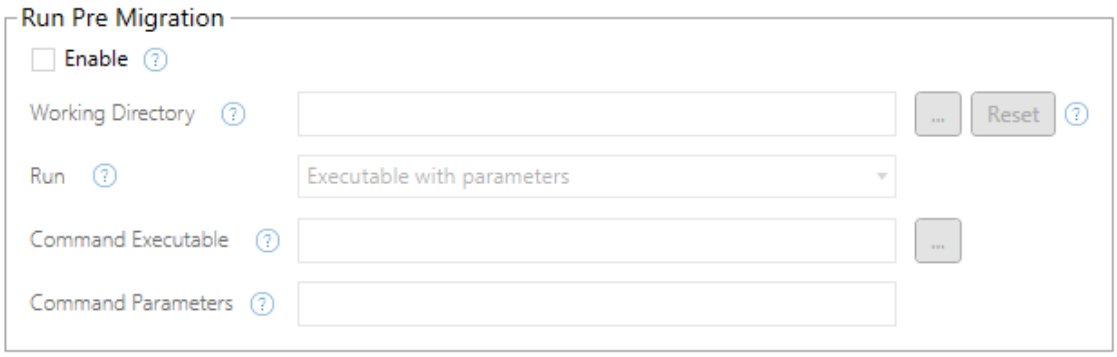
capabilities for target projects on the destination site. For more information, see Permissions.

Migration Plans: Migration Scripts

The next step of creating a migration plan in the Tableau Content Migration Tool is to create any scripts you want to run with your plan before or after migration.

Step 1: Pre-Migration

The **Run Pre Migration** section of the screen is dedicated to scripts that will run before the migration.



Each field has a help icon you can get information from by moving your cursor over it. To start with your pre-migration scripts, select **Enable**, which will then activate the fields below.

## Working Directory

This is the working directory for the script. The default directory is the same folder as the migration plan. Click on the browse button to select a different folder. The **Reset** button will restore the current migration plan folder as the working directory.

## Run

This drop down allows you to choose either to run a custom script or an executable with parameters.

## Command Executable

If you selected **Executable with Parameters** from the **Run** menu, this field will appear. This is the file path to the command executable to run before migration. Type it in directly or use the browse button to find the executable. This is a required field.

## Command Parameters

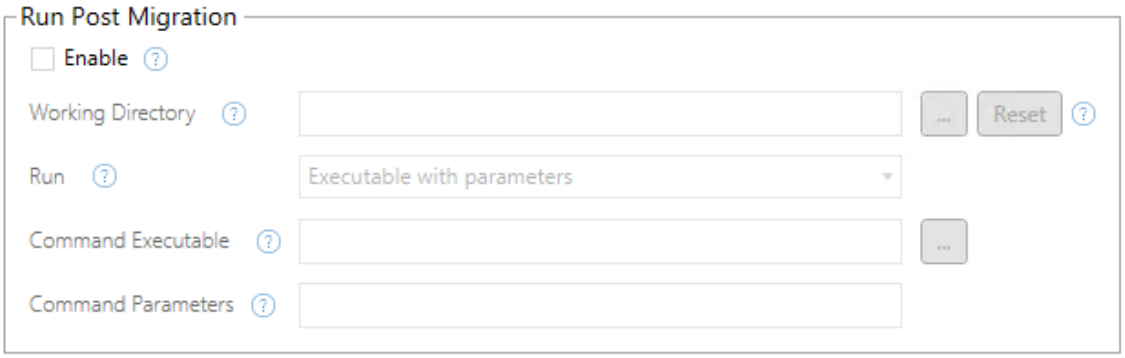
If you selected **Executable with Parameters** from the Run drop-down menu, this field will appear. Enter in command line parameters here to use with the command executable.

## Script

If you selected **Custom script** from the **Run** menu, enter in your pre-migration script here. It will be executed as a *.cmd file. This is a required field.

Step 2: Post-Migration

The **Run Post Migration** half of the screen is dedicated to scripts that will run after migration.



Each field has a help icon you can get information from by moving your cursor over it. To start with your post-migration scripts, select **Enable**, which will then activate the fields below.

## Working Directory

This is the working directory for the script. The default directory is the same folder as the migration plan. Click on the browse button to select a different folder. The **Reset** button will restore

the current migration plan folder as the working directory.

### Run

This drop down allows you to choose either to run a custom script or an executable with parameters.

### Command Executable

If you selected **Executable with Parameters** from the **Run** menu, this field will appear. This is the file path to the command executable to run before migration. Type it in directly or use the browse button to find the executable. This is a required field.

### Command Parameters

If you selected **Executable with Parameters** from the **Run** menu, this field displays. Enter in command line parameters here to use with the command executable.

### Script

If you selected **Custom script** from the **Run** menu, enter in your post-migration script here. It will be executed as a *.cmd file. This is a required field.

Step 3: Continue to Next Step

When you are ready, click **Next**.

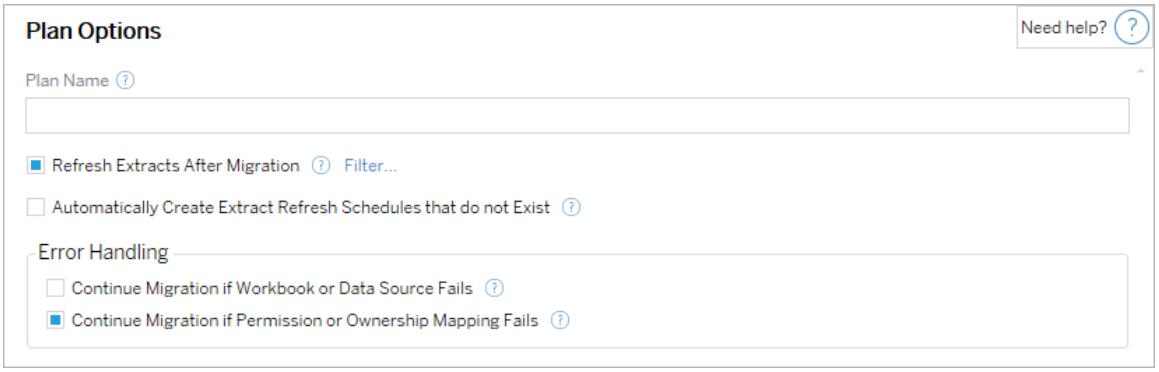
Who can do this

Tableau site user with an Explorer role or higher. To migrate content, you must have **View** and **Download/Save a Copy** capabilities for workbooks on the source site and **View** and **Publish** capabilities for target projects on the destination site. For more information, see Permissions.

## Migration Plans: Plan Options

The last step of creating a migration plan in the Tableau Content Migration Tool is configuring the plan options.

### Step 1: Configure options



The **Plan Name** is the name of the plan as it will appear in Content Migration Tool. We recommend using a user-friendly name for your plan name.

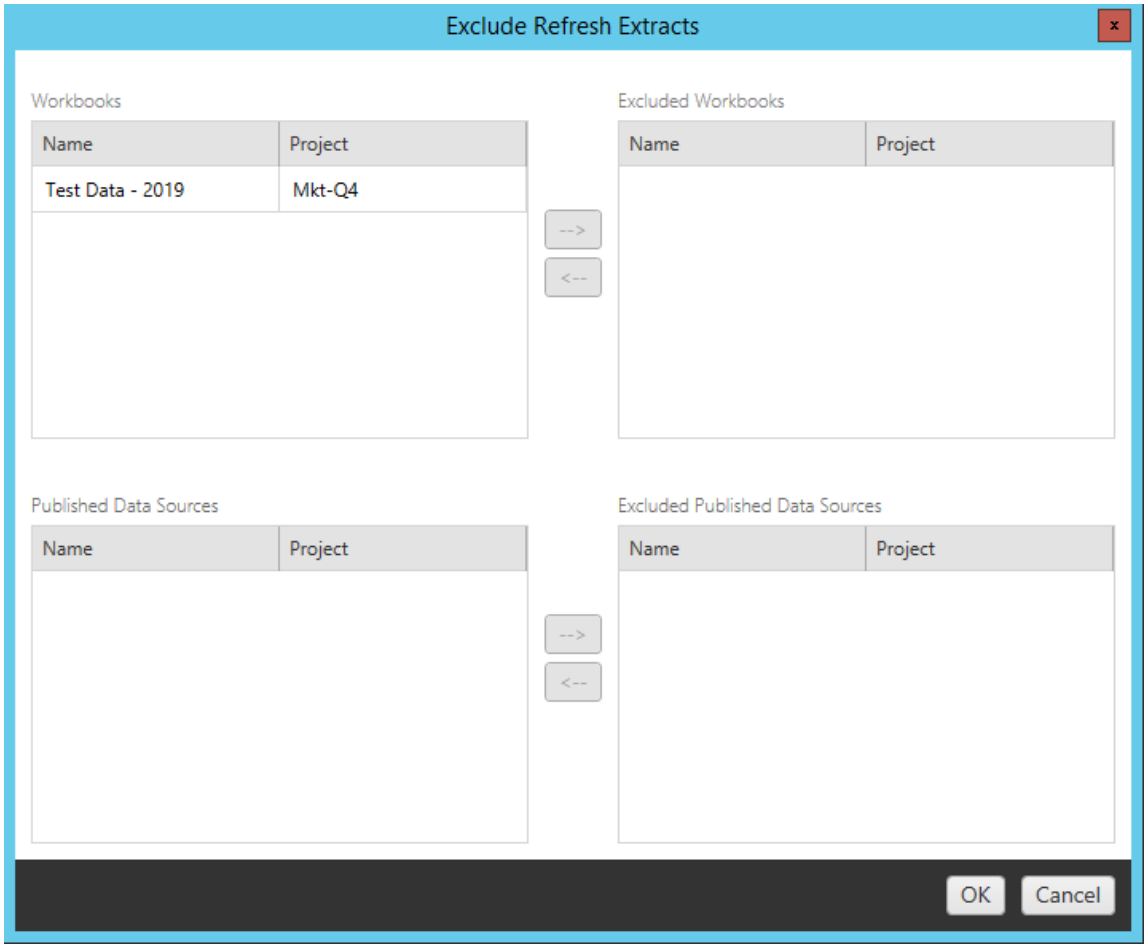
The following are available options:

- **Refresh Extracts After Migration**: If selected, data extracts will be refreshed immediately after migration if Content Migration Tool detects they have been modified during migration. Click the **Filter** link to exclude specific extracts. For more information, see Exclude extract refreshes below.
- **Automatically create Extract Refresh Schedules that do not Exist**: Automatically creates destination extract schedules that do not exist. If not checked, source schedules that do not exist on the destination server will not be copied.
- **Continue Migration if Workbook or Data Source Fails**: If checked, errors migrating a workbook or data source will not cause the migration to stop. The errors will be logged and the migration will continue. Errors during version control will always stop the migration.

- **Continue Migration if Permission or Ownership Mapping Fails**: If checked, errors copying permissions or ownership will not cause the migration to stop. The errors will be logged and the migration will continue.

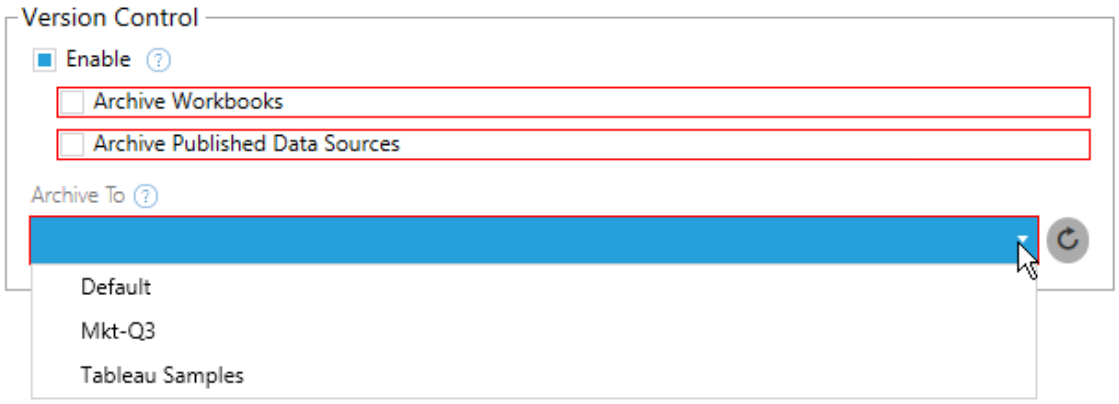
## Exclude extract refreshes

By clicking **Filter** next to **Refresh Extracts After Migration**, you can choose the workbooks or published data sources that will not be refreshed automatically. Use the arrow buttons to select the items you want to exclude, and click**OK**.



Step 2: Version control

These options allow you to avoid losing the existing workbooks in the destination site that might be replaced by the migrated workbooks.



Select **Enable** to save previous versions of your content. You can choose to archive workbooks and/or published data sources. Once version control is enabled, you must select a project from the **Archive To** menu, which lists all of the projects in your destination site. We recommend creating a separate archive project to store your versioned content. Click the refresh button to display any projects that have been added or modified on the site.

Step 3: Save plan

Once you have selected your plan options, click **Save Plan** to save your plan for future use. The plan will be saved to the `Documents\Tableau Content Migration Tool Plans` folder on your local machine.

Step 4: Continue to next step

When you are ready, click **Verify & Run** to end the Planning phase and prepare to run your plan.

Who can do this

Tableau site user with an Explorer role or higher. To migrate content, you must have **View** and **Download/Save a Copy** capabilities for workbooks on the source site and **View** and **Publish**

capabilities for target projects on the destination site. For more information, see Permissions.

Migrate Workbooks and Data Sources with Extracts

Tableau Server users can publish extracts which are copies, or subsets of the original data. These extracts may be embedded in a workbook or a data source. By default, when you use the Tableau Content Migration Tool to migrate a workbook or data source that contains an extract, that extract is migrated along with the workbook or data source that contains it. The Content Migration Tool gives you a couple options for controlling this behavior:

- **Switching to a Live Connection**

  You can add the **Remove Extract** transformation to your migration plan to remove the extract from your workbook or data source during migration. As always, the source workbook or data source will not be modified. The copy of the workbook or data source migrated to the destination site will have the extract removed from it. This effectively switches the data connection back to a live connection.

- **Refreshing Extracts after Migration**

  You can enable the **Refresh Extracts After Migration** option in your migration plan to have an immediate extract refresh task scheduled after the workbook or data source is migrated.

  We don't recommend using the **Refresh Extracts After Migration** option if your migration plan also uses the **Set Connection Info** transformation to change the data connection to point to a different set of data (for example, a different database server or database). When you change the connection information to point to different data and use the **Refresh Extracts After Migration** option, this can unintentionally expose data in a way that is a potential security issue.

  For more information, see Option 3: Refresh Extracts After Migration.

## Changing data connections that use extracts

Tableau data connections are either live connections that directly query a data source, or they are extracts of a data source. Extracts are copies or subsets of the original data and can be embedded in a workbook or data source. When present, the views will query data from the extract instead of the underlying data source.

Commonly, you'll want to modify the data source connection during the migration so that it points to a different database on the destination site than it did on the source site.

For example, if you are migrating a workbook from your staging site to your production site, you will likely want to update the data connections inside the workbook to connect to your production database. You can implement this by using the **Set Connection Info** transformation in your migration plan. Now you have a migration plan which copies a workbook from staging to production and updates the data connections to point to the production database.

If your workbook uses an extract, additional work is required. In this scenario, the workbook will be migrated and the live data connection updated. However, the views will still show data from the staging database since it still contains the staging database extract - copied from the source (staging) site. There are a few ways to address this.

## Option 1: Use Published Data Sources

You can change your workbooks so that they use published data sources instead. This way, the extract will be managed as part of the published data source and migrating updates to the workbooks that use that data source can be simplified by not having to worry about the connection to the live database or the data extract.

## Option 2: Remove the Extract During Migration

You can add a **Remove Extract** transformation to your migration plan. This will remove the extract from your workbook, effectively switching the data source to a live connection.

## Option 3: Refresh the Extract After Migration

You can use the **Refresh Extracts After Migration** option in your migration plan. This will migrate the extract along with the workbook but will schedule an immediate extract refresh task for that workbook after the migration is complete.

This option is usually not recommended when used in combination with a **Set Connection Info** transformation because of potential security issues that it can introduce.

The issue is that the migrated workbook on your destination site will still show the old (source) extract data for the period between the completion of migration and the completion of the extract refresh task. If the extract refresh task fails, then the old/source extract data will remain until the extract is refreshed.

In a scenario like we've outlined above, migrating from a staging to production environment, this may be acceptable but you should be aware that the users of your workbooks may not be aware that the workbook is showing old/staging data due it being recently migrated and the extract not being refreshed yet.

In other scenarios where you may be using **Set Connection Info** to change data connections to point to a different set of customer or client data, this could introduce serious security issues where the workbook's extract contains data from a different client or customer until the extract has been refreshed post-migration.

One way to mitigate this issue is to implement a 2-stage migration. This approach requires you to create two migration plans, one for each step described below and ensures the workbooks and data sources have an up-t-o-date extract before they are accessible.

- **Stage 1:** Migrate your content to a project on your destination site that only administrators have access to. This migration allows you to use the **Refresh the Extract After Migration** option along with the **Set Connection Info** transformation to update the data connection, because no unauthorized users will have an opportunity to see the old data, even if the extract refresh fails.

- **Stage 2:** After stage 1 is complete and you confirm there is a successful extract refresh, run a second migration plan to migrate the content from the stage 1 destination to the final destination where it is visible to end-users.

Who can do this

Tableau site user with an Explorer role or higher. To migrate content, you must have **View** and **Download/Save a Copy** capabilities for workbooks on the source site and **View** and **Publish** capabilities for target projects on the destination site. For more information, see Permissions.

Migrate Workbooks and Data Sources with Embedded Credentials

Starting in version 2023.1, authorized users can migrate workbooks and published data sources with embedded credentials from Tableau Server to Tableau Cloud. Additional configuration is required before migrating with Content Migration Tool.

> **Note:** Content Migration Tool does not support embedded credential migration for OAuth connections. For more information, see Migration Limitations.

Overview

Migrating embedded credentials using Content Migration Tool (CMT) is available when connecting to Tableau Server as the source site and Tableau Cloud as the destination site. Both sites must have an Advanced Management license.

Now that we've covered the requirements, let's discuss how migration works. You'll need to work closely with the Tableau Cloud site administrator and TSM administrator (sometimes the same person) to allow the feature and authorize a site user. After the feature is activated, the authorized site user builds a migration plan and selects the publish options *Migrate Embedded Credentials for Workbooks* and *Migrate Embedded Credentials for Data Sources*.

When running the migration plan, all required content credentials are transmitted in an encrypted content manifest from Tableau Server to Tableau Cloud. As CMT publishes content, the destination Tableau Cloud site embeds matched credentials securely from the manifest into

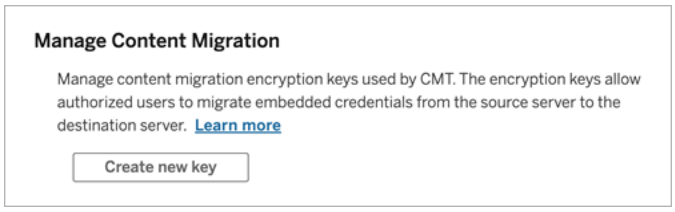
the content (workbooks or published data sources). Any problems that occur during migration will appear in the Errors and Warnings tab in CMT. For more information, see Migration Plan Overview.

Allow embedded credential migration

Use the following steps to allow embedded credential migration from Tableau Server to Tableau Cloud.

## Tableau Cloud

1. Open a browser window and sign in to Tableau Cloud as a site administrator.
2. Select **Settings** > **General**, and scroll down to **Manage Content Migration**.



3. Click **Create new key** to generate an encryption key pair.

> **Note:** The public key is only displayed once. If you lose the key before completing the configuration, you'll need to generate a new key.

4. In the resulting window, click **Copy to clipboard** and then close the window.
5. Paste the public key to a file and store it in a safe location. The TSM administrator will use the public key to allow migration. You can view the public key expiration date on the Settings page.

## TSM Command Line Interface

1. Open a command prompt with an account that is a member of the `tsmadmin` group on a node in the cluster.
2. Use `tsm security authorize-credential-migration` to allow embedded credential migration to the Tableau Cloud site. For more information, see tsm security.

   ```
   tsm security authorize-credential-migration --source-site-url-namespace <Tableau Server site ID> --destination-site-url-namespace <Tableau Cloud site ID> --destination-server-url <Tableau Cloud site url> --authorized-migration-runner <username> --destination-public-encryption-key <public key>
   ```

   **Note:** When running TSM commands from a remote node, use `tsm login` to authenticate a session with the Tableau Server Administration Controller service before running `tsm security authorize-credential-migration`.
3. (Optional) Use `tsm security cancel-credential-migrations` to cancel granted authorizations. By default, migration authorization will expire in 7 days or the number of days specified with the `--expiration-time-in-days` option.

## Content Migration Tool

1. Open Content Migration Tool and select **Create New Plan** or **Browse for a Plan**.
2. On the Sites page, click **Sign in to Tableau**, and connect to Tableau Server as the source and Tableau Cloud as the destination. Embedded credential migration is only available when migrating from Tableau Server to Tableau Cloud.
3. Build your migration plan and select the following Publish Options:

- On the Workbook Publish Options page, select **Migrate Embedded Credentials for Workbooks**. For more information, see Migration Plans: Workbooks.
- On the Data Source Publish Options page, select **Migrate Embedded Credentials for Data Sources**. For more information, see Migration Plans: Published Data Sources.

4. When you are ready, click **Verify & Run** to start the migration.

The workbooks and published data sources you selected are migrated to your Tableau Cloud site and should not prompt for authentication. If you experience issues while migrating embedded credentials, see Troubleshooting.

Troubleshooting

This section includes some common migration issues you might encounter and suggestions to resolve them.

## There is no option to migrate embedded credentials

You can only migrate embedded credentials from a Tableau Server to a Tableau Cloud site. Tableau Server and Content Migration Tool must be running versions 2023.1 or later. For more information, see Install Tableau Content Migration Tool.

## Migrating embedded credentials failed

In the Errors and Warnings tab of CMT, you may receive an error indicating that migrating the embedded credentials failed. This can occur when the public key used to authorize migration has expired.

As a Tableau Cloud site administrator, go to the Settings page and verify that the public key is valid. You'll have to create a new encryption pair to authorize the migration if the public key expires. For more information, see Allow embedded credential migration.

Who can do this?

- Tableau Cloud site administrator and TSM administrator are required to allow embedded credential migration.
- The authorized site user must have an Explorer role or higher. They must also have View and Download/Save a Copy capabilities for workbooks on the source site and View and Publish capabilities for target projects on the destination site.

For more information, see Permissions.

## Using the Tableau Content Migration Tool Console Runner

The Tableau Content Migration Tool includes a command-line utility for running migrations, `tabcmt-runner.exe`, located in the installation folder. The default installation folder is `%PROGRAMFILES%\Tableau\Tableau Content Migration Tool`.

**Note:** The `tabcmt-runner.exe` utility is not the same as the `tabcmt.cmd` command line utility which is used to configure the Content Migration Tool graphical application. For more information about `tabcmt.cmd`, see Using the Tableau Content Migration Tool Command Line Interface.

Usage:

- tabcmt-runner [options] <plan_file.tcmx>
- tabcmt-runner license --remove
- tabcmt-runner license <new license key>
- tabcmt-runner license <license file path> [--passphrase=<license file passphrase>]
- tabcmt-runner encryption --reset
- tabcmt-runner encryption <new_key>
- tabcmt-runner improvement [on|off]
- tabcmt-runner --help
- tabcmt-runner --version
- tabcmt-runner script-warning [on|off]

Options:

- --version
- --help
- --quiet
- --info
- --logfile=VALUE
- --src-user=VALUE
- --src-password=VALUE
- --dest-user=VALUE
- --dest-password=VALUE
- --https=VALUE
- --allow-scripts

Run Plan

Executes a migration plan immediately.

```
tabcmt-runner [options] <plan file>
```

Available options:

- `--logfile=<file name>` sets the file name to log output to
- `--https=<secure|legacy>` sets the HTTPS mode
- `--quiet` disables logging to stdout
- `--src-user=<username>` sets the username of the source connection
- `--src-password=<password>` sets the password of the source connection
- `--dest-user=<username>` sets the username of the destination connection
- `--dest-password=<password>` sets the password of the destination connection

Exit codes:

- 0 indicates that the migration was successful.
- 1 indicates that the migration was successful but warning messages were logged.
- 2 indicates that the migration failed. Specific errors will be included in the log output.

Show Plan Summary

Shows a summary of the migration plan and then exits.

```
tabcmt-runner --info <plan file>
```

help

Shows usage information for the command line utility.

```
tabcmt-runner --help
```

version

Shows the current application version information.

```
tabcmt-runner --version
```

encryption

Reset the encryption key, or specify a new one. You must specify the encryption key before using the `tabcmt-runner` utility, even if you already done so from the Content Migration Tool UI.

```
tabcmt-runner encryption <new_key> | --reset
```

improvement

Default value: `on`

Enables or disables collection of anonymous usage information by the application. This information is completely anonymous and is sent periodically to Tableau to help us improve Content Migration Tool.

## Examples

Show whether the improvement program is enabled or disabled:

```
tabcmt-runner improvement
```

Enable or disable the improvement program:

```
tabcmt-runner improvement <on|off>
```

license

Deprecated in July 2022.

This command is only applicable for legacy licenses. Manages a legacy application license for the current user. When using a legacy key, to use the `tabcmt-runner` utility you must activate the license using this command, even if you already activated it from the Content Migration Tool UI.

## Examples

Show the current license information:

```
tabcmt-runner license
```

Set/activate a serial key or offline license key:

```
tabcmt-runner license <key>
```

Remove/deactivate the current license:

```
tabcmt-runner license --remove
```

Set/activate using a license file:

```
tabcmt-runner license <file path> [--passphrase=<password>]
```

script-warning

Default value: `on`

Shows a warning message when running a migration plan that includes migration scripts.

> **Note:** This command updates your selection on the Settings page. For more information, see Tableau Content Migration Tool Settings.

## Examples

Show if script warning is turned on or off.

```
tabcmd-runner script-warning
```

Turn script warning on or off

```
tabcmd-runner script-warning <on|off>
```

If turned on, you must include the option `--allow-scripts` to execute migration plans.

```
tabcmd-runner --allow-scripts <plan file>
```

Who can do this

To use the console runner, you must have all the following:

- Administrator permissions on the Content Migration Tool machine.
- Tableau site user account with an Explorer role or higher.
- View and Download Workbook/Save a Copy permissions on the source site.
- Publishing rights for the destination site.

Example: Scripting Migration Plans

> **Note:** This topic includes a sample script you can use as the basis for scripting a multi-plan migration that satisfies your needs and environment. This script is intended to be used as a sample only, and not to be run as-is. For detailed instructions on using the console runner, see Using the Tableau Content Migration Tool Console Runner.

Tableau Content Migration Tool command line utility for running migrations can be used to automate the running of a migration plan from an external scheduler (such as Windows Task Scheduler) or from a custom script. The console runner only runs one migration plan (stored in a .edt file) at a time. If you have a group of migration plans you want to run as a group, then you can use a custom script in combination with the Content Migration Tool console runner.

The example below is written in PowerShell and uses the console runner to execute a list of migration plans as a group.

The following example code demonstrates:

- Running multiple migration plans as a group using the console runner.
- Optionally halting deployment of the group of plans immediately when any single migration in the group fails.

- Using the console runner's exit code to determine whether the migration failed or logged warnings.

```
# List of migration plans to execute as a group.
$planFiles = @(
       'customer 1.tcmx',
       'customer 2.tcmx'
)

# True of false whether to continue with the next plan if a migra-
tion fails.
$continueOnFailure = $false

# Path to the CMT console runner executable
$runnerExe = 'C:\Program Files (x86)\Tableau\Tableau Content Migra-
tion Tool\tabcmt-runner.exe'

# Store the exit code from the previously run migration plan.
$lastResult = -1

# Loop through and run each migration plan one at a time.
$planFiles | % {
       $file = $_

       if ($lastResult -ge 2 -and -not($continueOnFailure)) {
               Write-Warning "Skipping plan because previous migration failed.
`nSkipped plan: $file"
               return
       }

       Write-Verbose "Running migration plan: $file"
       & $runnerExe $file
       $lastResult = $LASTEXITCODE

       if ($lastResult -ge 2) {
```

```
                Write-Error "Migration failed. See output or log file for error
details.`nPlan: $file" -ErrorAction 'Continue'
        }
        elseif ($lastResult -eq 1) {
                Write-Warning "Migration completed with warnings. See output or
log file for warning details.`nPlan: $file"
        }
}
```

Who can do this

To script migration plans, you must have all the following:

- Administrator permissions on the Content Migration Tool machine.
- Tableau site user account with an Explorer role or higher.
- View and Download Workbook/Save a Copy permissions on the source site.
- Publishing rights for the destination site.

## Using the Tableau Content Migration Tool Command Line Interface

The Tableau Content Migration Tool includes a command line interface, `tabcmt.cmd`, located in the installation folder. The default installation folder is `%PROGRAMFILES%\Tableau\Tableau Content Migration Tool` (32-bit Windows) or `%PROGRAMFILES(x86)%\Tableau\Tableau Content Migration Tool` (64-bit Windows).

> **Note:** The `tabcmt.cmd` utility is not the same as the Content Migration Tool console runner, `tabcmt-runner.exe`. The console runner is a separate command line utility used for running migrations from the command line. For information on using the Content Migration Tool console runner, see Using the Tableau Content Migration Tool Console Runner.

Here are the commands that can be used with the `tabcmt` command line:

- migrate
- help
- update
- version

migrate

Opens a migration plan file to the migrate step in the GUI:

```
tabcmt migrate <plan file>
```

help

Shows general help about the command line interface and the available commands.

Examples

Show all commands available:

```
tabcmt help
```

Show help and usage information for a specific command:

```
tabcmt help <command>
```

license

Deprecated in July 2022.

This command is only applicable for legacy licenses. Manages the application license for the current user.

Examples

Show the current license information:

```
tabcmt license
```

Remove/deactivate the current license:

```
edt license remove
```

Set/activate a serial key or offline license key:

```
tabcmt license <key>
```

Set/activate using a license file:

```
tabcmt license <file path> [--passphrase=<password>]
```

update

Manages the options for application updates.

Examples

Show the current update settings:

```
tabcmt update
```

Enable or disable the automatic update notifications:

```
tabcmt update --disabled=<true|false>
```

Set the URL to detect/download updates from:

```
tabcmt update --url=<url>
```

Enable or disable showing beta updates. Set to false to only show stable release updates.

```
tabcmt update --beta=<true|false>
```

version

Shows the current application version information.

```
tabcmt version
```

Who can do this

To use the command line interface, you must have all the following:

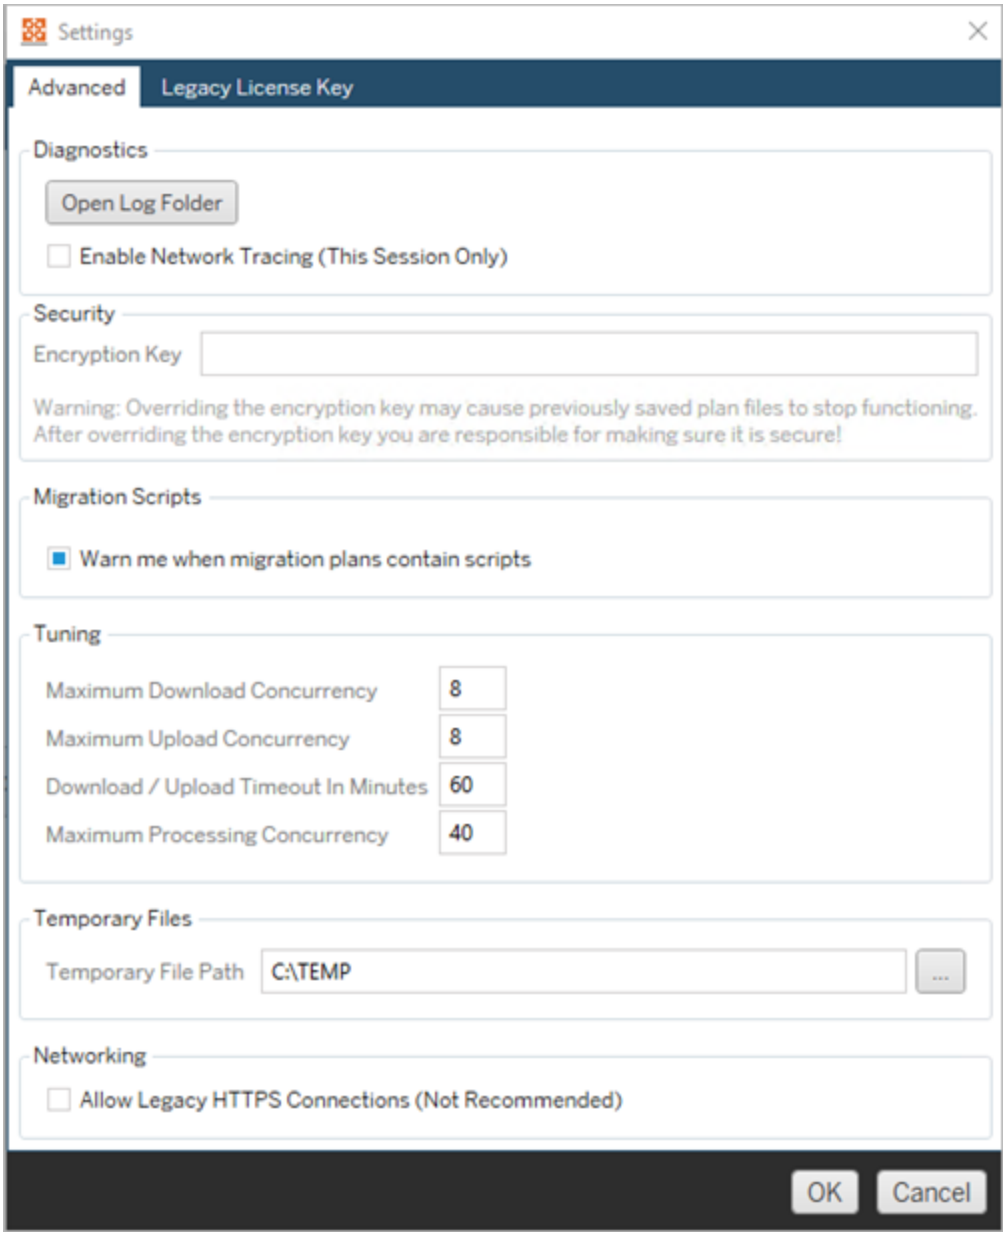
- Administrator permissions on the Content Migration Tool machine.
- Tableau site user account with an Explorer role or higher.
- View and Download Workbook/Save a Copy permissions on the source site.
- Publishing rights for the destination site.

## Tableau Content Migration Tool Settings

The Tableau Content Migration Tool default settings work in most cases, but you can change these if you need to, or if you are working with Tableau Support and they ask you to make changes.

To view or update the Content Migration Tool settings:

1. Open Content Migration Tool.
2. Click **Help** > **Settings**. The Settings dialog opens:



**Diagnostics**—Click **Open Log Folder** to open the logs location. Here you can view the logs, and zip them up if you need to send them to Tableau. For more information, see Tableau Content Migration Tool Log Files.

Select **Enable Network Tracing** if you are working with Support and they ask you to include a network trace in the logs. This applies until you clear the option or restart the Content Migration Tool.

**Security**—The encryption key is automatically generated on installation. If you change the encryption key, any migration plans with embedded passwords that were created with the previous key cannot be opened. If you have multiple installations of Tableau Content Migration Tool and want to share migration plans, you need to make sure the encryption key used by each instance of the tool is the same.

**Migration Scripts**—By default, a warning is displayed when running a migration plan that includes migration scripts or executables. Other users can edit these files, so verify that they're safe before running the migration. Toggling this setting on and off will also update your warning preference for the console runner. For more information, see Using the Tableau Content Migration Tool Console Runner.

**Tuning**—In almost all cases you can leave these set to the defaults. If you are working with Support, they may ask you to change these settings.

**Temporary Files**—Select a location for temporary files if you want to change the default. This is the location where content is copied during a migration. You may want to change this if the default location does not have enough space to temporarily hold migrated content.

**Networking**—Selecting **Allow Legacy HTTPS Connections** gives you the ability to connect to Tableau Server installations running with older HTTPS configurations (for example, SSL v3). This is not recommended.

Who can do this

Typically, the tasks listed above can only be done by a user with Administrator access on the machine where Content Migration Tool is installed.

## Tableau Content Migration Tool Log Files

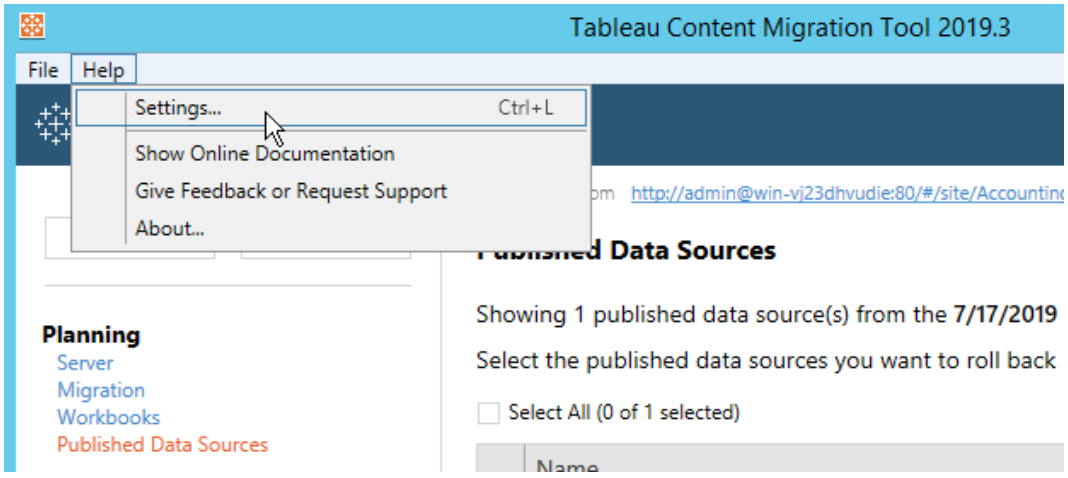
Tableau Content Migration Tool generates log files when you run migrations. These can be helpful for troubleshooting problems.

> **Note:** For information on all the Content Migration Tool settings, see Tableau Content Migration Tool Settings.

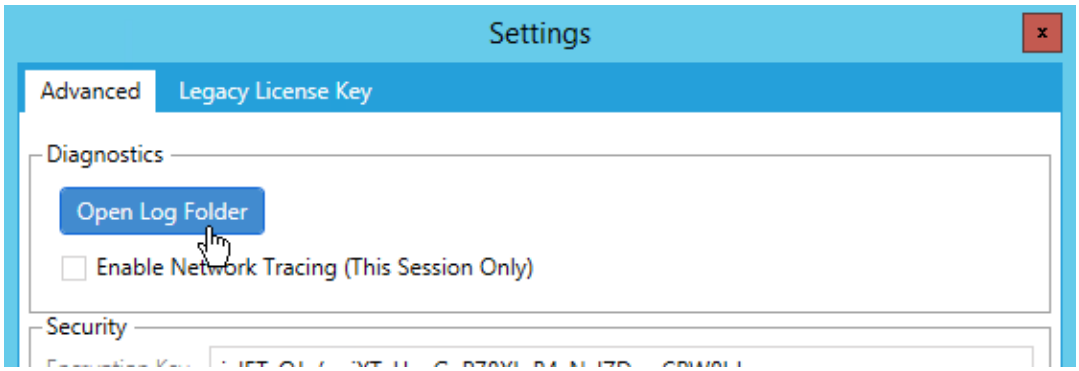
Content Migration Tool Log File Location

To find the Content Migration Tool log files from within the Content Migration Tool:

1. Start Content Migration Tool.
2. Click **Help** and **Settings**:



3. In the **Settings** dialog, click **Open Log Folder**:



A window opens with the log files.

If you are working with Tableau Support and they ask you to send log files, zip the files up before you send them. For more information on sending log files to Tableau, see the Tableau Knowledge Base.

Who can do this

Typically, the tasks listed above can only be done by a user with Administrator access on the machine.

## Activity Log

If you have Tableau Server with Advanced Management, Activity Log files are automatically recorded for detailed analysis and auditing.

Use these logs to:

- **View and analyze event data:** Access detailed event data for Tableau Server, capturing compliance information and tracking activities across your sites. All events include a timestamp and the ID of the actor, and if relevant, the ID of the affected content.
- **Audit permissions changes:** Track and audit permissions changes, such as adding or removing users from a group, moving content between projects, and explicitly changing content permissions. This is essential for implementing robust controls for compliance

purposes.

- **Supplement Admin Views:** Enhance the information provided by Admin Views to track site activity and usage metrics. You can integrate Activity Log data with monitoring tools, such as Splunk or Amazon EventBridge to query log fields and answer questions like the last 10 actions taken by a user, who last performed an event on content, and what the last action on content was.

## Accessing Activity Log events

Activity Log events are stored in the `vizportal` and `vizqlserver` folders on the local hard drive. By default, the folders are located at `/var/opt/tableau/tableau_server-/data/tabsvc/logs/`. Within each directory, you'll find files named `<process name>-cepp-canonical-events_*.log` that record events and operations for your deployment.

For a full list of Activity Log events, see Activity Log Site Event Type Reference.

## Audit Permissions Using the Activity Log

Permission auditing allows system administrators to monitor which users have modified access controls to Tableau content. There are two ways to modify access control: *explicit* changes (by changing permission capabilities on a project or content item) and *effective* changes (by changing user site roles, group membership, moving content, and so on). All of these changes are recorded, so administrators can certify that security and access controls are maintained.

For more information about how permission rules are evaluated, see Effective permissions.

Log format

Every action that modifies user or group access to content will get a log entry. Each log entry is structured in a JSON format, with specific keys representing different pieces of information. A log entry contains two parts:

- Metadata: Contains information about when and where an action occurred and what user performed the action.
- Action: Contains information about what piece of content had its permissions changed, what capabilities were changed, and to what values the capabilities were changed.

**Note:** Activity Log records changes made through the Permissions Dialog UI and REST API. For more information about API methods, see Permissions Methods.

The Activity Log entries are not formatted, and the keys are not sorted in any particular order in the logs. When auditing permissions, you can combine Activity Log data with other data sources to link IDs to names and make the events easier to interpret.

Example

The following is an example log entry showing a group was allowed to connect to a data source.

```
{
        "actorUserId": 39872,
        "actorUserLuid": "4e6b42bf-9040-4e60-b326-1c56a4fb96f8",
        "authorizableType": "DATASOURCE",
        "capabilityId": 32,
        "capabilityValue": "connect",
        "contentId": 2099835,
        "contentName": "Superstore ExtractNeal3",
        "eventTime": "2023-01-31T22:44:23.650058Z",
        "granteeId": 22,
        "granteeLuid": "dae0717a-d524-436d-b469-fadeaa22a5dd",
        "granteeType": "Group",
        "granteeValue": "GROUP_ALLOW",
        "initiatingUserId": 39872,
        "initiatingUserLuid": "4e6b42bf-9040-4e60-b326-1c56a4fb96f8",
        "isError": false,
        "eventCategory": "security",
        "eventType": "set_permissions",
```

```
        "eventVersion": "1.0",
        "permissionType": "explicit",
        "siteLuid": "b45e272d-10c7-49d5-9037-e53ce47dbf4e"
}
```

The log entry captures essential information regarding the event, including:

- `eventType` shows a set permissions event occurred
- `permissionType` shows an explicit change to permissions
- `contentId` shows the ID of the content that was modified
- `authorizableType` shows the content type, in this case, a data source
- `capabilityValue` shows the capability that was changed
- `granteeId` shows the grantee that was affected
- `actorUserId` shows the ID of the user who performed the change
- `eventTime` shows the date and time of the change

Events

Log entries contain various event types for permissions changes, such as `content_owner_change` when the content owner changes or `delete_permissions` when an explicit permission rule is deleted on content. For more information about event types, attributes, and when they're recorded, see Activity Log Site Event Type Reference.

## Activity Log Site Event Type Reference

This topic describes the Activity Log site event types and attributes.

Event type details

The following content describes site event types and attributes in Activity Log. Use the alphabetically sorted list of event types on the right, or **ctrl/cmd-f** to go directly to keywords you have in mind.

**Note:** Timestamps for events are recorded in ISO 8601 UTC.

Common attributes

The table contains common attributes for all Activity Log site events. For event-specific attributes, review the individual event tables in this topic.

| Attribute Name | Type | Description |
|---|---|---|
| actorUserId | integer | ID of the user who performed the action that initiated the event |
| actorUserLuid | string | LUID of the user who performed the action that initiated the event |
| eventOutcome | string | Represents the final outcome of the operation. Possible values are:<br>• **success:** The attempted operation completed successfully.<br>• **unauthorized:** The initiating user wasn't authorized to perform the operation.<br>• **client_error:** The operation failed due to a cause attributable to the client/caller. For example, invalid API request parameters, client connection timeout, or throttling.<br>• **internal_error:** The operation failed due to an unexpected internal error. |
| eventOutcomeReason | string | Provides additional details about the event outcome |
| eventTime | string | Timestamp when the event occurred |
| initiatingUserId | integer | ID of the initiating user. For impersonation, it's the ID of the administrative user who initiated impersonation. For standard login, the value is the same as `userId`. |

| | | |
|---|---|---|
| initiatingUserLuid | string | LUID of the initiating user. For impersonation, it's the LUID of the administrative user who initiated impersonation. For standard login, the value is the same as `userLuid`. |
| licensingRoleName | string | Name of the user's licensing role when the event occurred |
| serviceName | string | Name of service that initiated the event, such as vizportal, vizqlserver, or sitesaml. |
| siteLuid | string | LUID of the Tableau site where the event occurred |
| siteRoleId | integer | The user's site role ID. The value 0 = SiteAdministratorExplorer, 1 = SupportUser, 2 = ExplorerCanPublish, 3 = Explorer, 7 = Guest, 8 = Unlicensed, 9 = Viewer, 10 = Creator, and 11 = SiteAdministratorCreator. |
| systemAdminLevel | integer | Indicates if the user is a system administrator. The value 10 = System Admin and 0 = Not a system admin. |

add_delete_user_to_group

The `add_delete_user_to_group` event is logged when a user is added or removed from a group.

| Attribute Name | Type | Description |
|---|---|---|
| groupId | integer | The ID of the group |
| groupLuid | string | The LUID of the group |
| groupOperation | string | Group operation, either add or delete user to a group |
| isError | boolean | Indicates if the audit scenario was completed successfully or failed with an error |

| | | |
|---|---|---|
| userId | integer | The ID of the user |
| userLuid | string | The LUID of the user |

content_owner_change

The `content_owner_change` event is logged when the content owner changes.

| Attribute Name | Type | Description |
|---|---|---|
| contentId | integer | The ID of the content that had the owner changed |
| contentLuid | string | LUID of the content that had the owner changed |
| contentName | string | Name of the content that had the owner changed |
| contentType | string | The type of content, such as data source, workbook, or view |
| isError | boolean | Indicates if the audit scenario was completed successfully or failed with an error |
| newOwnerId | integer | The ID of the new content owner |
| newOwnerLuid | string | The LUID of the new content owner |
| oldOwnerId | integer | The ID of the old content owner |
| oldOwnerLuid | string | The LUID of the old content owner |

create_delete_group

The `create_delete_group` event is logged when a group is created or deleted.

| Attribute Name | Type | Description |
|---|---|---|
| groupDomain | string | The domain of the group, such as local |
| groupId | integer | The ID of the group |

| | | |
|---|---|---|
| groupLuid | string | The The LUID of the group |
| groupName | string | The name of the group that had its permissions changed |
| groupOperation | string | Group operation, either create or delete |
| isError | boolean | Indicates if the audit scenario was completed successfully or failed with an error |

create_permissions

The `create_permissions` event is logged when a new explicit permission rule is created.

**Note:** Deprecated in October 2024. Use the set_permissions event instead.

| Attribute Name | Type | Description |
|---|---|---|
| authorizableType | string | The type of content that had its permissions changed, such as a project or workbook |
| capabilityId | integer | The ID of the capability. A capability is the ability to perform actions on content, such as view, filter, download, or delete |
| capabilityValue | string | Description of the capability |
| contentId | integer | The ID of the content that had the permissions updated |
| contentLuid | string | The LUID of the content item |
| contentName | string | The name of the content that had the permissions updated |
| granteeId | integer | The ID of the grantee |
| granteeLuid | string | The LUID of the grantee |
| granteeType | string | The type of grantee, either user or group |

| granteeValue | string | The updated permissions value, such as 'user allow' or 'group allow' |
|---|---|---|
| isError | boolean | Indicates if the audit scenario was completed successfully or failed with an error |

delete_all_permissions

The `delete_all_permissions` event is logged when all explicit permission rules for content are deleted, typically when content is deleted.

| Attribute Name | Type | Description |
|---|---|---|
| authorizableType | string | The type of content that had its permissions changed, such as a project or workbook |
| contentId | integer | The ID of the content that had the permissions updated |
| contentLuid | string | The LUID of the content |
| contentName | string | The name of the content that had the permissions updated |
| isError | boolean | Indicates if the audit scenario was completed successfully or failed with an error |

delete_permissions

The `delete_permissions` event is logged when an explicit permission rule is deleted on content.

| Attribute Name | Type | Description |
|---|---|---|
| authorizableType | string | The type of content that had its permissions changed, such as a project or workbook |
| capabilityId | integer | The ID of the capability. A capability is the ability to perform actions on content, such as view, filter, download, or delete |

| | | |
|---|---|---|
| capabilityValue | string | Description of the capability |
| contentId | integer | The ID of the content that had the permissions updated |
| contentLuid | string | The LUID of the content |
| contentName | string | The name of the content that had the permissions updated |
| granteeId | integer | The ID of the grantee |
| granteeLuid | string | The LUID of the grantee |
| granteeType | string | The type of grantee, either user or group |
| granteeValue | string | The updated permissions value, such as 'user allow' or 'group allow' |
| isError | boolean | Indicates if the audit scenario was completed successfully or failed with an error |

delete_permissions_grantee

The `delete_permissions_grantee` event is logged when all explicit permission rules for a user are deleted, typically when the user is deleted.

| Attribute Name | Type | Description |
|---|---|---|
| granteeId | integer | The ID of the grantee |
| granteeLuid | string | The LUID of the grantee |
| granteeType | string | The type of grantee, either user or group |
| isError | boolean | Indicates if the audit scenario was completed successfully or failed with an error |

display_sheet_tabs

The `display_sheet_tabs` event is logged when the "Tabbed Views" value is updated on a workbook.

| Attribute Name | Type | Description |
|---|---|---|
| displayTabs | boolean | Indicates whether sheets of the workbook are displayed as tabs or not |
| isError | boolean | Indicates if the audit scenario was completed successfully or failed with an error |
| workbookId | integer | The ID of the workbook |

move_content

The `move_content` event is logged when content is moved, for example, moving a workbook between projects.

| Attribute Name | Type | Description |
|---|---|---|
| contentId | integer | The ID of the content that had the owner changed |
| contentLuid | string | LUID of the content that had the owner changed |
| contentName | string | Name of the content that had the owner changed |
| contentType | string | The type of content, such as data source, workbook, or view |
| isError | boolean | Indicates if the audit scenario was completed successfully or failed with an error |
| newContainerLuid | string | LUID of the new container |
| newContainerType | string | The new container type, such as a project |
| oldContainerLuid | string | LUID of the previous container |
| oldContainerType | string | The previous container type, such as a project |

project_lock_unlock

The `project_lock_unlock` event is logged when project permissions are locked or unlocked.

| Attribute Name | Type | Description |
|---|---|---|
| controllingProjectLuid | string | LUID of the project that controls permissions for the nested project |
| isError | boolean | Indicates if the audit scenario was completed successfully or failed with an error |
| projectLuid | string | LUID of the project |
| projectOperation | string | Project operation, either lock or unlock |

set_permissions

The `set_permissions` event is logged when an explicit permissions rule is created or updated for a content item.

| Attribute Name | Type | Description |
|---|---|---|
| authorizableType | string | The type of content that had its permissions changed, such as project or workbook |
| capabilityId | integer | The ID of the capability. A capability is the ability to perform a certain action on a particular piece of content, such as view, filter, download or delete. |
| capabilityValue | string | Description of the capability |
| contentId | integer | The ID of the content that had the permissions set |
| contentLuid | string | The LUID of the content item |
| contentName | string | The name of the content that had the permissions set |
| granteeId | integer | The ID of the grantee |

| | | |
|---|---|---|
| granteeLuid | string | The LUID of the grantee |
| granteeType | string | The type of grantee, either user or group |
| granteeValue | string | The set permissions value, such as 'user allow' or 'group allow' |
| isError | boolean | Indicates if the audit scenario was completed successfully or failed with an error |
| permissionType | string | The permission type, either explicit or unspecified |

update_permissions

The `update_permissions` event is logged when an explicit permission rule is updated for a content item.

**Note:** Deprecated in October 2024. Use the set_permissions event instead.

| Attribute Name | Type | Description |
|---|---|---|
| authorizableType | string | The type of content that had its permissions changed, such as a project or workbook |
| capabilityId | integer | The ID of the capability. A capability is the ability to perform actions on content, such as view, filter, download, or delete |
| capabilityValue | string | Description of the capability |
| contentId | integer | The ID of the content that had the permissions updated |
| contentLuid | string | The LUID of the content |
| contentName | string | The name of the content that had the permissions updated |
| granteeId | integer | The ID of the grantee |

| | | |
|---|---|---|
| granteeLuid | string | The LUID of the grantee |
| granteeType | string | The type of grantee, either user or group |
| granteeValue | string | The updated permissions value, such as 'user allow' or 'group allow' |
| isError | boolean | Indicates if the audit scenario was completed successfully or failed with an error |
| permissionType | string | The permission type, either explicit or unspecified |

update_permissions_template

The `update_permissions_template` event is logged when a permission template for a project is updated.

| Attribute Name | Type | Description |
|---|---|---|
| authorizableType | string | The type of content that had its permissions changed, such as a project or workbook |
| capabilityId | integer | The ID of the capability. A capability is the ability to perform actions on content, such as view, filter, download, or delete |
| capabilityValue | string | Description of the capability |
| contentId | integer | The ID of the content that had the permissions updated |
| contentLuid | string | The LUID of the content |
| contentName | string | The name of the content that had the permissions updated |
| granteeId | integer | The ID of the grantee |
| granteeLuid | string | The LUID of the grantee |
| granteeType | string | The type of grantee, either user or group |

| | | |
|---|---|---|
| granteeValue | string | The updated permissions value, such as 'user allow' or 'group allow' |
| isError | boolean | Indicates if the audit scenario was completed successfully or failed with an error |
| permissionType | string | The permission type, either explicit or unspecified |
| templateType | string | The type of permission template used to change permissions, such as workbook or data source |

user_create_delete

The `user_create_delete` event is logged when a user is created or deleted.

| Attribute Name | Type | Description |
|---|---|---|
| forUserName | string | The name of the user whose account was either created, updated or deleted |
| isError | boolean | Indicates if the audit scenario was completed successfully or failed with an error |
| siteRole | string | Site role of the user. Determines the maximum level of access a user can have on the site |
| targetUserId | integer | The ID of the user whose account was either created, updated, or deleted |
| targetUserLuid | string | The LUID of the user whose account was either created, updated, or deleted |
| userOperation | string | The action performed on a user, either create, delete, or site role change |

# Tableau Server Key Management System

Tableau Server has three Key Management System (KMS) options that allow you to enable encryption at rest. One is a local option that is available with all installations of Tableau Server. Two additional options require Advanced Management capabilities, but allow you to use a different KMS.

> **Important:** As of September 16, 2024, Advanced Management is no longer available as an independent add-on option. Advanced Management capabilities are only available if you previously purchased Advanced Management, or if you purchase certain license editions - either Tableau Enterprise (for Tableau Server or Tableau Cloud) or Tableau+ (for Tableau Cloud).

Beginning in version 2019.3, Tableau Server added these KMS options:

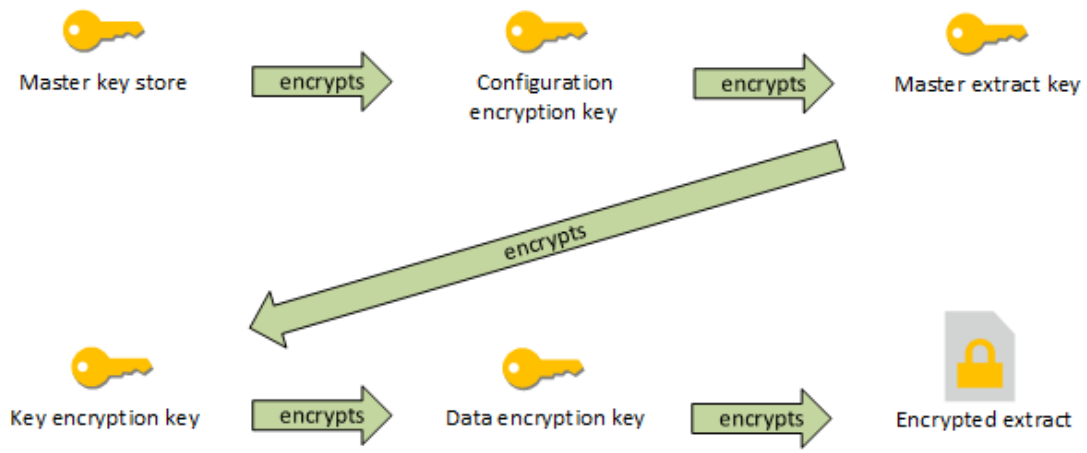
- A local KMS that is available with all installations. This is described below.
- An AWS-based KMS that comes as part of Advanced Management. For details, see AWS Key Management System.

Beginning in version 2021.1, Tableau Server added another KMS option:

- An Azure-based KMS that comes as part of Advanced Management. For details, see Azure Key Vault.

## Tableau Server local KMS

The Tableau Server local KMS uses the secret storage capability described in Manage Server Secrets to encrypt and store the master extract key. In this scenario, the Java keystore serves as the root of the key hierarchy. The Java keystore is installed with Tableau Server. Access to the master key is managed by native file system authorization mechanisms by the operating system. In the default configuration, the Tableau Server local KMS is used for encrypted extracts. The key hierarchy for local KMS and encrypted extracts is illustrated here:



## Troubleshoot configuration

Multi-node misconfiguration

In a multi-node setup for AWS KMS, the `tsm security kms status` command may report healthy (OK) status, even if another node in the cluster is misconfigured. The KMS status check only reports on the node where the Tableau Server Administration Controller process is running and does not report on the other nodes in the cluster. By default the Tableau Server Administration Controller process runs on the initial node in the cluster.

Therefore, if another node is misconfigured such that Tableau Server is unable to access the AWS CMK, those nodes may report Error states for various services, which will fail to start.

If some services fail to start after you have set KMS to the AWS mode, then run the following command to revert to local mode: `tsm security kms set-mode local`.

## Regenerate RMK and MEK on Tableau Server

To regenerate the root master key and the master encryption keys on Tableau Server, run the `tsm security regenerate-internal-tokens` command.

## AWS Key Management System

Tableau Server has three Key Management System (KMS) options that allow you to enable encryption at rest. Two of these require Advanced Management capabilities, while a local one is available with all installations of Tableau Server.

> **Important:** As of September 16, 2024, Advanced Management is no longer available as an independent add-on option. Advanced Management capabilities are only available if you previously purchased Advanced Management, or if you purchase certain license editions - either Tableau Enterprise (for Tableau Server or Tableau Cloud) or Tableau+ (for Tableau Cloud).

Beginning in version 2019.3, Tableau Server added these KMS options:

- A local KMS that is available with all installations. For details, see Tableau Server Key Management System.
- An AWS-based KMS that comes as part of Advanced Management. This is described below.

Beginning in version 2021.1, Tableau Server added another KMS option:

- An Azure-based KMS that comes as part of Advanced Management. For details, see Azure Key Vault.

With the release of version 2019.3, Tableau Server supports the AWS key management system (KMS) as part of Advanced Management.

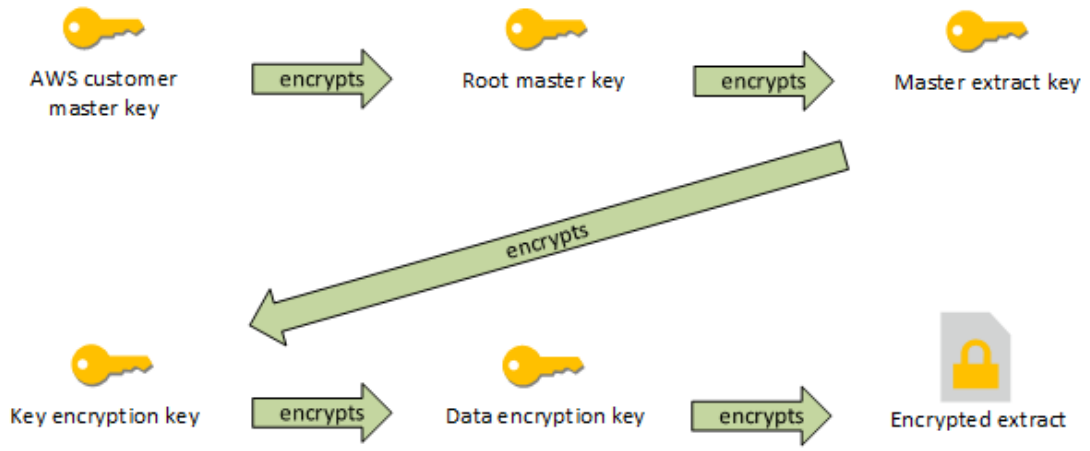
AWS KMS for encryption at rest

> AWS KMS is available as part of Advanced Management in Tableau Server. For more information see About Tableau Advanced Management on Tableau Server.

If your organization is deploying Data Extract Encryption at Rest, then you may optionally configure Tableau Server to use AWS as the KMS for extract encryption. To enable AWS KMS,

you must deploy Tableau Server in AWS EC2. In the AWS scenario, Tableau Server uses the AWS KMS customer master key (CMK) to generate an AWS data key. Tableau Server uses the AWS data key as the root master key for all encrypted extracts. However, even when configured for AWS KMS, the native Java keystore and local KMS are still used for secure storage of secrets on Tableau Server. The AWS KMS is only used to encrypt the root master key for encrypted extracts.

Using AWS to encrypt the master root key provides better security properties by not storing the master key under the same permissions as the extracts.



The key hierarchy when Tableau Server is configured with AWS KMS

Configure AWS KMS for Tableau Server encrypted extracts

To use the AWS customer master key (CMK) to encrypt the root key in the Tableau Server KMS hierarchy, you must configure Tableau Server as described in this section.

Before you begin, verify that you meet the following requirements:

- Tableau Server must be deployed in AWS EC2
- Tableau Server must be configured with Advanced Management. See About Tableau Advanced Management on Tableau Server.
- You must have administrative control of a customer master key (CMK) created in AWS Key Management Service

Step 1: Create CMK and set key policy for Tableau Server in AWS

The following procedures are performed in the AWS KMS service. References are included to AWS documentation.

1. Create the CMK that you will use for Tableau Server. See the AWS topic, Creating Keys.
2. Update the server instance's IAM role.

   Tableau Server needs to be able to authenticate with AWS KMS using the instance's IAM role. The role needs to have a policy attached to it. The policy should be giving the instance permissions to call the "GenerateDataKey" and "Decrypt" actions on the CMK. See IAM Roles for Amazon EC2..

   In a multi-node deployment of Tableau Server, all nodes of the server must be running under roles that have this policy (or equivalent) attached. You can assign the same role to all nodes in the cluster.

3. At a minimum, the CMK must have a key policy where the `Effect` is set to `Allow` the `Prinicpal` (the IAM role that is attached to the server instances) the `Action: GenerateDataKey` and `Decrypt`. See Using Key Policies in AWS KMS.

Step 2: Collect AWS configuration parameters

You will need the full ARN string from AWS KMS. This string is in the "General configuration" section of the AWS KMS management pages. The ARN is presented in this format: arn:aws:kms:<region>:<account>:key/<CMK_ID>, for example, `arn:aws:kms:us-west-2:867530990073:key/1abc23de-fg45-6hij-7k89-1l0mn1234567`.

You will also need to specify the AWS region, which is also included in the ARN string. In the example above, the region is `us-west-2`. The region is where your KMS instance resides. In the next step, you will need to specify a region as shown in the Region column in the Amazon API Gateway table.

Step 3: Configure Tableau Server for AWS KMS

Run the following command on Tableau Server. This command will restart the server:

- `tsm security kms set-mode aws --aws-region "<region>" --key-arn "arn:aws:kms:<region>:<account_number>:key/<CMK_ID>"`

  The `--key-arn` option takes a direct string copy from the ARN in the "General configuration" section of the AWS KMS management pages.

  For example, if your AWS KMS instance is running in us-west-2 region, your account number is 867530990073, and your CMK key is 1abc23de-fg45-6hij-7k89-1l0mn1234567, then the command would be as follows:

  ```
  tsm security kms set-mode aws --aws-region "us-west-2" --key-arn "arn:aws:kms:us-west-2:867530990073:key/1abc23de-fg45-6hij-7k89-1l0mn1234567"
  ```

Step 4: Enable encryption at rest

See Extract Encryption at Rest.

Step 5: Validate installation

1. Run the following command:

   ```
   tsm security kms status
   ```

   The following information may be returned:

   - The ARN (ID) of the customer master key (CMK)
   - The region the CMK is in
   - The ID of the root master key (RMK) in use. The RMK is a key that is encrypted by the CMK. Tableau Server decrypts the CMK by making calls to AWS KMS. The RMK is then used to encrypt/decrypt the master extract key (MEK). The RMK can change, but there will be only one at a time.
   - KMS stores a collection of master extract keys (MEKs). Each MEK has:
     - An ID, for example, 8ddd70df-be67-4dbf-9c35-1f0aa2421521
     - Either a “encrypt or decrypt key” or “decrypt-only key” status. If a key is "encrypt or decrypt", Tableau Server will encrypt new data with it. Otherwise, the key will only be used for decryption
     - A creation timestamp, for example, "Created at: 2019-05-29T23:46:54Z."

- First transition to encrypt and decrypt: a timestamp indicating when the key became an encrypt or decrypt key.
- Transition to decrypt-only: a timestamp indicating when the key transitioned to decrypt-only.

2. View logs after you encrypt and decrypt extracts:

   - Publish extracts to your site and then encrypt them. See Extract Encryption at Rest.
   - Access the extracts with Tableau Desktop or with Web Authoring on a browser (this will decrypt the extracts for use).
   - Search the vizqlserver_node log files for the `AwsKmsEncryptionEnvelopeAccessor` and `AwsKmsEncryptionEnvelope` strings. The default location of the logs are at `/var/opt/tableau/tableau_server/data/tabsvc/logs/`

     Log entry examples that indicate successful configuration include the following:

     - Decrypted the RMK with ID 1abc23de-fg45-6hij-7k89-1l0mn1234567 using the CMK with ARN arn:aws:kms:us-west-2:867530990073:key/1234567d-a6ba-451b-adf6-3179911b760f
     - Using RMK with ID 1abc23de-fg45-6hij-7k89-1l0mn1234567 to decrypt KMS store

     For publishing and extract refreshes related to KMS, search the backgrounder logs. For more information about logs, see Tableau Server Logs and Log File Locations.

Troubleshoot configuration

Multi-node misconfiguration

In a multi-node setup for AWS KMS, the `tsm security kms status` command may report healthy (OK) status, even if another node in the cluster is misconfigured. The KMS status check only reports on the node where the Tableau Server Administration Controller pro-

cess is running and does not report on the other nodes in the cluster. By default the Tableau Server Administration Controller process runs on the initial node in the cluster.

Therefore, if another node is misconfigured such that Tableau Server is unable to access the AWS CMK, those nodes may report Error states for various services, which will fail to start.

If some services fail to start after you have set KMS to the AWS mode, then run the following command to revert to local mode: `tsm security kms set-mode local`.

Refresh AWS CMK

Refreshing the AWS CMK is a task that you perform with AWS. By default, the AWS CMK will refresh once a year. See the AWS topic, How Automatic Key Rotation Works. Since the ARN and region do not change, you do not need to update the KMS configuration on Tableau Server for normal CMK refresh scenarios.

After AWS CMK refreshes, you must regenerate the internal RMK and MEKs on Tableau Server. You should also re-encrypt all extracts with the new CMK:

1. Run the `tsm security regenerate-internal-tokens` command to regenerate all internal keys on Tableau Server, including the RMK and MEKs used for extract encryption.
2. Run `tabcmd reencryptextracts <site-name>` to re-encrypt extracts on a given site. Run this command on every site where you are storing encrypted extracts. Depending on the number of encrypted extracts on the site, this operation could consume significant server processing load. Consider running this operation outside of business hours. See Extract Encryption at Rest.

Regenerate RMK and MEK on Tableau Server

To regenerate the root master key and the master encryption keys on Tableau Server, run the `tsm security regenerate-internal-tokens` command.

Back up and restore with AWS KMS

A server backup can be taken in AWS mode with no additional configurations or procedures. The backup contains encrypted copies of the RMK and MEKs. Decrypting the keys requires access and control of the AWS CMK.

For the restore scenario, the server being restored to can be in either KMS mode, including Local. The only requirement is that the server the backup is being restored to has decrypt access to the CMK the backup itself used.

Upon restore, the MEKs from the backup are imported as decrypt-only keys. The RMK is not migrated over. A new RMK is generated as part of the installation/restore process.

## Azure Key Vault

Tableau Server has three Key Management System (KMS) options that allow you to enable encryption at rest. Two of these require Advanced Management capabilities, while a local one is available with all installations of Tableau Server.

> **Important:** As of September 16, 2024, Advanced Management is no longer available as an independent add-on option. Advanced Management capabilities are only available if you previously purchased Advanced Management, or if you purchase certain license editions - either Tableau Enterprise (for Tableau Server or Tableau Cloud) or Tableau+ (for Tableau Cloud).

Beginning in version 2019.3, Tableau Server added these KMS options:

- A local KMS that is available with all installations. For details, see Tableau Server Key Management System.
- An AWS-based KMS that comes as part of Advanced Management. For details, see AWS Key Management System.

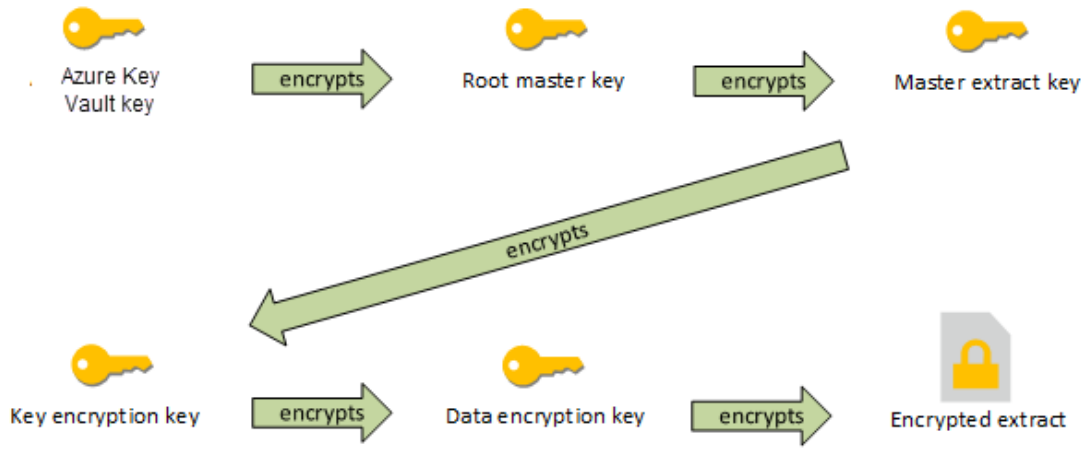
Beginning in version 2021.1, Tableau Server added another KMS option:

- An Azure-based KMS that comes as part of Advanced Management. This is described below.

## Azure Key Vault for encryption at rest

> Azure Key Vault is available as part of Advanced Management in Tableau Server beginning in version 2021.1.0. For more information see About Tableau Advanced Management on Tableau Server.

If your organization is deploying Data Extract Encryption at Rest, then you may optionally configure Tableau Server to use Azure Key Vault as the KMS for extract encryption. To enable Azure Key Vault, you must deploy Tableau Server in Azure. In the Azure scenario, Tableau Server uses the Azure Key Vault to encrypt the root master key (RMK) for all encrypted extracts. However, even when configured for Azure Key Vault, the Tableau Server native Java keystore and local KMS are still used for secure storage of secrets on Tableau Server. The Azure Key Vault is only used to encrypt the root master key for encrypted extracts.



The key hierarchy when Tableau Server is configured with Azure Key Vault

### Configure Azure Key Vault for Tableau Server encrypted extracts

To use the Azure Key Vault to encrypt the root key in the Tableau Server KMS hierarchy, you must configure Tableau Server as described in this section.

Before you begin, verify that you meet the following requirements:

- Tableau Server must be deployed in Azure.
- Tableau Server must be configured with a Advanced Management license. See About Tableau Advanced Management on Tableau Server.
- You must have administrative control over the key vault in Azure where the key resides.

Step 1: Create a key vault and key for Tableau Server in Azure

The following procedures are performed in the Azure Key Vault service. References are included to Azure documentation.

1. Create the key vault that you will use for Tableau Server. See the Azure topic, Create a key vault.
2. Create a key in the vault. See the Azure topic, Manage keys and secrets.

   The key must be an asymmetric, RSA type, but can be any size (Tableau Server does not care about the key size). We recommend you use the Principle of Least Privilege to have maximum security.

   Tableau requires permissions to perform the GET, UNWRAP KEY, and WRAP KEY commands operations and we recommend you allow access for only these operations for least privilege. Assign the access policy to the VM you are running Tableau Server on.

   In a multi-node deployment of Tableau Server, the access policy must be assigned to all nodes of the server cluster.

Step 2: Collect Azure configuration parameters

You will need the key vault name and the key name from Azure.

Step 3: Configure Tableau Server for Azure Key Vault

Run the following command on Tableau Server. This command will restart the server:

- `tsm security kms set-mode azure --vault-name "<vault name>" --key-name "<key name>"`

The `--vault-name` and `--key-name` options a direct string copies from your Azure key vault.

For example, if your Azure key vault is named `tabsrv-keyvault` and your key is `tab-srv-sandbox-key01`, then the command would be as follows:

```
tsm security kms set-mode azure --vault-name "tabsrv-keyvault"
--key-name "tabsrv-sandbox-key01"
```

Step 4: Enable encryption at rest

See Extract Encryption at Rest.

Step 5: Validate installation

1. Run the following command:

   ```
   tsm security kms status
   ```

   The following information may be returned:

   - Status: OK (indicates the Key Vault is accessible by the controller node):
   - Mode: Azure Key Vault
   - Vault name: <key_vault_name>
   - Azure Key Vault key name: <key_name>
   - List of available UUIDs for MEKs indicating which key is active
   - Error information if the KMS data is not accessible

2. View logs after you encrypt and decrypt extracts:

   - Publish extracts to your site and then encrypt them. See Extract Encryption at Rest.

   - Access the extracts with Tableau Desktop or with Web Authoring on a browser (this will decrypt the extracts for use).

   - Search the vizqlserver_node log files for the `AzureKeyVaultEn-velopeAccessor` and `AzureKeyVaultEnvelope` strings. The default location

of the logs are at `/var/opt/tableau/tableau_server-/data/tabsvc/logs/`

For publishing and extract refreshes related to the Azure Key Vault, search the backgrounder logs. For more information about logs, see Tableau Server Logs and Log File Locations.

Troubleshoot configuration

Multi-node misconfiguration

In a multi-node setup for Azure Key Vault, the `tsm security kms status` command may report healthy (OK) status, even if another node in the cluster is misconfigured. The KMS status check only reports on the node where the Tableau Server Administration Controller process is running. It does not report on the other nodes in the cluster. By default the Tableau Server Administration Controller process runs on the initial node in the cluster.

Therefore, if another node is misconfigured so that Tableau Server is unable to access the Azure key, those nodes may report Error states for various services, which will fail to start.

If some services fail to start after you have set KMS to the "azure" mode, then run the following command to revert to local mode: `tsm security kms set-mode local`.

Refresh Azure Key

You refresh the Azure key in Azure. There is no required or scheduled key refresh period. You can refresh your key by creating a new key version in Azure. Because the Key Vault name and Key Name do not change, you do not need to update the KMS configuration on Tableau Server for normal Azure Key refresh scenarios.

Back up and restore with Azure Key Vault

A server backup can be taken in Azure Key Vault mode with no additional configurations or procedures. The backup contains encrypted copies of the RMK and MEKs. Decrypting the keys requires access and control of the Azure Key Vault.

For the restore scenario, the server being restored to can be in either Azure Key Vault or Local KMS mode. The only requirement is that the server to which the backup is being restored has access to the Azure Key Vault the backup itself used.

# Tableau Server External File Store

This topic provides an overview of Tableau Server External File Store.

Tableau Server File Store stores extracts and workbook revisions. Typically, Tableau Server File Store is a built-in Tableau Server process that is installed locally on Tableau Server. Starting in Tableau Server 2020.1, you can configure Tableau Server to use an external storage to store the File Store data. The external storage must be a network share, a dedicated file storage that enables multiple users and heterogeneous client devices to retrieve data from a centralized disk capacity. This can be a Server Message Block (SMB) for Windows or a Network File System (NFS) for Linux installations. Users on a local area network (LAN) access the shared storage via a standard Ethernet connection.

With this new feature, Tableau Server can now be configured in two ways:

- Install File Store locally, meaning File Store is installed on the Tableau Server nodes.
- Use External File Store (Beginning in 2020.1).

## Why use External File Store?

Using external storage has the following key benefits over installing File Store locally:

- **Centralized location:** When File Store is installed locally, the data needs to be replicated across multiple File Store nodes, which will consume network bandwidth. Moving data to a centralized location will eliminate the need for running File Store on multiple nodes in a Tableau cluster and replication between the nodes. This also reduces the disk space requirements on an individual node and also reduce the network bandwidth usage since the data will not be replicated on multiple nodes.
- **Improving backup time:** Snapshot backup technologies are efficient, and by using snapshot backup of the Tableau Data, you can expect to significantly reduce the amount of time it takes to do a Tableau backup.

# Managing External File Store

## License Management

To configure External File Store, you must have Advanced Management capabilities for Tableau Server. For more information, see About Tableau Advanced Management on Tableau Server. If you don't have Advanced Management capabilities, you will see the following behavior:

- If you try to configure Tableau Server with External File Store during installation, you will see an error message, but you will be able to continue the installation and Tableau Server File Store will be installed locally.
- If you are already using External File Store, and Advanced Managementis no longer available to your installation, you will see the following behavior:
    - The server will fail on restart.
    - Backups will fail.
    - If you no longer have Advanced Management capabilities, but have a valid Tableau Server license, you can migrate the External File Store to local File Store, to get your server up and running again. For more information on how to migrate from external repository to local repository, see Reconfigure File Store .

## Supported Migration Scenarios

- Moving File Store installed locally on Tableau Server to an external managed storage (network attached storage).
- Move File Store from external managed storage to Tableau Server.

## Backup and Restore

Backup on Tableau Server with External File Store is different than how you would create backup when File Store is installed locally. For more information on how to do backup and restore on Tableau Server with External File Store, see Backup and Restore with External File Store.

## Upgrade Considerations

There are no special steps necessary when upgrading Tableau Server configured with an External File Store. You can follow the normal upgrade process.

Tableau Server does not manage or setup high availability for the External File Store. Your managed storage may have solutions to support redundancy and high availability.

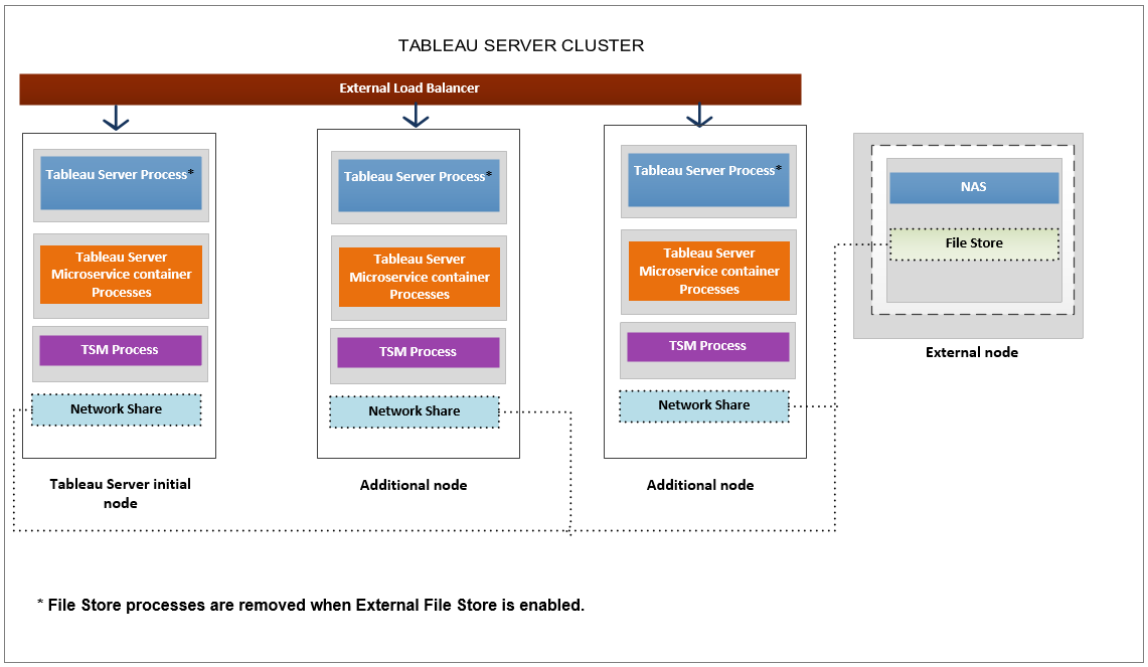
## Topology

When you configure Tableau Server with External File Store, you will no longer run File Store locally. The Server status page will indicate that the File Store process is on an external node.

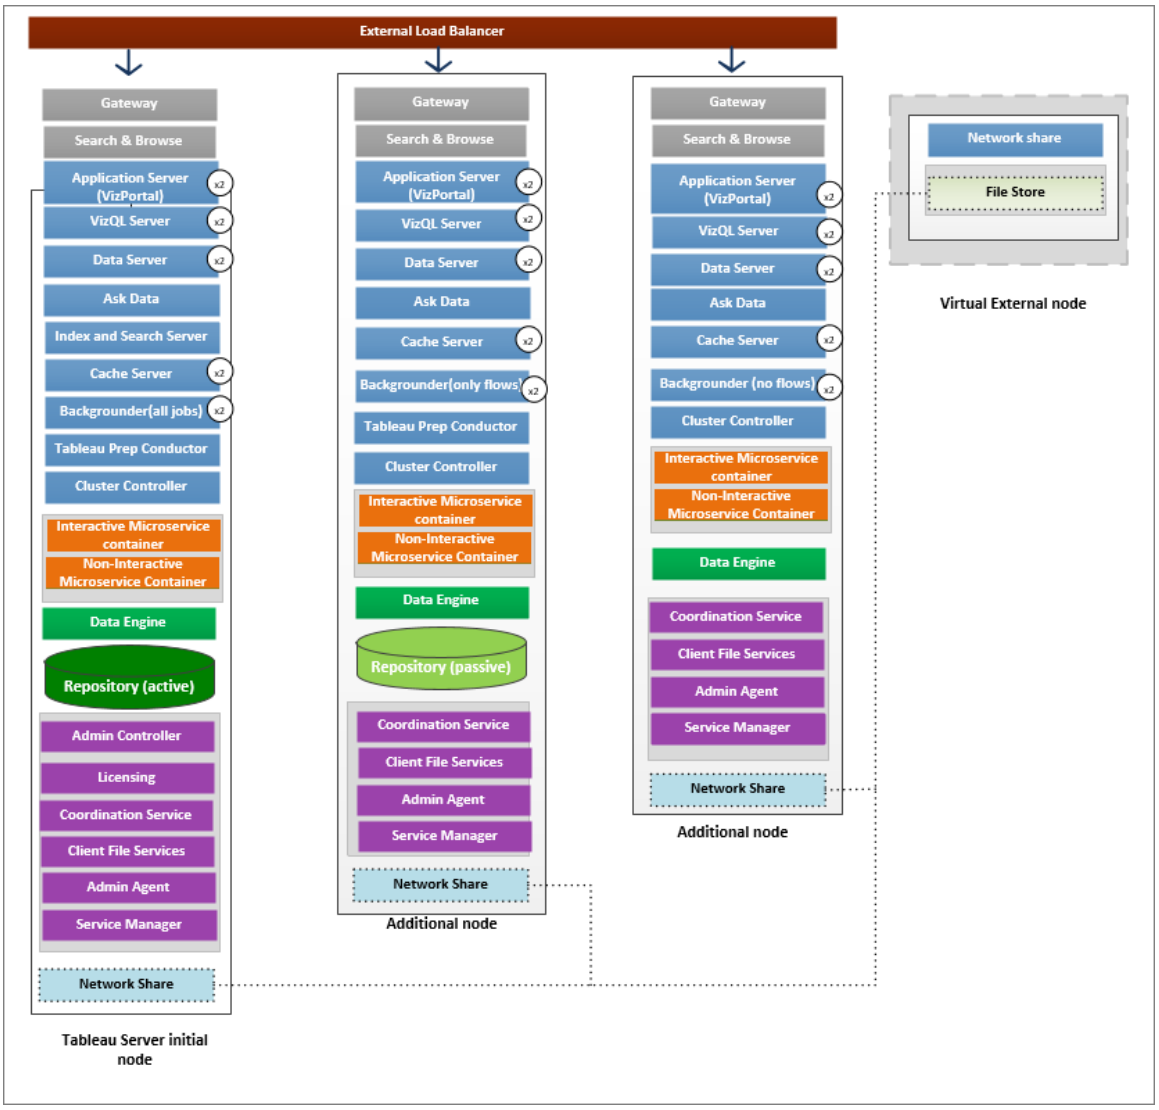
When File Store is configured external to Tableau Server, Data Engine and File Store are no longer co-located. During setup, Data Engine will continue to be automatically installed with other processes as described in Tableau Server Data Engine, except for File Store. However, when you have Tableau Server configured with External File Store, you will be able to install Data Engine on a separate node without any other processes.

When File Store is configured externally, Data Engine will access the File Store data (extracts) on the storage system across the network. To make sure that your overall system performs to your requirements, there are a few things you must consider for your network and storage system. For more information, see Performance Considerations for External File Store.

**The diagram below is a summarized version of the Tableau Server topology with External File Store.**



**The diagram below is a detailed version of the Tableau Server topology with External File Store and shows all the processes installed on each node.**



## Next

Install Tableau Server with External File Store

## Install Tableau Server with External File Store

This topic walks you through the process of configuring network share as your Tableau Server File Store for a new installation. If you are trying to do this on an existing installation of Tableau Server that has File Store running locally, see Reconfigure File Store .

Prerequisites

- You must use Tableau Server 2020.1 or later.
- You must have network share that you can use as your storage option. For recommendations on the storage solution, see Performance Considerations for External File Store.

  Use **NFS** for Linux installations.

  Estimating the storage size: You must take into account the amount of storage needed for publishing and refreshing extracts. In addition, you must also take into account the repository backup size unless you specifically choose the option to do your repository backup separately as described in the Option 2: Back up repository separately topic.

  - Extracts:
    - Consider the number of extracts that will be published to Tableau Server and the size of each extract. Test your needs by publishing several extracts to Tableau Server, and then checking the disk space used. You can use this amount of disk space to help you figure out how many extracts will be published to Tableau Server over time as well as how each existing extract will increase in size.
    - Consider the space needed by the temp directory during an extract refresh. The temp directory, which is where an extract is stored to during a refresh, may require up to three times the final file size of the extract.
  - Repository Backup:
    - To obtain an estimate of the repository data, check the size of `<data directory>/pgsql/data/base` directory.
    - To obtain the exact size of the repository data, open the backup file and use the size of the `workgroup.pg_dump` file.
- You must have Advanced Management capabilities enabled on your server. To learn more about Advanced Management, see About Tableau Advanced Management on Tableau Server.

## Install Tableau Server with External File Store

You can install Tableau Server with File Store using a network share to store Tableau Server data. This solution replaces the need for running the File Store process locally. To learn more about this solution and its benefits, see Tableau Server External File Store.

Use the following steps to install your Tableau Server with External File Store during install:

### Step 1: Configure a network share

On your file server:

1. Create and share a directory to use as the Tableau Server External File Store.
2. Make sure the network share is accessible as a directory in the same location on all the Tableau Server nodes.
3. Create the tableau directory in your network share and give full access to **tableau user** and **tableau group**. The tableau user will need read and write permissions to the directory on the network share. We recommend calling the directory '**tableau**'.

   ```
   /mnt/<network share>/tableau/
   ```

4. **Validate that the network share is configured properly**: From Tableau Server run a command to write to a network share and confirm that you are able to write to it.

### Step 2: Download and install TSM

1. Download the appropriate installer based on the distribution of Linux you are using.
2. Log on as a user with sudo access to the computer where you want to install Tableau Server.
3. Download the .rpm or .deb installer package.
4. Navigate to the directory where you copied the .rpm or .deb package.
5. Use the package manager to install the Tableau Server.

- On **RHEL-like** distributions, including CentOS, you have the option to install Tableau Server to a non-default location.

- Default location—To install to the default location (/opt/tableau/tableau_server), run the following commands:

  ```
  sudo yum update

  sudo yum install tableau-server-<version>.x86_64.rpm
  ```

- Non-default location—to install to a non-default location, you must use rpm -i. You will also need to install all dependent packages. See the note below.

  Run the following command:

  ```
  sudo rpm -i--prefix/preferred/install/path tableau-server.rpm
  ```

  **Note:** When you use yum to install Tableau Server, all dependent packages are automatically downloaded and installed. This is the preferred method for installing Tableau Server. If you want to install to a non-default location, or your organization does not allow you to use yum and you must install using rpm -i, you must also install all dependent packages separately. For information about installing dependent packages, see Installing Tableau Server on an Air-Gapped Computer Running Linux.

- On **Ubuntu and Debian**, run the following commands:

  ```
  sudo apt-get update

  sudo apt-get -y install gdebi-core

  sudo gdebi -n tableau-server-<version>_amd64.deb
  ```

Step 3: Initialize TSM

1. Run the following script to start TSM:

   ```
   sudo ./initialize-tsm --accepteula --<optional_parameters>
   ```

The only required parameter for the initialize-tsm script is --accepteula. You must include this parameter to accept the Tableau Server End User License Agreement (EULA). The EULA is available in the following location:

```
/opt/tableau/tableau_server/packages/docs.<version_code>/Commercial_EULA.txt
```

2. Log off and log on again to the terminal before you configure Tableau Server.

   When you log on again, you create a new session in which group membership changes have taken effect. The new session also has access to the environment variables added by the initialize-tsm script.

   Alternatively, you can run the following command to update your path for the current session (but not to update your group membership):

   ```
   source /etc/profile.d/tableau_server.sh
   ```

Step 4: Activate and register Tableau Server

Provide the Tableau Server Key and the Advanced Management key in the activate step. You will need to run the following command twice, first with the Tableau Server product key and then with the Advanced Management product key:

```
tsm licenses activate -k <product key>
```

Step 5. Enable External File Store

Configuring Tableau Server with external repository can only be done using TSM CLI.

1. Enable the network storage feature using the following tsm commands:

   ```
   tsm topology external-services storage enable --network-share /mnt/<network share name>/tableau
   ```

   The setup program automatically creates the following directory structure in the share:

   **PostgreSQL data backups:**

*tableau_data/tabsvc/repository_backup*

> **Note:** This directory will be created the first time you create a backup.

**Extracts and workbook revisions:**

*tableau_data tabsvc/dataengine/extracts*

*tableau_data/tabsvc/dataengine/revisions*

Step 6: Configure the initial node settings

Follow the instructions provided in the Configure Initial Node Settings topic.

Step 7: Complete the install

You must create the initial administrative account for Tableau Server.

- If you configured a local identity store during setup, then specify a name and password that you want to use.
- If you configured a LDAP or Active Directory identity store during setup, then you must specify a user account that is a member of the directory.

To create the initial user, run the following tabcmd command:

```
tabcmd initialuser --server localhost:80 --username '<new-admin-username>'
```

After you run the command, the shell will prompt for an administrative password.

Step 8: Post-installation tasks

After you have created the Tableau Server administrator account, continue your deployment by working through the configuration steps described in the Post Installation Tasks topics.

Who can do this

Tableau Server Administrators can install and configure Tableau Server and External File Store. In addition, you must have permissions and access to configure the network share to use with Tableau Server.

Next

Backup and Restore with External File Store

## Reconfigure File Store

Your Tableau Server may be configured with a locally running File Store or an External File Store. This topic describes the steps needed to reconfigure your existing Tableau Server:

- Reconfigure your Tableau Server to use External File Store. This will move your File Store to a network share.
- Reconfigure your Tableau Server to run File Store locally. This will move your File Store from the external storage to your Tableau Server.
- Configure your Tableau Server to use a different storage. An example of this might be when your current network share is at the end of life and you need to use a new network share with new hardware.

Reconfigure Tableau Server with External File Store

Prerequisites

- Tableau Server should be version 2020.1 or later.
- You must have a network share to use as the external storage.

  Use **NFS** for Linux installations.

  Storage and network considerations: See Performance Considerations for External File Store.

Estimating the storage size: You must take into account the amount of storage needed for publishing and refreshing extracts. In addition, you must also take into account the repository backup size unless you specifically choose the option to do your repository backup separately as described in the Option 2: Back up repository separately topic.

- Extracts:
  - Consider the number of extracts that will be published to Tableau Server and the size of each extract. Test your needs by publishing several extracts to Tableau Server, and then checking the disk space used. You can use this amount of disk space to help you figure out how many extracts will be published to Tableau Server over time as well as how each existing extract will increase in size.
  - Consider the space needed by the temp directory during an extract refresh. The temp directory, which is where an extract is stored to during a refresh, may require up to three times the final file size of the extract.
- Repository Backup:
  - To obtain an estimate of the repository data, check the size of `<data directory>/pgsql/data/base` directory.
  - To obtain the exact size of the repository data, open the backup file and use the size of the `workgroup.pg_dump` file.
- Tableau Server should have a valid and activated Advanced Management license.

Step 1: Upgrade Tableau Server

Upgrade your Tableau Server to 2020.1 or later: Upgrading from 2018.1 and Later (Linux) . If your Tableau Server is already on version 2020.1 or later, you can skip this step.

Step 2: Activate the Advanced Management license

1. View Server Licenses to make sure you have a Advanced Management license activated on your Tableau Server.
2. If you don't have a Advanced Managementon your Tableau Server, use the following tsm command to activate the license. Provide the Advanced Management key as your

product key:

```
tsm licenses activate -k <product key>
```

Step 3: Configure File Store to use an external storage

After completing the upgrade and verifying the licenses, configure Tableau Server with External File Store. This will move any existing data from your local File Store to the external storage of your choice.

1. Configure a network share. On the File Server:
   - Create and share a directory to host the files
   - On all the Tableau Server nodes, map the network share or use a UNC path.
2. Create a tableau directory in your network share and give full access to **tableau user** and **tableau group**. The tableau user will need read and write permissions to the directory on the network share. We recommend calling the directory **tableau**.
3. Enable the network share feature using the following tsm commands:

   ```
   tsm topology external-services storage enable --network-share
   /mnt/<network share name>/tableau
   ```

   The setup program automatically creates the following directory structure and will move the data from the local File Store to the external storage. The local File Stores will be automatically decommissioned during this process.

   **Extracts and workbook revisions:**

   *tableau_data tabsvc/dataengine/extracts*

   *tableau_data/tabsvc/dataengine/revisions*

   **PostgreSQL data backups:**

*tableau_data/tabsvc/repository_backup*

> **Note:** This directory will be created the first time you create a backup.

Reconfigure Tableau Server to use local File Store

1. Stop Tableau Server by running the following command:

   ```
   tsm stop
   ```

2. Run the following command to move the File Store data from the external storage to Tableau Server:

   ```
   tsm topology external-services storage disable –fsn <node1, node2>
   ```

3. Start Tableau Server by running the following command:

   ```
   tsm start
   ```

For a Tableau Server cluster, specify the nodes where File Store should be installed. The data is copied to the first node specified in the command and then replicated to the other nodes.

> **Note:** When moving File Store from external to local, make sure Data Engine process is not installed by itself on a separate node and is installed along with one of the core services which include File Store, Application Server (VizPortal), VizQL Server, Data Server. and Backgrounder.
>
> Typically, when you install Tableau Server Data Engine installation happens automatically and is installed on the nodes that have one or more of the core services. However, when you configure Tableau Server to use external storage, you will have the ability to manually install Data Engine on a node on its own without co-locating with the

core processes.

If you currently have a Data Engine process installed on a separate node, you can either choose to install File Store on that node or remove Data Engine from that node, before running the disable command. If you install File Store on a node that currently does not have Data Engine installed, Data Engine will be added automatically.

If you have a Data Engine only node when you run the disable command, it will result in an error.

Configure Tableau Server to use a different external storage

1. Configure the new network share. On the File Server:
    1. Create and share a directory to host the files.
    2. On all the Tableau Server nodes, map the network share or use a UNC path.
2. Create a tableau directory in your network share and give full access to **tableau user** and **tableau group**. The tableau user will need read and write permissions to the directory on the network share. We recommend calling the directory **tableau**.
3. Stop Tableau Server by running the following command:

    ```
    tsm stop
    ```

4. Run the following command to configure Tableau Server to use the new network share:

    ```
    tsm topology external-services storage switch-share --network-share /mnt/<newshare>/tableau
    ```

5. Start Tableau Server by running the following command:

    ```
    tsm start
    ```

Who can do this

Tableau Server Administrators can move File Store locations. In addition, you will need access to the external storage that is used for the External File Store.

## Backup and Restore with External File Store

When you have External File Store enabled on your Tableau Server, you cannot use the `tsm maintenance backup` command to do a backup of the Tableau Server repository and File Store Data. Instead, use a "snapshot" backup process to create a point in time snapshot of your network share.

- Tableau Server configured with External File Store
- Tableau Server configured with External File Store and External Repository

Backup strategies:

The backup strategy you use depends on your recovery plan. The snapshot backup process may not be sufficient by itself as it only creates a backup of the File Store (and repository data if requested), and there are other configurations and settings that you may need in order to do a full recovery.

> **Important:** We strongly recommend disabling scheduled tasks before you perform an upgrade. This includes all updates to data content and should be done before you create your pre-upgrade backup. This may involve disabling jobs that are triggered outside of Tableau Server, such as those initiated through REST API-based extract refreshes or using tabcmd.

Here are some scenarios that illustrate when the snapshot backup process may or may not be enough:

- **Standby Tableau Server**—If you maintain a standby Tableau Server to use if your production Server is down, creating a snapshot backup and restoring it to your standby server on a regular schedule may be sufficient. Your backup schedule should be based on your recovery point objective.
- **New Tableau Server, existing configuration not needed**—If you plan to use a new Tableau Server installation in case of a disaster, but don't necessarily need to use the configurations and settings from your existing Tableau Server installation you can install a fresh instance of Tableau Server and use the snapshot to restore your data.
- **New Tableau Server, existing configuration needed**—If you plan to use a new Tableau Server installation that includes your existing configurations and settings as well as your backed up date, you need additional files in along with the snapshot backup. To do a full backup including all the configurations and settings, follow these instructions:
    1. Export topology and configuration data. This exports most of the Tableau Server configuration and topology. For more information, see Perform a Full Backup and Restore of Tableau Server.
    2. Create a network share snapshot of the File Store (and repository data, if desired) as described in the Backup and Restore with External File Store section of this topic.
    3. Document the settings that are not included in the export. These include values for system user accounts, coordination service deployment configuration, and customized settings. For more information, see Perform a Full Backup and Restore of Tableau Server.

Tableau Server configured with External File Store

When you have Tableau Server configured with an External File Store your backup process needs to include creating a point-in-time snapshot backup of the network share with the External File Store. The following procedure describes how to do this.

> **Note:** If you have both an External File Store and an external repository, see Tableau Server configured with External File Store and External Repository.

Creating a snapshot backup

Use the following steps to create a snapshot backup:

1. Prepare for the snapshot backup.

   Run the following command to create a repository backup file and temporarily copy it to the network share. Tableau Server continues to operate normally during the snapshot prepare process. To ensure a consistent snapshot, the internal process that deletes unused extracts will be paused. This process will resume once you complete the backup process described in a later step.

   ```
   tsm maintenance snapshot-backup prepare
   ```

   You should see the following message when the prepare step is complete: **Preparation for snapshot backup succeeded**.

   Confirm that the repository backup file was created on the network share.

   > **Note:** The prepare step creates a backup file of the repository and KMS and Asset keys. If you are using a cloud solution for your encryption key solution, you will need access to the CMK used to decrypt the keys which is necessary for restore. For more information on encryption key solution with AWS, see AWS Key Management System. For more information on encryption key solution with Azure, see Azure Key Vault.

2. Create a snapshot of your network share.

   Use the appropriate process to create a snapshot of your network share. The snapshot is a read-only version of the share, taken at a particular point in time. This will include your File Store data, along with the repository backup file that was temporarily copied to the share in the previous step. The steps you take to create this network share snapshot depend on your network. See your networking documentation for details.

3. Complete the snapshot backup process.

Run the following command to complete the backup process and restart the paused internal processes. This removes the temporary repository backup file that was copied to your network share.

```
tsm maintenance snapshot-backup complete
```

Confirm that the temporary repository backup file was removed from the network share.

### Restoring a snapshot backup

These steps apply to both single node and multi-node Tableau Server installations.

1. Stop Tableau Server.

   At the command prompt, run the following command:

   ```
   tsm stop
   ```

2. Restore your File Store data by restoring your network share snapshot to your network. Your specific steps will depend on your network.

3. Restore the repository data.

   Use the following command to restore the repository data:

   ```
   tsm maintenance snapshot-backup restore
   ```

   **Note:** If you are using a cloud solution for your encryption key solution, make sure the server where the backup is being restored has decrypt access to the cloud instance where the CMK is deployed.

4. Restart Tableau Server.

   At a command prompt, run the following command:

   ```
   tsm start
   ```

### Tableau Server configured with External File Store and External Repository

When you have Tableau Server configured with both an External File Store and an external repository, there are special steps you need to take to create a backup. These include creating a point-in-time snapshot backup of the network share with the External File Store, and may include separately backing up your external repository. The following procedure describes how to do this.

> **Note:** If you have an External File Store but are using the default repository, see Tableau Server configured with External File Store.

#### Backing up the repository

When you have both an External File Store and an external repository, you have two options for backing up the repository data. There are reasons why you might choose each of these:

- Include the repository backup with the network share snapshot:

  Ease of management. You do not have to do a separate backup of the repository, and the backup is in sync with the File Store data.

- Back up the repository independently:

  Doing a backup of an External Repository separately can be faster, especially if you are using a cloud solution that allows for snapshot backups of the instance. The size of the backup file can significantly impact the time it takes to prepare for a network share snapshot.

Option 1: Include repository backup with network share snapshot

## Create a snapshot backup

1. Prepare for the snapshot backup.

   Run the following command to create a repository backup file and temporarily copy it to the network share. Tableau Server continues to operate normally during the snapshot prepare process. To ensure a consistent snapshot, the internal process that deletes unused extracts will be paused. This process will resume once you complete the backup process described in a later step.

   ```
   tsm maintenance snapshot-backup prepare --include-pg-backup
   ```

   **Note:** Starting in 2021.1, if you have both External File Store and External Repository enabled, you *must* use the `--include-pg-backup` option to create the repository backup. If you are upgrading from a version earlier than 2021.1 and you have scripts to run or schedule your backups, and want to continue to include the repository backup, add the **`--include-pg-backup`** option in the prepare command as shown above. For versions prior to 2021.1 you do not need the option, the repository backup is automatically included.

   You should see the following message when the prepare step is complete: **Preparation for snapshot backup succeeded**.

   Confirm that the repository backup file was created on the network share.

   **Note:** The prepare step creates a backup of the repository and KMS and Asset keys. If you are using a cloud solution for your encryption key solution, you will need access to the CMK used to decrypt the keys which is necessary for restore. For more information on encryption key solution with AWS, see AWS Key Management

System. For more information on encryption key solution with Azure, see Azure Key Vault.

2. Create a snapshot of your network share.

   Use the appropriate process to create a snapshot of your network share. The snapshot is a read-only version of the share, taken at a particular point in time. This will include your File Store data, along with the repository backup file that was temporarily copied to the share in the previous step. The steps you take to create this network share snapshot depend on your network. See your networking documentation for details.

   **Important:** The snapshot of the network share and the Repository backup must be completed within 3 hours after completing the Prepare step (step 1). This is to make sure that the File Store and the Repository backups are in sync and to allow the restore to work properly.

3. Complete the snapshot backup process.

   Run the following command to complete the backup process and restart the paused internal processes. This also removes the temporary repository backup file that was copied to your network share.

   ```
   tsm maintenance snapshot-backup complete
   ```

## Restoring a snapshot backup

These steps apply to both single node and multi-node Tableau Server installations.

**Important:** If you perform Blue/Green upgrades or manually upgrade Tableau Server 2021.4 (or earlier) using the tsm maintenance (backup and restore) method, you must enable `legacy-identity-mode` before you can restore to Tableau Server 2022.1 (or later). For more information, see Troubleshoot Issues with the Identity Migration.

1. Stop Tableau Server.

   At the command prompt, run the following command:

   ```
   tsm stop
   ```

2. Restore your File Store data by restoring your network share snapshot to your network. Your specific steps will depend on your network.

3. Restore the repository data.

   Use the following command to restore the repository data:

   ```
   tsm maintenance snapshot-backup restore
   ```

   > **Note:** If you are using a cloud solution for your encryption key solution, make sure the server where the backup is being restored has decrypt access to the cloud instance where the CMK is deployed.

4. Restart Tableau Server.

   At a command prompt, run the following command:

   ```
   tsm start
   ```

Option 2: Back up repository separately

This option is recommended only when the host platform for the External Repository allows you to do snapshot backup. If you are using Azure as your host platform, we recommend using Option 1.

## Create snapshot backups

1. Prepare for the snapshot backup.

   Run the following command to create a repository backup file and temporarily copy it to the network share. Tableau Server continues to operate normally during the snapshot prepare process. To ensure a consistent snapshot, the internal process that deletes unused extracts will be paused. This process will resume once you complete the backup process described in a later step.

   ```
   tsm maintenance snapshot-backup prepare
   ```

   You should see the following message when the prepare step is complete: **Preparation for snapshot backup succeeded**.

   > **Note:** The prepare step creates a backup of the KMS and Asset keys. If you are using a cloud solution for your encryption key solution, you will need access to the CMK used to decrypt the keys which is necessary for restore. For more information on encryption key solution with AWS, see AWS Key Management System. For more information on encryption key solution with Azure, see Azure Key Vault.

2. Create a snapshot of your network share.

   Use the appropriate process to create a snapshot of your network share. The snapshot is a read-only version of the share, taken at a particular point in time. This will include your File Store data. The steps you take to create this network share snapshot depend on your network. See your networking documentation for details.

3. Create a backup of the repository: Use the backup technology of platform where you are hosting your external repository to create a backup.

> **Important:** The snapshot of the network share and the Repository backup must be completed within 3 hours after completing the Prepare step (step 1). This is to make sure that the File Store and the Repository backups are in sync and to allow the restore to work properly.

For more information on creating a snapshot of AWS DB instance, see Creating a DB snapshot.

For more information on creating a backup of Azure DB instance, see Backup and Restore on Flexible Server (PostgreSQL 12 and later) or Backup and Restore on Single Server (PostgreSQL 11 or earlier).

> **Note:** If you are using a cloud solution for your encryption key solution, make sure the server where the backup is being restored has decrypt access to cloud instance where CMK is deployed.

4. Complete the snapshot backup process.

   Run the following command to complete the backup process and restart the paused internal processes.

   ```
   tsm maintenance snapshot-backup complete
   ```

## Restoring a snapshot backup

These steps apply to both single node and multi-node Tableau Server installations.

1. Use the database backup of your External Repository. If you are using a cloud platform to host your Repository, this generally requires that you create a new database instance into which you restore the backup.

   For detailed instructions on creating a new instance, see the option for your hosting solution in Install External Repository.

2. Use the instructions in Step 1 of the Install Tableau Server with External PostgreSQL Repository topic to create a configuration file for the new instance.

3. Stop Tableau Server.

   At the command prompt, run the following command:

   ```
   tsm stop
   ```

4. If the restore of the external repository requires a new database instance, use the following commands to point Tableau Server to the new database instance and then apply the changes to Tableau Server:

   ```
   tsm topology external-services repository replace-host -f <file-name>.json -c <ssl certificate file>.pem
   ```

   ```
   tsm pending-changes apply
   ```

   The `.json` file is the configuration file you created in Step 2. The certificate file is the SSL certificate you downloaded from the new database instance.

5. Restore your File Store data by restoring your network share snapshot to your network. Your specific steps will depend on your network.

   **Note:** Some technologies require you to create a new network share when doing a restore. If this applies to your network attached storage, you can do your restore **before** stopping the Tableau Server. If you are restoring the File Store data to a new network share, you must configure Tableau Server to use the new network share. For more information, see Configure Tableau Server to use a different external storage.

6. Run the following command to restore the KMS and Asset keys:

   ```
   tsm maintenance snapshot-backup restore
   ```

> **Note:** If you are using a cloud solution for your encryption key solution, make sure the server where the backup is being restored has decrypt access to cloud instance where CMK is deployed.

7. Run the following command to restart Tableau Server:

```
tsm start
```

Who can do this

Tableau Server Administrators can backup and restore Tableau Server. In addition you must have permission to access and perform snapshot backups on the external storage.

## Performance Considerations for External File Store

This topic lists the factors you must consider when you have External File Store to make sure you have optimal performance.

In this scenario where File Store is configured external to Tableau Server, you are storing the extracts on a network share. This means that Tableau Server will be accessing this data across the network. To ensure optimal performance, we recommend the following:

- Use Enterprise grade storage system to to ensure reliability and high data access performance.
- The storage system supports enough read IOPS:
  - Use Solid State Drives. If using spinning disks is the only option, use the fastest and as many as possible.
- The network infrastructure supports the following:
  - At least 10 GB Ethernet to support high speed data transfers between Tableau Server and the storage system.
  - No more than 10 millisecond storage latency between Tableau Server and the storage system.

The above recommendations are based on testing done by the Tableau team. Your requirements and performance may vary. We highly recommend that you create your own benchmarks to assess the performance and determine resource requirements.

When creating benchmarks, consider overall performance of Tableau Server with workbook load times as one of the key metrics. This is especially relevant to this configuration since External File Store mostly impacts extract based workbooks.

You can use Tabjolt to do your benchmarks.

Who can do this

Tableau Server Administrators monitor Tableau Server performance. However, there are network, hardware, and storage considerations that might either need access to make configuration changes to these resources. You may also choose to work with your network administrator to make any changes if you don't have access to these resources.

## Tableau Server External Repository

The Tableau Server Repository is a PostgreSQL database that stores data about all user interactions, extract refreshes, and more.

The repository can be installed as locally on the same nodes as the Tableau Server or installed externally:

- **Local repository:** The PostgreSQL Database is installed and deployed locally, meaning it is deployed along with Tableau Server.
- **External repository:** The PostgreSQL Database is deployed externally. The external repository can be installed on Amazon RDS, Azure Database, Google Cloud, or as a stand-alone installation.

For more information about what Tableau Server Repository is in general, see:

- About the Tableau Server Data Dictionary
- Collect Data with the Tableau Server Repository

The supported hosts for the external repository are:

- Amazon RDS - Beginning in version 2019.3
- Azure Database - Beginning in version 2020.4
- Stand-alone PostgreSQL Instance - Beginning in version 2021.2
- Google Cloud SQL for PostgreSQL Instance - Beginning in version 2021.4

This topic is an overview of the Tableau Server external repository.

## External Repository Considerations

Both Amazon RDS and Azure Database offer better scalability, reliability, high availability and security built-in for PostgreSQL. By integrating more closely with these cloud offerings, you will be able to take advantage of these additional benefits.

If you are setting up a stand-alone PostgreSQL instance, you must set up and manage high availability and scale as needed.

> **Important:** Do not directly modify the repository. Doing so can break Tableau Server. Any customer modifications of the repository will make your installation unsupportable by Tableau.

Cloud Platform

When using a cloud platform to host your external repository, you have the option of running PostgreSQL instances on hosted infrastructure and managing them yourself or choosing the fully managed service option.

- **Self-managed:** Setting up and managing PostgreSQL instances on hosted infrastructure yourself. For example, if you are using AWS as your cloud platform, you can use EC2 instances to run, manage and maintain PostgreSQL instances.
- **Fully managed:** Select a fully managed service. For example, if you are using AWS as your cloud platform, you can use the RDS option to host your external repository.

One of the key considerations when making a choice between self-managed and fully managed is that in a self-managed option you have the most control but with it comes the

responsibility of maintaining the VMs and many database administrative tasks. A fully managed option offers ease of setup, configuration management, and maintenance.

Here is a more comprehensive list of things to consider when choosing between the two:

- Setup and maintenance requirements.
- High availability and disaster recovery options
- Performance, Scalability, and Monitoring capabilities
- Security maintenance
- Operational costs, service costs, personnel costs.

Here is an example of how the two options can be compared for Azure on the Microsoft site: Choose the right PostgreSQL server option in Azure,

## Requirements

- Your Tableau Server must be using the following versions:
  - 2019.3 or later to use with AWS
  - 2020.4 or later to use with Azure.

    For the right version of PostgreSQL to use, see Azure Database for PostgreSQL Flexible Server .
  - 2021.2 or later to use with stand-alone PostgreSQL instance. (Can be used for on-premises, Azure VM, or AWS EC2 installations).
  - 2021.4 or later to use with Google Cloud for both PostgreSQL Instance or a stand-alone PostgreSQL on Google Cloud VM.
- Your Tableau Server must have the Advanced Management keys activated.
- Depending on where you are planning to host the External Repository, you will need to be familiar with one of the following:
  - Amazon RDS Database setup and management.
  - Azure Database setup and management.
  - PostgreSQL database setup and management as a standalone installation.
  - Google Cloud PostgreSQL instance setup and management

## Versioning

You must be running the correct version of PostgreSQLfor standalone Tableau Server repository. The following table shows Tableau Server version compatibility.

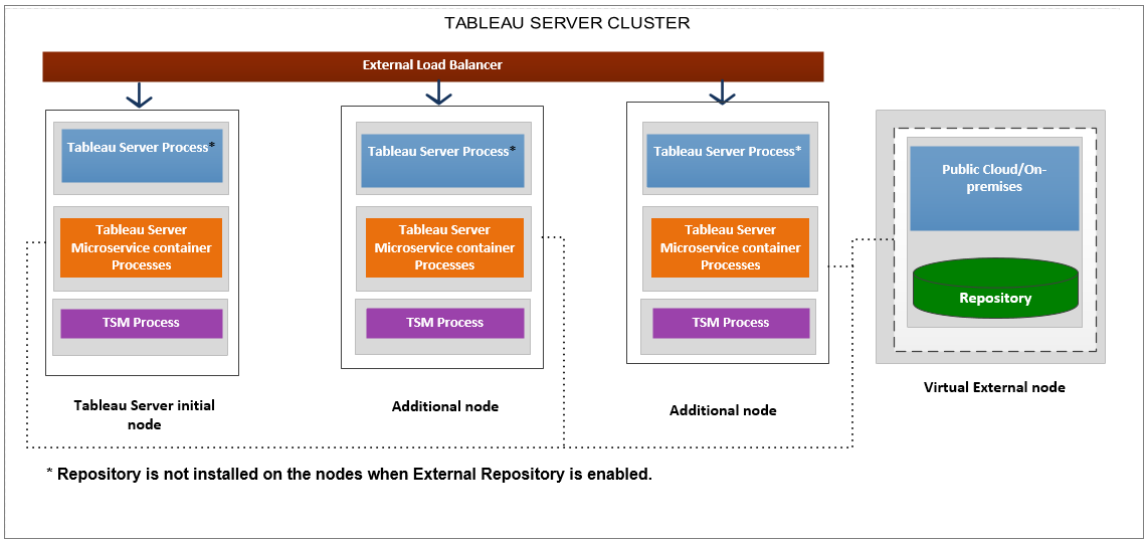
**Note:** The maximum compatibility version for any Tableau Server version is the minimum major version or any minor update to that. For example, if the PostgreSQL minimum compatible version is 13.4, the maximum compatible version is 13.x where <x> is equal or higher than 4.

| Tableau Server versions | PostgreSQL minimum compatible versions |
|---|---|
| 2022.3.0 - 2022.3.7<br>2023.1.0 - 2023.1.4 | 13.7 |
| 2022.1.17 - 2022.1.19<br>2022.3.8 - 2022.3.19<br>2023.1.5 - 2023.1.15<br>2023.3.0 - 2023.3.8 | 13.11 |
| 2022.3.20 - 2022.3.x<br>2023.1.16 - 2023.1.x<br>2023.3.9 - 2023.3.x | 13.14 |
| 2024.0 - 2024.2.8 | 15.6 |
| 2024.2.9 - 2024.2.13<br>2025.1.0 - 2025.1.6 | 15.10 |
| 2024.2.14 - 2024.2.16 | 15.13 |

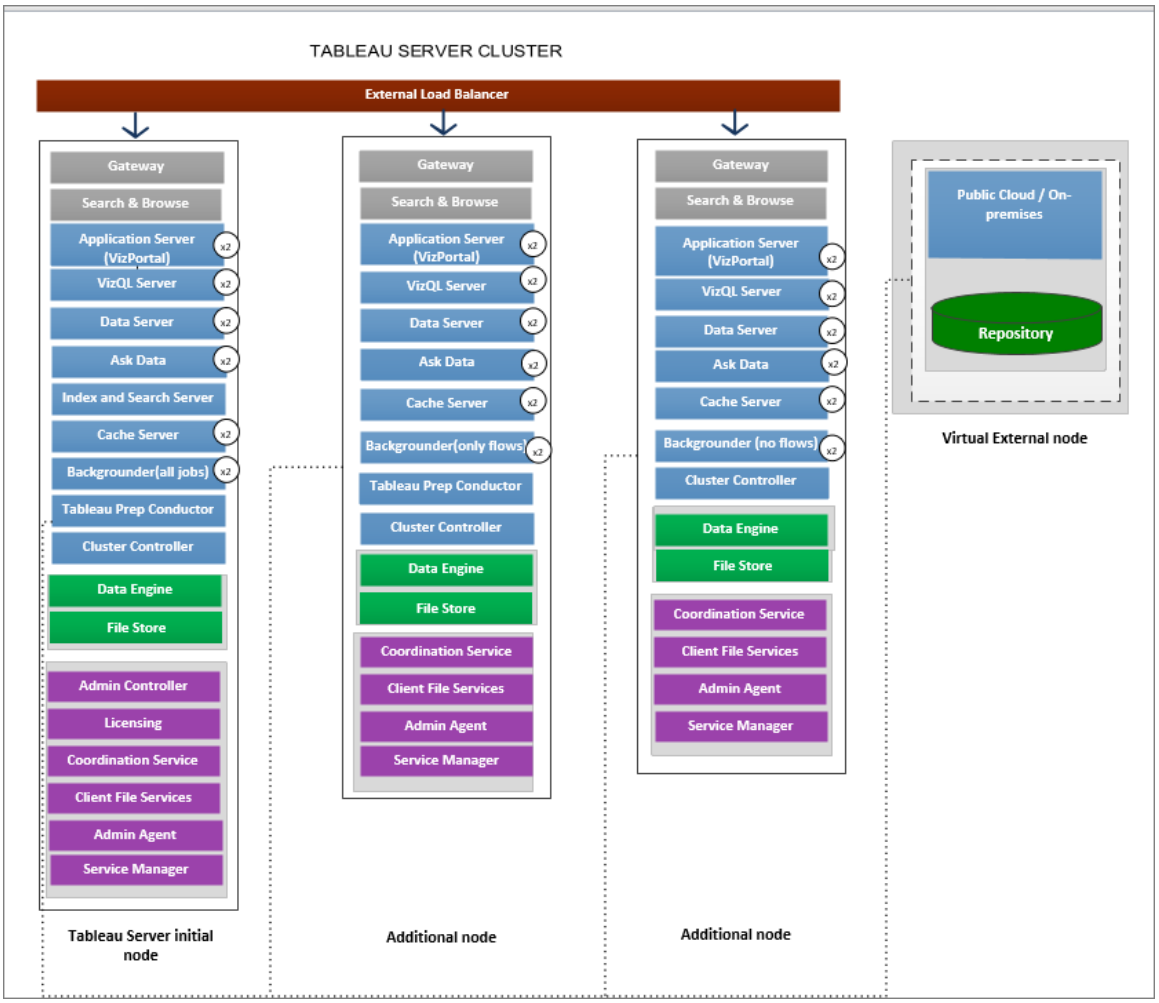
| | |
|---|---|
| 2025.1.7 - 2025.1.9 | |
| 2024.2.17<br>2025.1.10<br>2025.3 | 15.14 |

## Topology

**The diagram below is a summarized version of the Tableau Server topology with External Repository.**



**The diagram below is a detailed version of the Tableau Server topology with External Repository and shows all the processes installed on each node.**



## Managing the External Repository

### License Management

To enable this feature you must first activate Advanced Management on Tableau Server. For more information, see About Tableau Advanced Management on Tableau Server. If you don't have Advanced Management or if the license is expired, you will see the following behavior:

- If you try to configure Tableau Server to use external repository during installation, you will see an error message, but you will be able to continue the installation and Tableau Server Repository will be installed locally.  For single server installations, the repository

is installed on the same machine as Tableau Server. For multi-node installations, the repository is installed on one of the nodes of your Tableau Server cluster.

- If you are already using an external Tableau Server Repository on your Tableau Server installation, and the Advanced Management license expires, the server will fail on restart. If you no longer have Advanced Management capabilities, but have a valid Tableau Server license, you will still be able to create a backup. You can also migrate the external repository to local repository which does not require Advanced Management to get your server up and running again. For more information on how to migrate from external repository to local repository, see Re-Configure Tableau Server Repository.

Supported Migration Scenarios

- Moving your repository from local to external.
- Moving your repository from external to local.

Backup and Restore

**If you have only External Repository configured:**

The backup and restore process remains is the same for both local and external repository and as described in the Back up Tableau Server Data topic.

- The backup and restore commands work in the same manner for both local and external repository. Backup in the case where Tableau Server uses external repository requires more disk space for backup, so you should keep that in mind when configuring your disk space.
- The default and other supported locations for storing the backup file are the same whether it the repository is local or external.

The following exceptions apply to Tableau Servers using external repository:

- Any custom user accounts that are created in the external Tableau Server repository will be included in the restore, but the passwords for the custom user accounts will not be. The passwords will have to be reconfigured after restore is complete. Custom user accounts are PostgreSQL database user accounts, used by SQL or other database client software to connect to the PostgreSQL database.

  **Note:** These custom accounts will be disabled as a security measure, but this can be reconfigured.

- Configuration and topology should not be included in the backup. For more information on how to export configuration and topology settings, see Perform a Full Backup and Restore of Tableau Server.

**If you have both External Repository and External File Store configured:**

You have a couple of options if you have both External Repository and External File Store configured for your Tableau Server. These options allow you to take advantage of the snapshot backup capabilities of the cloud platforms you might be using to host the External Repository and File Store. For more information, and detailed step by step instructions, see Backup and Restore with External File Store.

SSL Connections

You have the option to require or not require TLS/SSL connections from Tableau Server to the External Repository.

If you do not need to use encrypted connections, you must configure the External Repository to allow unencrypted connections, and use the `--no-ssl` option when you configure the External Repository for Tableau Server. For more information, see tsm topology external-services repository enable.

If you want to enable or disable SSL at a later time, post installation, use the tsm security repository-ssl enable or tsm security repository-ssl disable. This option is available starting in 2021.4.

Updating the SSL Certificate

If as part of a planned expiration of the SSL certificate of the RDS or Azure Database, Google Cloud PostgreSQL instance, or a stand-alone PostgreSQL instance, you need to update the instance with the new certificate file, you will also need to update Tableau Server settings to use the new certificate file. You can do this by downloading the latest file and running the *tsm topology external-services repository replace-host* command and providing the new certificate file.

## High Availability Considerations

Tableau Server does not manage or setup high availability for the external repository.

- **AWS:** Amazon RDS offers features that can be used to provide high availability and manage failover. For more information, see Amazon RDS High Availability.
- **Azure:** Azure offers features that can be used to provide high availability and manage failover. For more information, see Azure Database High Availability.
- **Google Cloud:** Google Cloud offers features that can be used to provide high availability and manage failover. For more information, see Google Cloud High Availability.
- **Stand-alone PostgreSQL instance:** PostgreSQL offers several features that can be used to provide high availability and manage failover. For more information, see PostgreSQL High Availability.

## Upgrade considerations

This applies only if you are using the External Repository configuration with Tableau Server.

If you are using an External Repository, you may need to take additional steps when upgrading:

- **No version change**—If there is no version change in PostgreSQL, there are no special actions required.
- **Minor version change**—If there is a minor version change in PostgreSQL, you need to upgrade your external repository before upgrading Tableau Server. In most cases

there are in-place methods for doing so. The method you use depends on the location of your repository and is beyond the scope of this documentation.

- **Major version change**—If there is a major version change in PostgreSQL, you need to follow the steps described in Upgrade Tableau Server with External Repository for a New Major Version of PostgreSQL.

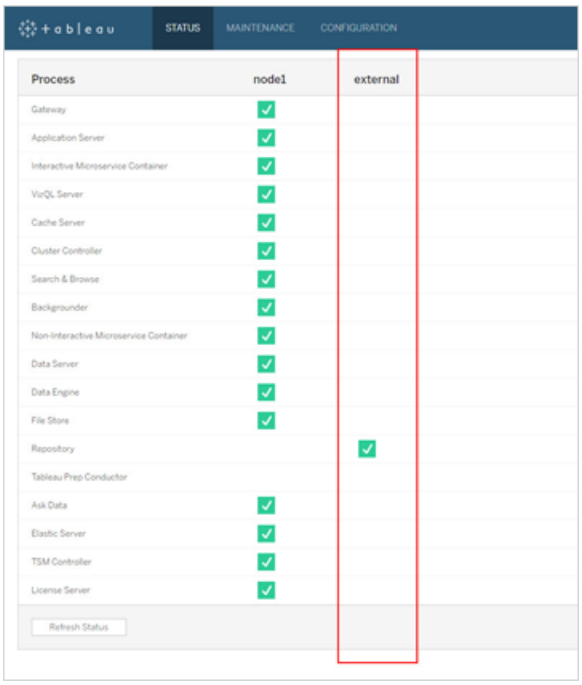
  Steps include:

  1. Creating a new instance of PostgreSQL DB. For more information, see:
     - Create a PostgreSQL DB Instance on AWS Relational Database Service (RDS)
     - Create a Azure Database PostgreSQL Instance on Azure
     - Create a Cloud SQL for PostgreSQL insatnce on Google Cloud
     - Create a PostgreSQL Database as a Stand-alone Installation
  2. Creating a configuration file and download the SSl certificate file for the new instance that you created in Step 1.

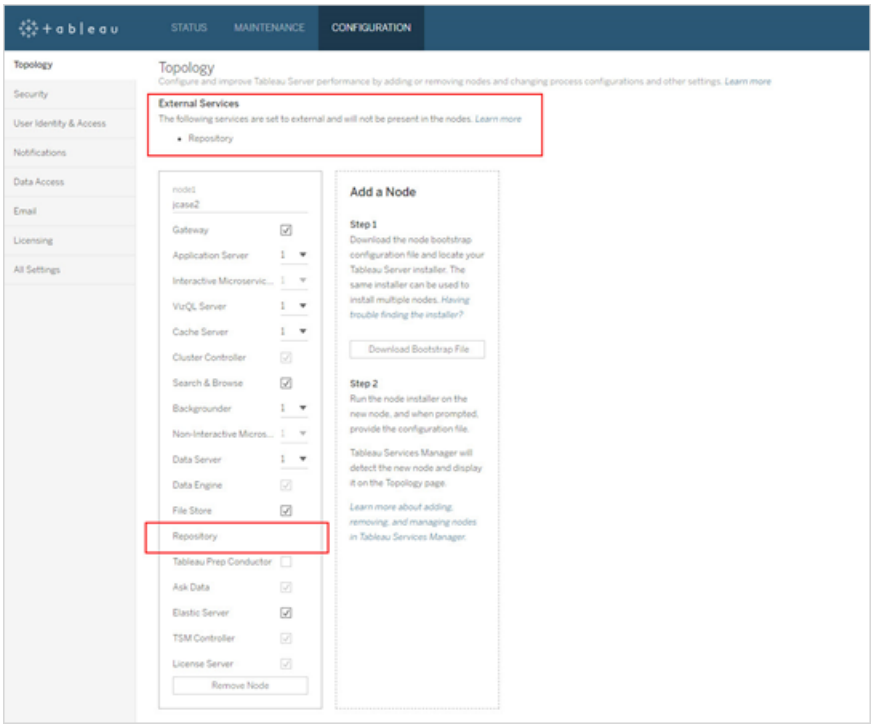
  During upgrade, you will need to point Tableau Server to the new instance using the configuration file. The upgrade process will migrate the content from your current external repository to your new instance. For more details, see Upgrade Tableau Server with External Repository for a New Major Version of PostgreSQL.

## Monitoring the Status of the Repository

TSM status page will show the Tableau Server external service as an additional node for your Tableau Server installation.



The topology tab indicates whether there are Tableau Server external services configured:



## Getting Logs

Tableau Server logs will not include logs from the external repository. Use the following ways to get the logs specific to your instance:

- **AWS:** For information on setting up logging for your Amazon RDS PostgreSQL instance, see PostgreSQL Database Log Files.
- **Azure:** For information on setting up logging for your Azure Database for PostgreSQL instance see Logs in Azure Database for PostgreSQL.
- **Google Cloud:** For information on how to view and query logs for your PostgreSQL instance, see Cloud SQL logging.
- **Stand alone PostgreSQL Instance:** For information on setting up logging for your stand alone PostgreSQL instance, see Error Reporting and Logging.

## Next Steps

- You can use one of the following to create a PostgreSQL database instance:
    - Create a PostgreSQL DB Instance on AWS Relational Database Service (RDS)
    - Create a Azure Database PostgreSQL Instance on Azure
    - Create a PostgreSQL Instance on Google Cloud
    - Create a PostgreSQL Database as a Stand-alone Installation
- Install Tableau Server with External PostgreSQL Repository
- Re-Configure Tableau Server Repository
    - Migrate from local to external
    - Migrate from external to local

# Create a PostgreSQL DB Instance on AWS Relational Database Service (RDS)

Beginning in version 2019.3, you can host your External Repository on the AWS Cloud Platform. This topic describes how to create a AWS RDS PostgreSQL DB instance to use as your Tableau Server external repository.

To see a full list of hosts that you can use for the your external repository, see Tableau Server External Repository.

Requirements and Recommendations

- At a minimum use an instance with 8vCPUs and 32GB RAM. This is the minimum recommended AWS RDS instance size to use for Tableau Server external repository, but the exact requirements will vary with your requirements and usage. We recommend using 16 vCPUs and 128GB RAM Amazon RDS memory optimized instance types for good performance.

  You can start with a smaller instance type and if you find later that you need a larger instance type, you can upgrade your existing RDS instance. For more information, see Upgrading your RDS Instance .

  Secure communication between Tableau Server and the external PostgreSQL DB instance using SSL connections is **not** required but recommended.

- The PostgreSQL DB instance must be reachable by all nodes in the Tableau Server cluster. One of the ways you can do this is by making the PostgreSQL DB instance a member of a security group that has the necessary permissions to be accessed by all the nodes in the Tableau Server cluster.

- The version of PostgreSQL should match the version used by Tableau Server when installed locally. Tableau Server 2020.4 uses PostgreSQL version 12.

- Tableau auto-generates passwords for internal use by internal database users. These passwords are 32 characters long and consist of lower-case letters and numbers. They cannot be accessed or configured by an admin. Your external PostgreSQL instance may allow you to set a password policy (this will depend on the platform you are using). If you specify a policy that includes character types other than numbers and lower-case letters, this can cause errors while configuring Tableau Server to use the external repository.

## Create a PostgreSQL DB instance on Amazon RDS

### Step 1: Create a parameter group

PostgreSQL parameters that you set for a local PostgreSQL instance in the *postgresql.conf* file are maintained in the DB parameter group for your DB instance. When you create a DB instance, the parameters in the associated DB parameter group are loaded.

From the Tableau Server perspective, most of the parameters can be set to defaults. You can modify the parameter values if you have specific performance or logging requirements, but we strongly recommend that the following parameters be left to default values and not be changed:

- `standard_conforming_strings`
- `escape_string_warning`

We also recommend the value for the `work_mem` be set to at least 16384 to help avoid performance issues.

For more information and a full list of PostgreSQL Parameters, see Working with PostgreSQL Parameters, on the AWS site.

### Step 2: Create a PostgreSQL DB instance on Amazon RDS

To create a new PostgreSQL DB instance, follow the instructions provided on the Amazon documentation site.

Following are configuration options and the recommended values for the new PostgreSQL DB instance:

- **Instance Specifications**
  - Use the parameter group created in **Step 1**.
  - Use the compatible version of PostgreSQL for the version of Tableau Server you are using. For a full list of PostgreSQL versions compatible with Tableau Server versions, see Product Compatibility.
  - Use DB instance class that is  db.m4.2xlarge or larger.
  - Allocate at least 100GB of storage.

    - Storage type and Provisioned IOPS: leave default (recommendations may change depending on load testing).

- **Settings**

    - You **must** use **rails** as the master username.

      **This is a requirement for the external repository to work properly with Tableau Server.**

    - Pick a password that meets AWS's requirements.

- **Network and Security**

    - Make sure that the RDS instance can be reached by all the Tableau Server nodes. This most often involves creating a security group that allows access from the nodes.

- **Database Options**

    - Don't create an initial database. The Database name should be left blank, as Tableau Server will create the needed databases in the RDS instance.

    - The port can be anything, but we recommend leaving it as the default 5432.

    - Set the DB Parameter Group to the one created in **Step 1**.

    - Leave the IAM DB authentication as disabled.

- **Encryption**

    - You can choose whether or not you want encryption.

- **Backup**

    - This is for AWS's automated backups, not Tableau Server's backups. You can specify the settings that meets the requirements.

- **Monitoring**

        - You can specify the settings based on your requirements.

    - **Log Exports**

        - You can specify the settings based on your requirements.

    - **Maintenance**

        - Disable auto minor version upgrade. Tableau Server is built to use a specific version of PostgreSQL. and you will be prompted to upgrade the PostgreSQL version if needed, during Tableau Server Upgrade.

    - **Delete Protection**

        - You can specify the settings based on your requirements.

Step 3: Get the PostgresSQL DB Instance Endpoint

After creating the PostgreSQL database instance, you can't use it until it's completed initialization by AWS and this can take several minutes. Once the instance is ready, get the endpoint information that you will use to configure Tableau Server to use this instance for the Tableau Server Repository.

Step 4: Download the SSL certificate file (.pem file)

Secure connections between Tableau Server and the External Repository using SSL is **not** required, but recommended.

If you want to set up secure connections between Tableau Server and the External Repository, you will need the .pem file when you configure Tableau Server to use the external DB instance for your Tableau Server Repository. For more information, see Using SSL to Encrypt the Connection to a DB Instance.

If you do not need to use secure connections between Tableau Server and External Repository, you need to configure the RDS instance to allow unencrypted connections.

**Important:** If as part of a planned expiration of the SSL certificate of the RDS instance, you need to update your RDS instance with the new certificate file, you also need to update

Tableau Server settings to use the new certificate file. You can do this by downloading the latest file and running the *tsm topology external-services repository replace-host* command and providing the new certificate file.

Configuring High Availability for your PostgreSQL DB

Tableau Server does not manage or setup high availability for the external repository. Amazon RDS offers high availability features that can be used to provide high availability, manage failover, etc. For more information, see Amazon RDS High Availability.

Disaster Recovery for your PostgreSQL DB

In the event of a disaster, you may need to setup a new RDS instance. There are other scenarios where you may need to recover from an issue with the RDS instance. For example, when you upgrade your Tableau Server, you might also need to upgrade the PostgreSQL version on your RDS instance. In the event that your PostgreSQL upgrade is not successful you might have to use a new RDS instance. In such scenarios, to configure your Tableau Server to use the new RDS instance, use the following steps:

1. **Restore the snapshot to a new RDS instance.** AWS does not support restoring a snapshot to an existing RDS instance. For more on RDS snapshot backup and restore, see Amazon RDS Backup and Restore.

2. **Create a new JSON settings file** containing connection information for the new RDS instance. For more information on creating a JSON settings file, see **Step 1** in Install Tableau Server with External PostgreSQL Repository.

3. **Use the `tsm topology external-services repository replace-host` command** to point your Tableau Server to the new RDS instance.

   For more information on the `tsm topology external-services repository replace-host` command, see tsm topology.

Who can do this

Only Tableau Server Administrators can configure Tableau Server to use the external repository. You will also need an AWS account to create a RDS instance.

Next Steps

For new installs: Install Tableau Server with External PostgreSQL Repository

If you want to configure your existing Tableau Server to use an external repository, see Re-Configure Tableau Server Repository.

## Create a Azure Database PostgreSQL Instance on Azure

Beginning in version 2020.4, you can host your External Repository on the Azure Cloud Platform. This topic describes how to create a Azure Database for PostgreSQL instance to use as your Tableau Server external repository.

Requirements and Recommendations

- We recommend that you use 8 vCore memory optimized server with 50 GB of storage for Tableau Server external repository, but the exact requirements will vary with your requirements and usage. If you already have a Tableau Server, review the usage of your existing repository to determine your storage needs.

  You can also scale your resources if you find that you need more. For more information, see Scaling your PostgreSQL Azure Database resources.

- Secure communications between Tableau Server and the external PostgreSQL DB instance using SSL is recommended, but not a requirement.

  If you do not want to use secure connections between Tableau Server and External Repository, you should configure the Azure Database to allow unencrypted connections.

- The PostgreSQL DB instance must be reachable by all nodes in the Tableau Server cluster. The database instance must be set up to allow connections from all the Tableau Server nodes. There are two ways to set this up:

  - This is most secure way: Configure Azure Database for PostgreSQL instance to only allow private access via the Virtual Network service endpoint. For more

information, see Use Virtual Network service endpoints and rules for Azure Database for PostgreSQL and Create and Manage VNet service endpoints.

You may also want to review the overview topic on Azure virtual networks.

- Alternatively Azure Database for PostgreSQL can be configured to allow connections from a range of public IP addresses. This method exposes the Azure Database endpoint to public access on the internet.

- When setting up the Azure Database instance, we recommend using **postgres** as the Administrator user name. If you choose to use a different user name, make sure that the user name does not start with **pg**, or **azure**. The user name also cannot be **rails**, **tblwgadmin**, **tableau**, **readonly**, or **tbladminviews**.

- The version of PostgreSQL should match the version used by Tableau Server when installed locally. For a full list of PostgreSQL versions compatible with Tableau Server versions, see Product Compatibility.

- Tableau auto-generates passwords for internal use by internal database users. These passwords are 32 characters long and consist of lower-case letters and numbers. They cannot be accessed or configured by an admin. Your external PostgreSQL instance may allow you to set a password policy (this will depend on the platform you are using). If you specify a policy that includes character types other than numbers and lower-case letters, this can cause errors while configuring Tableau Server to use the external repository.

Create a Database PostgreSQL instance on Azure

Step 1: Create a delegated subnet for the Azure Database for PostgreSQL instance

This step is a prerequisite for setting up private access for your networking option when you create the instance. Setting up private access to the database is a must for secure communications. This let the virtual machines created anywhere in that Virtual Network to connect to the database instance, but none outside of the Virtual Network is able to do so.

On the same virtual network where you are currently hosting your Tableau Server, create a new delegated subnet for the Azure Database instance. For more information on setting up

private access see Networking Options for Azure Database for PostgreSQL - Flexible Server on the Azure website.

Step 2: Create an Azure Database for PostgreSQL instance

To create a new Azure Database for PostgreSQL, follow the instructions provided on the Azure documentation site.

Following are configuration options and the required values and our recommendations for the new PostgreSQL DB instance:

- **Server Details**
  - Specify None as the Data source to create a new server.
  - For Admin user name, we recommend using **postgres** as the Administrator user name. If you choose to use a different user name, make sure that the user name does not start with **pg**, or **azure**. The user name also cannot be **rails**, **tbl-wgadmin**, **tableau**, **readonly**, or **tbladminviews**.
  - Pick a password that meets Azure's requirements.
  - Use the compatible version of PostgreSQL for the version of Tableau Server you are using. For a full list of PostgreSQL versions compatible with Tableau Server versions, see Product Compatibility.
  - Allocate at least 512GB of storage.
  - The uuid-ossp and unaccent extensions must be allowed for use by "azure_pg_admin" users in Azure Database for PostgreSQL.
- **Compute and Storage**
  - At a minimum, use Flexible Server with General Purpose computer tier, and Standard_D8s_v3 (8 vCores, 32 GB RAM) compute size.
- **Network Options**

    - Select Private Access (Virtual Network). This ensures private and secure communications for the database.

- **High availability**

    - Enable the high availability option per your requirements.

- **Backup**

    - Set the retention period per your requirements. This is for Azure automated backups, not Tableau Server's backups. You can specify the settings that meets the requirements.

Step 3: Configure a server-level firewall rule

Once the database is created, configure a server-level firewall rule to allow access to the Tableau Server nodes.

Make sure that the Database instance can be reached by all the Tableau Server nodes using the dedicated subnet described in Step 1.

Step 4: Configure the Azure Database for PostgreSQL Instance.

From the Tableau Server perspective, most of the parameters values for the instance can be set to defaults. You can modify the parameter values if you have specific performance or logging requirements, but we strongly recommend that the following parameters be left to default values and not be changed:

- `standard_conforming_strings`
- `escape_string_warning`

We also recommend the value for the `work_mem` be set to at least 16384 to help avoid performance issues.

For information on how to configure server parameters, see this Azure documentation.

Step 5: Get the PostgresSQL DB Instance Endpoint

Once the instance is ready, get the endpoint information that you will use to configure Tableau Server to use this instance for the Tableau Server Repository.

Step 6: Download the SSL certificate file

Secure communications between Tableau Server and the External Repository using SSL is **not** required but recommended.

If you want to set up secure connections between Tableau Server and the External Repository, download the certificatie file. You will need this certificate file when you configure Tableau Server to use this external repository. For more information, see Configure TLS connectivity for Azure Database for PostgreSQL.

If you do not need to use secure connections between Tableau Server and External Repository, configure the Azure Database instance to allow unencrypted connections.

Configuring High Availability for your PostgreSQL DB

Tableau Server does not manage or setup high availability for the external repository. Azure offers high availability features that can be used to provide high availability. For more information, see Azure Database High Availability.

Disaster Recovery for your PostgreSQL DB

In the event of a disaster, you may need to setup a new Azure Database for PostgreSQL instance. There are other scenarios where you may need to recover from an issue with the database instance. In such scenarios, to configure your Tableau Server to use the new Azure Database instance, use the following steps:

1. **Restore the backup to a new Azure Database instance.** In Azure Database for PostgreSQL, performing a restore creates a new server from the original server's backups. For more on Azure Database for PostgreSQL backup and restore, see Azure Database for PostgreSQL Backup and Restore.

2. **Create a new JSON settings file** containing connection information for the new Azure Database for PostgreSQL instance. For more information on creating a JSON settings file, see **Step 1** in Install Tableau Server with External PostgreSQL Repository.

3. **Use the `tsm topology external-services repository replace-host` command** to point your Tableau Server to the new Azure Database for PostgreSQL instance.

   For more information on the `tsm topology external-services repository replace-host` command, see tsm topology.

Who can do this

Only Tableau Server Administrators can configure Tableau Server to use the external repository. You will also need an Azure account to create the Azure Database.

Next Steps

For new installs: Install Tableau Server with External PostgreSQL Repository

If you want to configure your existing Tableau Server to use an external repository, see Re-Configure Tableau Server Repository.

## Create a PostgreSQL Instance on Google Cloud

Beginning in version 2021.4, you can host Tableau Server External Repository on the Google Cloud Platform. This topic describes how to create a PostgreSQL instance on Google Cloud to use as your Tableau Server external repository.

To see a full list of hosts that you can use for your external repository, see Tableau Server External Repository.

Requirements and Recommendations

- At a minimum, use high memory machine type with 8vCPUs and 32GB RAM. This is the minimum recommended PostgreSQL instance size to use for Tableau Server external repository, but the exact requirements will vary with your requirements and usage. We recommend high memory instance type with 16 vCPUs and 128GB RAM for good performance in most scenarios.
- Secure communication between Tableau Server and the external PostgreSQL DB instance using SSL connections is not required but recommended.
- The PostgreSQL instance must be reachable by all nodes in the Tableau Server cluster. One of the ways you can do this is by making the PostgreSQL instance a member of a security group that has the necessary permissions to be accessed by all the nodes in the Tableau Server cluster.
- The version of PostgreSQL must should be a supported version. For more information, see Product Compatibility for supported version information.
- Tableau auto-generates passwords for internal use by internal database users. These passwords are 32 characters long and consist of lower-case letters and numbers. They cannot be accessed or configured by an admin. Your external PostgreSQL instance may allow you to set a password policy (this will depend on the platform you are using). If you specify a policy that includes character types other than numbers and lower-case letters, this can cause errors while configuring Tableau Server to use the external repository.

Create a Database PostgreSQL instance on Google Cloud

Step 1: Create a new PostgreSQL instance

Create a PostgreSQL instance using the directions provided on the Google website, here.

We recommend using a high memory machine type, with 16 vCPUs, and 128GB RAM.

Step 2: Configure database flags for your PostgreSQL Instance

From the Tableau Server perspective, most of the parameters values for the instance can be set to defaults. You can modify the parameter values if you have specific performance or logging requirements, but we strongly recommend that the following parameters be left to default values and not be changed:

- `standard_conforming_strings`
- `escape_string_warning`

We also recommend the value for the `work_mem` be set to at least 16384 to help avoid performance issues.

For more information on database flags, see this topic on the Google website.

Step 3: Get the PostgreSQL DB Instance Endpoint

Once the instance is ready, get the endpoint information that you will use to configure Tableau Server to use this instance for the Tableau Server Repository.

Step 4: Download the SSL certificate file

Secure communications between Tableau Server and the External Repository using SSL is not required but recommended.

To setup secure connections between Tableau Server and the External Repository, you must use the certificate file when you configure Tableau Server to use this external repository. For more information, see Configuring SSL/TLS certificates on the Google website.

Configuring High Availability for your PostgreSQL DB

Tableau Server does not manage or setup high availability for the external repository. Google Cloud offers high availability features that can be used to provide high availability. For more information, see Enable High Availability on an Instance on the Google website.

Disaster Recovery for your PostgreSQL DB

In the event of a disaster, you may need to set up a new PostgreSQL Database for the PostgreSQL instance. There are other scenarios where you may need to recover from an issue with the database instance. In such scenarios, to configure your Tableau Server to use the new PostgreSQL instance, use the following steps:

1. **Restore the backup to a new PostgreSQL instance.**In the Google Cloud platform, you can choose to either restore to the same instance or create a new instance. For more information, see Restoring an instance on the Google website.

   We recommend creating a new instance and do the following steps to recover.

2. If this is an new instance, **Create a new JSON settings file** containing connection information for the new Azure Database for PostgreSQL instance. For more information on creating a JSON settings file, see **Step 1** in Install Tableau Server with External PostgreSQL Repository.

3. **Use the `tsm topology external-services repository replace-host` command** to point your Tableau Server to the new Azure Database for PostgreSQL instance.

   For more information on the `tsm topology external-services repository replace-host` command, see tsm topology.

Who can do this

Only Tableau Server Administrators can configure Tableau Server to use the external repository. You will also need an Google Cloud account to create the PostgreSQL database instance.

Next Steps

For new installs: Install Tableau Server with External PostgreSQL Repository

If you want to configure your existing Tableau Server to use an external repository, see Re-Configure Tableau Server Repository.

## Create a PostgreSQL Database as a Stand-alone Installation

Beginning in version 2021.2, you can host the Tableau Server repository separately as a stand alone installation. This is different from using a managed cloud service such as AWS RDS, or Azure Database. This configuration can be done on-premises, on AWS EC2, or on an Azure VM. Such an installation of the Tableau Server Repository will be to referred to as stand-alone External Repository.

To see a full list of hosts that you can use for the your external repository, see Tableau Server External Repository.

This topic provides guidance on the requirements and configurations that are necessary for Tableau Server to connect to a PostgreSQL installation and use it as the Tableau Server External Repository. This topic does not provide you with the detailed instructions on how to install PostgreSQL We recommend that you follow the documentation on the PostgreSQL site for this information.

Requirements and Recommendations

- **Hardware Recommendations:** CPU and storage depend on your requirements. For smaller installations, you should have at least 50 GB of disk storage, and a quad processor (or 4 virtual cores) system with 32 gig of RAM. Review the guidance in this topic to calculate the disk space requirements for backup and restore. The general recommendation is to start with more hardware resources and scale back after monitoring.
- **Networking:** The PostgreSQL database instance must be reachable from all nodes in the Tableau Server cluster. One of the ways you can do this is by making the PostgreSQL database instance a member of a security group that has the necessary permissions to be accessed by all the nodes in the Tableau Server cluster.
- **Version Compatibility:** The version of PostgreSQL should match the version of the Tableau Server Repository when installed locally. For more information about compatibility, see Product Compatibility.
- **Security:** Secure connections between Tableau Server and the External Repository using SSL is **not** required, but recommended.

If you do not want to set up secure connections between Tableau Server and External Repository, you should configure the stand-alone PostgreSQL Database to allow unencrypted connections.

Create a stand-alone PostgreSQL Database Instance

Step 1: Install and initialize PostgreSQL

1. Use the PostgreSQL documentation to install PostgreSQL database instance to serve as the External Repository for Tableau Server. You may want to set up a PostgreSQL database cluster to meet any high availability requirements you may have.
2. Install the contrib package that includes the uuid-ossp extension. This module is used to generate the UUIDS that Tableau Server uses for keys in the database.
3. Initialize the PostgreSQL instance.

Step 2: Configure your PostgreSQL Instance

You will be using two configuration files to configure your PostgreSQL instance:

- `pg_hba` : This is the configuration file for host-based authentication.
- `postgresql.conf`: This is the general server configuration file.

By default these files are located here:

`/var/lib/pgsql/12/data` (This may be different depending on the distribution)

## Super User Settings

Choose a user name that meets your requirements. We recommend using **postgres** as the Administrator user name. If you choose to use a different user name, make sure that the user name does not start with **pg**. The user name also cannot be **rails**, **tblwgadmin**, **tableau**, **readonly**, or **tbladminviews**.

**This is a requirement for the external repository to work properly with Tableau Server.**

## Network and Security

Make sure that the database instance can be reached by all the Tableau Server nodes. This most often involves creating a security group that allows access from the nodes.

## Database Options

The port can be anything, but we recommend leaving it as the default `5432`.

## Update Parameters

From the Tableau Server perspective, most of the parameters values for the instance can be set to defaults. You can modify the parameter values if you have specific performance or logging requirements, but we strongly recommend that the following parameters be set to default values and not be changed:

- `standard_conforming_strings`
- `escape_string_warning`

We also recommend the value for the `work_mem` be set to at least `16384` to help avoid performance issues.

## Configure remote connections

Use the following steps to make updates to the configuration files:

1. By default, the configuration in the `postgresql.conf` is configured to only listen to local connections. Enable remote connections by making the following changes in the connections and authentication section of the `postgresql.conf` file:

   Add this line to allow remote connections:

   ```
   listen_addresses = '*'
   ```

2. Restart the PostgreSQL instance.

## Configure SSL

Secure connections between Tableau Server and the External Repository is **not** required, but recommended.

To configure encrypted connections between Tableau Server and the External Repository, follow the guidance and the detailed steps described below:

When configuring Tableau Server to use the stand-alone PostgreSQL database instance, you will need to provide a trusted root certificate authority (CA) which is used to verify the connection to the server. Ideally, the stand-alone PostgreSQL instance's server certificate should specify a resolvable hostname so Tableau Server can use sslmode, **verify-full**. This mode verifies that the PostgreSQL server's certificate was signed by a trusted CA and that the hostname in the PostgresSQL Server's certificate matches the hostname used to connect to the PostgreSQL instance. However, if that is not possible, sslmode, **verify-ca** will just verify that the Postgres server's certificate was signed by a trusted CA.

The following procedure provides the general steps to generating a root CA certificate on the PostgreSQL Server. For more detailed information, read the SSL documentation on the PostgreSQL website (The link points to version 12):

1. Generate signing root certificate authority (CA) key.
2. Create the root CA certificate.
3. Create the certificate and related key (for example - `server.csr` and `server.key`) for the PostgreSQL Server. The subject name for the certificate must match the DNS name of the PostgreSQL Server. The subject name is set with the -subj option with the format "`/CN=<private DNS name>`".
4. Sign the new certificate with the CA certificate that you created in step 2.
5. Copy the crt and key files to the data directory (`/pgsql/<version>/data`).
6. The `pg_hba.conf` file controls the connections to the database. Add the following line to allow remote connections. For example:

```
host all all 10.0.0.0/8 md5
```

7. To enable SSL add or update the `postgresql.conf` file with:

   ```
   ssl = on
   ```

   To restrict connections to only SSL only, use *hostssl* instead of *host*.

High Availability and Disaster Recovery

Tableau Server does not manage or setup high availability for the external repository. PostgreSQL database supports several solutions for these purposes including replication and log-shipping. For more information, see the high availability documentation on the PostgreSQL website.

In the event of a disaster, if you need to setup a new PostgreSQL instance, make sure to follow these steps to configure Tableau Server to use the new instance.

1. **Create a new JSON settings file** containing connection information for the new RDS instance. For more information on creating a JSON settings file, see **Step 1** in Install Tableau Server with External PostgreSQL Repository.
2. **Use the `tsm topology external-services repository replace-host` command** to point your Tableau Server to the new PostgreSQL instance.

   For more information on the `tsm topology external-services repository replace-host` command, see tsm topology.

Who can do this

Only Tableau Server Administrators can configure Tableau Server to use the external repository. If you are using AWS EC2 or Azure VM to set up a stand-alone External Repository, you need to have accounts to access these platforms.

## Install Tableau Server with External PostgreSQL Repository

This topic describes how to install and configure Tableau Server to use an external service for Tableau Server Repository.

Before you install

- You must have Advanced Management activated on your Tableau Server. For more information about Advanced Management, see About Tableau Advanced Management on Tableau Server.
- Your Tableau Server environment must be one of the following:
  - Public Cloud Services:
    - AWS cloud services.
    - Azure cloud services. For more information on Tableau Server installation on Azure, see Install Tableau Server on Microsoft Azure.
    - Google cloud services. For more information on Tableau Server installation on Google Cloud, see Install Tableau Server for Healthcare on the Google Cloud Platform.
  - On-premises: This is Tableau Server running on the hardware located in your organization or company and not on a public cloud.
- You must have an instance of PostgreSQL database install and ready. You will also need the endpoint of your PostgreSQL DB instance.
  - Tableau Server on **AWS**
    - For a fully managed Server option, using Amazon RDS, follow the guidance detailed in Create a PostgreSQL DB Instance on AWS Relational Database Service (RDS).
    - For a self-managed Server option: Use AWS EC2, and Create a PostgreSQL Database as a Stand-alone Installation
  - Tableau Server on **Azure**:
    - For a fully managed Server option using Azure DB, see Create a Azure Database PostgreSQL Instance on Azure.
    - For a self-managed Server option use Azure VM, and Create a PostgreSQL Database as a Stand-alone Installation .
  - Tableau Server on **Google Cloud**:
    - For a fully managed Server option using Google Cloud PostgreSQL instance, follow the guidance in Create a PostgreSQL Instance on Google Cloud
    - For a self-managed Server option use Google Cloud VM, and Create a PostgreSQL Database as a Stand-alone Installation

    - If you are installing this on-premises, see Create a PostgreSQL Database as a Stand-alone Installation

- Download the SSL certificate:

  Secure connections between Tableau Server and the External Repository are **not** required, but recommended.

  If you want to set up SSL connections for communications between Tableau Server and the External Repository, do the following:

    - Amazon RDS: See Using SSL to Encrypt the Connection to a DB Instance.
    - Azure Database for PostgreSQL: See Configure TLS connectivity for Azure Database for PostgreSQL.
    - Google Cloud database: See Configure SSL/TLS certificates.
    - Stand alone PostgreSQL database: The CA certificate that you used to configure SSL for the database should be copied to the Tableau Server initial node. For more information on configuring SSL for your PostgreSQL database, see Configure SSL .

Install and Configure Tableau Server

Step 1: Create a configuration file

Create a json file with the following configuration settings:

```
{
 "flavor":"<flavor name>",
 "masterUsername":"<admin user name>",
 "masterPassword":"<password>",
 "host":"<instance host name>",
 "port":5432
}
```

- **flavor:** This is the type of external service you are going to use for Tableau Server repository.

    - Amazon RDS: use “rds”
    - Azure Database: use "azure"

- Google Cloud Database: use "gcp"
- Stand-alone PostgreSQL database: use "generic"

- **masterUsername:**

  - Amazon RDS: Use "rails" for the user name. This is the user that you specified when creating the RDS instance.

    You must use "rails" as the masterUsername. This is required for the external repository to work with Tableau Server properly.

  - Azure Database, Google Cloud PostgreSQL instance, or Standalone PostgreSQL Database: Choose a user name that meets your requirements. We recommend using **postgres** as the Administrator user name. If you choose to use a different user name, make sure that the user name does not start with **pg**, or **azure**. The user name also cannot be **rails**, **tblwgadmin**, **tableau**, **readonly**, or **tbladminviews**.

- **masterPassword:** This is the same password you specified when creating the PostgreSQL database instance.

- **host:** This is the endpoint of your PostgreSQL database instance.

- **port:** The database port you specified when creating the PostgreSQL DB instance.

Step 2: Install Tableau Server and Configure the External Repository

**Using TSM CLI:**

1. Install and Initialize TSM: Follow the "Use the TSM CLI" instructions provided in this topic and complete steps 1-5 which runs the setup program and installs TSM.

2. Activate and Register Tableau Server: Provide the Tableau Server Key and the Advanced Management key in the activate step. You will need to run the following command twice, first with the Tableau Server product key and then with the Advanced Management product key:

   ```
   tsm licenses activate -k <product key>
   ```

3. Configure Initial Node Settings: Follow the "Use the TSM CLI" instructions provided in the topic to configure the initial node settings.

   Important! Do not run the **Initialize and Start Tableau Server** step when you configure the initial node. After completing the other steps in the Configure Initial Node Settings topic, return to this page and follow the rest of the instructions.

4. Configure Tableau Server to use the external repository by using the following commands:

- Specify the external repository settings using the json file that you created in the previous step:

  ```
  tsm topology external-services repository enable -f <file-name>.json -c <ssl certificate file>
  ```

  The json file is the file that you created in the first step with the configuration settings.

  > **Note:** The SSL certificate is needed only if you are using encrypted connections between Tableau Server and the External Repository. If this is not a must for you, you must specify the --no-ssl option. In this case, the tsm command would look like this:
  > ```
  > tsm topology external-services repository enable -f <file-name>.json --no-ssl
  > ```

- Apply the changes:

  ```
  tsm pending-changes apply
  ```

Step 3: Complete tsm Initialize

To initialize and start Tableau Server:

```
tsm initialize --start-server --request-timeout 1800
```

Step 4: Complete the install

Add an Administrator Account and complete the installation.

Who can do this

Tableau Server Administrators can install and configure Tableau Server.

## Re-Configure Tableau Server Repository

Your Tableau Server may be configured to use either a local or an external repository. This topic describes the steps needed to reconfigure your existing Tableau Server with one of the following options:

- Move a local Tableau Server Repository to an external repository and configure your Tableau Server to use an external repository.
- Move the external Tableau Server Repository to your local Tableau Server installation, and configure your Tableau Server to use the local repository. This means that the Tableau Server repository will be installed on the same machine or machines as your Tableau Server.

To learn more about these options and external repositories, see Tableau Server External Repository.

Move local repository to external

Tableau Server must be stopped to migrate from a local repository to an external repository.

Use the following steps to move Tableau Server Repository from local to external:

1. Activate the Advanced Management product key on your Tableau Server if it is not already activated. Advanced Management license is required to configure your Tableau Server with an external repository.
2. Configure Amazon PostgreSQL DB instance to use as the external repository.
    1. Amazon: Create a PostgreSQL DB Instance on AWS Relational Database Service (RDS).
    2. Azure Database: Create a Azure Database PostgreSQL Instance on Azure.

3. Google Cloud Database: Create a PostgreSQL Instance on Google Cloud
4. Stand-alone PostgreSQL Instance: Create a PostgreSQL Database as a Stand-alone Installation .

3. Create a json file with the following configuration settings:

```
{
 "flavor":"<flavor name>",
 "masterUsername":"<admin user name>",
 "masterPassword":"<password>",
 "host":"<instance host name>",
 "port":5432
}
```

- **flavor:** This is the type of external service you are going to use for Tableau Server repository.
    - Amazon RDS: use “rds”
    - Azure Database: use "azure"
    - Google Cloud Database: use "gcp"
    - Stand-alone PostgreSQL database: use "generic"
- **masterUsername:**
    - **Amazon RDS:** Use "rails" for the user name. This is the user that you specified when creating the RDS instance.

      You must use "rails" as the masterUsername. This is required for the external repository to work with Tableau Server properly.
    - **Azure Database, Google Cloud instance, and Stand-alone PostgreSQL instance:** Choose a user name that meets your requirements. We recommend using **postgres** as the Administrator user name. If you choose to use a different user name, make sure that the user name does not start with **pg** or **azure**. The user name also cannot be **rails**, **tblwgadmin**, **tableau**, **readonly**, or **tbladminviews**. When choosing a user name other than "postgres", after each backup restore, the suffix "_bak"

will be added to the initial "postgres" system user in the repository, such as "postgres_bak".

- **masterPassword:** This is the same password you specified when creating the PostgreSQL database instance.
- **host:** This is the endpoint of your PostgreSQL database instance.
- **port:** The database port you specified when creating the PostgreSQL DB instance.

4. Run the following TSM CLI command to configure Tableau Server to use external repository:

```
tsm topology external-services repository enable -f file.json -
c <ssl certificate file>.pem
```

> **Note:** The SSL certificate is needed only if you are using encrypted connections between Tableau Server and the External Repository. If this is not a requirement for you, you must specify the `--no-ssl` option. In this case, the tsm command would look like this:
> `tsm topology external-services repository enable -f <file-name>.json --no-ssl`

The json file is the file that you created in the first step with the configuration settings. The SSL certificate file can be downloaded as described in this topic.

Running the above command will migrate the local repository to your new external PostgreSQL DB instance.

Move external repository to local

Use the following steps to move Tableau Server Repository from external location to the local installation:

1. Run the following TSM CLI command to move the repository to a specific node:

   ```
   tsm topology external-services repository disable -n nodeN
   ```

2. If you are setting up HA for your repository, install the repository on a second node. For more information, see Example: Install and Configure a Three-Node HA Cluster.

   **Note:** To install the repository on a second node, you must run the command described in the previous step first. The first step migrates your external repository to the local repository. You can then install the repository on a second node on your Tableau Server.

Who can do this

Tableau Server Administrators can reconfigure external repository. You will also need to have access to create PostgreSQL database instance on Amazon or Azure.

## Upgrade Tableau Server with External Repository for a New Major Version of PostgreSQL

When there is a change in the PostgreSQL major version requirement for Tableau Server, there are some specific instructions you must follow to ensure that your Tableau Server upgrade is successful. For example, Tableau Server 2020.4 requires that the repository use PostgreSQL version 12. This is a major version change from PostgreSQL version 9.x used in Tableau Server versions earlier than 2020.4. So if you are upgrading from an earlier version of Tableau Server to version 2020.4 or later, you will need to take the steps described in the following sections to complete the upgrade.

This topic also includes the product compatibility between PostgreSQL and Tableau Server.

Before you upgrade

You cannot do an in-place upgrade to update the PostgreSQL version on your existing PostgreSQL DB instance on Amazon RDS or Azure Database for PostgreSQL DB. Instead, you must create a new instance and point the Tableau Server to the new instance during upgrade. Use the following information to create a new instance and prepare for the upgrade:

1. Create a new instance of PostgreSQL Database instance:
    1. Create a PostgreSQL DB Instance on AWS Relational Database Service (RDS)
    2. Create a Azure Database PostgreSQL Instance on Azure
    3. Create a PostgreSQL Instance on Google Cloud
    4. Create a PostgreSQL Database as a Stand-alone Installation
2. SSL connections are **not** required but recommended. If you want to setup SSL connections for communications between Tableau Server and the External Repository, do the following:
    - **Amazon RDS:** See Using SSL to Encrypt the Connection to a DB Instance.
    - **Azure Database:** See Configure TLS connectivity for Azure Database for PostgreSQL.
    - **Google Cloud Instance:** See Configuring SSL/TLS certificates
    - **Stand-alone PostgreSQL Instance:** See Configure SSL .
3. Create a configuration file for the new instance you created in step 1.

    Create a json file with the following configuration settings:

    ```
    {
     "flavor":"<flavor name>",
     "masterUsername":"<admin user name>",
     "masterPassword":"<password>",
     "host":"<instance host name>",
     "port":5432
    }
    ```

    - **flavor:** This is the type of external service you are going to use for Tableau Server repository.
        - Amazon RDS: use “rds”
        - Azure Database: use "azure"

  - Google Cloud Database: use "gcp"
  - Stand-alone PostgreSQL database: use "generic"

- **masterUsername:**

  - **Amazon RDS:** Use "rails" for the user name. This is the user that you specified when creating the RDS instance.

    You must use "rails" as the masterUsername. This is required for the external repository to work with Tableau Server properly.

  - **Azure Database, Google Cloud Instance or Stand-alone PostgreSQL Instance:** Choose a user name that meets your requirements. We recommend using **postgres** as the Administrator user name. If you choose to use a different user name, make sure that the user name does not start with **pg**, or **azure**. The user name also cannot be **rails**, **tblwgadmin**, **tableau**, **readonly**, or **tbladminviews**.

- **masterPassword:** This is the same password you specified when creating the PostgreSQL database instance.

- **host:** This is the endpoint of your PostgreSQL database instance.

- **port:** The database port you specified when creating the PostgreSQL DB instance. Default port for PostgreSQL is 5432.

Tableau Server Upgrade

> **Note:** If you are using Tableau Server External Repository, you must upgrade Tableau server using the command line option.

The following are the high level steps of how to specify the external repository parameters when running the upgrade script.

For a full walk-through of Tableau Server upgrade process, see Upgrading from earlier versions

1. On the Tableau Server, open a command prompt as administrator.

   **Note:** You must open a new command window because the Setup program updates the path for the new installation.

2. Navigate to the scripts folder for your new installation.

   By default:

   ```
   /opt/tableau/tableau_server/packages/scripts.<version_code>/
   ```

3. Run the upgrade script and specify the configuration file and the SSL certificate:

   ```
   upgrade-tsm --external-repository-config-file=<json config
   file> --external-repository-cert-file=<SSL certificate file>
   ```

Product Compatibility

The table below lists the version of PostgreSQL that is supported with Tableau Server. Use this table to determine the version of PostgreSQL to install for your External Repository.

**Amazon RDS support:** External Repository using Amazon RDS is supported on Tableau Server versions 2019.3 and later.
**Azure Database support:** External Repository using Azure Database instance is supported on Tableau Server versions 2020.4 and later.

**Google Cloud support:** External Repository using Google Cloud SQL intance is supported on Tableau Server versions 2021.4 and later.
**Stand alone PostgreSQL instance support:** External Repository using a stand alone installation of PostgreSQL database is supported on Tableau Server versions 2021.2 and later.

Google Cloud Platform support: External Repository using a PostgreSQL instance on Google Cloud Platform is supported on Tableau Server versions 2021.4 and later.

| Tableau Server versions | PostgreSQL minimum compatible versions |
|---|---|
| 2022.3.0 - 2022.3.7<br>2023.1.0 - 2023.1.4 | 13.7 |
| 2022.1.17 - 2022.1.19<br>2022.3.8 - 2022.3.19<br>2023.1.5 - 2023.1.15<br>2023.3.0 - 2023.3.8 | 13.11 |
| 2022.3.20 - 2022.3.x<br>2023.1.16 - 2023.1.x<br>2023.3.9 - 2023.3.x | 13.14 |
| 2024.0 - 2024.2.8 | 15.6 |
| 2024.2.9 - 2024.2.13<br>2025.1.0 - 2025.1.6 | 15.10 |
| 2024.2.14 - 2024.2.16<br>2025.1.7 - 2025.1.9 | 15.13 |
| 2024.2.17<br>2025.1.10<br>2025.3 | 15.14 |

## Legacy compatibility

The table below includes two columns:

1. PostgreSQL version shipped with Tableau Server, which is the version that is installed with Tableau Server for local Repositories.
2. All PostgreSQL versions supported for External Repository.

**Notes:**
- For PostgreSQL versions earlier than version 10, the first two digits indicate the major version, and the minor version is represented by the last digit. For example, in the version 9.4.1, 9.4 indicates the major version and the .1 indicates the minor version.
- For PostgreSQL versions 10 or later, the first digit indicates the major version, and the minor version is the represented by the last digit. For example, in the version 11.1, 11 is the major version and .1 is the minor version.
- A PostgreSQL version with a major version equal to, and a minor version greater than, the Postgres version shipped with Tableau server is always acceptable for use with the external repository, along with any explicitly allowed older versions.

| Tableau Server Version | PostgreSQL Version (Shipped with Tableau Server) | Alternate PostgreSQL Versions supported for External Repository |
|---|---|---|
| 2019.3 - 2019.3.3 | 9.6.11 | 9.6.x, where x is greater than 11 |
| 2019.3.4 - 2019.3.10 | 9.6.15 | 9.6.x, where x is greater than 15 |
| 2019.3.11 - 2019.3.14 | 9.6.17 | 9.6.15, or 9.6.x, where x greater than 17 |
| 2019.4 - 2019.4.1 | 9.6.14 | 9.6.x, where x is greater than 14 |
| 2019.4.2 - 2019.4.6 | 9.6.15 | 9.6.x, where x is greater than 15 |
| 2019.4.7 - | 9.6.17 | 9.6.15, or 9.6.x, where x is greater than |

| | | |
|---|---|---|
| 2019.4.13 | | 17 |
| 2020.1 - 2020.1.6 | 9.6.15 | 9.6.x, where x is greater than 15 |
| 2020.1.7 - 2020.3.2 | 9.6.17 | 9.6.15, or 9.6.x, where x is greater than 17 |
| 2020.4 - 2021.4 | 12.8 | 12.8, or 12.x, where x is greater than 8 |
| 2022.1 and later | 13.3 | 13.3 or 13.x, where x is greater than 3 |

Who can do this

Tableau Server Administrators can upgrade and configure Tableau Server.

## Upgrading your RDS Instance

If you find that the current RDS instance you are using to host Tableau repository is a performance bottleneck, you can upgrade your RDS instance to a larger size. This topic describes the steps that you can use to upgrade your RDS instance.

1. Back up Tableau Server Data.
2. Stop Tableau Server:

   ```
   tsm stop
   ```

3. After confirming that the server has shutdown, sign in to the AWS Management Console and open the Amazon RDS console at

   https://console.aws.amazon.com/rds/.

4. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
5. Choose **Modify**. The Modify DB Instance page appears.
6. Modify your RDS instance by setting the DB instance class to the one you want.

7. Choose **Apply immediately** to make sure that the changes are applied right away. For more detailed information, see Modifying a DB Instance Running the PostgreSQL Database Engine on AWS documentation site.

8. Monitor the status of the RDS instance in the AWS console. It may take a while, but when the status shows as Available, you can start Tableau Server and resume normal operations:

   ```
   tsm start
   ```

Who can do this

Tableau Server Administrator who has have access to the Amazon RDS account can perform all the steps required to upgrade the Amazon RDS instance.

## Workload Management through Node Roles

Using node roles, you can configure where certain types of workloads are processed on your Tableau Server installation. The node roles features allows you to dedicate and scale resources to specific workloads. You can configure node roles for Backgrounder and File Store.

The Backgrounder node role specifies the type of background tasks that should run on a node, whereas the File Store node role specifies the type extract workload that should run on a node. Both node roles are specified at a node level. Although these node roles can work independently to optimize selected workload, the two node roles in combination can be used to specialize server nodes to preferentially execute selected workloads to optimize performance extract heavy workloads. This combination is discussed in more detail later in the File Store node roles section.

### Backgrounder node roles

The Backgrounder process runs Tableau Server tasks, including extract refreshes, subscriptions, flow tasks, ‘Run Now’ tasks, and tasks initiated from *tabcmd*. Running all these tasks can use a lot of machine resources. If you have more than one Backgrounder node in

your cluster, you can manage your Backgrounder workload by specifying the type of tasks a Backgrounder can run on a node using the Backgrounder node role feature.

This configuration option is currently available only through TSM CLI commands and is only useful on multi-node clusters. If you have only one node, the Backgrounder is set to run all tasks by default and that cannot be changed.

Using Backgrounder node roles

The Backgrounder node role feature is intended to give you more control and governance over where certain type of Backgrounder workloads are processed in your Tableau Server installation and allows you to dedicate and scale resources to specific workloads.

For example, if your deployment is heavy on extract and users are running a lot of extract refreshes or encryption jobs, it could be beneficial to dedicate a node to extract refreshes. Similarly, in the case of subscriptions, if your Tableau Server installation processes a lot of subscriptions and you want to ensure that other jobs do not take resources from subscriptions, then you can dedicate a node to subscriptions. In these cases, you would also want to dedicate other backgrounder nodes to workloads other than extract refreshes or subscriptions.

To support high availability, Tableau recommends having multiple nodes that are dedicated towards a specific workload. For example, if you dedicate a node to extract refreshes, you should also configure a second node to process extract refresh workload. This way if a node dedicated to extract refreshes becomes unavailable, extract refreshes can still be processed by the other node.

Configuration options

| **Configuration** | **Jobs** |
|---|---|
| all-jobs (default) | All Tableau Server jobs |
| flows | Flow run jobs. |
| no-flows | All jobs except flows. |

| | |
|---|---|
| extract-refreshes | Jobs that are created for:<br><br>Incremental refreshes, full refreshes, encryption and decryption of all extracts including extracts that flow outputs create. |
| subscriptions | Subscription jobs |
| system | System maintenance jobs that interact with other Tableau Server processes. For example, cleaning crashed jobs, reaping database events, and synching Active Directory. |
| extract-refreshes-and-subscriptions | Extract-refreshes, encryption and decryption of all extracts including extracts that flow outputs generate, and subscription jobs. |
| no-extract-refreshes | All jobs except extract-refreshes, extract encryption and decryption of all extracts including extracts created from flow outputs. |
| no-subscriptions | All jobs except subscriptions. |
| no-extract-refreshes-and-subscriptions | All jobs except extract-refreshes, encryption and decryption of all extracts including extracts created from flow outputs, and subscriptions. |
| no-system | All jobs except system maintenance jobs. |

For more information on how to use the tsm commands to set the node role, see tsm topology.

**Note:** Making configurations to node roles require a restart of the server and will require some downtime. For more information, see tsm pending-changes.

License requirements

Configuring a node to do only a specific type of tasks, like, flows, extract refreshes, and subscriptions, you must have one of the following licenses activated on your Tableau Server:

- To configure a node to run flows, you must have a valid Data Management license activated on your server, and have Tableau Prep Conductor running on that node. To learn more about Tableau Prep Conductor, see Tableau Prep Conductor.
- To configure a node to run extract refreshes, subscriptions, and any combination related to extract refreshes and subscriptions you must haveAdvanced Management capabilities enabled on your Tableau Server. If the license expires or is deactivated, you will see an error any time you make a change to the Server configuration. For more information on Advanced Management. see About Tableau Advanced Management on Tableau Server.

Important!
While flows, extract refreshes, and subscriptions can be expensive and resource heavy, they are not the only jobs that may require dedicated resources. In the **all jobs** group, there are a variety of System jobs that the Backgrounder executes, such as thumbnail generation for workbooks. Make sure that the nodes that run jobs other than extract refreshes, subscriptions, or flows have enough machine resources.

For more information on configuring node roles using TSM commands, see tsm topology set-node-role.

Considerations

There are some rules you must consider when configuring Backgrounder node roles, which are listed below:

- Only one node role configuration can be set for a node at a time. You cannot configure multiple node roles on a node.
- To configure a node role, there must be at least one Backgrounder process on that node.
- If you have only one Backgrounder node, you must configure this node to run all jobs. This is the default configuration and does not require additional licensing.

- If you have more than one Backgrounder node, combined, they must be configured to handle all jobs. This can be achieved in the following ways:
    - Configure one of the nodes to run all jobs using the all jobs option. This is the easiest and most straightforward way.
    - Using one of the exception configurations on one of the nodes:
        - no-flows
        - no-subscriptions
        - no-extract-refreshes
        - no-extract-refreshes-and-subscriptions

For example, in a cluster where there are three backgrounders, you could have one node configured to run flows, one to run subscriptions and extract refreshes, and one to run all jobs except flows, subscription and extract refreshes.

**Note:** The ability to specify node roles to run flows, or run all jobs except flows, or run all jobs was introduced in 2019.1.

## File Store node roles

The Tableau Server File Store controls the storage of extracts. There are three broad categories of workloads that are extract dependent.

| Extract Workload | Execution Service |
|---|---|
| Refresh | Backgrounder |
| Query | Data Engine |
| Backup/Restore | Backup/Restore |

File Store node role management in combination with Backgrounder node role management gives server admins the ability to specialize server nodes to preferentially execute selected workloads to optimize performance of all categories of extract heavy workloads.

It is possible to specialize a node to execute extract query workloads through a topology that has only stand-alone Data Engine nodes. For more information, see Optimize for Extract Query-Heavy Environments. However, this is at the expense of extract refresh workloads, which are executed by Backgrounder nodes. With the topology-based isolation approach, extract refresh heavy Backgrounder workloads can get slower as none of the Backgrounder nodes have a File Store and thus all extract refresh traffic goes over the network.

With the File Store Node Role configuration option, it is possible to designate certain server nodes that process extract queries to be preferentially selected from the list of server nodes that can do so. This helps speed up workloads such as backup and extract refreshes by allowing server admins to enable File Store on Backgrounder server nodes, which prevents extract queries from running on these nodes. This feature is useful if you have an extract-heavy query workload and an extract-heavy refresh workload and want to achieve optimal extract query and refresh performance.

Guidelines to optimize for extract refresh and backup or restore workloads.

Start from a topology with specialized Data Engine nodes (see Optimize for Extract Query-Heavy Environments).

**Note:** In the below diagram and procedure, node 1 is Initial Node, node 2 is Additional Node 1, node 3 is Additional Node 2, and node 4 is Additional Node 3.

| Process | Initial Node | Additional Node 1 | Additional Node 2 | Additional Node 3 |
|---|---|---|---|---|
| Cluster Controller | ✓ | ✓ | ✓ | ✓ |
| Gateway | ✓ | ✓ | | |
| Application Server | ✓ | ✓ | | |
| VizQL Server | ✓ ✓ | ✓ ✓ | | |
| Cache Server | ✓ ✓ | ✓ ✓ | | |
| Search & Browse | ✓ | ✓ | | |
| Backgrounder | ✓ ✓ ✓ ✓ | ✓ ✓ ✓ ✓ | | |
| Data Server | ✓ ✓ | ✓ ✓ | | |
| Data Engine | ✓ | ✓ | ✓ | ✓ |
| File Store | | | ✓ | ✓ |
| Repository | ✓ | ✓ | | |

Topology 1 - Dedicated Data Engine Nodes

1. Add File Store to Node 1.

   ```
   tsm topology set-process -n node1 -pr filestore -c 1
   ```

2. Designate Node 3 and Node 4 to preferentially execute extract-query workloads

   ```
   tsm topology set-node-role -n node3, node4 -r extract-queries
   ```

3. Designate Node 1 to preferentially execute extract-refresh workloads.

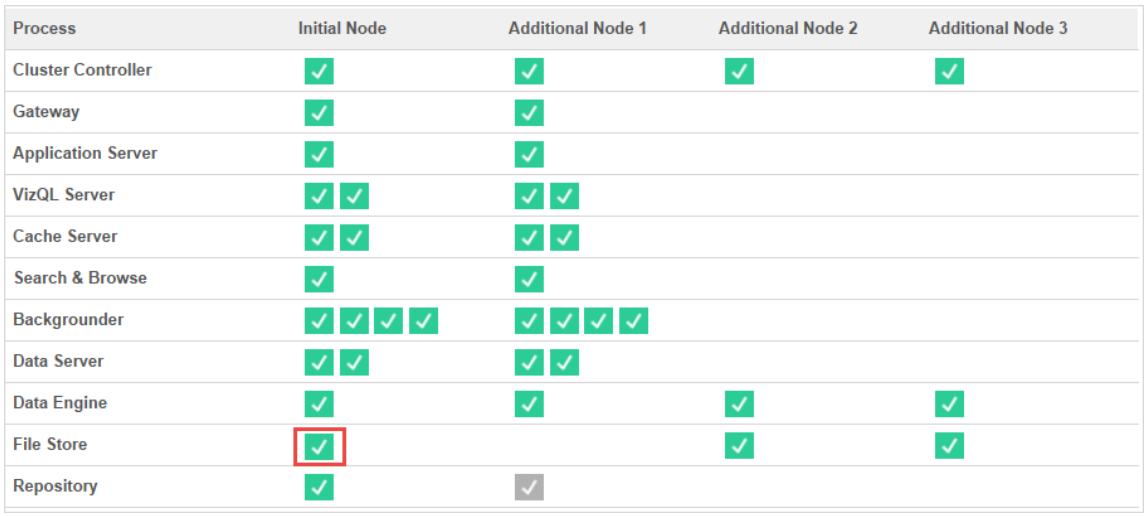
   ```
   tsm topology set-node-role -n node1 -r extract-refreshes
   ```

4. Designate Node 2 to preferentially execute non-extract-refresh workloads.

   ```
   tsm topology set-node-role -n node2 -r no-extract-refreshes
   ```

5. Apply pending changes.

   ```
   tsm pending-changes apply
   ```



Topology 2 - Extra File Store Node

**Note:** In your Tableau Server deployment, adding File Store roles to existing nodes will temporarily increase network I/O between all File Store nodes while the new File Store is being synchronized. The duration of this operation is dependent on the volume of data on the File Store and the network bandwidth capacity. The status of synchronization can be monitored using the TSM Web GUI. If you are adding more than one File Store to your deployment, it is recommended to add them consecutively and wait for the initial synchronization to complete in between each File Store addition.

Fine tune extract query workload management

When extract queries for email subscriptions and metric alerts are running at the same time that users are interactively viewing extract-based visualizations, users may experience slower than normal viz load times. Use the following node roles to fine tune how these workloads are prioritized.

| Node role to use | Type of extract query workload | Example |
|---|---|---|
| `extract-queries` | scheduled | email subscriptions and metric alerts |

| | | |
|---|---|---|
| `extract-queries-interactive` | interactive | users viewing an extract-based visualization |

If your server deployment is seeing growth in email subscriptions and metric alerts, you can add nodes and assign the `extract-queries` node role, which makes them more available to handle subscriptions and alerts.

If your server deployment is seeing growth in users viewing extract-based visualizations, you can add nodes and assign the `extract-queries-interactive` node role, which makes them prioritize interactive extract queries to reduce extract-based viz load times. The `extract-queries-interactive` node role is a preference and not strict isolation. This means that queries will be routed to nodes that have the `extract-queries-interactive` node role assigned. If you have multiple nodes with the `extract-queries-interactive` role, queries will be routed based on node health.

For example, add a node and designate it to preferentially execute `extract-queries-interactive` workloads.

- `tsm topology set-node-role -n node4 -r extract-queries-interactive`

Configuration options

| **Configuration** | **Jobs** |
|---|---|
| all-jobs (default) | All Tableau Server jobs |
| extract-queries | Jobs that are created for extract queries. The nodes selected will run as all-jobs and will prioritize the processing of extract queries. |
| extract-queries-interactive | Jobs that are created for extract queries. The nodes selected will run as all-jobs and will prioritize the processing of interactive extract queries, such as those that run when a user is looking at their screen and waiting for an extract-based dashboard to load. This is an advanced setting and it should only be used if the cluster has a heavy subscription and alert job workload that causes users to experience degraded per- |

| | |
|---|---|
| | formance on viz load times that run around the same time as scheduled loads. |

For more information on configuring node roles using TSM commands, see tsm topology set-node-role.

License requirements

To configure a node to run extract queries you must have a valid Advanced Management license activated on your Tableau Server.

### How to see node roles

Use the following command to see what node roles are currently configured on Tableau Server:

```
tsm topology list-nodes -v
```

### Who can do this

Tableau Server Administrators can configure node roles and activate any required product keys.

## Tableau Server Independent Gateway

This topic provides an overview of Tableau Server Independent Gateway.

Independent Gateway is a reverse proxy server and load balancer based on Apache httpd. It uses the same Apache httpd version as the Tableau Server Gateway process internal to Tableau Server cluster, but it is suitable for deployment in a network DMZ. Because Independent Gateway is a part of Tableau Server, it is managed by TSM and does not need separate configuration.

Its configuration has full knowledge of the topology of externally accessible Tableau Server components, and is updated when the cluster topology changes. After a simple Independent

Gateway installation process, configuration choices are made centrally using Tableau Services Manager (TSM) configuration items.

With this feature, Tableau Server can now be configured in two ways:

- Install Tableau Server in a self-contained installation. Any reverse proxy needs to be installed and managed separately.
- Install Tableau Server and install Independent Gateway as a reverse proxy that is managed by Tableau Server (version 2022.1 and later).

## Why use Independent Gateway?

Using Independent Gateway has the following benefits over installing a separate reverse proxy:

- **Fully supported:** The Independent Gateway is part of a Tableau Server installation, and is fully supported by Tableau.
- **Tableau Server aware:** When you use a separate reverse proxy, it needs to be updated when the topology of Tableau Server changes. Independent Gateway is fully aware of all externally-callable Tableau Server components, and is updated when these change.

## Managing Independent Gateway

License Management

To use Independent Gateway you must have Advanced Management capabilities in Tableau Server. There is no licensing done on the Independent Gateway node. For more information, see About Tableau Advanced Management on Tableau Server. If you don’t have an Advanced Management key activated or if the license is expired, you will see the following behavior:

- If you try to configure Tableau Server with Independent Gateway it will fail.
- If you are already using Independent Gateway, and the Advanced Management license expires, the server will fail on restart.

Backup and Restore

There is no impact to backup or restore with Independent Gateway. A backup or restore of Tableau Server will not include any information or configuration for Independent Gateway. If

you use the backup to create a new installation of Tableau, you will need to separately install, configure, and enable Independent Gateway for the new Tableau Server installation.

High Availability Considerations

You can install multiple instances of Independent Gateway to provide robust high availability in your reverse proxy. You might also want to increase the number of Independent Gateway nodes if you have large numbers of client sessions accessing Tableau.

All nodes must be running the same operating system. For more information, see Software Requirements for Multi-node Server.

## Topology

When you configure Tableau Server with Independent Gateway, you no longer need to set up and configure a separate reverse proxy. Independent Gateway will appear on the TSM status page as an external service.

> **Note:** The status page and the status output on the CLI will only show a single instance of Independent Gateway, even if you have installed multiple Independent Gateway nodes.

## Next

Install Tableau Server with Independent Gateway

## Install Tableau Server with Independent Gateway

This topic walks you through the process of installing Tableau Server Independent Gateway.

Following this process will result in a Independent Gateway configuration with a direct connection to the backend Tableau Server deployment. You can learn more about *direct* vs *relay* connection modes in the topic, Configure Tableau Server with Independent Gateway.

### Prerequisites

- You must have a dedicated server with at least 2 cores (4 vCPUs), 8 GB of RAM, and 100 GB free disk space.
- You must use Tableau Server 2022.1 or later.
- You must use an installer for Tableau Server Independent Gateway with a major version (**2022.1** for example) that matches the version of Tableau Server. We recommend maintenance versions (2022.1**.1** or 2022.1**.5** for example) match as well, but this is not a requirement. If "static assets" change between versions and versions do not match, you may see some unexpected image impact. For example, maps may not be up-to-date if Independent Gateway is an earlier version than Tableau Server.
- You must have Advanced Management enabled in Tableau Server. To learn more about Advanced Management, see About Tableau Advanced Management on Tableau Server.
- By default, the Independent Gateway must be able to communicate with the backend Tableau Server deployment on ports 80 and 21319 during installation. You can change these default ports during initialization as described later in this topic.
- Verify that your Tableau Server deployment is complete and healthy before installing and configuring Independent Gateway.
- Verify that you are not running any other web-aware applications on the computer where you are installing Independent Gateway. For example if Apache httpd is installed on the computer, uninstall it, or configure `httpd` so that it is not actively listening on port 80.

### Install Tableau Server and Independent Gateway

Installing Independent Gateway is done using a standalone installation package that includes "tsig" as part of the file name to distinguish it from the full Tableau Server installer. We strongly recommend you install Independent Gateway after installing Tableau Server and confirming that it is functioning as expected. To install you must be the root user (or be able to sudo to root). You can install one or more instances of Independent Gateway, but each instance of Independent Gateway must be installed separately. If you are installing multiple instances for high availability or to distribute a heavy client load, repeat the installation steps for each instance.

After installation, you are prompted to run a script called `initialize-tsig` to complete the installation. The script takes information your provide using parameters, and configures

Independent Gateway. Once Independent Gateway is fully installed, you need to run a TSM command on the initial Tableau Server node to configure the server with details about the instance of Independent Gateway.

The IG installation consists of these steps:

- Run the platform-specific installer.
- Run the post-install script.
- Enable the Independent Gateway instance using TSM.

Step 1: Download and install Tableau Server

1. Install and Initialize TSM: Follow the instructions provided in this topic and complete steps 1-5 which runs the setup program and installs TSM.
2. Activate and Register Tableau Server: Provide the Tableau Server Key and the Advanced Management key in the activate step. You will need to run the following command twice, first with the Tableau Server product key and then with the Advanced Management product key:

   ```
   tsm licenses activate -k <product key>
   ```

3. Configure Initial Node Settings: Follow the instructions provided in the topic to configure the initial node settings.

Step 2: Download and install Independent Gateway

Install Tableau Server Independent Gateway with your distribution's package manager, then run a script to initialize Independent Gateway. The script is included with the installed package.

Independent Gateway is installed in the `/opt` directory.

1. Log on as a user with `sudo` access to the computer where you want to install Independent Gateway.

   > **Note:** To avoid possible complications, we recommend a user account that does not include any special characters (for example, non-ASCII, "+", "-"). These may cause problems, including a failure to fully install Independent Gateway, depending on how your environment is configured.

2. Download the `.rpm` or `.deb` installer package from the Tableau Server Downloads and Release Notes page.

3. Navigate to the directory where you copied the `.rpm` or `.deb` package.

4. Use the package manager to install the Independent Gateway package.

   Do not install to a location using a symbolic link or to a directory on a Network File System (NFS) volume. Run the following commands to install Independent Gateway, where `<version>` is formatted as major-minor-maintenance (example: `2022-1-0`).

   - On RHEL-like distributions, including CentOS:

     ```
     sudo yum update

     sudo yum install tableau-tsig-<version>.x86_64.rpm
     ```

   - On Ubuntu:

     ```
     sudo apt-get update
     sudo apt-get upgrade
     sudo apt-get -y install gdebi-core
     sudo gdebi -n tableau-tsig-<version>_amd64.deb
     ```

## Initialize Tableau Server Independent Gateway

The next step is to run the `initialize-tsig` script.

1. Navigate to the `scripts` directory:

   ```
   cd /opt/tableau/tableau_tsig/packages/scripts.<version_code>/
   ```

2. Run the following script to initialize and start Independent Gateway:

   ```
   sudo ./initialize-tsig --accepteula -c <ts_cluster_location> --
   <optional_parameters>
   ```

   The only required parameters for the `initialize-tsig` script are `--accepteula` and `-c`.

   - **--accepteula** - You must include this parameter to accept the Tableau End User License Agreement (EULA). A link to the EULA is available in the following location:

     ```
     /opt/tableau/tableau_tsig/packages/docs.<version_code>/
     ```

   - **-c** - You must include this parameter to specify the network location of all the nodes in the Tableau Server cluster. These nodes may be sending "housekeeping" requests to the Independent Gateway. Wild cards and subnet masks can be used to specify multiple nodes. To specify multiple addresses, separate addresses by spaces and use quotes around the complete set. Values must be provided in one of the forms acceptable to the Apache `httpd mod_authz_host` "Require" directive. For more information, see https://httpd.apache.org/docs/2.4/mod/mod_authz_host.html.

   All other parameters, for example default ports used by HTTP and the housekeeping process, are optional and if left off will be given default values. Review the parameters and their default values before running the script: Help Output for initialize-tsig Script.

Step 3: Enable Independent Gateway in Tableau Server

The last step of installing and configuring Independent Gateway is to enable Independent Gateway in Tableau Server. To do this, use the TSM command `tsm topology external-services gateway enable -c <file>` with a JSON file that identifies the Independent Gateway instance or instances, and provides Tableau Server with the details necessary for communication between the server and the Independent Gateway.

Tableau Server must be in a stopped state to enable Independent Gateway.

## The Independent Gateway JSON file contents

The JSON file that you use to enable the instances of Independent Gateway on Tableau Server needs to contain the following:

- **id**—The id value must match the `tsig_instance_id` for the particular instance. If you did not provide this, the default is the fully qualified domain name of the Independent Gateway computer, in lowercase. The value in the json file must match the output of the `hostname` command.
- **host**—The host value must be a DNS-resolvable name for the Independent Gateway computer that can be resolved by the Tableau Server nodes using DNS.
- **port**—The port must match the housekeeping port (`tsig_housekeeping_port`) specified on the Independent Gateway instance. If you did not provide this during initialization, the default is "21319".
- **protocol**—The protocol must be the same as the housekeeping protocol (`tsig_housekeeping_port_protocol`) specified on the Independent Gateway instance. If you did not provide this during initialization, the default is "http".
- **authsecret**—The authsecret must match the secret created by the initialization script on the Independent Gateway instance.

## The Independent Gateway auth secret

The initialization script creates a unique, shared secret on each Independent Gateway computer. You need this secret to enable Independent Gateway in Tableau Server. Copy the secret and include it in your JSON file as the "authsecret".

The shared secret is located in the `tsighk-auth.conf` file here:

```
/var/opt/tableau/tableau_tsig/config/tsighk-auth.conf
```

## Independent Gateway JSON file example

The JSON file should be in the format below. This example JSON file shows default values where there are defaults. Your file should have use the actual values that match your installation of Independent Gateway and your organization.

```
{
 "independentGateways": [
  {
    "id": "<mycomputer.example.com>",
    "host": "<DNS name of Independent Gateway computer>",
    "port": "21319",
    "protocol": "http",
    "authsecret": "<shared-secret01>"
  },
  {
    "id": "<mycomputer2.example.com>",
    "host": "<DNS name of second Independent Gateway computer>",
    "port": "21319",
    "protocol": "http",
    "authsecret": "<shared-secret02>"
  }
 ]
}
```

Enabling Independent Gateway in Tableau Server

To complete the installation of Independent Gateway , you need to enable it using TSM.

1. Copy the JSON configuration file to the initial node of Tableau Server.
2. On the initial node, open a command prompt using an account hat is a member of the `tsmadmin` group.
3. Run the following commands to stop Tableau Server, enable Independent Gateway using the json configuration file, and restart the server:

   ```
   tsm stop
   tsm topology external-services gateway enable -c tsig.json
   tsm start
   ```

Step 4: Verify Independent Gateway in Tableau Server

You should be able to navigate to the Tableau Server sign-in page by entering the address of the Independent Gateway in a browser.

If there is a firewall between the Independent Gateway and the backend Tableau Server deployment, then you will need to open the ports for the Tableau Server processes for direct connection. See Direct connection for more information.

Alternatively, you may choose to minimize port requirements by configuring Independent Gateway for a relay connection. See Relay connection for more information.

## Configure Tableau Server with Independent Gateway

This topic describes how to configure Tableau Server with Independent Gateway for different connection scenarios and for a custom authentication module.

For installation procedure, see Install Tableau Server with Independent Gateway.

For an end-to-end deployment example running on Tableau Server for Linux in AWS, see Configuring Web Tier in the Enterprise Deployment Guide.

Direct vs relay connection

The Independent Gateway can communicate directly with the back-end Tableau Server processes over multiple ports. We refer to this communication as *direct* connection.

Alternatively. you can configure Independent Gateway to relay client communication over a single port to the gateway process on Tableau Server. We refer to this as a *relay* connection.

The TSM configuration key that sets the connection type is `gateway.tsig.proxy_tls_optional`.

The following sections describe how these connections differ and how to set them.

Direct connection

In this configuration, the Independent Gateway communicates directly with the backend processes on Tableau Server over multiple ports. This requires that you open the ports between the firewall that separates Independent Gateway from the Tableau Server back end deployment.

The current implementation of Independent Gateway does not support TLS connections on these processes.

A direct connection allows Independent Gateway to communicate with the backend Tableau Server processes without proxying through the Gateway process. Direct connection provides better performance than the alternative relay connection.

## Configuration

Direct connection is the default configuration. As such you do not need to run a command to set it. However, should you need to reset to the default direct connection, run the following commands:

```
tsm configuration set -k gateway.tsig.proxy_tls_optional -v all --
force-keys
tsm pending-changes apply
```

## Manage port ingress

After installation, Independent Gateway must be able to communicate with Tableau Server over multiple ports. These ports are dynamically assigned during setup and are in the range, TCP 8000-9000. The specific ports and corresponding processes used to communicate to Tableau Server are written to a CSV file on the computer running Independent Gateway at `TSIG_DATA/config/httpd/proxy_targets.csv`.

In a default installation: `/var/opt/tableau/tableau_tsig/config/httpd/proxy_targets.csv`.

Use `proxy_targets.csv` to set or automate port ingress configuration through your network to Tableau Server. We recommend automating port ingress configuration since the ports may change if the topology Tableau Server deployment changes. Adding nodes or reconfiguring processes on the Tableau Server deployment will trigger changes to the port access required by Independent Gateway.

Relay connection

In a relay connection configuration, the Independent Gateway does not connect directly to the backend processes. Instead, the Independent Gateway relays communication to the Gateway process on the backend Tableau Server deployment over HTTP. This relay process results in an extra hop and therefore degrades performance as compared to the direct connection configuration.

One benefit of configuring Independent Gateway as a relay connection is to secure traffic with TLS. See Configure TLS on Independent Gateway.

## Configuration

To configure Independent Gateway for relay connection to Tableau Server, run the following commands:

```
tsm configuration set -k gateway.tsig.proxy_tls_optional -v none --
force-keys
tsm pending-changes apply
```

Housekeeping protocol

Both direct and relay connections require communication with the Tableau Server housekeeping (HK) protocol. The HK process maintains configuration state between the backend Tableau Server deployment and the Independent Gateway. During installation the Tableau Server must be able to communicate with Independent Gateway over port 21319.

Housekeeping protocol communication details:

- The HK requests check Independent Gateway status and update configuration as needed. There is no customer data in these requests. The configurations do not include passwords or other secrets.
- The configuration files do contain details about the Tableau Server cluster topology so that Independent Gateway can perform reverse proxy functions. Cluster topology configuration can be considered sensitive because the configuration could provide targeting information to an attacker. Note that such configuration data would only be useful to attackers who could then access the Tableau Server cluster.

- The configuration update files include a check of the hashed contents. This provides an extra layer of security to validate the integrity of the configuration files that are used to update Independent Gateway.

By default, the HK process uses TCP 21319.

Beginning with Tableau Server 2022.1.2, TLS is supported on HK connection. See Configure TLS on Independent Gateway.

Change the HK port

You can change the port used by the HK protocol as part of the Independent Gateway initialization. See Help Output for initialize-tsig Script.

If you have already installed Independent Gateway, you can change the port by updating the `TSIG_HK_PORT` value in `environment.bash`.

By default, `environment.bash` is located at `/etc/opt/tableau/tableau_tsig`.

After you have updated the file you must restart tsig-httpd:

```
sudo su - tableau-tsig
systemctl --user restart tsig-httpd
exit
```

Log file locations

The most useful log entries on Tableau Server are in the `tabadminagent` log file directory. However, if you are running Tableau Server in a cluster, you must look on each instance to locate the latest tabadminagent logs.

On the Independent Gateway, the following log files are written to the `TSIG_DATA/logs/` directory.

By default, this is at the path `/var/opt/tableau/tableau_tsig/logs`:

- `access.log`: Independent Gateway will write to `access.log` for logging that is generated by the httpd.conf.stub configuration. Timestamped log files (e.g. `access_date.log`) are generated by httpd.conf configuration.

- `error.log`
- `startup.log`

These logs are also relayed verbatim to the Tableau Server deployment and stored in sub-directories of the Cluster Controller logs directory. As such, the Independent Gateway logs are included in the ziplog file generated by `tsm maintenance ziplogs` command.

Troubleshooting

For troubleshooting tips, see Troubleshooting Tableau Server Independent Gateway in the Enterprise Deployment Guide (EDG). The EDG provides example deployment of Tableau Server on Linux. The troubleshooting steps are useful for Windows or Linux versions of Tableau Server.

Configure Authentication Module with Independent Gateway

A common security practice is to allow only authenticated requests to pass through the inner firewall of the DMZ servers. The Independent Gateway supports the traditional Tableau Server authentication methods, but it also includes configuration properties that allow integrating an Apache httpd loadable module for custom authentication.

For example, by configuring SAML on Tableau Server and configuring a custom authentication module, you can require all users to authenticate with your IdP at the Independent Gateway. Only those users who are authenticated will then be able to access Tableau Server, which can then authenticate and authorize user access.

For a more detailed explanation of this authentication scheme, see Pre-authentication with an AuthN module in the Enterprise Deployment Guide.

To configure the authentication module, you must complete the following steps:

1. Generate authentication module configuration files. When setup is complete, each module and its configuration directives will be treated as Include options making the included files logically part of the overall httpd configuration.
2. Copy the configuration files to each computer running Independent Gateway. All files must be copied to the same locations on each Independent Gateway computer. Each file maps to a configuration property that is managed by Tableau Server.

3. Set the configuration properties with the `tsm configuration set` command on Tableau Server.

Do not edit the httpd configuration file (httpd.conf) on the Independent Gateway, since Independent Gateway includes logic to update httpd configuration based on changes made with TSM commands on Tableau Server.

Example authentication module configuration

For an end-to-end authentication module configuration example, see Example authentication configuration: SAML with external IdP in the Enterprise Deployment Guide. The example describes how to setup and configure SAML with Okta IdP and Mellon authentication module for a Tableau Server on Linux deployment running in AWS. Although the example describes the process for Linux, the configuration example is also useful for Tableau Server on Windows.

Configuration properties

The following table describes the various configuration files that you may reference. Each file maps to a configuration property that is set onTableau Server. You only need to define the properties necessary to formulate your custom authentication configuration. Skip any configuration properties that are not needed.

| Configuration property | Description |
|---|---|
| gateway.tsig.authn_module_block | Appears at the end of the set of normally loaded Apache httpd modules. The intent is that the file includes one or more `LoadModule` directives. The modules themselves should be identified with full paths. |
| gateway.tsig.authn_global_block | Appears after all of the `LoadModule` references and before most other Apache httpd directives. The intent is to provide a place for any configuration directives needed by the custom module. |
| gateway.tsig.authn_glob- | Appears at the very bottom of the configuration file, |

| | |
|---|---|
| albottom_block | again at the global level. The intent is to provide a place for any configuration directives needed by the custom module that must specifically come after various other directives. (You are unlikely to need this.) |
| gateway.tsig.authn_location_ block | Appears inside a `<Location "/">` block, covering all URL paths. |
| gateway.tsig.authn_directory_ block | This appears inside a `<Directory "/">` block, covering all paths to files served by the Independent Gateway. (You are unlikely to need this. Most files served by Independent Gateway are non-sensitive static assets, like images and JavaScript files.) |
| gateway.tsig.authn_virtualhost_ block | Appears inside one or two `<VirtualHost>` blocks: one for TLS (if enabled) and one for non-TLS. If configured, the same file is included in both places. If you need to distinguish the two cases, you can use the standard Apache httpd HTTPS environment variable. |

The `<Location "/tsighk">` block

In addition to the expected `<Location "/">` block for normal request traffic, there is also a `<Location "/tsighk">` block used to service internal Independent Gateway housekeeping (HK) requests. These HK requests have their own authentication guards and will not work with typical custom SSO solutions.

You may need to explicitly exclude your custom module from attempting authentication for the HK URL path.

To determine whether you need to exclude your module, first configure the module. Then look for HK requests in the Independent Gateway access log. You should see at least a status check once or twice a minute. If those requests are receiving a 200 response code, things are probably OK. On the other hand, if those requests receive a 3xx response code (redirecting to your custom authentication provider), then you need to do something about it.

Possible solutions include:

- The `<Location "/tsighk">` block contains the directive `AuthType None`, and that may be sufficient.
- The Independent Gateway httpd.conf has the standard Apache httpd directive `ProxyPreserveHost On`. If there is an unusual circumstance that requires it to be Off or some other value, that value can be set with the TSM configuration item `gateway.tsig.proxypreservehost`.
- You might need some module-specific directives to disable your authentication module for `<Location "/tsighk">`. You can't directly modify that block in the httpd.conf file. Instead, you can make another `<Location "/tsighk">` block in your `gateway.tsig.authn_global_block` file and let Apache httpd logically merge them. For example, some versions of mod_auth_mellon, a popular open source authentication module, requires `MellonEnable Off` for sections where it doesn't apply, even if `AuthType None` is set in those sections.
- When creating an additional `<Location "/tsighk">` section, as described in the previous bullet, you may find that the order of appearance of the various sections in the httpd.conf file makes a difference in how they affect each other. The standard `<Location "/tsighk">` section appears before the standard `<Location "/">` section. If your experimentation shows that some different order is needed, you might have to define another `<Location "/">` section in your `gateway.tsig.authn_global_block` block in addition to another `<Location "/tsighk">` section, in which case you might not need anything in a `gateway.tsig.authn_location_block` block.

Troubleshoot custom authentication module configuration

A handy way to understand how the Independent Gateway will compose the httpd.conf file is to set the TSM configuration items with values that point to empty files on your Independent Gateway computers. (The files must exist, but they can be empty.) You can then look at the Independent Gateway's httpd.conf file to get a concrete understanding of where the `Include` directives for the various configuration files will actually appear.

Configuration problems in the Independent Gateway httpd.conf can result in the `tsig-httpd` service being unable to start. Other configuration problems may interfere with receiving configuration updates from the Independent Gateway companion service on the Tableau Server cluster. One way to recover, after you've fixed whatever caused the problem, is to

copy `TSIG_DATA/config/httpd.conf.stub` to `TSIG_DATA/config/httpd.conf`, and then restart the `tsig-httpd` service.

For more troubleshooting tips, see Troubleshooting Tableau Server Independent Gateway in the Enterprise Deployment Guide (EDG). The EDG provides example deployment of Tableau Server on Linux. The troubleshooting steps are useful for Windows or Linux versions of Tableau Server.

### Configure TLS on Independent Gateway

TLS support for Independent Gateway is in Tableau Server 2022.1.2 and later.

Both Tableau Server and Tableau Server Independent Gateway use the SSL module (mod_ssl) built with OpenSSL to implement Transport Layer Security (TLS) features.

Because of its complexity and security-sensitive nature, we recommend that TLS configuration is planned and implemented by an IT professional who is familiar TLS on Apache httpd.

In many cases, we use "SSL" in the names of things for compatibility with existing TSM or Apache httpd configuration properties or concepts. "SSL" actually refers to protocol versions now considered insecure and obsolete. However, the legacy name persists and is often used interchangeably with TLS as convention. Tableau Server and Independent Gateway do not support SSL-era protocols.

> **Important:** Beginning with version 2025.3, Tableau uses OpenSSL 3.4.0 and Level-2 security. Level-2 security requires keys of 2048 bits or longer. Any existing Level-1 security keys will no longer work and you will need to generate and deploy a new key pair. If you have been generating at least 2048-bit length keys as recommended, no action is necessary. For more information see Generate a key.

### TLS configuration example

For an end-to-end TLS configuration example, see Configure SSL/TLS from load balancer to Tableau Server in the Enterprise Deployment Guide. The topic shows a step-by-step example

of configuring TLS on Tableau Server on Linux in an AWS deployment. Although the example describes the process for Linux, the configuration example is also useful for Tableau Server on Windows.

TLS configuration overview

You can configure TLS for HTTPS on any of the following sections of the internet-to-Tableau Server path:

- From the external network (internet or front-end load balancer) to Independent Gateway
- From Independent Gateway to Tableau Server
- For housekeeping (HK) process from Tableau Server to Independent Gateway

This topic provides procedures to configure each of these hops.

You will need to make configuration changes to Independent Gateway computers and to the Tableau Server cluster.

## Certificate requirements and considerations

The certificate requirements for Independent Gateway are the same as those specified for Tableau Server "external SSL." See SSL certificate requirements.

Other considerations:

- To simplify certificate management and deployment, and as a security best practice, we recommend using certificates generated by a major trusted third party certificate authority (CA). Alternatively, you may generate self-signed certificates or use certificates from a PKI for TLS. In this case, pay attention to the configuration options for trusting CA certificates and validating certificates.
- If your implementation requires the use of a certificate chain file, see the Knowledge Base article, Configure TLS on Independent Gateway when using a certificate that has a certificate chain.
- If you are running multiple instances of Independent Gateway, then you must distribute certificates to each computer in the same location (file path).

- If you are running a Tableau Server deployment with more than one node, certificates that you upload with TSM commands are automatically distributed across the nodes. Run all TSM commands on the initial node.

Global TLS configurations

The following configurations are global. The configuration options below refer to configuration keys that must set with the `tsm configuration set` command. The commands must include the `--force-keys` option.

It's unlikely that you will need to change these values.

Note that each pair of keys shares the same naming format, where the string, `tsig`, sets the value for the Independent Gateway. The key that does *not* include the string, `tsig`, sets the value for the gateway process on the Tableau Server cluster.

If you do not set a value for the `tsig` key, then the default Tableau Server gateway value will be used.

`gateway.tsig.httpd.socache or gateway.httpd.socache`

Default: `shmcb`

Alternate value: `dbm`

The storage type of the inter-process SSL Session Cache. For more information about the shmcb and dbm storage types, see SSLSessionCache Directive on Apache website.

`gateway.tsig.httpd.shmcb.size or gateway.httpd.shmcb.size`

Default: `2048000`

Amount of memory, in bytes, to use for the circular buffer when using `shmcb` storage type.

**Note**: Another global key is `gateway.tsig.ssl.key.passphrase.dialog`. If applicable, there is only a single configuration for `gateway.tsig.ssl.key.passphrase.dialog`. By design, it collects passphrases for all encrypted private key files in the configuration. The applicable sections later in this topic describe the use of this key.

External TLS to Independent Gateway

The process of configuring external connections to terminate TLS on the Independent Gateway servers is conceptually similar to how "external SSL" is configured for a Tableau Server cluster. The mechanics are different. TSM does not automatically distribute certificate and key material to Independent Gateway nodes. Additionally, Independent Gateway does not automatically provide a way to supply the optional TLS key passphrase on startup.

The following steps describe how to configure TLS from external source to Independent Gateway computers.

## Step 1: Distribute files to Independent Gateway computers

1. Place certificates and related files in a location and with permissions that allow the Independent Gateway service (tsig-httpd) to read them. We recommend restricting access to the key files such that only the Independent Gateway service can read them.
2. Place all files, certificates, and keys in exactly the same locations on all Independent Gateway computers. Place the files outside of the TSIG_INSTALL and TSIG_DATA paths so that they do not get removed if you reinstall or upgrade Independent Gateway.

## Step 2: Update environment variables on Independent Gateway computers

On each Independent Gateway computer, set the `TSIG_PORT` and `TSIG_PROTOCOL` environment variables to `443` (by convention, but any unused TCP port number is supported) and `https` respectively.

Change these values by updating the `TSIG_PORT` and `TSIG_PROTOCOL` environment variables in `environment.bash`.

By default, `environment.bash` is located at `/etc/opt/tableau/tableau_tsig`.

After you have updated the file you must restart tsig-httpd:

```
sudo su - tableau-tsig
systemctl --user restart tsig-httpd
exit
```

## Step 3: Set TLS configuration properties on Tableau Server

Most of the TSM configuration keys in the following table are derived from Apache httpd directives. As such, the configuration values for these TSM configuration keys map directly to the valid values for the corresponding Apache directive. Links to corresponding directives are included in the following table.

In some cases. the configuration will use fallback configurations if a particular key is not set. These are called out in the table below.

The configuration options in the following table refer to configuration keys that you must set with the `tsm configuration set` command. All commands must include the `--force-keys` option. For example:

```
tsm configuration set -k gateway.tsig.ssl.enabled -v true --force-keys
```

After you have set the configuration keys, you must run `tsm pending-changes apply`.

| Configuration property | Description | Corresponding Apache directive |
|---|---|---|
| gateway.tsig.ssl.enabled | Required.<br><br>Enables TLS. Must be set to `true`. | N/A |

| | | |
|---|---|---|
| gateway.tsig.ssl.cert.file_name | Required.<br><br>Path + file name of the certificate file for Independent Gateway. For example, `/etc/ssl/certs/tsig-ssl.crt`. | SSLCertificateFile |
| gateway.tsig.ssl.key.file_name | Required.<br><br>Path + file name of the certificate key file for Independent Gateway. For example, `/etc/ssl/keys/tsig-ssl.key`. | SSLCertificateKeyFile |
| gateway.tsig.ssl.key.passphrase.dialog | If your key requires a passphrase, then you must configure this key with the correct string expected by the Apache httpd SSLPassPhraseDialog directive. Do not enter the literal passphrase for this key. Refer to the Apache documentation for information about how to configure this key.<br>This configuration is global for Independent Gateway. | SSLPassPhraseDialog |
| gateway.tsig.ssl.protocols<br><br>Fallback: ssl.protocols | Specify supported versions of SSL/TLS. See Security Hardening Checklist for more information about default configuration. | SSLProtocols |

| | | |
|---|---|---|
| gateway.tsig.ssl.ciphersuite<br><br>Fallback: ssl.ciphersuite | Specifies ciphers that the client is permitted to negotiate for SSL connection. | SSLCipherSuite |
| gateway.tsig.ssl.client_certificate_login.required | Set this value to `true` to enable mutual TLS on this connection.<br><br>You must also set the `gateway.tsig.ssl.cacert.file` property as specified below. | N/A |
| gateway.tsig.ssl.cacert.file | Specifies the file containing the concatenated CA certificates for client authentication process. | SSLCACertificateFile |
| gateway.tsig.ssl.revocation.file | Specifies the file containing the concatenated CA revocation lists for clients that connect to Independent Gateway. | SSLCARevocationFile |
| gateway.tsig.ssl.redirect | When Independent Gateway has been configured for TLS, this option forces client requests from port 80 (default) to redirect to TLS.<br><br>Default: `true`. | N/A |
| gateway.tsig.ssl.redirect_from_port | When `gateway.tsig.ssl.redirect` is set to `true`, this option allows you to specify the port from which traffic is redirected. | N/A |

| | | |
|---|---|---|
| | Default: `80`. | |

Independent Gateway to Tableau Server

This section describes how to encrypt the connection between the Independent Gateway and Tableau Server.

## Step 1: Configure and enable TLS on Tableau Server

See Configure SSL for External HTTP Traffic to and from Tableau Server.

Note that "SSL" is actually a TLS implementation, and "external" refers to an external connection to Tableau Server. In this scenario, the Independent Gateway is the "external" connection.

We recommend enabling and verifying that clients can connect with TLS directly to Tableau Server before configuring Independent Gateway.

## Step 2: Distribute certificate files on Independent Gateway computers

You will need to distribute certificate files on the Independent Gateway computers if either of the following are true:

- You are using self-signed or PKI certificates for the TLS certificates on the Tableau Server deployment.
- You are enabling mutual TLS on the connection from Independent Gateway to Tableau Server.

As with all TLS-related files on Independent Gateway computers, you must put the files in the same paths on each computer. All file names for TLS shared files must also be the same.

## Step 3: Set TLS configuration properties on Tableau Server

Most of the TSM configuration keys in the following table are derived from Apache httpd directives. As such, the configuration values for these TSM configuration keys map directly to the valid values for the corresponding Apache directive. Links to corresponding directives are included in the following table.

In some cases. the configuration will use fallback configurations if a particular key is not set. These are called out in the table below.

The configuration options in the following table refer to configuration keys that you must set with the `tsm configuration set` command. All commands must include the `--force-keys` option. For example:

```
tsm configuration set -k gateway.tsig.ssl.enabled -v true --force-keys
```

After you have set the configuration keys, you must run `tsm pending-changes apply`.

| Configuration property | Description | Corresponding Apache directive |
|---|---|---|
| gateway.tsig.ssl.proxy.cacertificatefile | If your organization uses a self-singed or PKI-generated TLS certificate for Tableau Server, then you must specify a path to the root CA certificate file. This root CA certificate file must be stored on the | SSLProxyCACertificateFile |

| | | |
|---|---|---|
| | Independent Gateway computers. | |
| gateway.tsig.ssl.proxy.protocols<br><br>Fallback: ssl.protocols | Specify supported versions of SSL/TLS. See Security Hardening Checklist for more information about default configuraiton. | SSLProtocols |
| gateway.tsig.ssl.proxy.ciphersuite<br><br>Fallback: ssl.ciphersuite | Specifies ciphers that the client is permitted to negotiate for SSL connection. | SSLCipherSuite |
| gateway.tsig.ssl.proxy.machinecertificatefile | For mutual TLS. Specifies the file containing concatenated certificate-key pairs for authentication of the Independent Gateway to Tableau Server. | SSLProxyMachineCertificateFile |

| | | |
|---|---|---|
| gateway.tsig.ssl.proxy.verify | Specify whether Independent Gateway should verify the certificate presented by Tableau Server.<br><br>Defaults to `require`. | SSLProxyVerify |
| gateway.tsig.ssl.proxy.checkpeername | Specify whether Independent Gateway inspects Tableau Server certificate to verify that sub-ject name matches server name.<br><br>Defaults to `off`. | SSLProxyCheckPeerName |
| gateway.tsig.ssl.proxy.checkpeerexpire | Specify whether Independent Gateway | SSLProxyCheckPeerExpire |

| | | |
|---|---|---|
| | inspects Tableau Server certificate to verify expiry:<br><br>Defaults to `off`. | |

## Step 4: Upload root CA certificate to Tableau Server

If the TLS certificate that you are using on the Independent Gateway computers is a self-signed or PKI-generated certificate then you must perform this additional step. If the TLS certificate that you are using on the Independent Gateway computer is a certificate from a trusted third-party certificate authority, then you can skip this step.

Copy the root CA certificate used for the Independent Gateway computers to the initial node of Tableau Server, and then run the following commands:

```
tsm security custom-cert add -c <root-certificate-file-name>.pem
tsm pending-changes apply
```

Housekeeping connection between Tableau Server and Independent Gateway

The housekeeping (HK) process maintains configuration state between the backend Tableau Server deployment and the Independent Gateway.

When Independent Gateway is installed, the default configuration provides an unencrypted HTTP connection. Independent Gateway listens for housekeeping requests originating in the Tableau Server cluster (as you defined it during installation).

If you are running multiple instances of Independent Gateway, then all servers must accept housekeeping requests with TLS or all without TLS. This section describes how to configure HK connection for TLS. This process requires restarting Tableau Server and will result in downtime.

As with the previous TLS scenarios described above, many of the configuration changes for HK connection are set on configuration properties managed by the Tableau Server cluster. However, HK TLS configuration requires additional steps on Independent Gateway.

## Step 1: Distribute files to Independent Gateway computers

If you have enabled TLS with external network and Independent Gateway, you may use the same certificate and key files for the HK connection.

If you are using the same assets, then the only other certificate file that you need to distribute is the root CA certificate for the certificate used by Tableau Server. If the TLS certificate presented by Tableau Server is generated by a trusted third-party CA, then you do not need to copy a root CA certificate to the Independent Gateway computers.

1. Place certificates and related files in a location and with permissions that allow the Independent Gateway service (tsig-httpd) to read them. We recommend restricting access to the key files such that only the Independent Gateway service can read them.
2. Place all files, certificates, and keys in exactly the same locations on all Independent Gateway computers.

## Step 2: Import Independent Gateway root CA certificate into Tableau Server trust store

If the TLS certificate that you are using on the Independent Gateway computers is a self-signed or PKI-generated certificate then you must perform this additional step. If the TLS certificate that you are using on the Independent Gateway computer is a certificate from a trusted third-party certificate authority, then you can skip this step.

You may only upload one root CA certificate to Tableau Server. Therefore, if you have already uploaded a root CA certificate, then the same root CA certificate must sign the certificate that you will be using for HK connection.

Copy the root CA certificate used for the Independent Gateway computers to the initial node of Tableau Server, and then run the following commands:

```
tsm security custom-cert add -c <root-certificate-file-name>.pem
tsm pending-changes apply
```

## Step 3: Update environment variables on Independent Gateway computers

On each Independent Gateway computer, set the `TSIG_HK_PROTOCOL` environmental variable to `https`. You may specify an alternative port for HK (default is 21319) by setting the `TSIG_HK_PORT` environment variable as well.

Change these values by updating the `TSIG_HK_PORT` and `TSIG_HK_PROTOCOL` environment variables in `environment.bash`.

By default, `environment.bash` is located at `/etc/opt/tableau/tableau_tsig`.

After you have updated the file you must restart tsig-httpd:

```
sudo su - tableau-tsig
systemctl --user restart tsig-httpd
exit
```

## Step 4: Update httpd.conf.stub on Independent Gateway

You must update the `httpd.conf.stub` file on each Independent Gateway server. The `httpd.conf.stub` file is used to seed the global httpd configuration.

The file is located at `TSIG_DATA/config/httpd.conf.stub`.

In a default installation: `/var/opt/tableau/tableau_tsig/-config/httpd.conf.stub`.

1. Open the `httpd.conf.stub` file in a text editor. You must update the `<VirtualHost *:${TSIG_HK_PORT}>` block with HK configuration details. The following example shows the required changes:

   ```
   <VirtualHost *:${TSIG_HK_PORT}>
    SSLEngine on
   ```

```
 #TLS# SSLHonorCipherOrder on
 #TLS# SSLCompression off
 SSLCertificateFile /etc/ssl/certs/tsig-ssl.crt
 SSLCertificateKeyFile /etc/ssl/private/tsig-ssl.key
 SSLCACertificateFile /etc/ssl/certs/rootTS-CACert.pem
#TLS# SSLCARevocationFile /path/to/file
</VirtualHost>
```

Notes:

- By default, each line in the `<VirtualHost *:${TSIG_HK_PORT}>` block is commented out by the string, `#TLS#`. To "enable" a line in the block, delete the `#TLS#` string at the beginning of the line.
- As with all httpd configurations, each referenced file requires an absolute path to the file.
- `SSLCACertificateFile` specifies the root CA certificate for the CA that generates the certificate presented by Tableau Server. You only need to set this if the TLS certificate used by Tableau Server is self-signed or generated by a PKI.

2. Stop the tsig-httpd service.

```
sudo su - tableau-tsig

systemctl --user stop tsig-httpd

exit
```

You will start receiving failed status checks at this point, indicating in TSM that your Independent Gateway component is degraded.

3. Copy `httpd.conf.stub` to `httpd.conf`.

The `httpd.conf` file is in the same directory. Overwrite the `httpd.conf` file with the `httpd.conf.stub` file.

```
cp httpd.conf.stub httpd.conf
```

4. Start the tsig-httpd service.

```
sudo su - tableau-tsig
systemctl --user start tsig-httpd
exit
```

You will continue receiving failed status checks at this point, indicating in TSM that your Independent Gateway component is degraded. These status checks will fail until you have completed the configuration as described in the following steps.

## Step 5: Set TLS configuration properties on Tableau Server

Applying the configuration changes requires a restart of the server. To avoid long timout times, we recommend stopping the server before applying changes that you set here. In Step 6, you will run an update command and then restart TSM. Stopping TSM at this phase of the configuration results in a shorter downtime.

1. Stop TSM. Run the following command:

   ```
   tsm stop
   ```

2. Most of the TSM configuration keys in the following table are derived from Apache httpd directives. As such, the configuration values for these TSM configuration keys map directly to the valid values for the corresponding Apache directive. Links to corresponding directives are included in the following table.

   There are TSM configuration property names that include the `hk` node in the prefix: `gateway.tsig.hk.xyz.abc`. If set, these values are used for the HK TLS configuration. If not set, many configuration properties will use the fallback to `gateway.tsig.xyz.abc`, which themselves may or may not fall back to `gateway.xyz.abc`. The fallback configuration property is listed when relevant.

   The configuration options in the following table refer to configuration keys that you must set with the `tsm configuration set` command. All commands must include the `--force-keys` option. For example:

```
tsm configuration set -k gateway.tsig.hk.ssl.enabled -v true --
force-keys
```

| Configuration property | Description | Corresponding Apache directive |
|---|---|---|
| gateway.tsig.hk.ssl.enabled<br><br>(No fallback) | Required.<br><br>Enables TLS. Must be set to `true`. | N/A |
| gateway.tsig.hk.ssl.cert.file_name<br><br>Fallback:<br><br>gateway.tsig.ssl.cert.file_name | Path + file name of the certificate file for Independent Gateway. For example, `/etc/ssl/certs/tsig-ssl.crt`. | SSLCertificateFile |
| gateway.tsig.hk.ssl.key.file_name<br><br>Fallback:<br><br>gateway.tsig.ssl.key.file_name | Path + file name of the certificate key file for Independent Gateway. For example, `/etc/ssl/keys/tsig-ssl.key`. | SSLCertificateKeyFile |
| gateway.tsig.ssl.key.passphrase.dialog<br><br>(Global property) | If your key requires a passphrase, then you must configure this key with the correct string expected by the Apache httpd SSLPassPhraseDialog directive.<br>This configuration is global for Independent Gateway. | SSLPassPhraseDialog |
| gateway.tsig.hk.ssl.protocols | Specify supported versions of | SSLProtocols |

| | | |
|---|---|---|
| Fallbacks:<br><br>gateway.tsig.ssl.protocols<br><br>ssl.protocols | SSL/TLS. See Security Hardening Checklist for more information about default configuration. | |
| gateway.tsig.hk.ssl.ciphersuite<br><br>Fallbacks:<br><br>gateway.tsig.ssl.ciphersuite<br><br>ssl.ciphersuite | Specifies ciphers that the client is permitted to negotiate for SSL connection. | SSLCipherSuite |
| gateway.tsig.hk.ssl.client_certificate_login.required<br><br>(No fallback) | Set this value to `true` to enable mutual TLS on this connection.<br><br>You must also set the `gateway.tsig.hk.ssl.cacert.file` property as specified below. | N/A |
| gateway.tsig.hk.ssl.cacert.file<br><br>Fallback:<br><br>gateway.tsig.ssl.cacert.file | Specifies the file containing the concatenated CA certificates for client authentication process. | SSLCACertificateFile |
| gateway.tsig.hk.ssl.revocation.file<br><br>Fallback:<br><br>gateway.tsig.hk.ssl.revocation.file | Specifies the file containing the concatenated CA revocation lists for clients that connect to Independent Gateway. | SSLCARevocationFile |

3. Apply changes. Run the following command:

```
tsm pending-changes apply.
```

## Step 6 Update Independent Gateway JSON configuration file

The final step is to update the Independent Gateway configuration with a JSON file reflecting the switch to `https` and, if applicable, other port numbers.

Refer to the installation topic for more information about editing this file. See Step 3: Enable Independent Gateway in Tableau Server.

After you have updated the JSON file, run the following commands:

```
tsm topology external-services gateway update -c tsig.json
tsm start
```

Troubleshooting

For troubleshooting tips, see Troubleshooting Tableau Server Independent Gateway in the Enterprise Deployment Guide (EDG). The EDG provides example deployment of Tableau Server on Linux. The troubleshooting steps are useful for Windows or Linux versions of Tableau Server.

## Upgrade Tableau Server Independent Gateway

This topic walks you through the process of upgrading Tableau Server Independent Gateway. The process described in this topic is the same for all version upgrades. This means you can use this process for major version (for example, 2022.1 to 2023.1) and maintenance version (2022.1.1 to 2023.1.1) upgrades.

You must use an installer for Tableau Server Independent Gateway with a major version that matches the version of Tableau Server. We recommend maintenance versions (2022.1.1 or 2022.1.2 for example) match as well, but this is not a requirement. If "static assets" change between versions and versions do not match, you may see some unexpected image impact. For example, maps may not be up-to-date if Independent Gateway is an earlier version than Tableau Server.-

Overview

The upgrade process for Independent Gateway is actually a process of uninstalling then reinstalling the software. However, you can minimize configuration and overall downtime by following the process as described in this topic.

The process described in this topic assumes that you have a functional deployment of Tableau Server and Tableau Server Independent Gateway running. If you are upgrading the backend Tableau Server deployment as part of your upgrade, we recommend upgrading the Independent Gateway server(s) first, validating basic connectivity with a Tableau client, then proceeding with Tableau Server upgrade.

The steps detailed in this topic are summarized here:

1. Copy some existing files for use during upgrade.
2. Run the obliterate script to remove Independent Gateway.
3. Install new version of Independent Gateway.
4. Optional: Overwrite tsighk-auth file with original copy.
5. Update TLS settings.
6. Optional: Update back end Tableau Server
7. Restart Independent Gateway service.

Step 1: Copy files for reference

You may need to reference the configuration settings stored in the following files. Copy these files to a secure and accessible location (file paths are default location):

- /var/opt/tableau/tableau_tsig/config/tsighk-auth.conf
- /var/opt/tableau/tableau_tsig/config/httpd.conf.stub
- /etc/opt/tableau/tableau_tsig/environment.bash

Step 2: Obliterate Independent Gateway

To remove Independent Gateway from the server(s), run the `tableau-tsig-obliterate` script:

1. On the initial node, open a terminal session.

2. Run the `tableau-tsig-obliterate` script:

```
sudo /opt/tableau/tableau_tsig/packages/scripts.<version_
code>/tableau-tsig-obliterate -y -y -y
```

3. Restart the computer.

Step 3: Install Independent Gateway

Download the version of Independent Gateway that you want to upgrade to and then follow the same installation procedure as described in the topic, Install Tableau Server with Independent Gateway.

As with the original installation, you will need to specify initialization settings as part of set up. To use the same values, reference the `enviornment.bash` file that you copied in step 1. Do not overwrite the new bash file with the original.

Step 4: (Optional) Overwrite tsighk-auth file with original copy

The `tsighk-auth` file is a configuration file that stores a unique string called the authsecret. The authsecret is used to verify that the back end Tableau Server is communicating with a trusted instance of Independent Gateway. When you set up the original instance of Independent Gateway, you had to update a configuration file on the back end Tableau Server with the authsecret.

If your security policy allows, you can continue to use the original authsecret on Independent Gateway. Doing so avoids the process of updating and restarting the back end Tableau Server with a new authsecret.

To maintain the original authsecret, overwrite the `tsighk-auth.conf` file (located at `/var/opt/tableau/tableau_tsig/config/tsighk-auth.conf`) with the copy that you saved in step 1.

If your security policy requires that you refresh the authsecret, then make note of the new authsecret that was generated by the installation process. You will update the back end Tableau Server with the new authsecret later in the process.

Step 5: Update housekeeping TLS settings

If you did not configure TLS for housekeeping (HK) communication between Independent Gateway instance(s) and the back end Tableau Server deployment, then you can skip this step.

If you configured HK TLS, then you must manually copy the configuration from the original `httpd.conf.stub` file into the file located at `/var/opt/tableau/tableau_tsig/-config/httpd.conf.stub`) . Do not overwrite the new file with original file, as the newer file may include other settings.

1. Update the relevant TLS configuration settings in the following block:

   ```
   <VirtualHost *:${TSIG_HK_PORT}>
   SSLEngine on
   #TLS# SSLHonorCipherOrder on
   #TLS# SSLCompression off
   SSLCertificateFile /etc/ssl/certs/tsig-ssl.crt
   SSLCertificateKeyFile /etc/ssl/private/tsig-ssl.key
   SSLCACertificateFile /etc/ssl/certs/rootTS-CACert.pem
   #TLS# SSLCARevocationFile /path/to/file
   </VirtualHost>
   ```

   For more information about these settings, see Configure TLS on Independent Gateway.

2. When you have finished updating `httpd.conf.stub`, save it.

3. Copy `httpd.conf.stub` and then save to overwrite `httpd.conf` in the same directory.

Step 6: (Optional) Update back-end Tableau Server deployment

If you copied the original authsecret file (`tsighk-auth.conf`) to the new instance of Independent Gateway as described in step 4, then you may skip this step.

If you are refreshing the authsecret in the back end Tableau Server deployment, then you must update the `tsig.json` file on the initial node with the new authsecret. See Install

Tableau Server with Independent Gateway. When you are finished, run the following TSM commands:

```
tsm stop

tsm topology external-services gateway update -c tsig.json

tsm start
```

Step 7: Restart the tsig-httpd service

When you have finished with the configuration. restart the `tsig-httpd` service.

```
sudo su - tableau-tsig

systemctl --user restart tsig-httpd

exit
```

## Uninstall Tableau Server Independent Gateway

This topic walks you through the process of uninstalling Tableau Server Independent Gateway.

Uninstalling Independent Gateway

Uninstalling Independent Gateway is a two step process:

1. Disable the Independent Gateway instance in Tableau Server using TSM.

   To disable Independent Gateway in Tableau Server, run this command at the command prompt of the initial Tableau Server node:

   ```
   tsm topology external-services gateway disable
   ```

2. Uninstall the Independent Gateway instance you are upgrading from the computer it is running on.

   To uninstall Independent Gateway from a Linux computer, run the `tableau-tsig-obliterate` script in the `/opt/tableau/tableau_`

`tsig/packaged/scripts.<version_code>` directory. This will entirely remove Independent Gateway from the computer.

```
sudo /opt/tableau/tableau_tsig/packages/scripts.<version_
code>/tableau-tsig-obliterate -y -y -y
```

To uninstall an instance of Independent Gateway, remove it from the server cluster using TSM, and then, after Tableau Server is fully reconfigured, uninstall Independent Gateway from the computer where it was installed. When you use TSM to remove the instance from Tableau Server, TSM no longer sends any communication to the Independent Gateway instance, so Independent Gateway is unaware of any configuration changes. but the Independent Gateway continues to respond based on the last known configuration and Tableau Server continues to accept those responses. You also need to remove the Independent Gateway instance from the computer it is running on.

## Help Output for initialize-tsig Script

The following help content is the output when you run the following command:

```
sudo ./initialize-tsig -h
```

The initialize-tsig script is installed to `/opt/tableau/tableau_tsig/packages/scripts.<version_code>/`.

Output

```
REQUIRED
--accepteula            Indicate that you have accepted the End User
License Agreement (EULA).
                        You can find a link to the EULA in /opt/tableau/tableau_
tsig/packages/docs.<version_code>

-c <ts_cluster_location>
                        The network location of all nodes in the Tableau
Server cluster. These may send
                        "housekeeping" requests to the TSIG node.
The locations must be one of the forms
```

```
                        that are acceptable to Apache httpd mod_
authz_host "Require" directive as described
                        at https://httpd.apache.org/docs/2.4/mod/mod_
authz_host.html. Use quotes if there are
                        embedded spaces.

OPTIONAL

-i <tsig_instance_id>   A unique identifier for the TSIG instance.
                        Default: The computer name.

-p <tsig_external_port>
                        Port listening for external requests.
                        Default: 80.

-t <tsig_external_port_protocol>
                        Protocol used for external requests. Options are "http" or
"https".
                        Default: "http".

-k <tsig_housekeeping_port>
                        Port listening for housekeeping requests from Tableau Server
                        Default: 21319.

-s <tsig_housekeeping_port_protocol>
                        Protocol used for housekeeping requests. Options are "http"
"https".
                        Default: "http".

-d data-dir             Set a custom location for the data directory
                        if it's not already set. If not set, the default is
                        "/var/opt/tableau/tableau_tsig".

-f                      Bypass warning messages and distribution version checks.

-g                      Do not add the current user to the "tableau-tsig" group.
```

```
                        Use this for easier access to log files and runtime files.

-a <username>           Name of the user to be added to the appropriate
groups instead of
                        the current user running the script. You cannot use both -g
-a.

-q                      Quiet, suppress output except for errors and warn-
ings.

--unprivileged-user=<name>
                        Name of the unprivileged account to run Tableau Server Indep
ent Gateway.
                        Default: "tableau-tsig".

--disable-account-creation
                        Do not create groups or user accounts for Tableau Server
Independent Gateway.
                        However, the values in: unprivileged-user will still be used
TSIG configuration.
```

# Tableau Server Backgrounder Resource Limits

Tableau Server Backgrounder resource limits feature was introduced in Tableau Server 2022.1.

## Overview and Concepts

### What it is

The Backgrounder resource limits feature gives you the ability to manage Backgrounder resources and control how they are used. Starting in 2022.1, you can set limits on the number

of background jobs that can run at the same time on a site. You can also specify the number of Backgrounder hours that a site can use to run jobs per day.

Default limits can be applied to all sites, but you can also set custom limits per site. This gives you the ability to manage the Backgrounder resources based on the specific requirements for a site.

When to use it

Use this feature when you want to make sure the resources are used where it is most needed. More importantly, you can prevent a single site from consuming a lot of backgrounder resources thus impacting job completion or job queue time on other sites.

If you are currently experiencing unbalanced Backgrounder resource usage or delays in background job completions, use this feature to optimize resource usage that is right for your organizational needs and content priorities.

Requirements and recommendations

1. This feature requires that Tableau Server be enabled with a Advanced Management license.
2. A new Tableau Server process called **Resource Limits Manager** is required to enforce the set resource limits. When you install or upgrade to Tableau Server 2022.1 or later, this process is automatically configured on the initial node.
    - We recommend having at least 5 Backgrounder processes in total running on Tableau Server for Backgrounder resource limits feature to run optimally. The default configuration and topology recommendations are described in detail in the Tableau Server Resource Limits Manager.
    - We do not recommend adding more Resource Limits Manager processes to your Tableau Server. The automatically installed process on the initial node is sufficient.

Terminology and concepts

- **Site job limits:** The background jobs concurrency and run time limits for a site.
- **Default site limits:** The default jobs concurrency and run time limits for a site.
- **Custom site limits:** Site limits specific to that site.
- **Job type:** Same as the task type. Includes extract refreshes, subscriptions, and flows.

- **Concurrent jobs limits:** The maximum number of jobs of a specific type that can run at the same time. The maximum number is equal to the total number of Backgrounder processes deployed on the Server.
- **Daily limit:** The daily limit includes run time limits and the reset time.
- **Runtime limit:** This is the total number of Backgrounder job hours allotted for a site per day. The maximum number is equal to the total number of Backgrounder processes deployed on the Server multiplied by 24, 24 being the number of hours in a full day.
- **Reset time:** The time at which the daily limits are reset. This is automatically set to midnight UTC and cannot be changed.
- **No limit:** This is the same as if there are no resource limits configured. In this case, the jobs on a site that can run in parallel could use all the available backgrounder processes on Tableau Server.

## What you can do

**As a Tableau Server administrator**,

1. You can specify concurrency jobs limit for each task type - extract refreshes, subscriptions, and flows. This limit controls the number of background jobs on a site that can be run at the same time, for a given task type. The limits are unique to each task type, meaning you can set different limits for extract refreshes, subscriptions, and flows.
2. You can specify the number of Backgrounder hours a site can use to run jobs in a 24 hour period - the daily job run time limit. Unlike the concurrency jobs limit, the daily job run time limit is cumulative across all task types.
3. You can find out how many Backgrounder hours have been used by a site in the last 24 hour time period.
4. You can see when a job is delayed due to set concurrency limits.
5. You can identify when a job is canceled due to lack of available Backgrounder resources.

You can see the job status and details on the Managing Background Jobs in Tableau Server page.

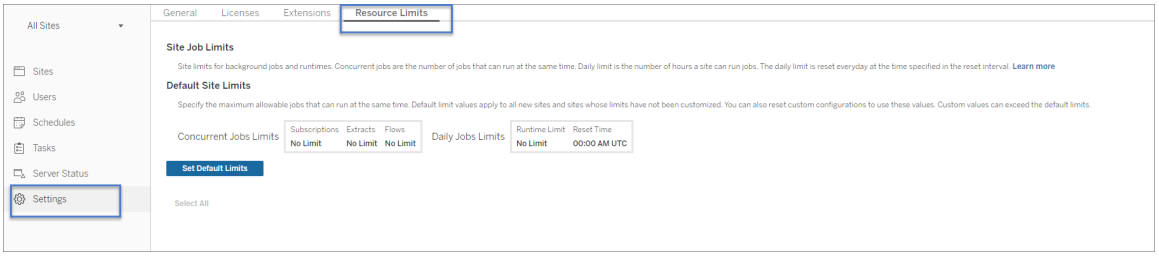
**As a task owner**, you will receive an e-mail when your background job is canceled because the site reached its daily run time limit.

## How to set Backgrounder resource limits

Tableau Server does not automatically set any resource limits. Until you configure resource limits, there is no resource limitation on backgrounder resource usage.

To set resource limits for the first time or make changes thereafter, navigate to the **Settings** page, and select the **Resource Limits** tab.

**You can only configure custom limits once you have configured the default limits**.

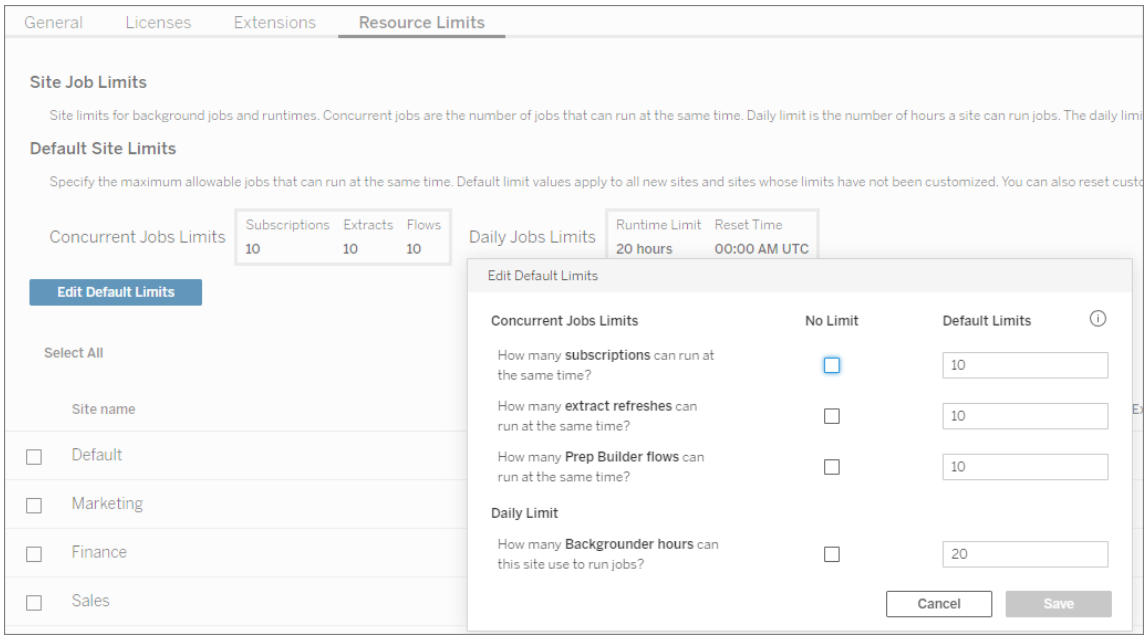


Default site limits

Default site limits are set at the server level so they can be applied to all sites. Changes to default site limits apply to all new sites and any existing sites that are set to use default limits. Sites that have custom limits will not be affected by this change.

- **Concurrent Jobs Limits** and the **Daily Runtime Limits** must be specified in whole numbers.
- Changes to default site limits are effective immediately and do not require a server restart.

To set default limits for the first time, on the **Resource Limits** tab, select **Set Default Limits**. If you are making updates to existing default limits, select **Edit Default Limits**.

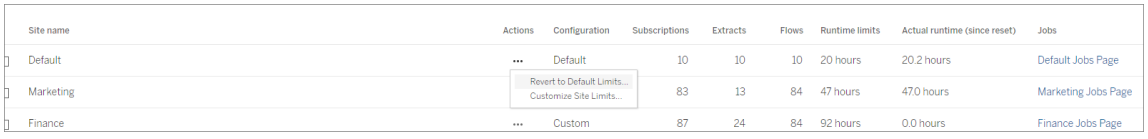


Custom site limits

For certain sites, you may need more or fewer resources than the default limits. This depends on the amount of content you have on the site and their importance to your business operations. When the default values are not the right capacity for a site, you can set custom resource limits for that site. Custom site limits can exceed default limits.

- **Concurrenct Jobs Limits** and the **Daily Runtime Limits** must be specified in whole numbers.
- Changes to custom site limits are effective immediately and do not require a server restart.

To configure custom limits for a site, on the **Resource limits tab**, under **Actions**, click the ellipses and select **Customize Site Limits**.



## What happens after you configure resource limits

Once you set the resource limits for your sites, Tableau Server monitors and keeps track of the backgrounder resource usage, and makes sure the appropriate limits are enforced.

Jobs are placed in a queue when the site is at its maximum concurrency limit and will not run until a a job that is currently running on that site is complete, and Backgrounder capacity becomes available.

If after 12 hours there is still no concurrency resource available, then jobs that are still pending will be removed from the queue. At the end of the daily run time limit, **any pending jobs will be canceled for the day** and the task owner will receive a notification.

This feature requires that Tableau Server is activated with a valid Server Management license without which the limits are not enforced. If the license is invalid or deactivated for any reason, previously configured limits are saved and will be enforced once the license issue has been resolved.

## When to make adjustments to the resource limits

*Before making configuration changes, make sure that Tableau Server is running and is in a good state.*

You can use the jobs page to identify jobs that are pending or canceled, and then determine which of those were due to resource limits.

Here are some patterns to monitor and make adjustments to the resource limits:

- If you are seeing that one or more jobs on a site are consistently getting canceled, you may need to increase the daily run time limits.
- If you are seeing that jobs on a site are consistently getting canceled early in the day, it probably means that the daily job run time is not enough for that site.
- If you are consistently seeing several jobs of a particular type stay pending over a period of time, you may want to consider increasing the concurrent jobs limits for that task type. Alternately consider scheduling the tasks over different time periods so everything is not

running at the same time. Also, you may want to consider creating schedules that are spread over a longer period, so tasks are not all scheduled to run too closely to one another.
- If you don't want to change the resource limits in the situations described above, you can choose to adjust the frequency of when the jobs are scheduled to run. For example, if the job is scheduled to run every hour, adjust it to run on a less frequent schedule.

Who can do this

Tableau Server Administrators can configure resource limits.

A Tableau Server user who owns extract refresh, subscription, or flow run tasks will receive email notifications when their jobs are canceled.

# Dynamic Scaling in a Container - Tableau Server Backgrounders

## Introduction

The dynamic scaling of Backgrounder in a container enables various scaling strategies to be applied to backgrounder and scheduled jobs in Tableau Server. Autoscaling in this context means services can be independently scaled to handle variable task loads without requiring human intervention or impacting uptime of other server systems. The Tableau Server Containers which contain complete nodes of Tableau Server processes will continue to run as monolithic systems. Instead a smaller set of decoupled independent container services which comprise the "backgrounder" service role will be dynamicly scalable and handle computational load that would normally be handled by Tableau Server Containers. Backgrounder services are responsible for processing system tasks that include refreshing/creating extracts, sending subscriptions, checking data alerts, and many maintenance jobs. If there are times, for example, where it would be advantageous to refresh a large number of datasets or compute a swath of computationally expensive data alerts, you can now leverage Kubernetes to scale up compute power to complete those tasks efficiently. This guide is covers the configuration and deployment requirements for Autoscaling Backgrounders in Kubernetes. This document is a supplement to the Tableau Server in a Container documentation.

## Prerequisites

Autoscaling Backgrounders is only available in Kubernetes and is based on Tableau Server in Containers. In order to use the autoscaling backgrounders feature, you must satisfy certain pre-requisite:

- Tableau Server must have Advanced Management capabilities. For more information, see About Tableau Advanced Management on Tableau Server.
- You must be using Role-based licensing. Core licenses are not supported. For details on licensing, see Understanding License Models and Product Keys.
- The following Advanced Management features must be enabled:
  - Tableau Server External File Store
  - Tableau Server External Repository
- You must have a Kubernetes cluster version 1.20 or later and understand how to use and manage it.

## Limitations

- This feature only works as a part of a Linux-based deployment.
- Flow jobs are not supported on the autoscaling backgrounders. Flow jobs will be handled by the backgrounder services that continue to run in the Tableau Server container.

## Creating Tableau Server and Backgrounder Pod Images

The first step for using autoscaling backgrounders in containers is to create the service images that comprise the Tableau Server installation. These images will include the Tableau Server image, as well as images for the separate backgrounder and supporting services. You use the same build tool that is used to create the comprehensive all-in-one Tableau Server container image, but the tool must be version 2022.3.0 or later, you must have an Advanced Management license, and you need to use a special flag when building the images.

1. To create the service images, run this command:

   ```
   build-image --accepteula -i <installer> --backgrounder-images
   ```

This creates the Tableau Server and four new images. These additional images contain individual services that comprise the new autoscalable backgrounder pod.

The `docker images` command lists the images created in the local docker repository:

```
hyper                          20214.21.1117.1006
52fd9843c178   10 seconds ago
gateway                        20214.21.1117.1006
2308e602a2a3   11 seconds ago
backgrounder                   20214.21.1117.1006
4540e459cf23   12 seconds ago
dataserver                     20214.21.1117.1006
c5345ed47f51   12 seconds ago
tableau_server_image           20214.21.1117.1006
b27817047dd1   7 minutes ago
```

The hyper, gateway, backgrounder, and dataserver images comprise the new Backgrounder pod. Custom drivers, installation scripts, and properties will be shared across all five of these images. For more information, see Customizing the image.

2. Publish all of these images to your internal image repository for deployment.

## Deployment Guide

The following information provides context for how to deploy Tableau Server in a Container and with Autoscaling Backgrounders. This information assumes you already understand and know how to deploy Tableau Server in a self-container container. For more information, see Tableau Server in a Container. The three Kubernetes configuration files in the Kubernetes Configuration section are templates that can be used to set up the deployment. The other sections in this guide cover the requirements and details of the deployment.

Deployment of Tableau Server and Autoscaling Backgrounders should be as simple as deploying the populated Kubernetes Configuration files at the bottom of the guide:

```
kubectl apply -f <tableau-kubeconfig-dir>
```

## Backgrounder Jobs

Backgrounder pods assist the Tableau Server in a Container compute additional scheduled workloads in parallel. Backgrounder handles extract refresh, subscription, alert, flow, and system workloads. Distributing jobs among backgrounder pods means there will be more compute resources available for Tableau Server to handle other tasks, like interactive user activities like rendering workbooks and dashboards. Flow jobs are the only type of backgrounder job that does not run in the backgrounderFor details about Backgrounder jobs, see Managing Background Jobs in Tableau Server.

Backgrounder pods can handle any kind of load, except flow jobs, which must be run in the main Tableau Server containers, which continue to run the backgrounder service.

The Node Roles feature give users the flexibility to dedicate backgrounder pods for specific type of jobs. This feature is an extension of the Node Roles Feature on Tableau server. The detailed description about different node roles can be found here. Note, by default flow jobs are disabled on the backgrounder pods (i.e. the role is set to "no-flows") since the backgrounder pods are unable to run flow jobs.

To setup up node roles for backgrounder, you need to set the environment variable `NODE_ROLES` as part of kubeconfig for the container running backgrounder service. For example to set backgrounder to run only extract-refresh jobs, set up `NODE_ROLES` environment variable to extract-refreshes as shown below:

NODE_ROLE_CONFIG

```
containers:
      - name: backgrounder
        image: <backgrounder_image> # Backgrounder Image
        ports:
        - containerPort: 8600
        volumeMounts:
        - name: logmount
          mountPath: /var/log/tableau
        - name: clone-volume
          mountPath: /docker/clone
        - name: dataengine-volume
          mountPath: /docker/dataengine
        - name: temp
          mountPath: /var/opt/tableau/tableau_server-
/data/tabsvc/temp
        env:
          - name: ROOT_LOG_DIR
            value: /var/log/tableau
          - name: CLONE_ARTIFACT_DIR
            value: /docker/clone/clone-artifacts
          - name: FILESTORE_MOUNT_PATH
            value: /docker/dataengine
          - name: NODE_ROLES
            value: extract-refreshes
```

The Tableau Server pods will have at least one backgrounder configured in their topology, which is required to ensure there is always a place to run backgrounder jobs. By default, TSM will require that there must be a backgrounder able to handle every role of background job. In some scenarios, you may want to have backgrounder pods handle all jobs of a particular type. To do so, you must set the Server configuration key `topology.roles_handle_all_jobs_constraint_disabled` to `true`, which will disable the requirement that the TSM topology handle all job types. With this parameter set, the backgrounder role for the Tableau Server backgrounder instance could be set to `no-extract-refreshes` and the role for the

backgrounder pods could be set to `extract-refreshes`, which would ensure that all extract refresh jobs run only on the backgrounder pods.

> **Note:** Disabling this constraint allows you to configure roles such that some job types are never scheduled. The role configuration of TSM backgrounders and backgrounder jobs must be set carefully because TSM will no longer be verifying that all backgrounder job types can be scheduled.

Tableau Server in a Container Pods

The containers with Tableau Server as part of the autoscaling backgrounder pods deploy in almost the same way that our existing Tableau Server in a Container does. There are a few key requirement changes:

- A network file share is *required* to transfer configuration between the Tableau Server container and the backgrounder pods.
- You must enable and use the External Filestore feature. This also requires a dedicated network file share.

Backgrounder Pods

Backgrounder pods consist of four independent service containers working together: **gateway**, **hyper**, **dataserver**, and **backgrounder**. You may deploy these pods like typical independent Kubernetes container pods. The pods have the following requirements:

- Backgrounder pods must be able to reach the Tableau Server node using hostname DNS resolution.
- External Filestore and Clone network file shares must be provided.

> **Note:** Backgrounder pods are configured with an init-container to wait until the Tableau Server container has successfully produced clone configuration output before proceeding to run.

Logs

Backgrounder pod services (like Tableau Server) still write logs predominately to disk. Because the backgrounder pods can be scaled in and out, they are ephemeral so it is essential to ensure that logs are stored off of the pods. Many customers with existing K8s environments will already be using a log aggregation service of some type to collect the logs from the pods they deploy. Examples of log aggregation services are Splunk, and fluentd. We strongly recommend that customers use some sort of log aggregation service to collect the logs from their backgrounder pods. To make log management easier, the kubeconfig we provide configures each service in the pod to write to a shared log volume. The path of the directory in each service container is specified by the `ROOT_LOG_DIR` environment variable.

If you need to open a support case and provide logs, you will provide two sets of logs: ziplogs gathered from the main Server containers, and logs from the backgrounder pods (either retrieved from your log aggregation service, or using the manual process below).

For customers that are unable to use a log aggregation service, logs can be retrieved manually from the pods.

**Note:** Logs from any pod that did not use a Persistent Volume Claim for the volume containing the logs will be lost when the pod is scaled down!

All the relevant logs are available at the `/var/log/tableau` directory (configurable via the `ROOT_LOG_DIR` environment variable) inside the backgrounder pod. We highly recommend you mount a PersistantVolumeClaim at this location so that logs are available when the pod dies.

Collecting logs when the backgrounder pod is running:

Create a tar file of the logs inside the container:

```
kubectl exec -it <backgrounder-pod-name> -- bash -c "tar -czf /docker/user/backgrounder-pod-logs.tar.gz /var/log/tableau"
```

Copy the tarfile to outside the container:

```
kubectl cp <backgrounder-pod-name>:docker/user/backgrounder-pod-log-
s.tar.gz ./backgrounder-pod-logs.tar.gz
```

Collecting logs when the backgrounder pod has exited (or failed to start)

Attach any long-running pod with PersistantVolumeClaim mount which is used for backgrounder pod deployment logs. One example configuration:

```
apiVersion: v1
kind: Pod
metadata:
  name: <name>
  namespace: <namespace>
spec:
  containers:
  - name: get-logs-pod
    image: busybox:1.28
    securityContext:
      runAsUser: 0
      allowPrivilegeEscalation: true
    command: ['sh', '-c', "while :; do sleep 5; done"]
    volumeMounts:
    - name: logmount
      mountPath: /var/log/tableau
restartPolicy: Never
volumes:
  - name: logmount
    persistentVolumeClaim:
      claimName: logvolume
```

Create a tar file of the logs inside container:

```
kubectl exec -it <backgrounder-pod-name> -- bash -c "tar -czf /back-
grounder-pod-logs.tar.gz /var/log/tableau"
```

Copy the tarfile to outside the container:

```
kubectl cp <backgrounder-pod-name>:/backgrounder-pod-logs.tar.gz
./backgrounder-pod-logs.tar.gz
```

### Live Configuration Changes

If you make configuration changes in Tableau Server in a Container (for example using the tsm command line) and want those configuration changes to be represented in Backgrounder pods, you need to run the `tsm settings clone` command to produce a new set of clone configuration files ("clone payload").

1. Use TSM to make configuration changes in the Tableau Server in a Container pod and apply the configuration changes to the server.
2. Run the following command in the Tableau Server in a Container pod:

   ```
   ## Run this command in the Tableau Server in a Container pod.
   tsm settings clone -d $CLONE_ARTIFACT_DIR
   ```

   This command creates a new set of configuration files and writes it to the Clone NFS drive location.
3. Redeploy your backgrounder pods. The pods should be configured to use the Clone NFS drive and will pick up the new configuration.

### Scaling Strategies

Backgrounder pods can be scaled in Kubernetes using a variety of techniques and strategies. We provide an example scaling strategy that changes Backgrounder pod pool size based on a time schedule.

Note that CPU and memory utilization are **not** good metrics for scaling Backgrounder pods. Memory and CPU utilization do not accurately portray the overall load demand on the cluster. For example, a Backgrounder pod could be at max utilization to refresh an extract, but there are no additional jobs waiting in the Backgrounder job queue. In this case autoscaling would not improve job throughput.

### Scheduled Scaling

Standard Kubernetes mechanisms using cron jobs allow you to schedule a scaling solution.

An example Kubernetes configuration for this is provided in the Kubernetes Configuration section below.

## Kubernetes Configuration

### New Environment Variables

In addition to the standard Tableau Server container environment variables (see Initial Configuration Options), there are some new required environment variables that must be set in the Kubernetes Configuration.

| Environment Variable | Recommended Value | Description |
|---|---|---|
| `FILESTORE_MOUNT_PATH` | `/docker/dataengine` | External Filestore directory mount location. This directory should point to the dataengine NFS directory mounted inside each deployed Tableau container. For more information about External Filestore, see Tableau Server External File Store. The value should be the same for the Tableau Server in a Container pod and the Backgrounder pod. |
| `CLONE_ARTIFACT_DIR` | `/docker/clone/clone-artifacts` | Clone configuration directory mount location. This directory should point to an NFS directory mounted inside each Tableau container. Tableau Server will ouput configuration data that Backgrounder Pods consume to become members of the cluster. |
| `ROOT_LOG_DIR` | `/var/log/tableau` | (Backgrounder pods only)<br><br>Common log directory location for all services running in a backgrounder pod. |

Backgrounder Pod Ports

Backgrounder pods consist of four services, each by default is set to run on a specified port. If you want to change the port the service attaches to inside the container, you need to supply the key that corresponds to the service's port assignment. This kind of configuration should not be necessary in most cases, unless there is a sidecar container or some other additional component that is being added to the pod and conflicts with a service's port.

| **Port Environment Variable** | **Default** |
|---|---|
| `BACKGROUNDER_PORT` | `8600` |
| `DATASERVER_PORT` | `8400` |
| `HYPER_PORT` | `8200` |
| `GATEWAY_PORT` | `8080` |

Dataserver also uses port 8300, which cannot be reconfigured.

Shared Network Directory

This deployment of Tableau Server requires two network shares to function properly. Note in all Tableau Server and Backgrounder od Kubernetes configuration templates these network directories are present:

- **Dataengine Directory** (`FILESTORE_MOUNT_PATH`): Backgrounder Pods require the External Filestore feature. This network share contains extracts and other file-based artifacts that will be shared between Tableau Server and Backgrounder Pods.
- **Clone Directory** (`CLONE_ARTIFACT_DIR`): Tableau Server writes static connection and configuration information to a network share. Backgrounder pods will consume this information to become members of the Tableau Server cluster. In future pre-releases this configuration will be incorporated into the standard life cycle of Kubernetes configuration.

**Important:** If you want to redeploy the cluster entirely (including a new Tableau Server Container), you must purge the contents of the clone NFS mount (otherwise backgrounder pods will attempt to attach to the old server).

### Kubernetes Configuration Examples

**Note:** The configuration examples include use of a readiness probe. You can use the readiness probe when your Tableau Server Container deployment is a single-node TSM deployment (the deployment can include multiple backgrounder pods). You cannot use a readiness probe with multi-node Tableau Server in a Container deployments.

#### Tableau Server Container Config

Kubernetes Job to clean Clone Configuration (Optional)

This is a convenience Kubernetes job you might use during testing. If you want to clear out the clone configuration produced by Tableau Server in a Container between distinct deployment runs, you can run a job like this to clean the NFS.

```
apiVersion: batch/v1
kind: Job
metadata:
```

```
name: delete-clone-artifacts-job
namespace: manatee-cluster
spec:
template:
spec:
containers:
- name: delete-clone-artifacts
image: busybox:1.28
command: ['sh', '-c', "rm -rf ${CLONE_ARTIFACT_DIR}"]
env:
- name: CLONE_ARTIFACT_DIR
value: /docker/clone/clone-artifacts
securityContext:
runAsUser: 0
allowPrivilegeEscalation: true
volumeMounts:
- name: clone-volume
mountPath: /docker/clone
restartPolicy: Never
volumes:
- name: clone-volume
nfs:
server: <nfs_ip> # IP for shared NFS directory for clone output
path: /clone
```

# About Data Management

**Important:** As of September 16, 2024, Data Management is no longer available as an independent add-on option. Data Management capabilities are only available if you previously purchased Data Management, or if you purchase certain license editions - either

> Tableau Enterprise (for Tableau Server or Tableau Cloud) or Tableau+ (for Tableau Cloud).

Data Management is a collection of features and capabilities that helps customers manage Tableau content and data assets in their Tableau Server or Tableau Cloud environment.

Starting in Tableau Server 2019.1, Tableau Prep Conductor is available for on-premise Tableau Server deployments, and in version 2019.3, Tableau Prep Conductor is available for Tableau Cloud deployments. You can use Tableau Prep Conductor to schedule and monitor flows.

Starting in Tableau 2019.3, Tableau Catalog is included in Data Management, making a variety of additional features available to you in the data management space. You can use Tableau Catalog to discover data, curate data assets, communicate data quality, perform impact analysis, and trace the lineage of data used in Tableau content.

Starting in Tableau 2021.4, more governance and security features are added to Data Management: virtual connections and data policies. Using the virtual connection editor, you can create:

- Virtual connections that provide a sharable central access point to data.
- Data policies to apply row-level security at the connection level.

## Data Management Features

The following table lists the features for Data Management, which include:

- Tableau Catalog
- Tableau Prep Conductor
- Virtual connections
- Data policies

## Tableau Catalog

| Feature | Description | |
|---|---|---|
| Permissions on metadata | Tableau Catalog enables you to control who can see and manage external assets and what metadata is shown through lineage by setting permissions. | |
| Expanded connect experience - data discovery | Whether you author in the web or in Tableau Desktop, you can now search for and connect to the specific databases and tables used by published data sources and workbooks on your Tableau Server or Tableau Cloud site. | |
| Expanded search | Tableau Catalog expands search to include results based on columns, databases, and tables. | |
| Tag external assets | You can categorize items on Tableau Server and Tableau Cloud with tags, helping users to filter external assets (databases, files, tables, and columns). | |
| Certify databases and tables | Help users find trusted data that meets the standards you set by certifying databases and tables. | |
| Set data quality warnings | You can set warnings to alert users to data quality issues, such as stale or deprecated data. | |
| Lineage and impact analysis | The Lineage tool traces the source of your data. You can use it to analyze the impact of changes to your data, identify which users might be impacted, and email owners of a workbook, data source, or flow, or contacts for a database or table, about data-related updates. | |
| Data Details | Enable users to better understand a published visualization by seeing information about the data used. | |
| Add descriptions to assets | Help users find the data they're looking for by adding descriptions to databases, tables, and columns. | |
| Developer resources | Tableau REST API - metadata methods | Programmatically add, update, and remove external assets; and add additional |

| Feature | Description | |
|---|---|---|
| | | metadata to Tableau content and external assets like descriptions. |
| | Tableau Metadata API | Programmatically query metadata from the content published to Tableau Server or Tableau Cloud. Programmatically update certain metadata using the metadata methods in the Tableau Server REST API.<br>**Note:** The Metadata API does not require Data Management. |
| | GraphiQL | Explore and test queries against the Metadata API schema using an interactive in-browser tool called GraphiQL.<br>**Note:** GraphiQL does not require Data Management. |

## Tableau Prep Conductor

| Feature | Description |
|---|---|
| *Schedule Flow Tasks* in the Tableau Cloud or Tableau Server help. | You can create scheduled flow tasks to run a flow at a specific time or on a recurring basis. |
| Monitor Flow Health and Performance | Set up email notifications at the site or server level when flows fail, view and resume suspended flow tasks, and view errors and alerts. |
| Administrative Views for Flows | Use Administrative Views to monitor the activities related to flows, performance history, and the disk space used at the server or site level. |
| Tableau REST API - flow methods | Programmatically schedule flows. |

### Virtual connections and data policies

| Feature | Description |
|---|---|
| Create a Virtual Connection | A Tableau content type that enables you to create a shareable re-usable connection to curated data. |
| Create a Data Policy for Row-Level Security | Use the virtual connection editor to create data policies with policy conditions that apply row-level security to the data at the connection level. |
| Test Row-Level Security with Preview as User | Test the data policy with Preview as user to ensure that users can see only their data. |
| Schedule Extract Refreshes for a Virtual Connection | Create an extract refresh schedule for the tables in your connection, ensuring that the data is fresh for any content that uses that virtual connection. |

## License Data Management

**Important:** As of September 16, 2024, Data Management is no longer available as an independent add-on option. Data Management capabilities are only available if you previously purchased Data Management, or if you purchase certain license editions - either Tableau Enterprise (for Tableau Server or Tableau Cloud) or Tableau+ (for Tableau Cloud).

Data Management includes Tableau Catalog, Tableau Prep Conductor, virtual connections, and data policies and is available when you purchase Tableau Enterprise. Contact your account manager (or go to the Tableau pricing page) for more information.

Data Management can only be activated on a licensed Tableau Server Deployment. A Deployment includes a licensed production Tableau Server installation and licensed non-production

Tableau Server installations that support the production installation. For more information on Deployment, see the EULA Documentation.

## Tableau Prep Conductor

When you purchase Tableau Enterprise, you must enable Prep Conductor on Tableau Server. For more information, see Enable and Configure Tableau Prep Conductor on Tableau Server.

- When Data Management is active and enabled, you can schedule flows in Tableau Server or Tableau Cloud and monitor flows.
- When Data Management is removed or deactivated, or if the Data Management license expires, then the ability to schedule flows is disabled.
- If your Tableau Server or Tableau Cloud license is still active and valid, you can download the flows using the Tableau Server REST API. For more information, see Flow Methods.

## Tableau Catalog

When you purchase Tableau Enterprise, you must enable Catalog on Tableau Server. For more information, see Enable Tableau Catalog.

- When Data Management is active and enabled, you can use Tableau Catalog to discover data, curate data assets, perform impact analysis, and trace the lineage of data used in Tableau content.
- When Data Management is removed, deactivated, or the license expires, the information remains on the server. The Tableau Catalog-specific information is then only accessible using the Tableau Metadata API; it no longer appears in the product. For more information, see the Metadata API.
- When Data Management is removed, deactivated, or the license expires, the write APIs for all new Tableau Catalog information (for example, table descriptions, data quality warnings, column descriptions) are disabled. You can still read information using the Metadata API, however permissions on tables and databases can't be explicitly managed in the product.

## Virtual connections and data policies

When you purchase Tableau Enterprise, and enable Data Management for Tableau, virtual connections and data policies are automatically enabled on Tableau Server.

After you purchase and license Data Management for Tableau, virtual connections and data policies are automatically enabled.

- When Data Management is active and enabled, you can use virtual connections to create sharable resources that provide a central access point to data. You can also create data policies that enable you to filter data for users using centralized row-level security.
- When Data Management is removed, deactivated, or the license expires, the information remains on the server but is not accessible.
- When Data Management is reactivated, the information is restored on the server and becomes accessible.

## How Data Management licensing works

A Tableau Server Deployment may be user-based or core-based, depending on which license you purchase.

User-Based

A User-Based license metric allows you to deploy Tableau Server on a single computer or on multiple computers in a cluster. Each user that accesses Tableau Server must be licensed. Administrators add users and license them. The first Creator or Explorer product key that you add to Tableau Server activates Tableau Server and will be used by a Server Administrator.

The Data Management product key enables the included features at the deployment level, and those features are licensed for all the users that are already licensed for Tableau Server.

Core-Based

A Core-Based license metric imposes no constraints on the number of user accounts in Tableau Server. Instead, the license specifies the maximum number of computer cores on which you can run Tableau Server.

**Note:** When you purchase and use core-based licensing, you must apply both the Data Management product key and the Resource Core product key to your Tableau Deployment. The first key allows flows to be run on Tableau Server though the Tableau Prep

Conductor and the second key adds the additional cores for the Tableau Prep Conductor nodes. All product keys are available through the Customer Portal.

Typically, the total number of cores in all the computers should not exceed the total number that the Tableau Server license allows. When you activate the Data Management product key on your Tableau Server deployment, it includes a specific number of Tableau Prep Conductor cores. In this scenario, the total number of cores on all computers should not exceed the total number that the Tableau Server license and the Data Management license together allow.

In this topic we will refer to the cores licensed through Tableau Server license as Tableau Server cores, and the cores licensed through Data Management as Tableau Prep Conductor cores.

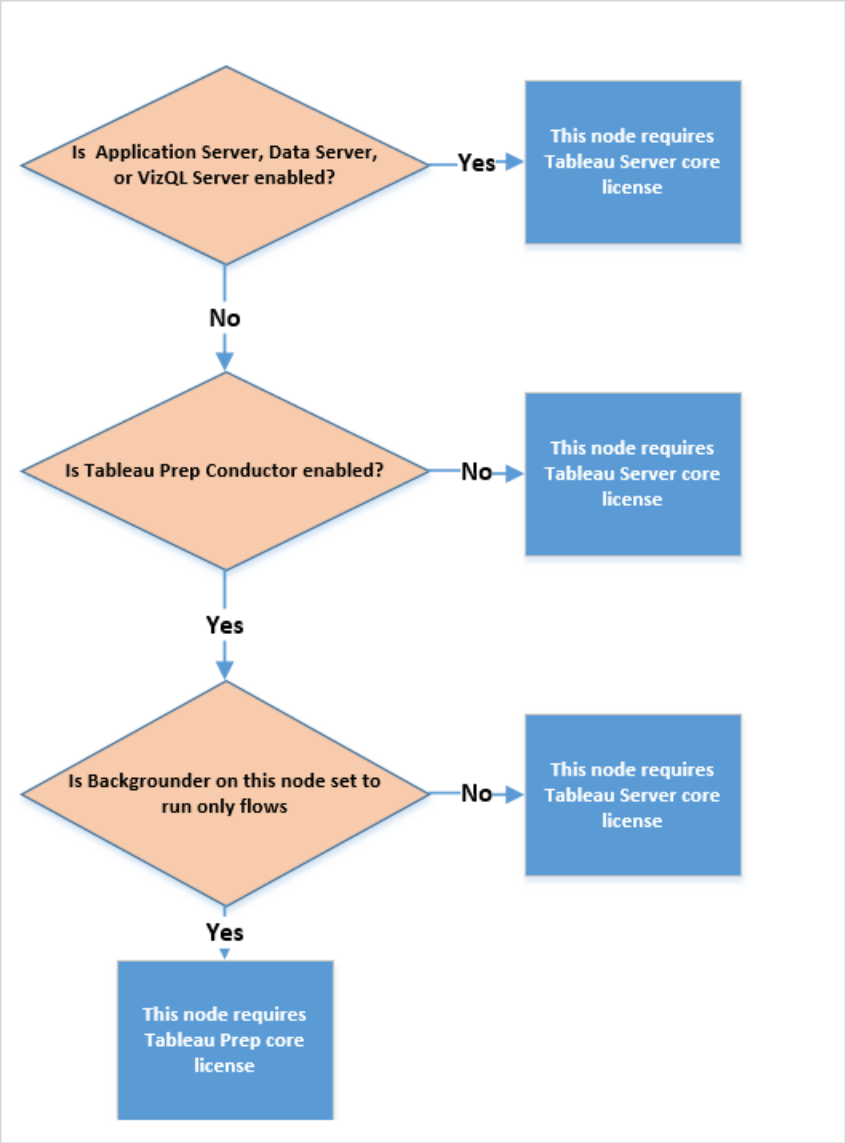
Here are some concepts that apply to how licensing is applied in a Core-Based metric:

- A node can be licensed by only one of type—Tableau Server Cores or Tableau Prep Conductor cores.
- The Tableau Prep Conductor cores are applied to any node that is dedicated to running Tableau Prep Conductor and when the Backgrounder on that node is set to run only flow background jobs. In this case, the total number of cores on this node cannot exceed the number of cores that the Data Management license allows. If this node has any other licensed process besides Tableau Prep Conductor, Backgrounder and Data Engine enabled, then this node will require and use a Tableau Server core license.
- As mentioned above, the Backgrounder node role also affects which license is used by a node. For example, if the Backgrounder node role is set to run jobs of all types (this is the default), then this node will be licensed through the Tableau Server cores. For more information on node roles, see Node Roles in Tableau Server.

  See the following table and decision flow to understand how a node is licensed:

| **If a node has...** | **the core on the node is counted towards...** | **the node is licensed using...** |
|---|---|---|
| one of the following | Total count of Tableau | Tableau Server cores. |

| | | |
|---|---|---|
| processes enabled:<br>• Application Server<br>• Backgrounder (node role is set to run all jobs)<br>• File Store<br>• Data Server<br>• VizQL Server | Server cores. | |
| only the following processes enabled:<br>• Tableau Prep Conductor<br>• Backgrounder (node role is set to run only flows)<br>• Data Engine | Total number of Tableau Prep Cores purchased through Data Management.<br><br>**Note:** If there are no Tableau Prep Conductor cores available, but Tableau Server cores are available, then Tableau Server cores are used. | Tableau Prep Cores included in Data Management.<br><br>**Note:** If there are no Tableau Prep Conductor cores available, but Tableau Server cores are available, then Tableau Server cores are used. |



For more information about licensed processes, see Tableau Server Processes.

To learn more about Tableau Server licensing, see Tableau Server Licensing Overview.

## Tableau Prep Conductor

Tableau Prep Conductor enables you to leverage the scheduling and tracking functionality available in Tableau Server to run your flows automatically to update the flow output. Tableau

Prep Conductor is part of Tableau Data Management introduced in Tableau Server version 2019.1 and must be enabled to schedule your flows to run.

For more information about the Tableau Prep Conductor process on Tableau Server, see Tableau Prep Conductor

> **Note**: Starting in version 2020.4, the Data Management license is required to run flows on a schedule and when using REST API to run flows.
> Data Management isn't required to publish flows and manually run them on the web, and as a Creator, create and edit flows directly on your server.

Flows created in Tableau Prep Builder must be published to Tableau Server before they can be scheduled to run.

Publishing flows is similar to publishing data sources and workbooks with Tableau Desktop. You can package files with the flow or specify a direct connection to data sources to update the flow input as data changes. If your flow connects to databases, specify the authentication type and set credentials to access the data.

You can also publish a flow to share it with others or to continue editing it on the web. For example, publish an incomplete flow to Tableau Server and then open the flow on the web in Edit mode to continue working on it. You could also create a flow with only Input steps (that are properly configured) and share it with co-workers who can then download the flow to their computers and create and publish their own flows.

For flows to run they must include output steps and have no errors or incompatible features. For more information about publishing a flow, see Publish a Flow to Tableau Server or Tableau Cloud. For more information about incompatibility, see Version Compatibility with Tableau Prep.

Keeping track of the health of your flows is easy. If a flow fails to run due to errors, such as a calculation that isn’t valid or a connection failed, you can fix the error right in Tableau Server.

You can edit the connection or edit the flow to fix the error, then republish it to pick up where you left off.

The following table shows the flow management features that are available with and without the Data Management and Tableau Prep Conductor enabled.

| **Data Management with Tableau Prep Conductor enabled** | **No Data Management** |
|---|---|
| • View and monitor the details about your flow, including recent activity in the **Content** pages.<br>• Edit your flow (starting in version 2020.4).<br>• View the results of the flow runs and any errors in the **Run History** tab.<br>• Use **Administrative Views** to monitor server and site activity including a new view that tracks flow performance history.<br>• Run flows using REST API.<br>• View detailed alerts for failed flow runs.<br>• Set up email notification alerts to send emails to flow owners notifying them when the flow failed to run and why.<br>For more information about setting up alerts, Monitor Flow Health and Performance. | • View the details about your flow, including recent activity in the **Content** pages.<br>• Edit your flow (starting in version 2020.4).<br>• View and edit your connections on the **Connections** tab. |

## Enabling Tableau Prep Conductor on Tableau Server

Before you can start publishing flows to your Tableau Server, there are server-level and site-level settings you must configure or verify to prepare your Tableau Server to allow publishing, scheduling and monitoring flows.

Review the following topics to understand Tableau Prep Conductor licensing, and learn how to enable Tableau Prep Conductor:

- Enable and Configure Tableau Prep Conductor on Tableau Server: This topic provides step-by-step instructions on how to enable and configure Tableau Prep Conductor, and preparing your Tableau Server to allow publishing, scheduling, managing, and maintaining flows.
- License Data Management

## About the Flow Workspace

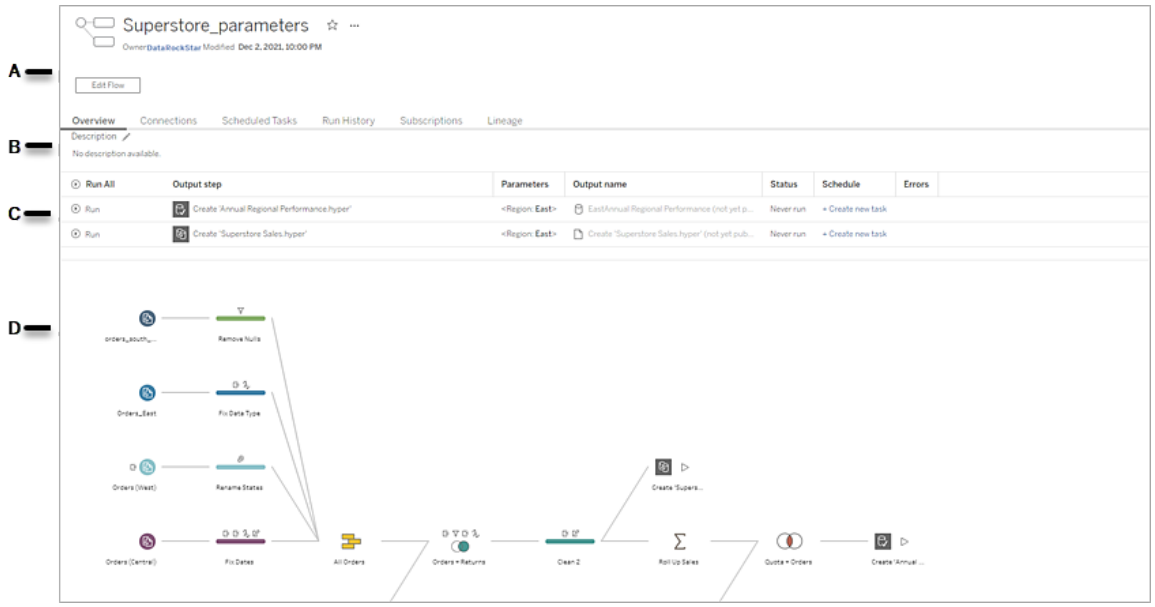
After you publish your flow you can schedule tasks or linked tasks (version 2021.3 and later) in Tableau Server  to automatically run your flows on a regular basis to keep your output data fresh. You can also run your flows manually at any time (no Data Management required).

Tableau Prep Conductor leverages much of the same functionality for managing flows that you might see when managing workbooks or data sources from Tableau Desktop in Tableau Server . For example, just like extract refreshes, scheduled flow tasks and on-demand flow runs are queued as background tasks. But when it comes to working with flows, there are a few differences.

Flow Overview page

The flow **Overview** page is the main landing page where you can view data about your flow and schedule, monitor, and maintain the flow. If you don't have the Data Management, you will have different options.

Open the flow **Overview** page by clicking on a flow in your list. You can navigate there from **Content** > **Explore** > **All Flows** or by opening the project that contains your flows.



A. The header lists the name of the flow, the flow owner and the date that the flow was last modified. Starting in version 2020.4, click **Edit** to edit existing flows.

   Add a flow to your favorites, or from the **More actions** ••• menu you can also edit, run, download the flow, set permissions, change the flow owner, restore previous flow versions, and more.

B. View and edit the flow description and set tags to help others find the flows they are looking for.

C. View the output steps for a flow along with any parameters applied to the flow (version 2021.4 and later), the status of the last update, any schedule the output is assigned to, and any errors from the last flow run. You can also click the **Run** button to run all output steps or individual output steps on-demand.

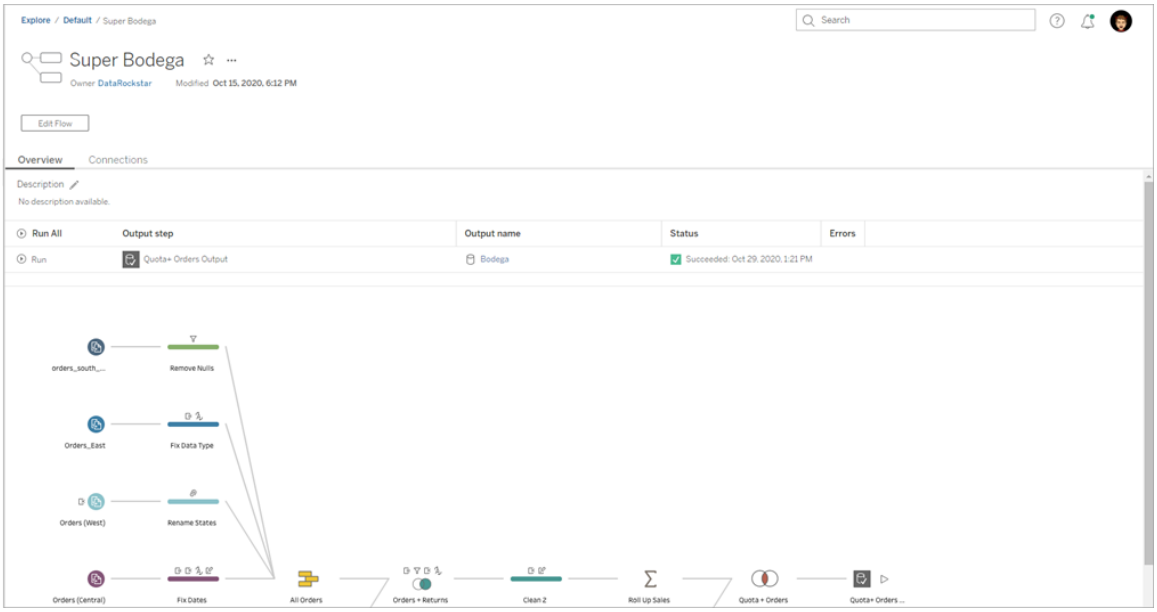
| | |
|---|---|
| **Parameters** | If the flow includes user parameters, the parameter value last run in the flow is shown and you can see all generated outputs in the **Output** column. When the flow is run, you'll be prompted to enter the parameter values. |

| | |
|---|---|
| | System parameters (version 2023.2 and later) are automatically generated at flow run time and the type of system parameter is shown in the **Parameters** column. To see the last system parameter value applied to the flow, edit the flow.<br><br>For more information about using parameters in flows, see Create and Use Parameters in Flows in the Tableau Prep help. |
| **Status** | After a flow has run successfully, outputs that are data sources become links that you can click to open the **Data Source** page to view more information about the data source or edit the flow input connection. |
| **Schedule** | In the **Schedule** field, view the scheduled tasks that the output step is assigned to. A flow output can be assigned to one or more tasks.<br><br>If no schedule has been assigned yet, click **Create new task** to add the output step to a schedule. To immediately run the flow to update a specific output step, click the **Run** button on the left-hand side of the row. |
| **Errors** | If the flow has errors, the flow run will fail. Connectivity errors can be resolved directly by navigating to the **Connections** tab for the flow and editing the input connections.<br><br>To resolve any other flow errors, edit the flow then republish it and try running the flow again. If you are using an earlier version of Tableau Prep Builder, from the **More actions** ... menu, you can also download and open the flow in Tableau Prep Builder, then republish it and try running the flow again. |

D. View an image of the flow.

### Flow Overview page without the Data Management

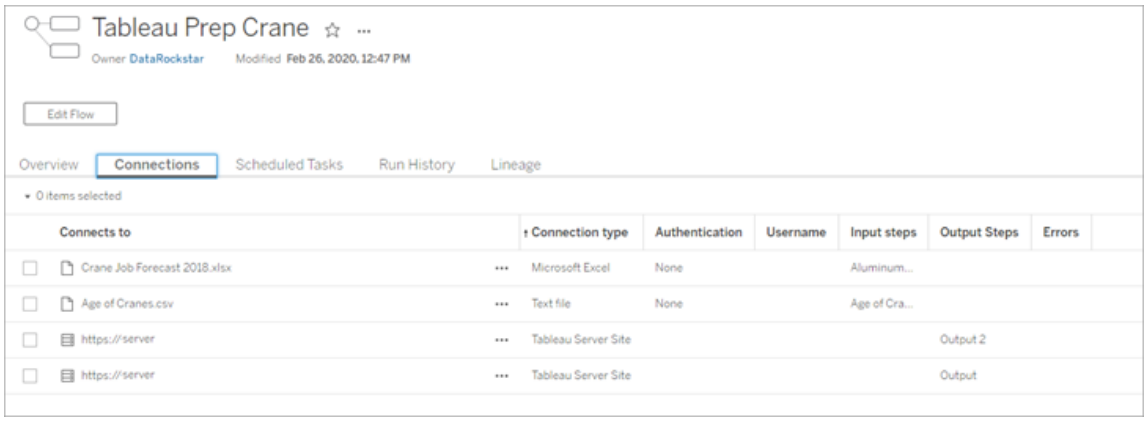
If you don't have the Data Management installed on your server, you can still publish flows to Tableau Server , but you will see fewer options to manage your flow.



### Flow Connections page

View both the input and output locations for a flow, connection types, authentication settings, input and output steps and any connectivity errors. You can set authentication settings when publishing a flow. For more information, see Publish a Flow.

For database input types, click the **More actions** ••• menu for an input connection to edit the connection and change the server name, port, user name and password.



Flow Scheduled Tasks page (Data Management required)

View any schedules that the flow is assigned to, the outputs that are included in those schedules, and any parameters applied to the flow (version 2021.4 and later). As an administrator, you can click the schedule link to open the **Schedules** page and see a list of flows that are assigned to that schedule. For more information about assigning flows to a schedule, see *Schedule Flow Tasks* in the Tableau Cloud or Tableau Server help.

To view the outputs on a schedule or the tasks assigned to a linked task (version 2021.3 and later), click the links in the **Schedule type** column.

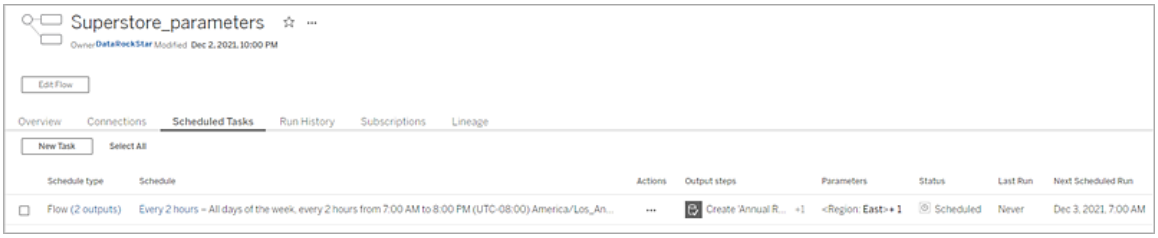
You can also add new tasks or manage existing ones from this page. To take action on an existing task, select the check box on a task card then click the **Actions** drop-down menu to run, edit, or delete the task.

If the flow fails to run after a configured number of consecutive attempts, the flow is automatically suspended.

You can see that status on the **Overview** tab as well as this tab. You can resume suspended tasks from this menu.

For information about how to set the threshold for suspended flow tasks, see Step 5: Optional Server Configurations. For more information about suspended flow tasks, see View and resolve errors.

**Note**: The Scheduled Tasks page for flows was redesigned in version 2021.3. Your view may look different depending on your server version.

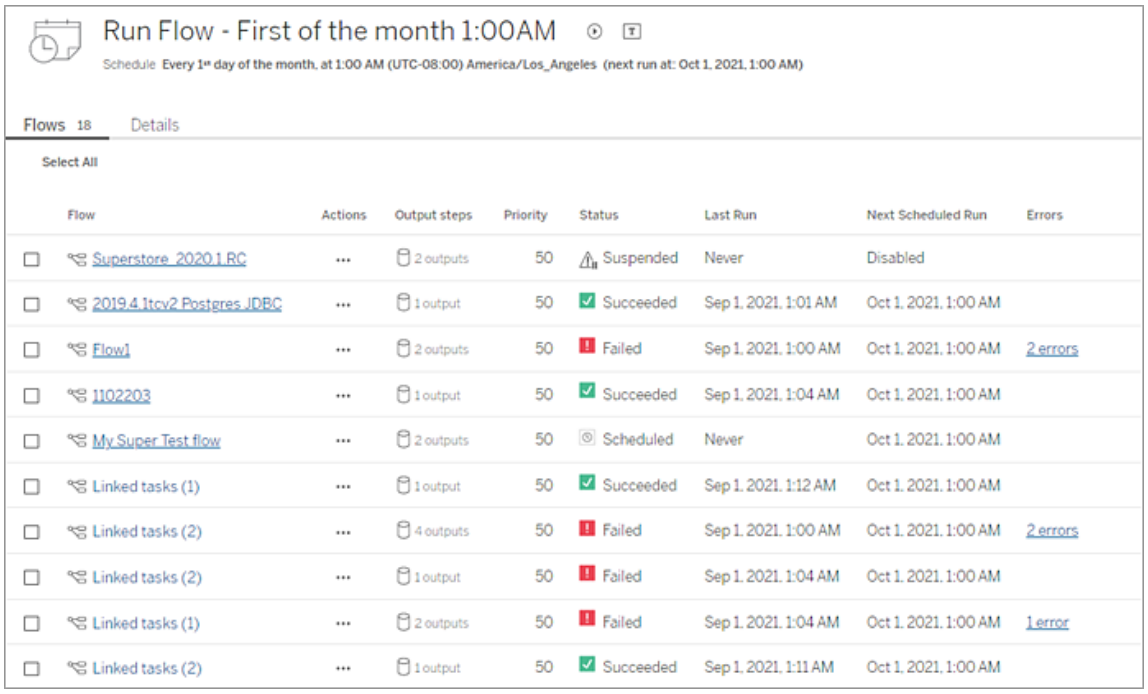


Schedules page

On the **Schedules** page, you can view the flows assigned to a schedule and the details about the flow runs. If the schedule includes linked tasks (version 2021.3 and later) the number of flows included in the linked tasks is shown.

You can run the schedule on-demand and run all flows assigned to it. You can also select one or more flows, then use the **Actions** menu to change the flow schedule or priority, delete selected flows from the schedule or resume suspended flows.

For information about how to set up a schedule, see Step 3: Create Schedules for Flow Tasks.

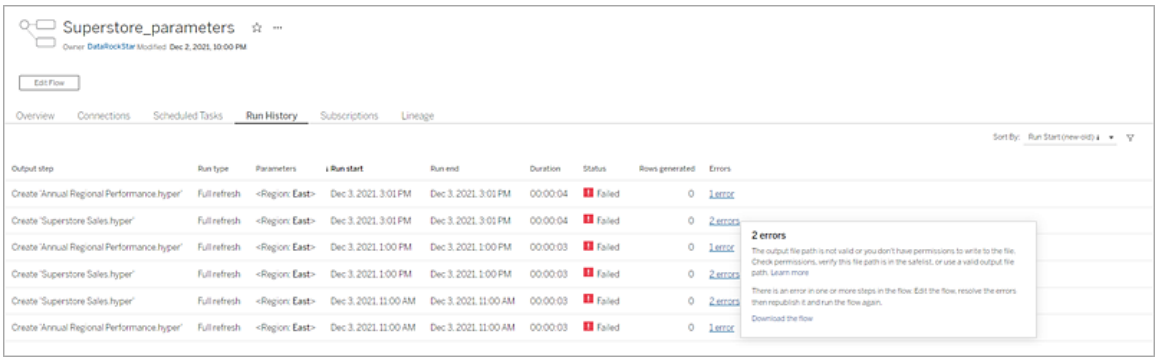


Flow Run History (Data Management required)

See, search, and sort through a list of historical runs for a flow. This page also includes details about the flow run such as run type, parameter values applied to flows included in each flow run (version 2021.4 and later), duration and number of rows that were generated.

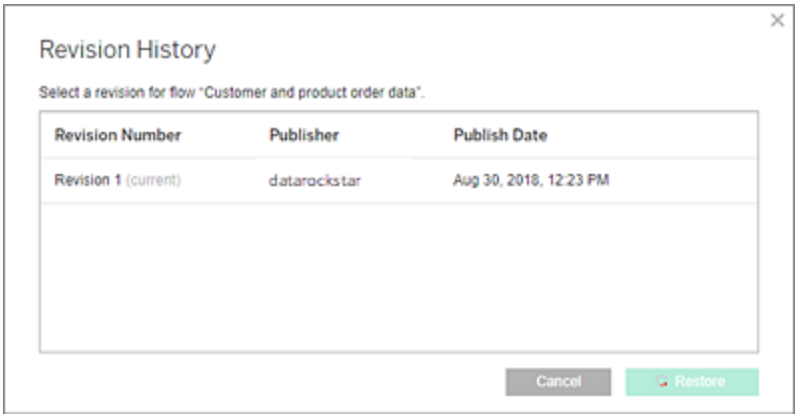
If the flow output has an error, hover over the error to view the messages. If applicable, click the **Go to Connections** link in the error message to navigate to the **Connections** page to fix connectivity errors. You can also edit the flow directly to fix any errors, or click **Download the flow** to download and fix flow errors in Tableau Prep Builder, then republish the flow to continue to manage it using Tableau Prep Conductor.

**Note**: The run history for a flow will persist unless the flow is deleted.



Flow Revision History

If you need to revert a flow to a previous version, from the **More actions** ••• menu for the flow, select **Revision History**. On the **Revision History** dialog, select the flow version from the list that you want to revert to.



Who can do this

Server Administrators can activate Data Management license keys.

Server administrators can enable Tableau Prep Conductor.

Creators can create, edit, and run flows manually. If the Data Management is installed, creators can run flows on a schedule.

## Enable and Configure Tableau Prep Conductor on Tableau Server

*Supported in Tableau Server version 2019.1 and later.*

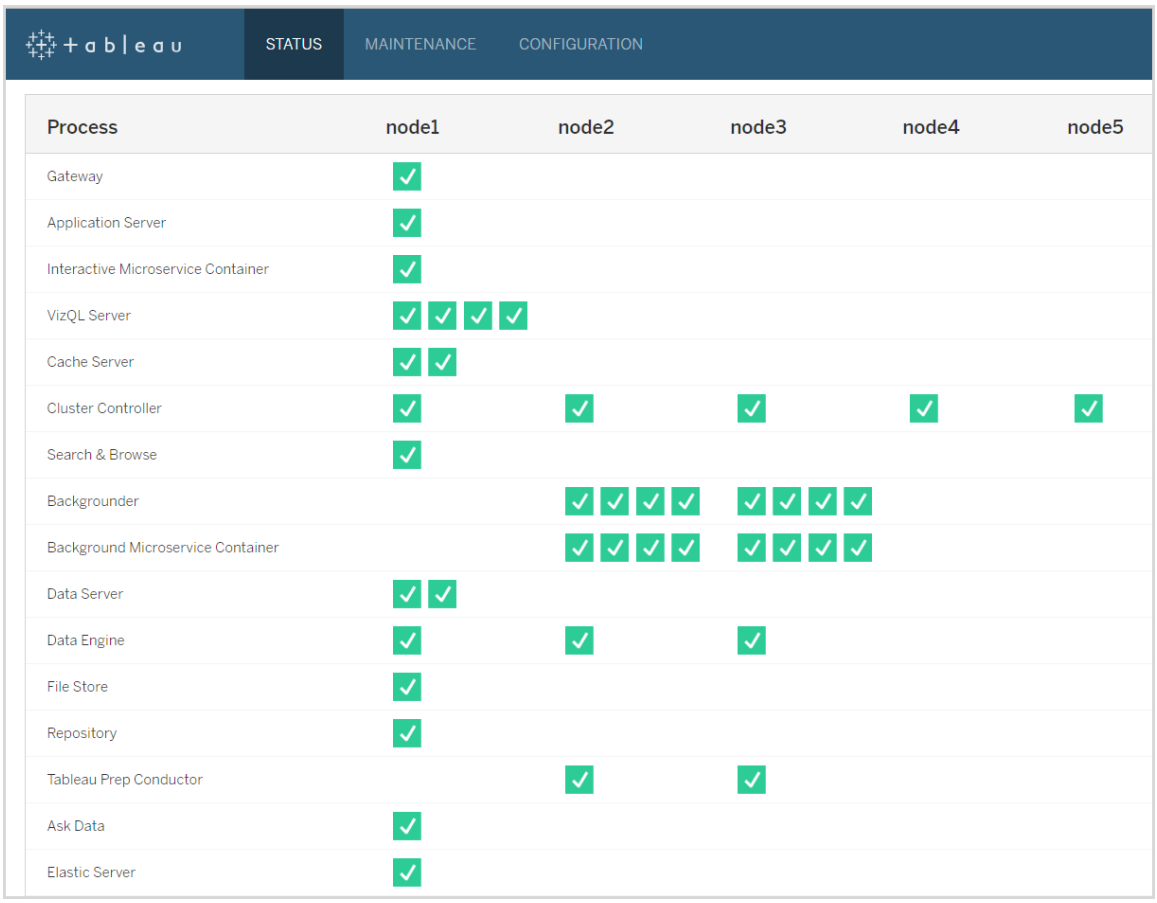
Tableau Prep Conductor is licensed through Data Management, on a per Deployment basis, which is User-Based or Core-Based. A Deployment includes a licensed production Tableau Server installation and licensed non-production Tableau Server installations that support the production installation. For more information on Deployment, see the Tableau Deployment Guide.

For more information on how Tableau Prep Conductor licensing works, see License Data Management.

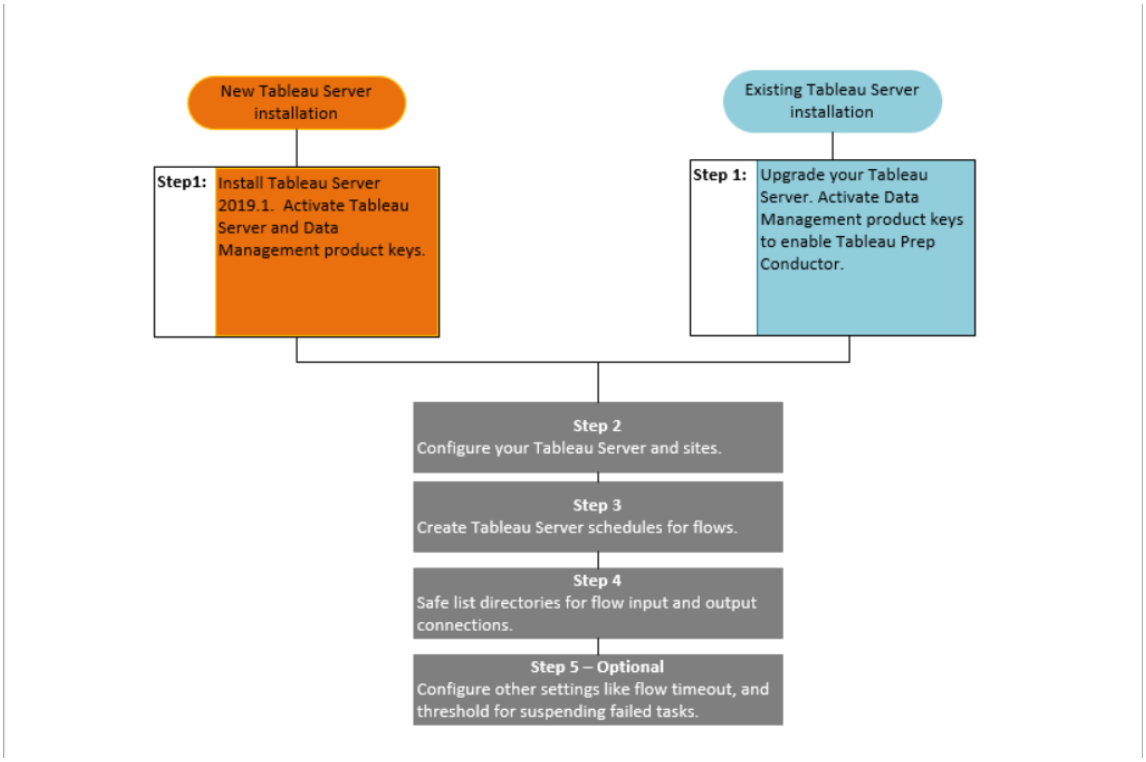
Server Topology

When you install Tableau Server and enable Tableau Prep Conductor, using the Data Management product key, Tableau Prep Conductor is automatically enabled by default by the setup program.

For multi-node installations, by default, one instance of Tableau Prep Conductor is enabled on any node that has backgrounder installed. In the example below, Tableau Prep Conductor is enabled on node 2 and 3 where the backgrounders are also enabled, but not on node 1,4, and 5.



Below is a visual representation of that work-flow:



Next step:

New Tableau Server Installations: Step 1 (New Install): Install Tableau Server with Tableau Prep Conductor

Existing Tableau Server Installations: Step 1 (Existing Install): Enable Tableau Prep Conductor

Who can do this

Server administrators can install Tableau Server and enable Tableau Prep Conductor.

Server-level settings can be configured by Tableau Server administrators, and site-level settings can be configured by Tableau Server and Site administrators.

Step 1 (New Install): Install Tableau Server with Tableau Prep Conductor

This topic describes how to Tableau Prep conductor on a new installation of Tableau Server.

Tableau Prep Conductor is supported only on Tableau Server versions 2019.1 or later.

Tableau Prep Conductor is licensed through Data Management, on a per Deployment basis. A Deployment includes a licensed production Tableau Server installation and licensed non-production Tableau Server installations that support the production installation. For more information on Deployment, see the Tableau Deployment Guide.

Before you install

The recommended topology for a production Tableau Server installation is a dedicated node for running flows. If you are currently planning to have a single node Tableau Server installation it is recommend that you add a second node and dedicate it to run flows.

- Review the hardware recommendations for Tableau Server and Tableau Prep conductor.
    - Minimum Hardware Requirements and Recommendations for Tableau Server installation on Windows.
    - Minimum Hardware Requirements and Recommendations for Tableau Server installation on Linux.

Install Tableau Server and enable Tableau Prep Conductor

Use the instructions provided in the following topics to install Tableau Server.

Windows: Install Tableau Server

Linux: Install Tableau Server topic

When you get to the **Activate** step, use the Tableau Server product keys to activate Tableau Server.

All product keys are available through the Customer Portal.

## Configure public gateway settings

If your Tableau Server is set up with one of the following:

- Load balancer to distribute requests across gateways.
- Reverse proxy to authenticate external (internet) client requests and offloading SSL-based encryption.

You must configure the following public gateway settings:

`tsm configuration set -k gateway.public.host -v <name>` (This should be the URL that your users are using to access Tableau Server)

```
tsm configuration set -k gateway.public.port -v 443
```

For more information on configuring gateway settings, see Configuring Proxies for Tableau Server.

## Enable Tableau Prep Conductor

Use the following steps to add the Data Management product key to your Tableau Server. This process requires a restart of the Tableau Server.

**Note:** If you are using core-based licensing, you must apply both the Data Management product key and the Resource Core product key to your Tableau Deployment. The first key allows flows to be run on Tableau Server though the Tableau Prep Conductor and the second key adds the additional cores for the Tableau Prep Conductor nodes. All product keys are available through the Customer Portal.

1. If the computer where you are running Tableau Server has been configured to connect to the internet through a forward proxy, follow the procedure in the topic, Configure Product Key Operations with Forward Proxy, before continuing.
2. Open TSM in a browser:

   ```
   https://<tsm-computer-name>:8850
   ```

3. Click **Licensing** on the **Configuration** tab and click **Activate License**.

4. Enter or paste your **Data Management product key** and click **Activate**.
5. On the Register page, enter your information into the fields and click **Register**.
6. Follow the prompts and restart Tableau Server after registration is complete.

## Verify Tableau Prep Conductor is enabled and running

When you activate the Data Management product key, a single instance of Tableau Prep Conductor is automatically enabled on any node that has Backgrounder enabled.

**Use the following steps to verify that it is enabled and running:**

1. Open a browser and enter the Tableau Server URL, and append the dedicated TSM web UI port. Here are some examples of what the URL might look like:

   https://localhost:8850/ (if you're working directly on the server computer)

   https://MarketingServer:8850/ (if you know the server's name)

   https://10.0.0.2:8850/ (if you know the server's IP address)

   In the sign-in page that appears, enter your administrator user name and password.

   > **Note:** Tableau Server creates and configures a self-signed certificate during the installation process. This certificate is used to encrypt traffic to the TSM Web UI. Because it's a self-signed certificate, your browser will not trust it by default. Therefore, your browser will display a warning about the trustworthiness of the certificate before allowing you to connect.

2. In the Tableau Services Manager web interface, click the **Status** tab to see the status.

   - If Tableau Prep Conductor is enabled and running, you should see Tableau Prep Conductor in the list of processes as **Active** on at least on one node. If Tableau Prep Conductor is not enabled, you will see Tableau Prep Conductor in the list of

processes, but with no status information for any of the nodes.

**Tableau Prep Conductor not enabled:**

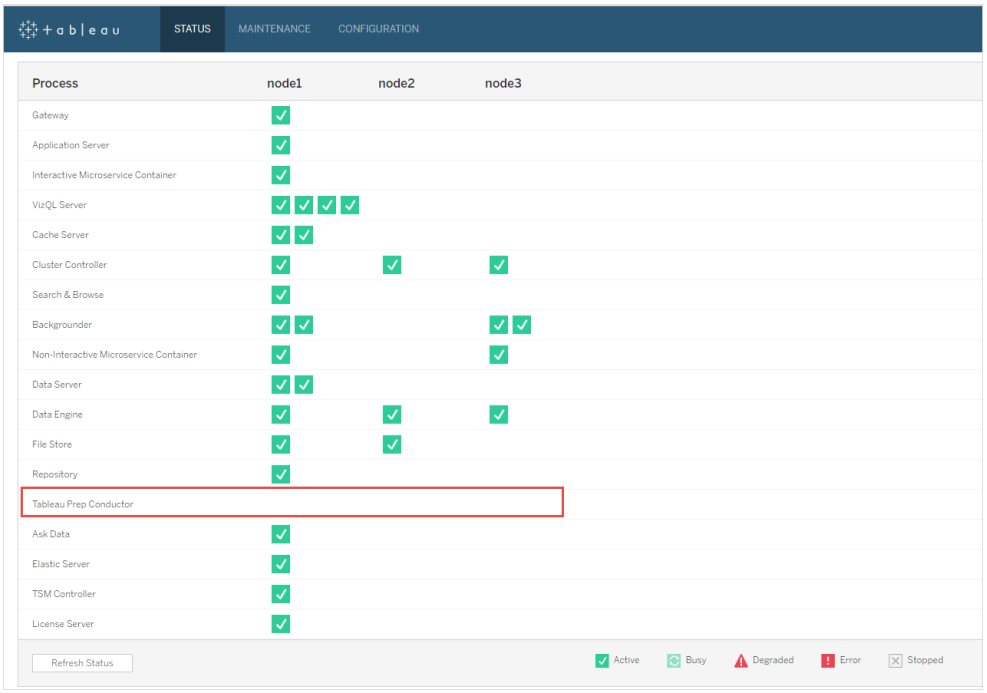


**Tableau Prep Conductor enabled and running. In the image below Tableau Prep Conductor is enabled on node1 and node3:**

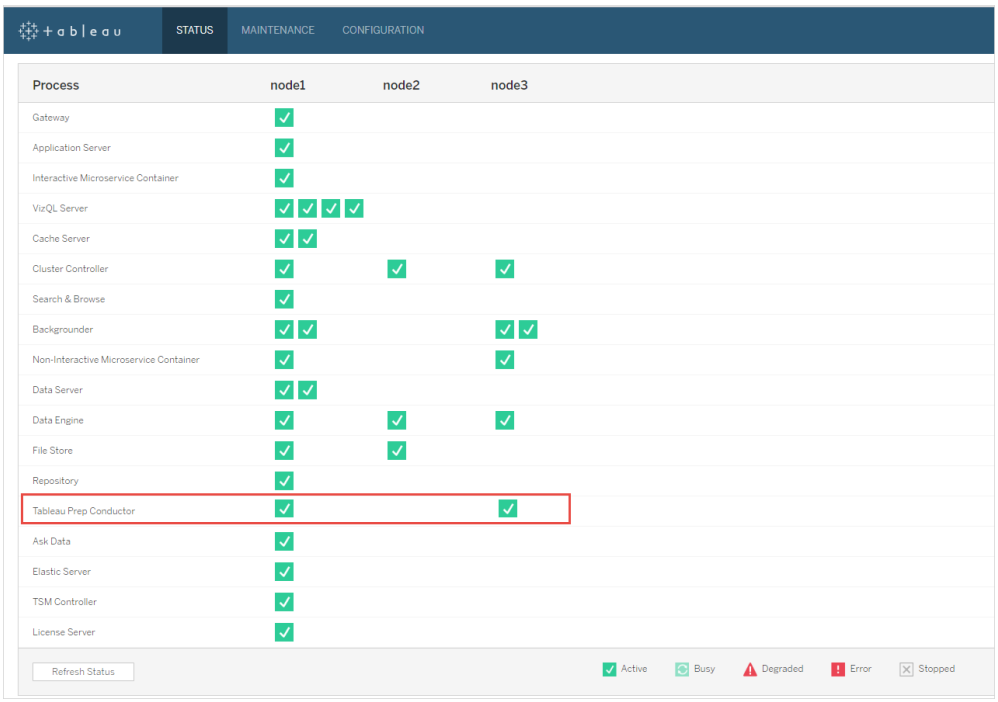

Dedicate a node for Tableau Prep Conductor

On the node you are planning to dedicate to running flows, enable Backgrounder process if it is not already enabled. It is recommended that you do not run other processes like VizQL server on this node.

Because you are dedicating this node to running flows, you must configure Backgrounder to run only flow tasks. By default, the Backgrounder process runs tasks of all types, including flows, extract refreshes, and subscriptions. For more information, see Node Roles in Tableau Server.

Run the following tsm commands on that dedicated node to run only flow tasks:

1. Run the following command to allow Backgrounders on this node to run only flow tasks.

```
tsm topology set-node-role -n node1 -r flows
```

2. Set the node role on the initial node to no flows. The backgrounder on this node will run all jobs except flows:

   ```
   tsm topology set-node-role -n node1 -r no-flows
   ```

3. Apply the changes and restart Tableau Server:

   ```
   tsm pending-changes apply
   ```

## Multi-node installations

If you have more than 2 nodes in your Tableau Server installation, you can choose to configure other nodes to run all tasks other than flows:

1. Restrict a node to not allow flows. This command removes Tableau Prep Conductor from this node and Backgrounders on this node will not run flow tasks.

   ```
   tsm topology set-node-role -n node1 -r no-flows
   ```

2. Apply the changes and restart Tableau Server:

   ```
   tsm pending-changes apply
   ```

Next step

Step 2: Configure Flow Settings for your Tableau Server

## Who can do this

Server administrators can install Tableau Server and enable Tableau Prep Conductor.

Step 1 (Existing Install): Enable Tableau Prep Conductor

This topic describes how to enable Tableau Prep conductor on your existing installation of Tableau Server.

Tableau Prep Conductor is supported only on Tableau Server versions 2019.1 or later. If you are using Tableau Server 2018.3 or earlier, you must first upgrade your Tableau Server to 2019.1 before enabling Tableau Prep Conductor on your Tableau Server installation.

Tableau Prep Conductor is licensed through Data Management, on a per Deployment basis, which is User-Based or Core-Based. A Deployment includes a licensed production Tableau Server installation and licensed non-production Tableau Server installations that support the production installation. For more information on Deployment, see the Tableau Deployment Guide.

This topic describes how to enable Tableau Prep conductor on your existing installation of Tableau Server.

Before you upgrade

## Prepare for upgrade:

- Know before you upgrade
- Licensing Tableau Prep Conductor
- Tableau Server Hardware Requirements and Recommendations

## Configure public gateway settings

If your Tableau Server is set up with one of the following:

- Load balancer to distribute requests across gateways.
- Reverse proxy to authenticate external (internet) client requests and offloading SSL-based encryption.

You must configure the following public gateway settings:

`tsm configuration set -k gateway.public.host -v <name>` (This should be the URL that your users are using to access Tableau Server)

```
tsm configuration set -k gateway.public.port -v 443
```

For more information on configuring gateway settings, see Configuring Proxies for Tableau Server.

Tableau Server Installations using User-Based licenses

The recommended topology for a production Tableau Server installation is a dedicated node for running flows. For more information, see Minimum Hardware Requirements and Recommendations for Tableau Server.

## Tableau Server single-node installations

If you currently have a single node Tableau Server installation, it is recommended that you add a second node and dedicate it to running flows.

1. Run upgrade on your current Tableau Server installation using the information in the topics below:

    - Windows
    - Linux

    When you get to the **Activate** step, use the Tableau Server product keys to activate Tableau Server.

    All product keys are available through the Customer Portal.

2. After completing the installation, add the Data Management product key to enable Tableau Prep Conductor on your node. The Data Management product key, like your other server keys, are available through the Customer Portal.

    - In the Tableau Services Manager web interface, click **Licensing** on the **Configuration** tab and click **Activate License**.
    - Enter or paste your new product key and click **Activate**.
    - On the **Register** page, enter your information into the fields and click **Register**.

3. You will be prompted to restart the server. Restart the server and verify that Tableau Prep Conductor is enabled and running.

    - In the Tableau Services Manager web interface, click the **Status** tab to see the status. If Tableau Prep Conductor is enabled and running, you should see Tableau Prep Conductor in the list of processes as **Active**. If Tableau Prep Conductor is not enabled, you will see Tableau Prep Conductor in the list of processes, but with no status information.

      **Tableau Prep Conductor not enabled:**

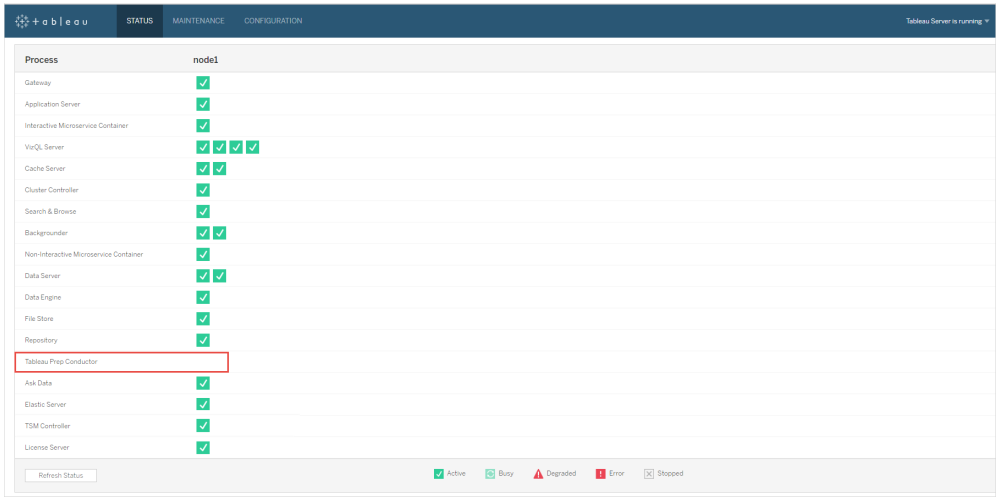

**Tableau Prep Conductor enabled and running:**

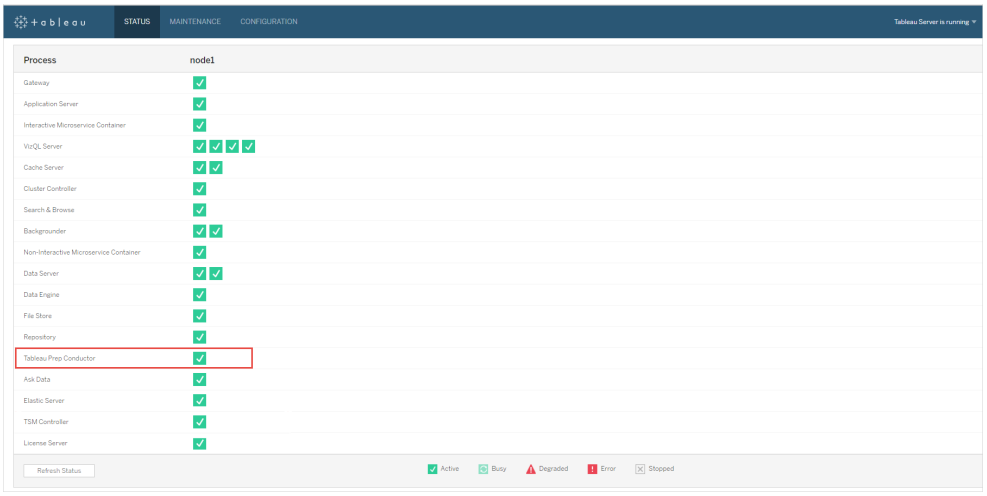


4. Add a second node to your Tableau Server installation. The installer will enable certain required processes like the Cluster Controller. Enable Backgrounder process on it as it is required to run scheduled flow tasks. When you enable the Backgrounder process, the installer automatically enables a single instance of Data Engine and Tableau Prep Conductor on the node. Do not add any other processes on this node.

5. Run the following commands to dedicate this node to do only flow tasks. For more information on node roles, see Node Roles in Tableau Server.

    - Get the nodeID for your dedicated node to see the list of services on each node:

      ```
      tsm topology list-nodes -v.
      ```

    - Set the node role for the dedicated node using the nodeID that you got from running the command described above:

      ```
      tsm topology set-node-role -n <nodeID> -r flows.
      ```

    - Apply the changes, and restart the server:

      ```
      tsm pending-changes apply.
      ```

- Review the status to ensure that all the processes are up and running and configured correctly:

  ```
  tsm status -v.
  ```

You have successfully added Tableau Prep Conductor to your Tableau Server installation.

## Tableau Server multi-node installations

1. Run upgrade on your current Tableau Server Installation using the information in the topics below:

   - Windows
   - Linux

   When you get to the **Activate** step, use the Tableau Server product keys to activate Tableau Server.

   All product keys are available through the Customer Portal.

2. After completing the installation, add the Data Management product key to enable Tableau Prep Conductor. Tableau Prep Conductor is automatically enabled on the nodes where you already have the Backgrounder process enabled. The Data Management product key, like your other server keys, are available through the Customer Portal.

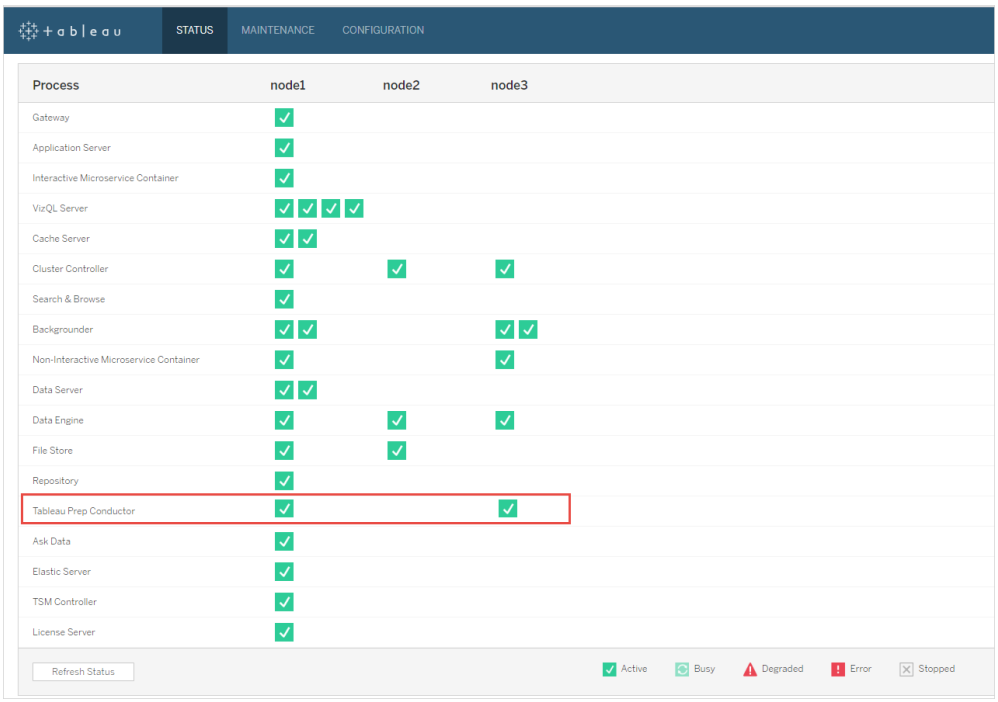
   - In the Tableau Services Manager web interface, click **Licensing** on the **Configuration** tab and click **Activate License**.
   - Enter or paste your new product key and click **Activate**.
   - On the **Register** page, enter your information into the fields and click **Register**.

3. You will be prompted to restart the server. Restart the server and verify that Tableau Prep Conductor is enabled and is running.

- In the Tableau Services Manager web interface, click the **Status** tab to see the status of all the processes. If Tableau Prep Conductor is enabled and running, you should see Tableau Prep Conductor in the list of processes as **Active**. If Tableau Prep Conductor is not enabled, you will see Tableau Prep Conductor in the list of processes, but with no status information.

  **Tableau Prep Conductor not enabled:**

  **Tableau Prep Conductor enabled and running:**



4. Add a new node to your Tableau Server installation. The installer will enable certain required processes like the Cluster Controller. Enable Backgrounder process on it as it is required to run scheduled flow tasks. When you enable the Backgrounder process, the installer automatically enables a single instance of Data Engine and Tableau Prep Conductor on the node. Do not add any other processes on this node.

   **Note:** The dedicated node counts towards the total count of the Coordination Service ensemble. You may need to deploy a Coordination Service on the new node depending on the total number of nodes you have in your cluster including the new dedicated node. For more information, see Deploy a Coordination Service Ensemble.

5. Run the following command to dedicate this node to only doing flow related operations. For more information on node roles, see Node Roles in Tableau Server.

- Get the nodeID for your dedicated node to see the list of services on each node:
- `tsm topology list-nodes -v`.
- Set the node role for the dedicated node using the nodeID that you got from running the command described above:
- `tsm topology set-node-role -n <nodeID> -r flows`.
- Apply the changes and restart the server:
- `tsm pending-changes apply`.
- Review the status to ensure that all the processes are up and running and configured correctly:
- `tsm status -v`.

6. At this stage, you may have Tableau Prep Conductor enabled on other nodes. By default, the Backgrounder process on a node performs all tasks of all types including flow tasks. To isolate Tableau Prep Conductor and flow tasks to only certain nodes, you can configure the Backgrounders to do one of the following:

    - To run only flow tasks: `tsm topology set-node-role -n <nodeID> -r flows`.
    - To run all other tasks except flows: `tsm topology set-node-role -n <nodeID> -r no-flows`.

You have successfully added Tableau Prep Conductor to your Tableau Server installation.

Tableau Server Installations using Core-Based licenses

The recommended topology for a production Tableau Server installation is a dedicated node for running flows. For more information, see Minimum Hardware Requirements and Recommendations for Tableau Server.

Data Management for Core-Based licenses includes product keys that enable Tableau Prep Conductor for your Tableau Server, and Tableau Prep Conductor cores that comes in units of four. The Tableau Prep Conductor cores should be applied to the node dedicated to running the flows. These product keys, like your other server keys, are available through the Customer Portal.

To learn more about Tableau Prep Conductor licensing, see Licensing Tableau Prep Conductor for Tableau Server.

## Tableau Server single-node installations

If you currently have a single node Tableau Server installation, it is recommended that you add a second node and dedicate it to running flows.

1. Run upgrade on your current Tableau Server Installation using the information in the topics below:
    - Windows
    - Linux
2. Activate the product keys. This will enable Tableau Prep Conductor on the nodes where you already have the Backgrounder process enabled. When you are using core-based licensing, you must apply both the Data Management product key and the Resource Core product key to your Tableau Deployment. The first key allows flows to be run on Tableau Server though the Tableau Prep Conductor and the second key adds the additional cores for the Tableau Prep Conductor nodes. All product keys are available through the Customer Portal.
    - In the Tableau Services Manager web interface, click **Licensing** on the **Configuration** tab and click **Activate License**.
    - Enter or paste your new product key and click **Activate**.
    - On the **Register** page, enter your information into the fields and click **Register**.
3. You will be prompted to restart the server. Restart the server and verify that Tableau Prep Conductor is enabled and is running.
    - In the Tableau Services Manager web interface, click the **Status** tab to see the status. If Tableau Prep Conductor is enabled and running, you should see Tableau Prep Conductor in the list of processes as **Active**. If Tableau Prep Conductor is not enabled, you will see Tableau Prep Conductor in the list of processes, but with no status information.

**Tableau Prep Conductor not enabled:**

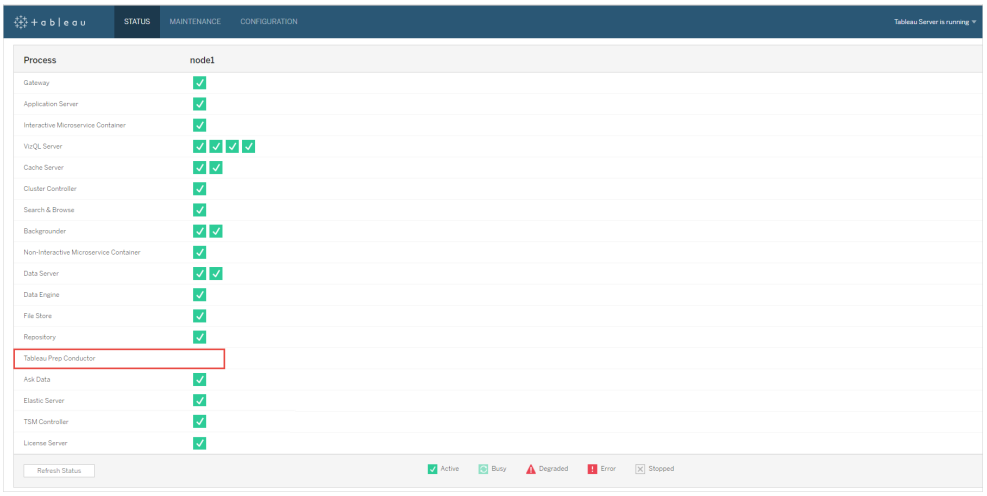


**Tableau Prep Conductor enabled and running:**

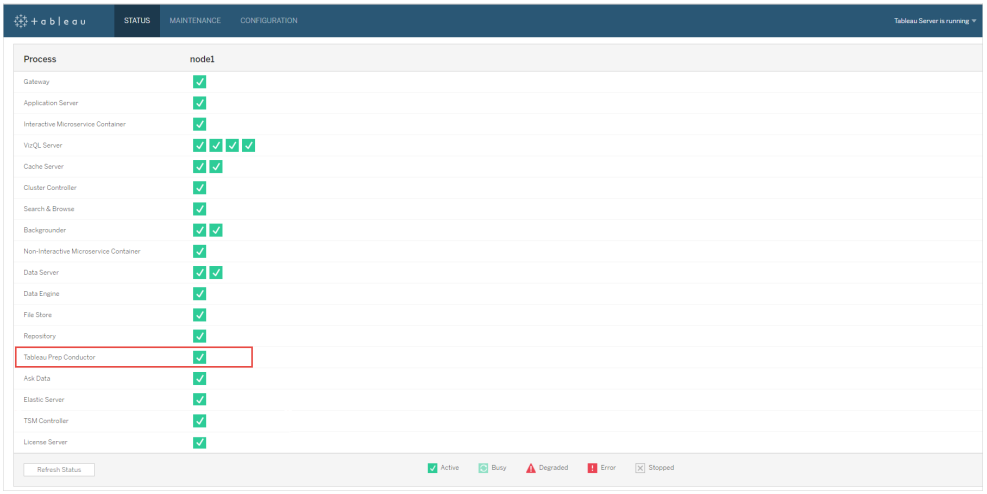

4. Add a second node to your Tableau Server installation. The installer will enable certain required processes like the Cluster Controller. Enable Backgrounder process on it as it is required to run scheduled flow tasks. When you enable the Backgrounder process, the installer automatically enables a single instance of Data Engine and Tableau Prep Conductor on the node. Do not add any other processes on this node.

**Important:** The number of physical cores on this machine must be equal to, or less than the Tableau Prep Conductor cores you purchased. For example, if you purchased four Tableau Prep Conductor cores, your node can only have up to four physical cores. To understand about how Tableau Prep Conductor licensing works, see Licensing Tableau Prep Conductor for Tableau Server.

5. Run the following commands to dedicate this node to only doing flow tasks. For more information on node roles, see Node Roles in Tableau Server.

    - Get the nodeID for your dedicated node to see the list of services on each node:

      ```
      tsm topology list-nodes -v.
      ```

    - Set the node role for the dedicated node using the nodeID that you got from running the command described above:

      ```
      tsm topology set-node-role -n <nodeID> -r flows.
      ```

    - Apply the changes and restart the server: `tsm pending-changes apply`.

    - Review the status to ensure that all the processes are up and running and configured correctly:

      ```
      tsm status -v.
      ```

You have successfully added Tableau Prep Conductor to your Tableau Server installation.

## Tableau Server multi-node installations

1. Run upgrade on your current Tableau Server installation using the information in the topics below:

    - Windows
    - Linux

2. Activate the product keys. This will enable Tableau Prep Conductor on the nodes where you already have the Backgrounder process enabled. When you are using core-based licensing, you must apply both the Data Management product key and the Resource Core product key to your Tableau Deployment. The first key allows flows to be run on Tableau Server though the Tableau Prep Conductor and the second key adds the additional cores for the Tableau Prep Conductor nodes. All product keys are available through the Customer Portal.

    - In the Tableau Services Manager web interface, click **Licensing** on the **Configuration** tab and click **Activate License**.
    - Enter or paste your new product key and click **Activate**.
    - On the **Register** page, enter your information into the fields and click **Register**.

3. You will be prompted to restart the server. Restart the server and verify that Tableau Prep Conductor is enabled and is running.

    - In the Tableau Services Manager web interface, click the **Status** tab to see the status. If Tableau Prep Conductor is enabled and running, you should see Tableau Prep Conductor in the list of processes as **Active**. If Tableau Prep Conductor is not enabled, you will see Tableau Prep Conductor in the list of processes, but with no status information.

      **Tableau Prep Conductor not enabled:**

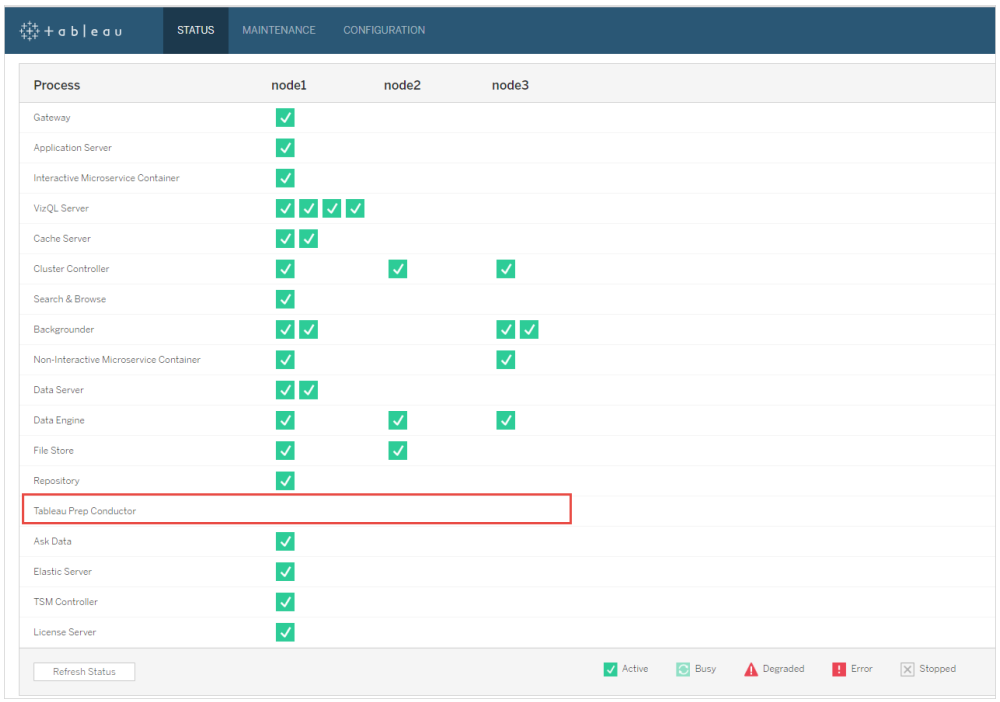

**Tableau Prep Conductor enabled and running:**

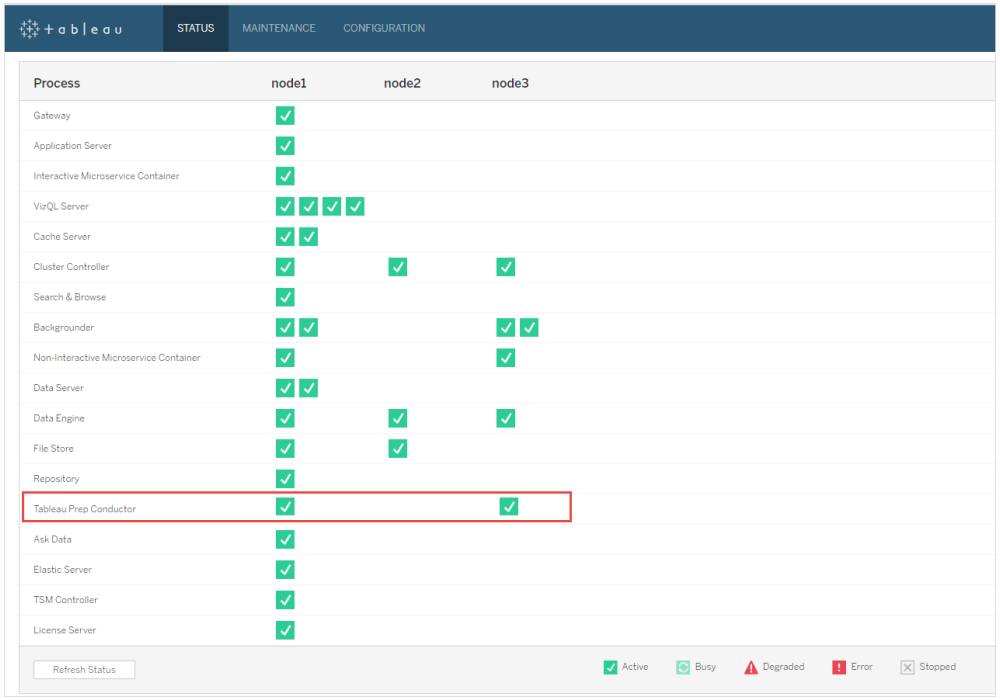


4. Add a new node to your Tableau Server installation. A dedicated node to run flow related operations is recommended for production Tableau Server installations. The installer will enable certain required processes like the Cluster Controller. Enable Backgrounder process on it as it is required to run scheduled flow tasks. When you enable the Backgrounder process, the installer automatically enables a single instance of Data Engine on the node. Do not add any other processes on this node.

   **Note:** The dedicated node counts towards the total count of the Coordination Service ensemble. You may need to deploy a Coordination Service on the new node depending on the total number of nodes you have in your cluster including the new dedicated node. For more information, see Deploy a Coordination Service Ensemble.

   **Important:**
   The number of physical cores on this machine must be equal to, or less than the Tableau Prep Conductor cores you purchased. For example, if you purchased four Tableau Prep Conductor cores, your node can only have up to four physical cores. To understand about how Tableau Prep Conductor licensing works, see Licensing Tableau Prep Conductor for Tableau Server.

5. Run the following commands to dedicate this node to only doing flow tasks. This will enable Tableau Prep Conductor on your new node. For more information, see Node Roles in Tableau Server.

   - Get the nodeID for your dedicated node to see the list of services on each node:

     ```
     tsm topology list-nodes -v.
     ```

   - Set the node role for the dedicated node using the nodeID that you got from running the command described above:

```
tsm topology set-node-role -n nodeID -r flows.
```

- Apply the changes and restart the server:

  ```
  tsm pending-changes apply.
  ```

- Review the status to ensure that all the processes are up and running and configured correctly:

  ```
  tsm status -v.
  ```

6. At this stage, you may have Tableau Prep Conductor enabled on other nodes that have the Backgrounder process. By default, the Backgrounder process on a node performs all tasks of all types including flow tasks. To isolate Tableau Prep Conductor and flow operations to only certain nodes, you can configure the backgrounders to do one of the following:

   - To run only flow tasks:

     ```
     tsm topology set-node-role -n <nodeID> -r flows.
     ```

   - To run all other tasks except flows:

     ```
     tsm topology set-node-role -n <nodeID> -r no-flows.
     ```

Next step

Step 2: Configure Flow Settings for your Tableau Server.

## Who can do this

Tableau Server Administrators can install or upgrade Tableau Server, and enable Tableau Prep Conductor on Tableau Server.

Step 2: Configure Flow Settings for your Tableau Server

This topic describes the various flow settings that you can configure for your Tableau Server. For more information about the different settings needed to enable web authoring for flows,

see Create and Interact with Flows on the Web.

Publishing, Scheduling, and Credential Settings

When you activate Tableau Prep Conductor using the Data Management product key, Tableau Prep Conductor is enabled for the entire Tableau Server installation. You can further modify and customize the setting for sites.

Use the following instructions to configure settings related to flows for all your sites or for individual sites:

Use the following instructions to sign in to Tableau Server Admin pages:

- Windows: Tableau Server Admin Pages.
- Linux: Tableau Server Admin Pages.

**Configure whether publishing and scheduling flow should be allowed for a site:**

1. **Enable users to publish and schedule flows:** This setting is enabled by default when you enable Tableau Prep Conductor. If you have multiple sites, you can selectively turn off Tableau Prep for Server for individual sites. If you disable this setting for a site that once allowed flows, see Implication of disabling Tableau Prep Conductor for more information.

   On the **General** page under **Settings**, scroll to the **Tableau Prep Conductor** section and clear the **Allow users to schedule and monitor flows** check box.

2. **Enable users to link flow runs together using Linked Tasks (version 2021.3 and later):** Enable users to schedule flow tasks to run one after the other. Starting in version 2022.1, this option is enabled by default. In prior versions, administrators needed to enable this feature first.

   If you have multiple sites, you can selectively turn off **Linked Tasks** for individual sites, but the option must first be enabled at the **Server Settings** level.

If the setting is turned off after linked tasks are scheduled, any tasks that are running will complete and the scheduled linked tasks are hidden and no longer show on the **Scheduled Tasks** tab.

3. **Embed Credentials**

   **-Allow publishers to embed credentials in a data source, flow or workbook**: This setting allows publishers to attach passwords to published flows that will automatically authenticate web users.

   **-Allow publishers to schedule flow runs and data extract refreshes**: This option is only available if setting above is enabled. When this setting is enabled, publishers will see scheduling options in the Publish dialog box.

## Implication of disabling Tableau Prep Conductor

If you disable Tableau Prep Conductor after using it for a while, you will not be able to see the flows, schedules, tasks, and other things related to flows. The following table gives you more information on what you can and cannot see when you disable Tableau Prep for Server completely or only for specific sites:

| | **Prep not enabled at Server level** | **Prep enabled at Server level, but disabled for a site** | **Prep enabled for both Server and site** |
|---|---|---|---|
| **Show flows** | Yes | Yes | Yes |
| **Show tasks/schedules in Server view** | No | Yes | Yes |
| **Show tasks/schedules in Site view** | No | No | Yes |
| **Show Site setting (only for Server Admins)** | Yes (disabled) | Yes | Yes |

| | | | |
|---|---|---|---|
| **Show TSM status** | Yes (Tableau Prep Conductor is not shown) | Yes | Yes |
| **Show TSM settings** | Yes (disabled) | Yes | Yes |

**Important**: Scheduled tasks will continue to run even when Tableau Prep Conductor is disabled for that site, but will fail.

Configure notifications for flow failures

You can configure Tableau Server to send email notifications for flow run failures. The notifications are sent for failures that occur when running the flows through either a scheduled task, linked task, or a manual run using the **Run now** menu option. You must first enable the server-wide setting, and then configure at the site level.

## To enable the server-wide email notification

You can either use the Tableau Services Manager (TSM) web interface or TSM CLI as described below:

## Use the TSM web interface

1. Open TSM in a browser:

   https://<tsm-computer-name>:8850.

2. Click **Notifications** on the **Configuration** tab and click **Email Server**.

3. Enter the email server information.

4. Click the **Events** tab.

5. Under **Content Updates**, select **Send emails when flow runs, encryption jobs, or scheduled refreshes fail** if not already turned on by default.
6. Click **Save Pending Changes** after you've entered your configuration information.
7. Click **Apply Changes and Restart**.

## Use the TSM CLI

The notification values can be set individually with the tsm configuration set command:

Windows: tsm configuration.

Linux: tsm configuration.

### Set notification values

Use the tsm configuration set command with the following syntax to

to enable flow failure notifications, run the following command:

```
tsm configuration set -k backgrounder.notifications_enabled -v true
```

> **Note:** This will enable email notification for both extract refresh failures and flow failures.

After you are done setting values, you must run the following command:

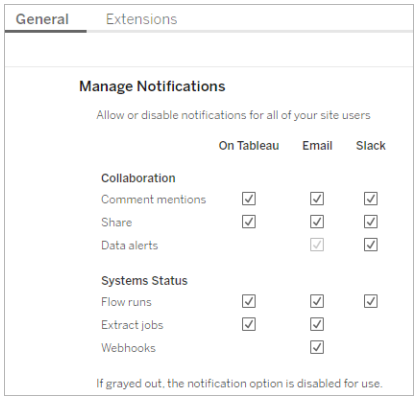
```
tsm pending-changes apply
```

The pending-changes apply command displays a prompt to let you know this will restart Tableau Server if the server is running. The prompt displays even if the server is stopped, but in the case there is no restart. You can suppress the prompt using the --ignore-prompt option, but this does not change the restart behavior.

## To configure notification for a site:

On the **General** page under **Settings**, scroll to the **Manage Notifications** setting and select the notification types that you want site users to receive.

You can receive notifications as an email, on the Tableau site, or in your Slack workspace if your administrator has connected your site to Slack. For more information, see Site Settings Reference.



**Note:** Recreate your notifications settings when upgrading from 2020.4 or earlier to 2021.1 and later. Older notifications settings are not automatically moved to the Manage Notifications setting.

Next step

Step 3: Create Schedules for Flow Tasks

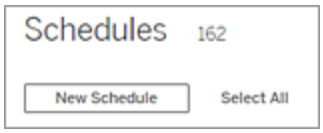
## Who can do this

Tableau Server Administrators can configure server and site level settings. Tableau Site Administrators can configure site level settings.

### Step 3: Create Schedules for Flow Tasks

Create a new schedule:

1. On the **Schedules** tab, click **New Schedule**.

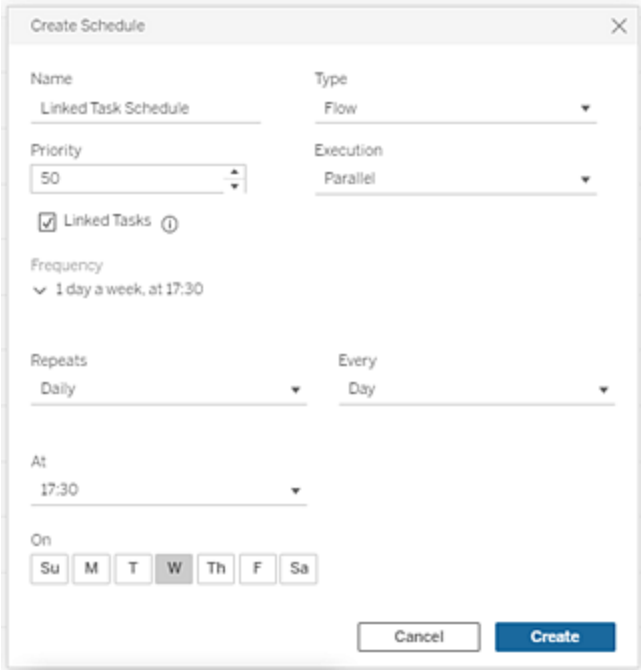


2. Enter the following information in the **New Schedule** dialog box and click **Create**.

   - **Name:** Enter a descriptive name for the schedule. Typically, this includes the description of the schedule frequency.
   - **Type:** Select Flow as the task type.
   - **Priority:** You can define a default priority from 1 to 100, where 1 is the highest priority. This value will be assigned to the tasks by default. If two tasks are pending in the queue, the one with the higher priority runs first.
   - **Execution:** Choose whether a schedule will run in parallel or serially. Schedules that run in parallel run on all available backgrounder processes so that they can complete faster.
   - **Linked Tasks (version 2021.3 and later):** Select the check box if the schedule can be used to schedule flows to run one after the other. Linked tasks require a **Parallel** execution method.

     Starting in version 2022.1, this option is enabled by default. In prior versions, the Server Administrator must first enable linked tasks for the server before you can configure schedules to support linked tasks. For more information, see Step 2: Configure Flow Settings for your Tableau Server

- **Frequency:** You can define an hourly, daily, weekly, or monthly schedule.



Next step

Step 4: Safe list Input and Output locations

## Who can do this

Tableau Server Administrators can create and modify schedules. Schedules are created at the server level and apply across all the sites on a server.

Step 4: Safe list Input and Output locations

This topic describes the rules that apply to this feature and how to safe list the directories on your network.

Flow input and output connections may need to connect to databases or files in the directories on your network. You must safe list the directories you want to allow access to. Input and Output connections will only be allowed to connect to data in the safe listed locations. By default, no connections are allowed.

> **Note**: You can still publish the flows and any data that is embedded in the flow file (tflx) to Tableau Server, but the flow will fail to run if the directories aren't included in your organization's safe list.

How to safe list input and output locations

The following rules apply and must be considered when configuring this setting:

- The directory paths should be accessible by Tableau Server. These paths are verified during server startup and at flow run time and are **not** verified at the time of publishing the flow to Tableau Server.
- If the flow reads from or writes to a .hyper file on a network share, add the path to the directory containing the file to the native_api.allowed_paths allowlist. For more information, see tsm configuration set Options.
- Network directory paths have to be absolute and cannot contain wildcards or other path traversing symbols. For example, `\\myhost\myShare\*` **or** `\\myhost\myShare*` are invalid paths and would result in all the paths as disallowed. The correct way to safelist any folder under *myShare* would be `\\myhost\myShare` **or** `\\myhost\\myShare\`.

  > **Note:** The `\\myhost\myShare` configuration will not allow `\\myhost\myShare1`. In order to safe list both of these folders safe list them as \\myhost\myShare; \\myhost\myShare1.

- **Windows:**
  - The value can be either `*`, (for example, `tsm configuration set -k maestro.input.allowed_paths -v "*"`) to allow any network directory, or a specified list of network directory paths, delimited by a semicolon (**;**). If you

specify a list of directory paths, be sure to specify particular directories rather than the root of the file share.

- If the path contains spaces or special characters you will have to either use single or double quotes. Whether you use single or double quotes depends on the shell that you are using.
- No local directory paths are allowed even when the value is set to `*`.
- To save flow output to a network share, you must first configure a Run As user service account on Tableau Server. You cannot save flows to a network share using the default system account. Then configure the target directory on the network share for Full Control permissions for the Run As user account you created.

  Depending on how your organization manages nested folder permissions, you may need to grant additional permissions in the folder hierarchy, with a minimum of Read, Write, Execute, Delete, and List Folder permission, to allow the Run As user account access to the target folder.

- **Linux:**
  - The value can be either `*`, (for example, `tsm configuration set -k maestro.input.allowed_paths -v "*"`) meaning that any path, including local (with the exception of some system paths configured using “native_api.internal_disallowed_paths”), or a list of paths, delimited by a semicolon (**;**).
  - You must be using a kernel version equal to or later than 4.7. Safe listing to or from a network share is not supported on kernel versions earlier than 4.7. On earlier versions, when the output is written to a network share, hyper fails to output files, resulting in flows failing at runtime. When reading input files from a network share on earlier versions, flow executions fail. To check the kernel version, in the Linux terminal, type the command `uname -r`. This will display the full version of the kernel you are running on the Linux machine. Note that for Red Hat

Enterprise Linux, kernel version 4.7 and later is only available with Red Hat Enterprise Linux version 8.

- To save flow output to a network share, the local Linux account that has access to Tableau Server resources must be given Full Control permissions to the target directory on the network share. If a path is both on the flows allowed list and internal_disallowed list, internal_disallowed takes precedence.
  The mount points for both input and output paths used by flows must to be configured using the `native_api.unc_mountpoints` configuration key. For example:
  `tsm configuration set -k native_api.unc_mountpoints -v 'mountpoints'`
  For information about configuring this, see this Tableau Knowledge Base article: Tableau Server on Linux - How to Connect to a Windows Shared Directory.

Use the following commands to create a list of allowed network directory paths:

**For input connections:**

```
tsm configuration set -k maestro.input.allowed_paths -v your_networkdirectory_path_1;your_networkdirectory_path_2

tsm pending-changes apply
```

**For output connections:**

```
tsm configuration set -k maestro.output.allowed_paths -v your_networkdirectory_path_1;your_networkdirectory_path_2

tsm pending-changes apply
```

Important:
These commands overwrite existing information and replace it with the new information you provided. If you want to add a new location to an existing list, you must provide a list of all the locations, existing, and the new one you want to add. Use the following commands to see the current list of input and output locations:

```
tsm configuration get -k maestro.input.allowed_paths
tsm configuration get -k maestro.output.allowed_paths
```

Next step

Step 5: Optional Server Configurations

## Who can do this

On Windows, members of the local computer Administrators group can run *tsm* commands.

On Linux, members of the **tsmadmin** group can run *tsm*commands. The **tsmadmin** group can be configured using the *tsm.authorized.groups* setting.

Step 5: Optional Server Configurations

The options described in this topic are not required to enable flow publishing and scheduling flows on Tableau Server. They can be used to customizing your environment according to your requirements.

Set the timeout period for flows

You can set time limits for how long a flow can run to make sure that subsequent tasks are not held up due to stalled tasks. The following two *tsm* command options determine how long a flow task can run before the flow background task is canceled. These two commands together determine the total timeout value for flow tasks.

The `backgrounder.default_timeout.run_flow` sets the number of seconds before a flow run task is canceled.

For example:

```
tsm configuration set -k backgrounder.default_timeout.run_flow -v
<new value>

tsm pending-changes apply
```

(Default value: 14400 seconds or 4 hours)

The `backgrounder.extra_timeout_in_seconds` command sets the number of seconds beyond the setting in `backgrounder.querylimit` before a background job is canceled. This setting makes sure that a stalled job does not hold up subsequent jobs. The setting applies to processes listed in `backgrounder.timeout_tasks`.

For example:

```
tsm configuration set -k backgrounder.extra_timeout_in_seconds -v
<value>
```

(Default value: 1800 seconds or 30 minutes)

Check the available resources on the server running flows. It's recommended that you have a dedicated node for Tableau Prep Conductor.

Set the threshold for suspended flow tasks

By default, a flow task is suspended after 5 consecutive flow task failures. To change the threshold number of flow task failures that can occur before they are suspended, use the following tsm configuration set command:

```
tsm configuration set -k backgrounder.flow_failure_threshold_for_
run_prevention -v <number>
```

This sets the threshold for the number of consecutive failed flow tasks necessary before suspending the tasks. This is a server-wide setting.

## Who can do this

Tableau Server administrators can make changes to server configurations.

### Schedule Flow Tasks

**Note**:Flows can be scheduled to run on Tableau Cloud or Tableau Server using Tableau Prep Conductor. Prep Conductor is licensed through Data Management on a per

deployment basis. After you purchase and license Data Management, you must enable Prep Conductor.
Starting in version 2020.4.1, you no longer need the Data Management license to publish flows to the web. As a Creator, you can also create and edit flows directly on your server. For more information authoring flows on the web, see Tableau Prep on the Web.

**Note**: With the 2024.1 release, changes were introduced for flow schedules on Tableau Cloud. The Schedules tab on the left navigation pane has been removed and users with permissions to schedule flow tasks can now create custom schedules directly from the flows Scheduled Tasks tab.

To schedule flows to run at a specific time or on a recurring basis you can create scheduled tasks. Scheduled tasks rely on pre-configured schedules. Schedules are created by the System Administrator. For information about how to create schedules on Tableau Server, see Step 3: Create Schedules for Flow Tasks in the Tableau Server help.

Starting in version 2021.3, you can link flow runs together when scheduling tasks to run flows one after the other. For more information, see Schedule linked tasks in this topic.

Starting in version 2022.1, you can also run linked tasks via the REST API using the new flow methods **Query Linked Tasks**, **Query Single Linked Tasks**, and **Run Linked Task Now**. For more information, see Flow Methods in the Tableau REST API help.

**Running flows that include parameters**

Starting in version 2021.4, you can include user parameters in your flows to make flows more dynamic. When the flow runs, you are prompted to enter your parameter values. When setting up flows on a schedule, you specify parameter values at that time.

You must specify the parameter values for any required parameters. For optional parameters, you can enter those values as well, or accept the current (default) value for the parameter. For more information about running flows with parameters, see Run flows on a schedule in the Tableau Prep help.

Starting in Tableau Prep Builder and Tableau Cloud version 2023.2, you can apply date or time system parameters to flow output names for file and published data source output types. The start time is automatically added to the flow output name.

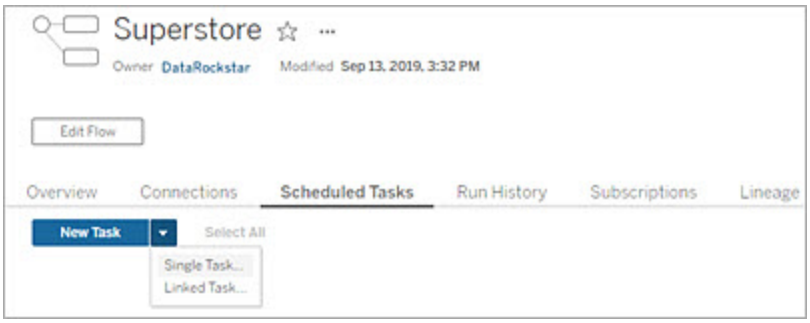
**Note**: Your administrator must enable the **Flow Parameter** server and site settings on your server before you can run flows that include parameters in Tableau Server or Tableau Cloud. For more information, see **Create and Interact with Flows on the Web** in the Tableau Server or Tableau Cloud help.

Schedule a flow task

1. Do one of the following:

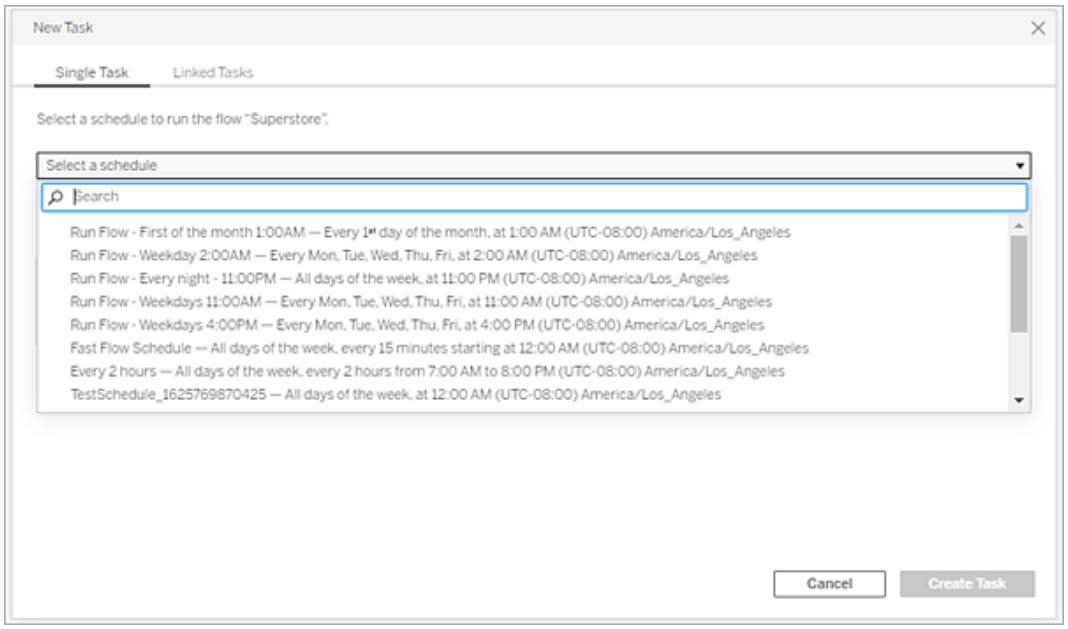
   - (version 2022.1 and later) From the **Explore** page, in **List** view, in the **Actions** menu, select **Schedule Flow** > **Single Task**. If you select a flow in the list, you can also use the top **Actions** menu.

   - From the **Overview** page for the flow, **Scheduled Tasks** tab, click **New Task** or click the drop-down and select **Single Task**.



If the output step isn't assigned to a task, you can also create a new task from the **Overview** page. On that page, in the **Schedules** field, click **Create new task**.

2. In the **New Task** dialog, on the **Single Task** (**New Task** in prior releases) tab, select a schedule from the drop-down list.

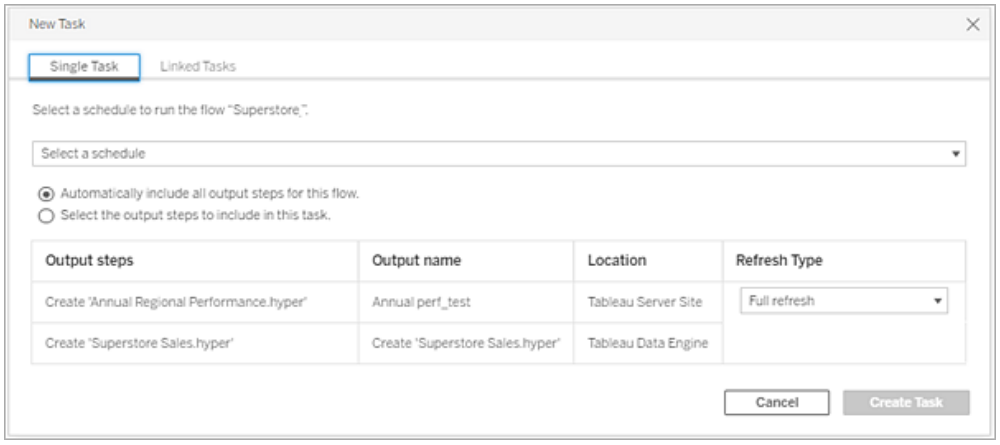


3. Select one of the following options:

- **Automatically include all output steps for this flow:**(default) Select this option to include all current and future output steps for this flow in the scheduled task. As new output steps are added to the flow over time, they are automatically included in the schedule when it runs.

- **Select the output steps to include in this task**: Select this option and manually select the output steps to include in this scheduled task.

  To include all output steps in the flow task, select the check box next to **Output Steps**. This area can't be edited if the **Automatically include all output steps for this flow** radio button is selected. Select the other radio button to enable this section.

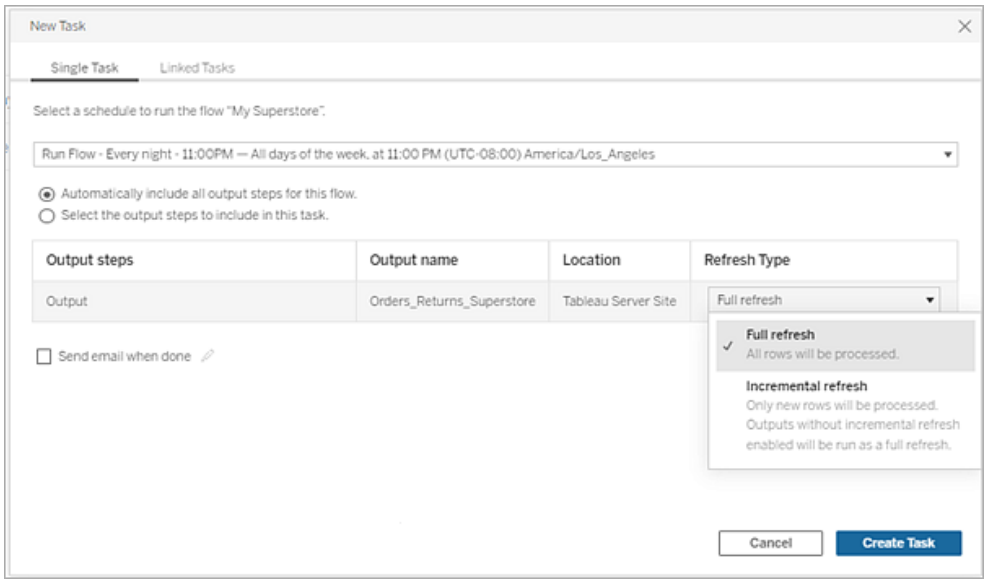


4. (version 2020.2.1 and later) Select a **Refresh Type**. For more information about these settings, see Refresh Flow Data Using Incremental Refresh.

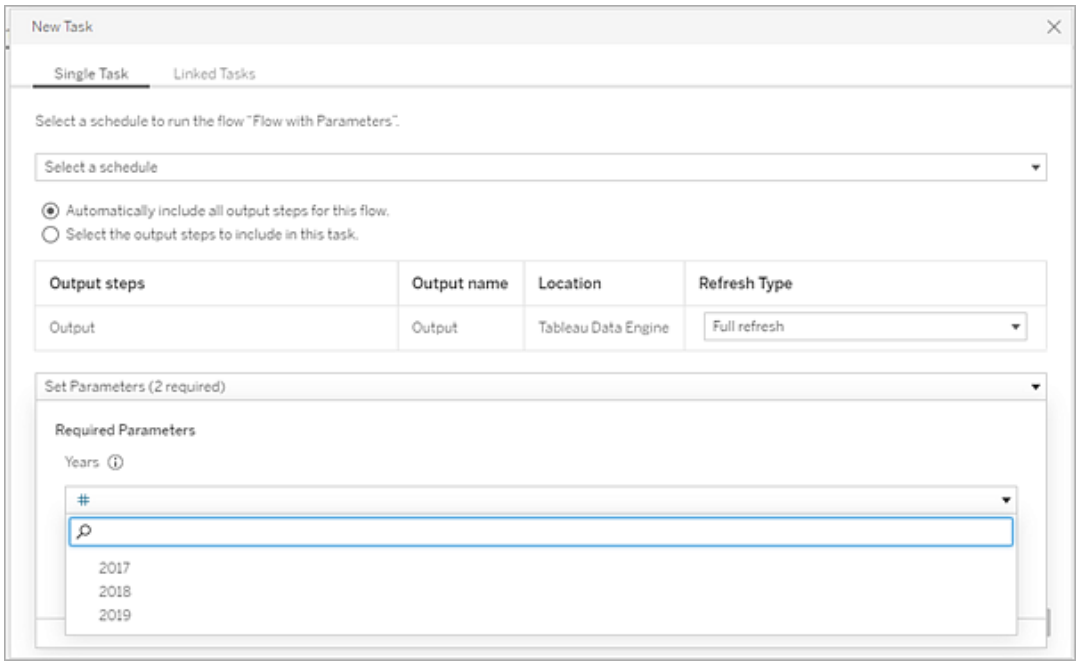
> **Note**: Starting in version 2020.2.1 and later, if one input is configured to use incremental refresh and it is associated with multiple outputs, those outputs must be run together and must use the same refresh type. Otherwise the flow will fail.

- **Full refresh** (default): Refresh all data and create or append data to your table based on the flow output setting.
- **Incremental refresh**: Refresh only the new rows and create or append data to your table based on the flow output setting. The incremental refresh option is only available when the flow is configured to use this refresh type.

> **Note**: Tableau Prep Conductor runs a full refresh for all outputs regardless of the run option you select if no existing output is found. Subsequent flow runs will use the incremental refresh process and retrieve and process only your new rows unless incremental refresh configuration data is missing or the existing output is removed.



5. (optional) If you are the flow owner, select **Send email when done** to notify users when the flow is successful. For more information about how to send email notifications on flow runs, see Notify Users of Successful Flow Runs.
6. (version 2021.4 and later) If your flows include parameters, enter any required or optional parameter values. You must enter required values for the flow to run.



7. Click **Create Task** to create the scheduled task.

Schedule linked tasks

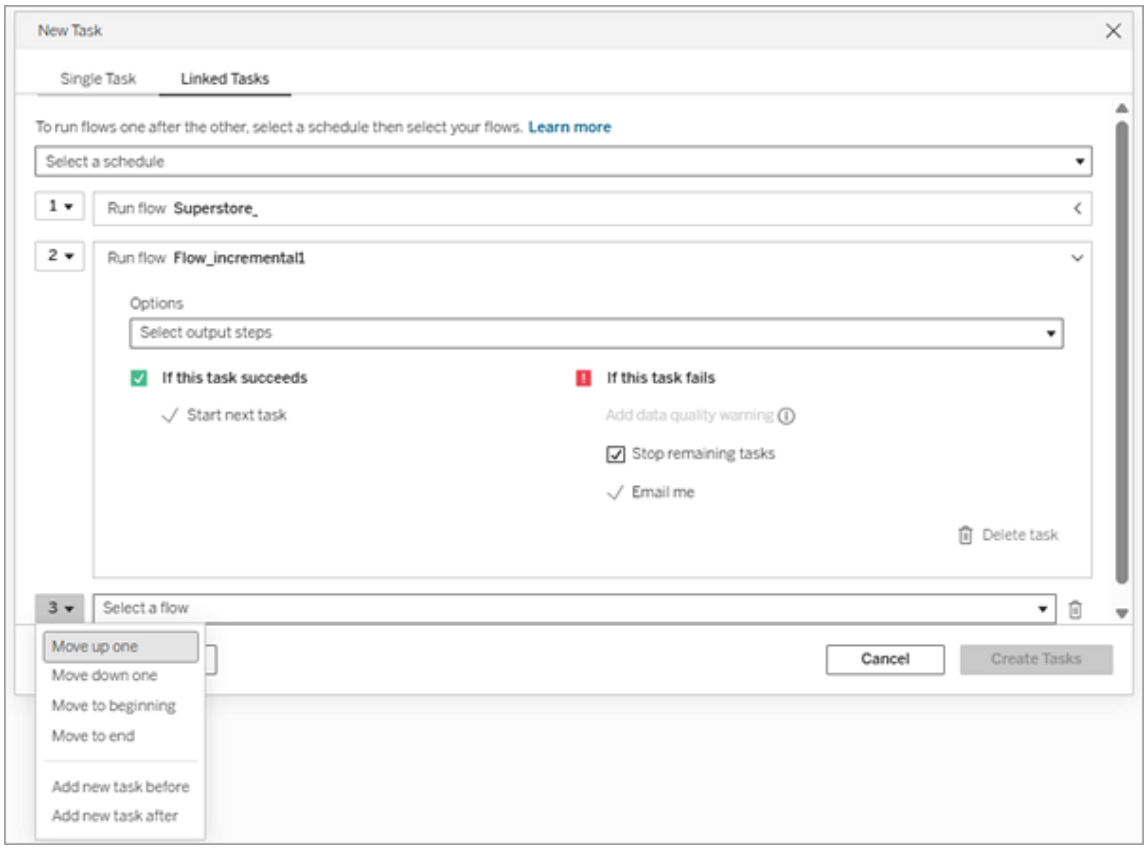
*Supported in Tableau Server and Tableau Cloud version 2021.3.0 and later.*

**Note**: Starting in version 2022.1, Linked tasks functionality is enabled by default. Server and Site Administrators can turn off this functionality on the **Settings** page and on flow schedules in the **Schedules** dialog. In previous versions, Server Administrators must first enable this functionality to use and manage it. For more information, see Step 2: Configure Flow Settings for your Tableau Server and Step 3: Create Schedules for Flow Tasks.

Use the **Linked Tasks** option to schedule up to 20 flows to run sequentially, one after the other. Easily set up your flow list by selecting your schedule, then select downstream flows to run in the order you choose.

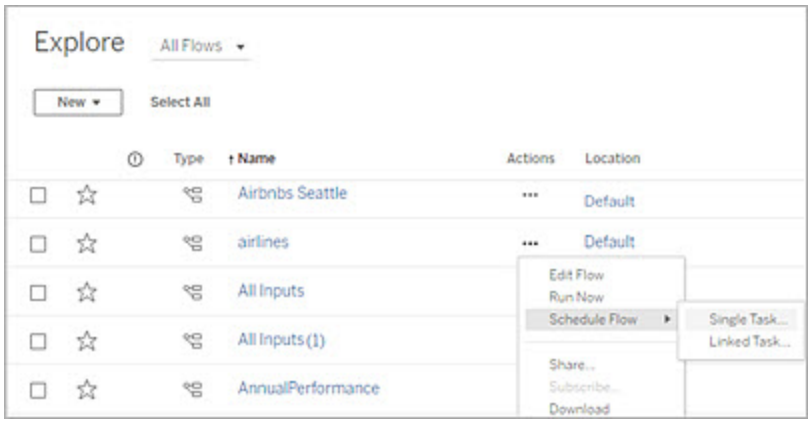
Flows run in the order specified in the list. Use the menu to move flows around in your list or add new upstream or downstream flows to the list at any time.

Select the outputs that you want to include in the flow run and configure the settings to tell Tableau what to do with remaining flows in the schedule when the previous flow run fails.

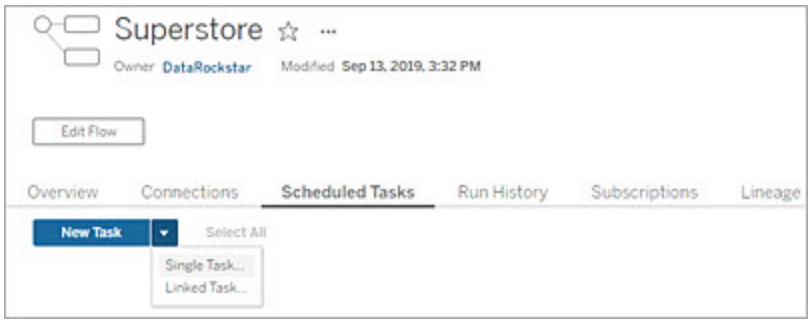


1. Do one of the following:

    - (version 2022.1 and later) From the **Explore** page, in **List** view, in the **Actions** menu, select **Schedule Flow** > **Linked Task**. If you select multiple flows in the list, you can also use the top **Actions** menu.

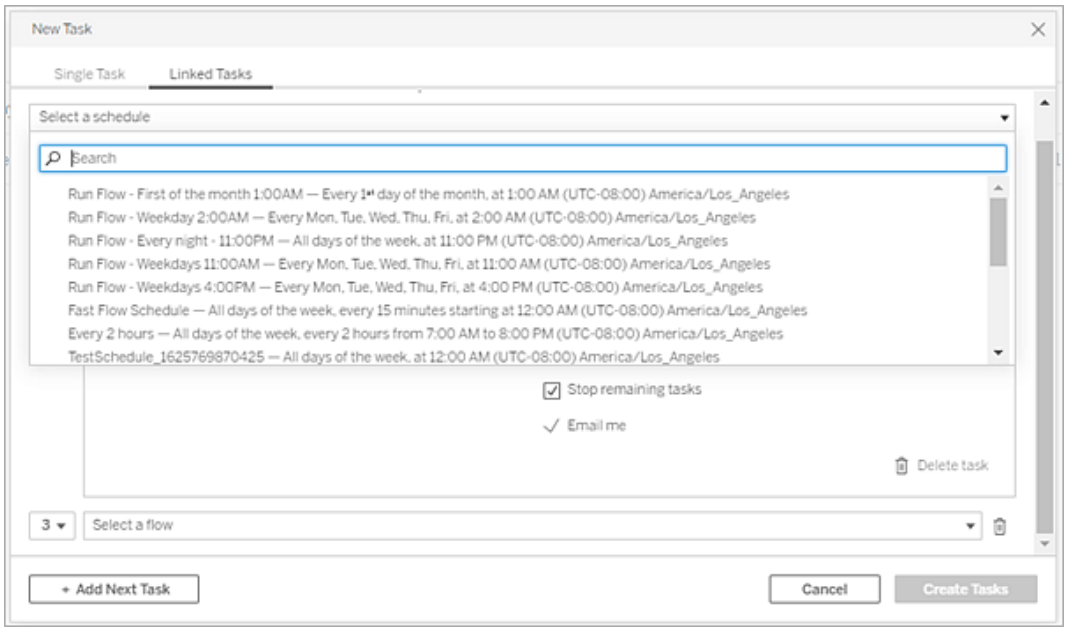


- From the **Overview** page for the flow, **Scheduled Tasks** tab, click **New Task** and select the **Linked Task** tab, or click the drop-down and select **Linked Task**.



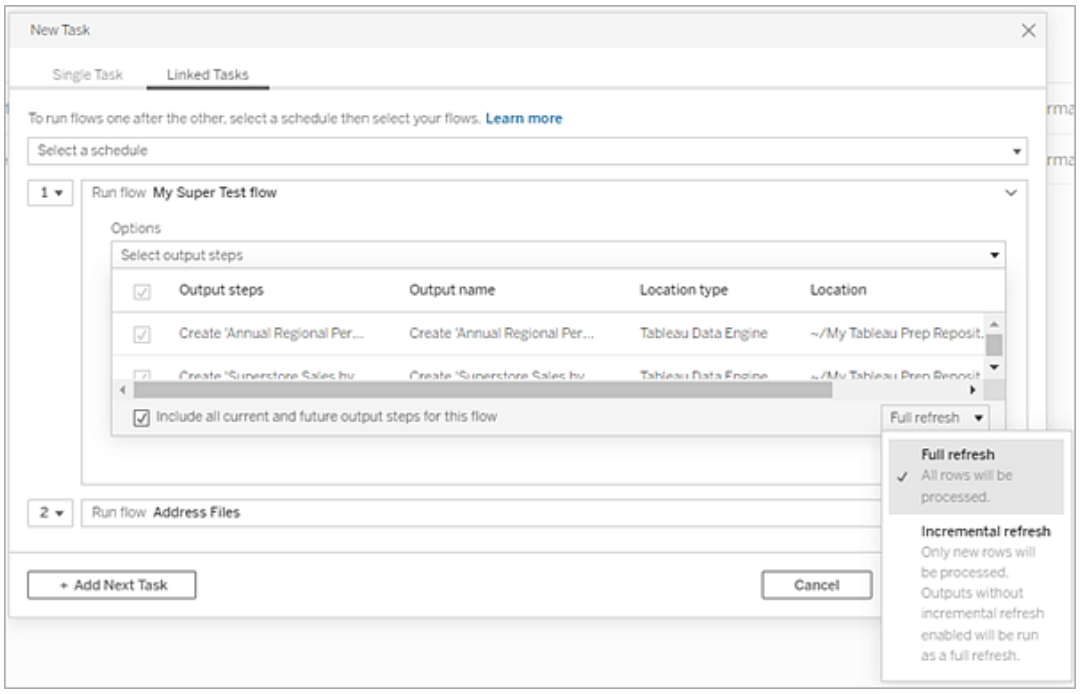
If the output step isn't assigned to a task, you can also create a new task from the **Overview** page. On that page, in the **Schedules** field, click **Create new task**.

2. In the **New Task** dialog, on the **Linked Tasks** tab, select a schedule from the drop-down list. Only schedules that are enabled for linked tasks are shown.



3. Click the **Select output steps** drop-down to select the flow outputs to run. By default, all flow outputs are included. To select specific outputs, clear the **Include all current and future output steps for this flow** check box.

   The flow where the task is initiated is automatically set as the first flow to run, but you can use the menu to change the run order after you add other flows to your list.



4. Select your refresh type from the following options:

> **Note**: If one input is configured to use incremental refresh and it is associated with multiple outputs, those outputs must be run together and must use the same refresh type. Otherwise the flow will fail.

- **Full refresh** (default): Refresh all data and create or append data to your table based on the flow output setting.
- **Incremental refresh**: Refresh only the new rows and create or append data to your table based on the flow output setting. The incremental refresh option is only available when the flow is configured to use this refresh type. For more information, see Refresh Flow Data Using Incremental Refresh.

> **Note**: Tableau Prep Conductor runs a full refresh for all outputs regardless of the run option you select if no existing output is found. Subsequent flow runs will use the incremental refresh process and retrieve and process only your new rows unless incremental refresh configuration data is missing or the existing output is removed.

5. (optional) If you are the flow owner, select **Send email when done** to notify users when the flow is successful. For more information about how to send email notifications on flow runs, see Notify Users of Successful Flow Runs.

6. Add a data quality warning. You can turn flow run monitoring on or off at the flow level to generate a data quality warning that shows on the flow if the flow run fails. For more information about turning on data quality warnings see, How to turn on a monitoring quality warning.

   - From the **More Actions** ··· menu, next to the Flow name, select **Data Labels** > **Flow Run Monitoring**.
   - In the Flow Run Monitoring dialog, turn flow run monitoring on or off and optionally enter a warning message so that users of the data are aware of issues. The message remains until the flow runs successfully.

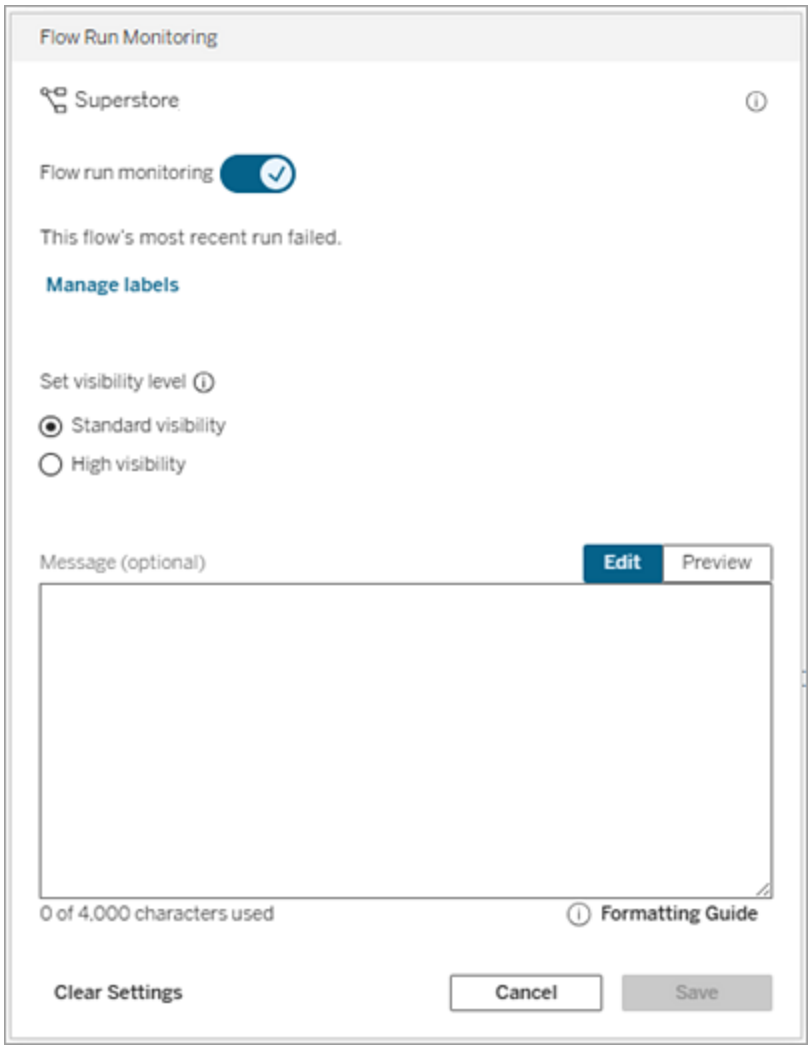
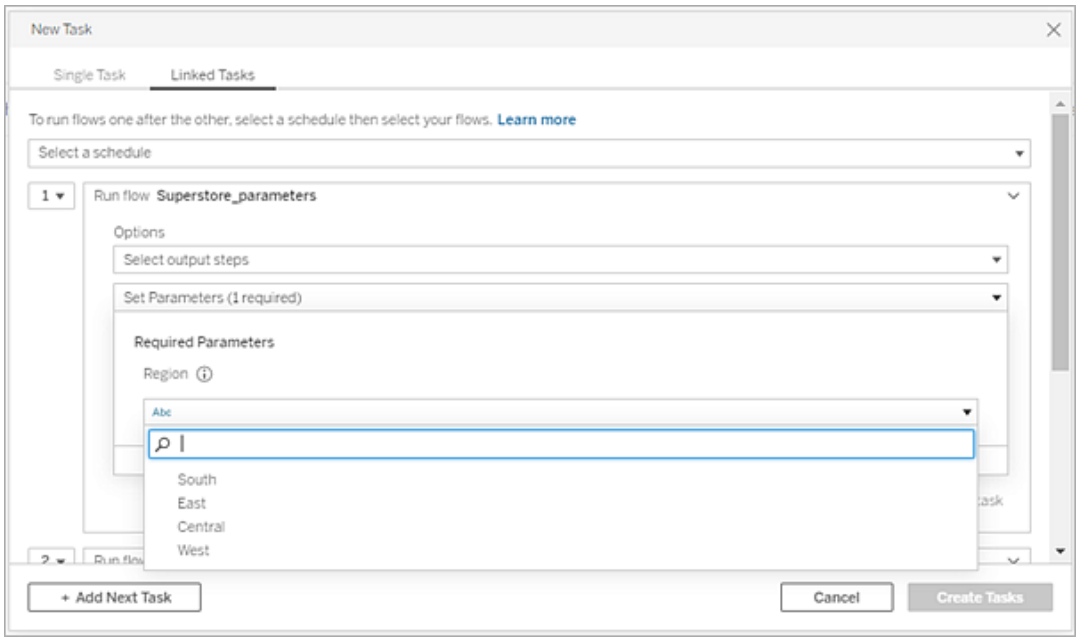
Flow Run Monitoring...

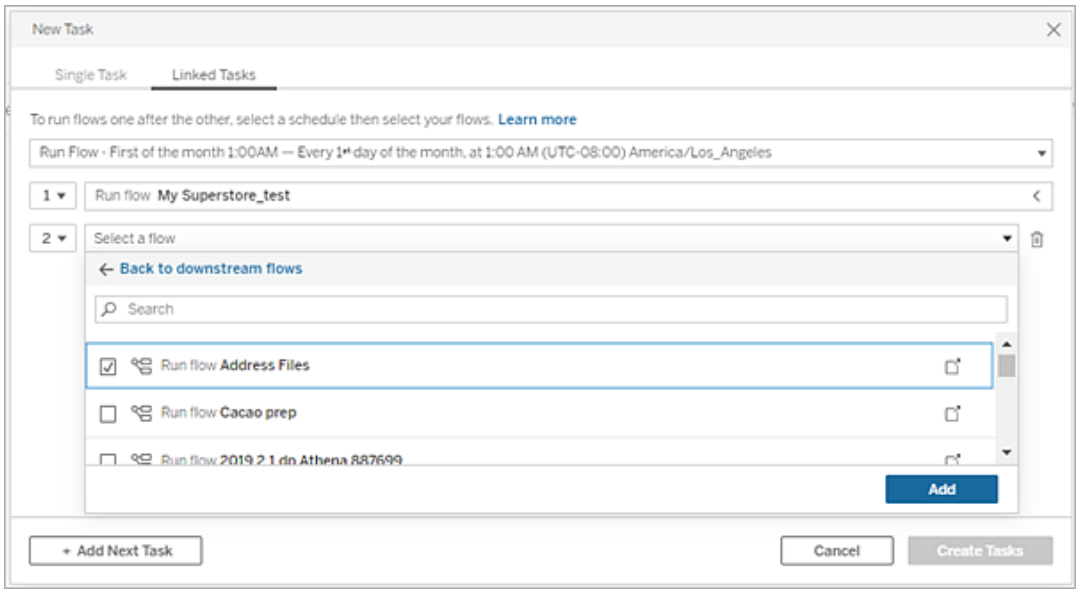


7. Set remaining flow failure options:
   - **Stop remaining tasks**: Select this option to prevent the downstream tasks in the list from being queued to run.
   - **Email me**:Email notifications are automatically sent to the flow owner and the linked task creator when the flow fails, is suspended, or is canceled.
8. (version 2021.4 and later) If your flows include parameters, enter any required or optional parameter values. You must enter required values for the flow to run.

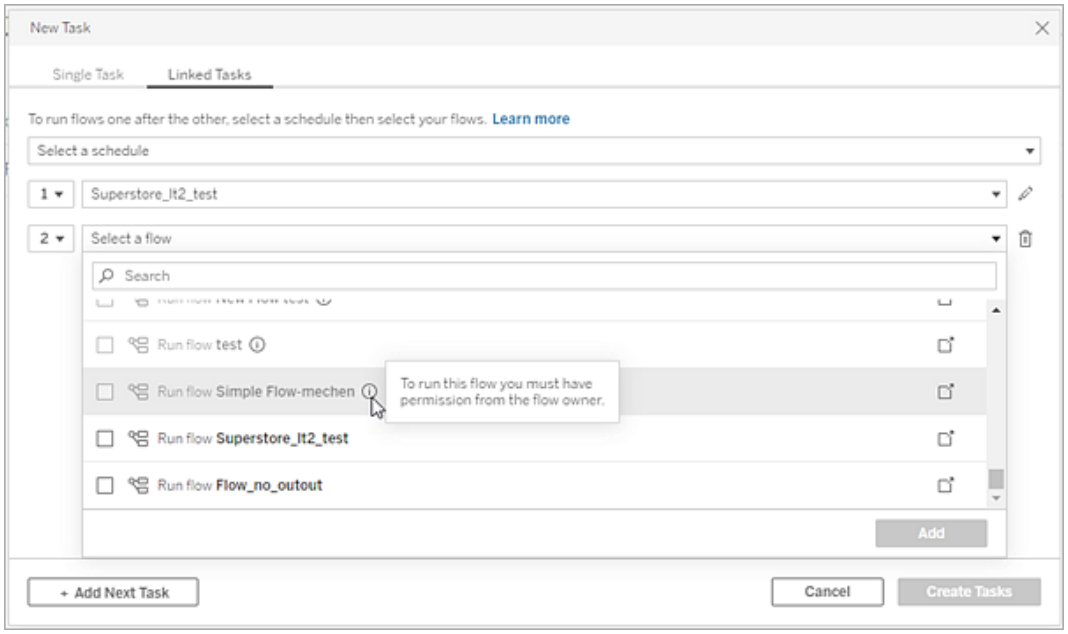


9. Click the drop-down for the 2nd task to add your next flow. Flows that use the previous flow's outputs are shown automatically or click **View all flows** to see all available flows.

   Select one or more flows and click **Add** or click **Add Next Task** to add more flow run tasks to your list.



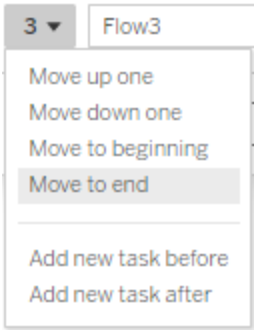
If you don't have permission to run the flow, you must contact the flow owner to grant permissions before adding the flow to your list.



10. Repeat steps 3-5 to configure your flow run options.

> **Note**: In version 2021.4 and earlier, click the **Edit** icon next to your new flow to expand the Options pane.

11. (Optional) Click the drop-down next to any numbered task to open the menu to change the order of your flow tasks or insert new tasks between existing tasks.



12. Click **Create Tasks** to create the scheduled linked tasks.

Who can do this

- The Server administrator can do this on all sites on the server. The Site administrator can do this on sites they have access to if the site settings to allow users to publish and schedule tasks is enabled.
- For linked tasks, the Server administrator can do this on all sites where the server settings to allow users to schedule linked tasks is enabled. The Site administrator can do this on sites they have access to if the site settings to allow users to schedule linked tasks is enabled.
- Flow owners and project leaders with the Creator site role can create flow tasks for flows or projects that they own respectively.

Site administrators, flow owners, and project leaders can create flow tasks for the flows and projects that they own respectively. Only the Creator site role and above can create or edit a flow task.

For more information, see Set Users' Site Roles and Content Ownership and Permissions

## Notify Users of Successful Flow Runs

*Supported in Tableau Prep Builder version 2021.4.1 and later and in Tableau Server and Tableau Cloud version 2021.4 and later. Data Management is required to use this feature.*

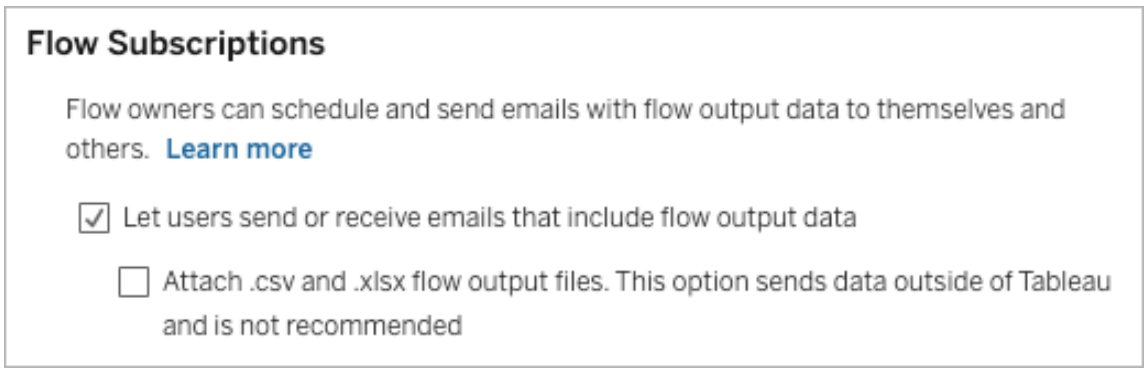
Flow owners can subscribe themselves, individual users, and groups to email notifications for information about scheduled tasks for successful flow runs. The email includes links to data

within the Tableau environment, and in Tableau Server, you can optionally include the details of the flow run in attached Excel and CSV files.

Flow subscriptions are added to scheduled tasks for flows. You can add flow subscriptions when you create a new flow task or to an existing flow task. Email notifications are sent when the scheduled task is completed successfully.

Configure the site settings for flow subscriptions

By default, the **Flow Subscriptions** site setting for sending and receiving email notifications is enabled.



- The **Let users send or receive emails that include flow output data** option allows the flow owner to receive, and subscribe users and groups to successful flow run notifications. From the notification email, users can access the full data source or view the flow details from within Tableau.
- Tableau Server only (not recommended): The **Attach .csv and .xlsx flow output files** option lets the flow owner attach files to notification emails. The email recipients must be added to Tableau server, however, the files contain the data source and can be exposed outside of the Tableau system. This option is available only for on-premise environments.

Publish the Flow

Publish the flow output as either a file, database table, or data source. Consider the following when saving the flow:

- (On-premise only) When publishing you can save the output as a file or as a database table and choose to attach either a .csv or .xlsx file type to the email.
- When publishing and saving the output as a published data source, the email notification provides a link to the flow in Tableau. Files cannot be attached to the email.
- When choosing to save as a file output, you must use a network share and the output and input location must be included in a safe list. For more information, see Step 4: Safe list Input and Output locations.
- Flow subscriptions are supported on Windows and Linux. The following restrictions apply to flow subscriptions on Linux:
  - File outputs must be output to a Windows server.
  - For flows that output to a file, use the UNC format for the path: *server**path**file-name*. Do not use a local drive letter.
  - The mounted path must be safe listed.
- When attaching files to an email, the file limit is approximately 25 MB for Tableau Cloud. When using an on-premise Tableau Server, you configure the size of attachment files.

Add a flow subscription

1. As the owner of the flow, select a published flow in Tableau Server or Tableau Cloud that you want to add subscriptions to for email notifications.
2. You can add subscriptions to a new or existing task:
   - If you are adding a subscription to a new task:
     1. Click **Scheduled Tasks** > **New Task**.
     2. In the New Task dialog select a schedule to run the flow from the **Select a schedule** drop-down list.
     3. Enable **Send email when done**

- If you are adding a subscription to an existing task:
  1. Click **Subscriptions** > **Subscribe**.
  2. In the **Add Flow Subscriptions** dialog, select a schedule from the **Frequency** drop-down list.

3. In the **Send to** field, start typing the name of the user or group to populate the field. Select the users and groups that you want to send a notification to.

   Users and groups must be added to the Tableau environment by the administrator.

4. (Optional) To be included in the notification, check the **Send to me** box.

5. (Optional) In the **Subject** field, customize the default email subject line for the flow run notification.

6. (Optional) Add information about the flow run in the **Email message** text box.

7. Click **Include output data** and select the type of output that you want to include in the email.

   - In Tableau Server, if you published your flow as a file or database table output you can choose to attach .csv or .xlsx files containing the data source to the email. This is not recommended because data can be exposed outside of the Tableau system.

   - If you published your flow as a data source, you can choose to include the link to the data source. Attaching files to the email is not supported.

8. If you are adding a subscription to an existing task, click Subscribe.

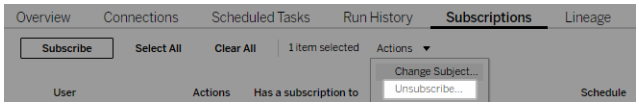
Unsubscribe from a flow subscription

To unsubscribe from notifications from the email, follow these steps.

1. Click **Unsubscribe** from the bottom of a subscription email.
2. As the flow owner, Sign in to Tableau Server or Tableau Cloud. At the top of the page, click the **Notifications** icon.
3. Expand the **…** menu, then select **Remove notification**.

To unsubscribe and remove the subscription as the flow owner, follow these steps.

1. Click **Subscriptions**.
2. Open the published flow in Tableau Server or Tableau Cloud.
3. From the list of flow subscriptions, click the selection box for the flow you want to unsubscribe from.
4. Select **Actions** > **Unsubscribe**.



View Subscriptions

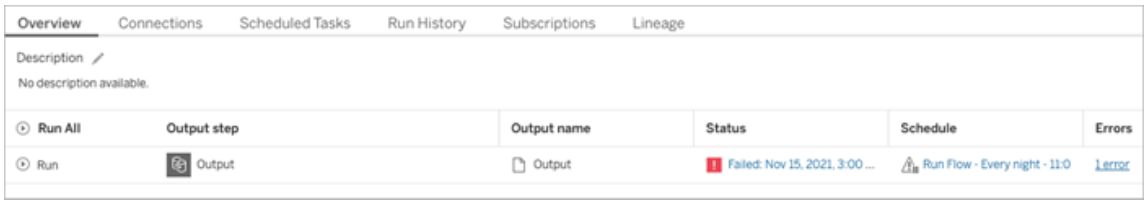
You can view your current flow subscriptions in Tableau Server or Tableau Cloud.

- From the **Subscriptions** tab on the **Overview** page of the flow, you can see the list of current subscriptions.
- From the **Subscriptions** tab on the **Tasks** page, you can see the list of subscriptions along with subscriptions to workbooks.

Resume suspended flow subscriptions

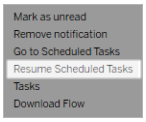
Sometimes, subscriptions fail because of an issue with the flow. If a subscription fails more than five times, you'll receive a notification email thatyour scheduled flow task has been suspended.

From the flow Overview page, you can see when a scheduled flow task fails.

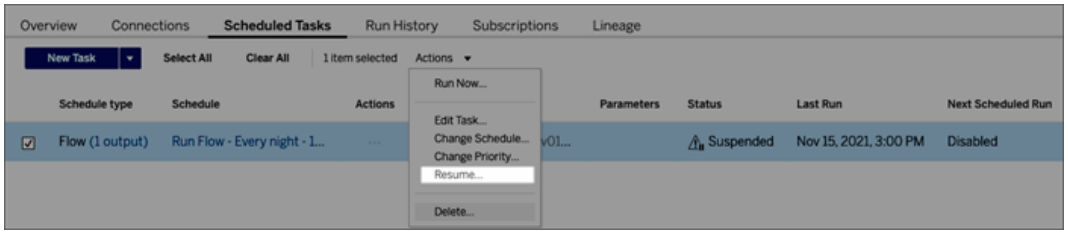


There are a few ways to resume a suspended flow task. If you're flow owner:

- From the My Content area of Tableau web pages, an icon appears in the Last update column to indicate that the subscription is suspended. Select **...** > **Resume Scheduled Tasks** to resume.



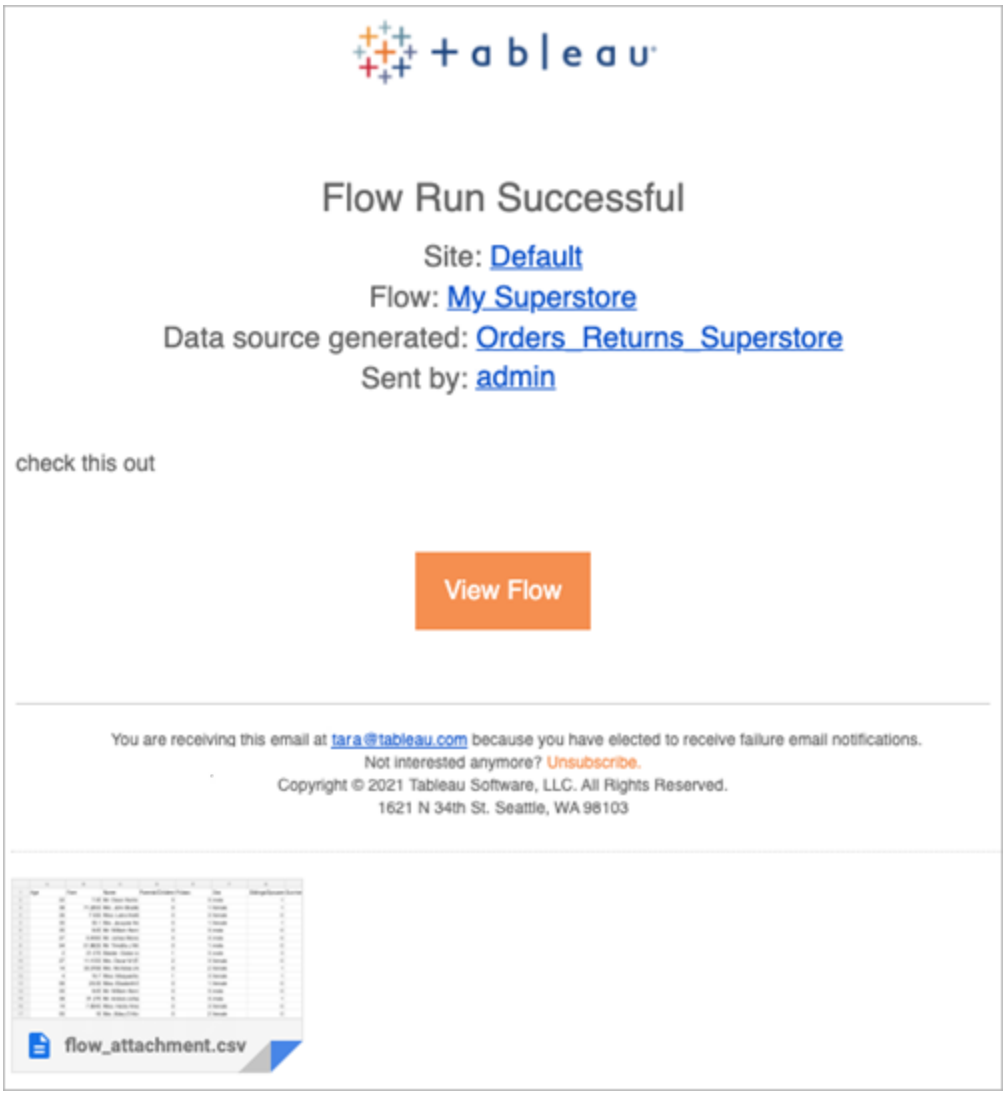
- From the Scheduled Tasks page, an icon appears in the last update column to indicate that the subscription is suspended. Select the flow, then click **Actions** > **Resume**.



Access the flow data from a notification email

Depending on how the flow notification was configured, you can access the data source and file attachments from the notification email.

- Click View Flow to open the flow in Tableau Server or Tableau Cloud.
- Click the attachment file to view the flow data.



Who can do this

- Flow owners can create flow notification subscriptions for flows that they own.
- To receive notifications, users and groups must be added to the Tableau environment by the administrator.

For more information, review the following articles:

- Windows: Set Users' Site Roles and Content Permissions and Ownership
- Linux: Set Users' Site Roles and Content Permissions and Ownership

## Manage a Flow

Once you publish a flow to Tableau Server or Tableau Cloud, you can manage your flows and make changes to them as necessary. This topic describes the various actions you can take to manage your flows.

> **Note**: The content in this topic applies to both Tableau Server and Tableau Cloud, exceptions are called out specifically.

Managing your flows

**Following is a list of actions you can take to manage your flows:**

- **Create flows:** Starting in version 2020.4, as a Creator you can create flows directly on the web. From the **Home** page, click **Create** > **Flow** or from the **Explore** page, click **New** > **Flow**. For more information, see Tableau Prep on the Web.
- **Edit flows:** Starting in version 2020.4, as a Creator you can edit flows directly on the web. Navigate to the list of flows, select **Actions** and click **Edit Flow**, or open a flow and click the **Edit** button.

  When you edit a flow, your changes are moved to a draft state. When you're finished, publish your flow to commit your changes and create a new version of the flow. For more information, see Autosave and working with drafts.

  You can edit the data connection using the **Edit Connection** menu option from the **Connections** view, **Actions** (…) menu for the data source. The new connection is saved and used the next time the flow runs in Tableau Prep Conductor. However, when you open the flow to view it, the original connection persists and won't be updated until you edit the flow, update the connector, and republish it.

If you open, edit, and republish the flow without changing the original connection, any connection changes made using the **Edit Connection** menu will be overridden and replaced with the original connection.

- **Run flows:** As a Creator, you can manually run a flow in addition to creating scheduled flows tasks that run at a specific time. Explorer (can publish) users can also run flows if the Server Administrator has granted this permission.
- 

> **Note**: The Data Management is not required to manually run flows, but is required to schedule flows to run.

- Navigate to the list of flows, select one or more flows you want to run, select **Actions** and click **Run Now**.
- **Tag:** Tags are keywords you can create for flows to help you find, filter, and categorize content. Authors can add tags to flows when they publish it. But you can also add tags to any workbook, view, or data source that you are allowed to access and you can delete any tags you have added. You can add a tag to a list of flows.

  Navigate to the list of flows, select one or more items you want to tag, select **Actions** and click **Tag**. To add a tag to a specific flow you can do it from the list of flows as described above. Open the Flow, from the Overview tab, select **Actions**, and click **Tag**.
- **Change Owner:** Administrators and flow owners can change owners to any Creator on their site. In versions 2025.1 and earlier, they could only change the owner to themselves. For more information, see Manage Content Ownership.
- **Permissions:** You can set permissions for users and specify if they can perform edit actions like save, download, move to a different project and delete. In addition, you can specify who can view and run the flow.
- **Download:** You can download a flow to view or modify it using Tableau Prep Builder. To download a flow, you need download permissions. You'll have that by default if you are

the owner, but you might need to add it for other users.

- **Revision History:** When you make a change to the flow, and republish it to the same project with the same name, a new version of the flow is created. You can view the revision history by selecting revision history from the actions menu. Flow owners have permissions to restore a previous version of a flow.
- **Move:** You can move flows between projects. To move a flow, users need Move permission. You'll have that by default for flows you own, but you might need to add it for other users.
- **Rename:** You can rename a flow. To rename a flow, users need the Save permission. You'll have that by default for flows you own, but you might need to add it for other users.
- **Delete:** You can delete a flow. To delete a flow, users need the Delete permission. You'll have that by default for flows you own, but you might need to add it for other users. Starting in version 2025.3, you can now retrieve deleted flows from the Recycle Bin. For more information, see Recover deleted flows.

Who can do this

## Tableau Server Administrator

**Can do the following tasks across all the sites:**

- Create flows
- Edit published flows
- View a list of all draft flows
- Run flows
- Delete flows
- Turn on and configure Recycle Bin

- Recover deleted flows
- Download flows
- Change Owner
- Change Permissions
- Change Project
- Add/Remove Tags
- Change Description
- Change Name
- Update Flow Task
- Delete Flow Task
- Create a Flow Task*
- Version Management*

*Some additional conditions apply to these actions:

- To create a flow task:
  - A flow schedule must be available. In Tableau Server, only Server Administrators can create a schedule. In Tableau Cloud, users with permissions to schedule flow tasks can create a custom schedule. For more information, see Schedule Flow Tasks.
  - The flow must have at least one output step.
  - The flow version must be compatible with the Tableau Server version.
- Version management:
  - Revision history must be enabled on the site.
  - User role is allowed to publish to the project.

## Tableau Site Administrator

**Can do the following tasks on flows published to the sites that they are site administrator for:**

- Create flows
- Edit published flows
- View a list of all draft flows
- Run flows
- Delete flows
- Turn on and configure Recycle Bin
- Recover deleted flows
- Download flows
- Change Owner
- Change Permissions
- Change Project
- Add/Remove Tags
- Change Description
- Change Name
- Update Flow Task
- Delete Flow Task

- Create a Flow Task*
- Version Management*

Some additional conditions apply to these actions:

- To create a flow task:
  - A flow schedule must be available. In Tableau Server, only Server Administrators can create a schedule. In Tableau Cloud, users with permissions to schedule flow tasks can create a custom schedule. For more information, see Schedule Flow Tasks.
  - The flow must have at least one output step.
  - The flow version must be compatible with the Tableau Server version.
- Version management:
  - Revision history must be enabled on the site.
  - User role is allowed to publish to the project.

## Project Leader

**Can do the following tasks on flows published to the projects where they have project leader permissions:**

- Create flows
- Edit published flows
- Run Flows
- Delete
- Download
- Change Permissions
- Change Project

- Add/Remove Tags
- Change Description
- Change Name
- Update Flow Task
- Delete Flow Task
- Create a Flow Task*
- Version Management*

*Some additional conditions apply to these actions:

- To create a flow task:
  - A flow schedule must be available. In Tableau Server, only Server Administrators can create a schedule. In Tableau Cloud, users with permissions to schedule flow tasks can create a custom schedule. For more information, see Schedule Flow Tasks.
  - The flow must have at least one output step.
  - The flow version must be compatible with the Tableau Server version.
- Version management:
  - Revision history must be enabled on the site.
  - User role is allowed to publish to the project.

## Project Owner

**Can do the following tasks on flows published to the projects that they own:**

- Create Flows
- Edit published flows

- Run Flows
- Delete
- Download
- Change Permissions
- Change Project
- Add/Remove Tags
- Change Description
- Change Name
- Update Flow Task
- Delete Flow Task
- Create a Flow Task*
- Version Management*

* Some additional conditions apply to these actions:

- To create a flow task:
  - A flow schedule must be available. In Tableau Server, only Server Administrators can create a schedule. In Tableau Cloud, users with permissions to schedule flow tasks can create a custom schedule. For more information, see Schedule Flow Tasks.
  - The flow must have at least one output step.
  - The flow version must be compatible with the Tableau Server version.
- Version management:
  - Revision history must be enabled on the site.
  - User role is allowed to publish to the project.

# Flow Owner

**Can do the following tasks on flows that they own:**

- Create Flows
- Edit Draft (flows they own) and Published Flows
- Run flows
- Delete flows
- Recover deleted flows (with Recycle Bin turned on by administrator)
- Download flows
- Change Owner
- Change Permissions
- Change Project
- Add/Remove Tags
- Change Description
- Change Name
- Update Flow Task
- Delete Flow Task
- Create a Flow Task*
- Version Management*

*Some additional conditions apply to these actions:

- To create a flow task:
  - A flow schedule must be available. In Tableau Server, only Server Administrators can create a schedule. In Tableau Cloud, users with permissions to schedule flow tasks can create a custom schedule. For more information, see Schedule Flow Tasks.
  - The flow must have at least one output step.
  - The flow version must be compatible with the Tableau Server version.
- Version management:
  - Revision history must be enabled on the site.
  - User role is allowed to publish to the project.

## User with Creator License

**Can do the following tasks:**

- Create Flows
- Edit Draft (flows they own) and Published Flows
- Run Flows (with Run flow permissions)
- Delete (with delete permissions)
- Recover deleted flows (with Recycle Bin turned on by administrator)
- Download (with download or Save as, and read permissions)
- Change Permissions (with Change Permissions)
- Change Project (with move permissions, and write permissions on the destination project)
- Add/Remove Tags (with read permissions)
- Change Description (with Save permissions)

- Change Name (with Save permissions)
- Update Flow task (with Execute permissions)
- Delete Flow Task (with Execute permissions)
- Create a Flow Task* (with Execute permissions)
- Version Management* (with view, read, save as, download permissions)

* Some additional conditions apply to these actions:

- To create a flow task:
  - A flow schedule must be available. In Tableau Server, only Server Administrators can create a schedule. In Tableau Cloud, users with permissions to schedule flow tasks can create a custom schedule. For more information, see Schedule Flow Tasks.
  - The flow must have at least one output step.
  - The flow version must be compatible with the Tableau Server version.
- Version management:
  - Revision history must be enabled on the site.
  - User role is allowed to publish to the project.

## User with Explorer License

**Can do the following tasks:**

**Note**: Starting in version 2020.4, Explorer license users can no longer run flows on Tableau Server, even if the Server Administrator assigns the **Run Flow: Allowed** permissions.

- Explorer (can publish) license users with **Run Flow: Allowed** permissions can run flows on Tableau Server and Tableau Cloud.
- Delete (with delete permissions)
- Recover deleted flows (with Explorer (can publish) permissions and Recycle Bin turned on by administrator)
- Download (with download or Save as, and read permissions)
- Change Permissions (with Change Permissions)
- Change Project (with move permissions and write permissions on the destination project)
- Add/Remove Tags (with read permissions)
- Change Description (with Save permissions)
- Change Name (with Save permissions)
- Update Flow task (with Execute permissions)
- Delete Flow Task (with Execute permissions)
- Create a Flow Task* (with Execute permissions)
- Version Management* (with view, read, save as, download permissions)

*Some additional conditions apply to these actions:

- To create a flow task:
  - A flow schedule must be available. In Tableau Server, only Server Administrators can create a schedule. In Tableau Cloud, users with permissions to schedule flow tasks can create a custom schedule. For more information, see Schedule Flow Tasks.
  - The flow must have at least one output step.
  - The flow version must be compatible with the Tableau Server version.
- Version management:

- Revision history must be enabled on the site.
- User role is allowed to publish to the project.

## User with Viewer License

Viewers cannot manage flows, they can however view the flow and the different versions of the flow.

For more information about the full capabilities you can set on flows, see Permission capabilities.

### Monitor Flow Health and Performance

After you publish Tableau Prep flows and schedule them to run periodically, you want to know that they are running as expected and resolve any issues as they occur. You will also want to monitor, troubleshoot, and understand the performance of your flows.

This topic describes the various methods that Tableau Server provides to help you monitor and troubleshoot your Tableau Prep flows.

Detect issues as they occur and resolve them

You can set up Tableau Server to send email notifications when flows fail, or find and review errors on Tableau Server using the Alerts menu or by reviewing the flow pages for the flows that you are interested in. This type of monitoring allows you to detect problems as they occur.

Get notifications when a flow fails:

You can configure Tableau Server to send notifications about flow failure through email, on the Tableau site, or Slack. To set up notifications for your Tableau Server and sites, follow the instructions in Step 2: Configure Flow Settings for your Tableau Server.

View and resolve errors

> **Note**: Starting in version 2020.4.1, you can now create and edit flows directly in Tableau Server and Tableau Cloud. The content in this section applies to all platforms, unless specifically noted. For more information about authoring flows on the web, see Tableau Prep on the Web.

The following errors can happen when running a flow:

- **Connection errors:** Connection errors generally happen when Tableau Server is unable to connect to one or more data inputs or is unable to make a connection in one or more output steps.
    - For Input connection errors, use the **Edit connections** option on the **Connections** tab to make changes to connection details, then run the flow again.
    - For output connection errors, check the output location for the flow output steps. If the flow output is going to a network share, make sure the output steps are pointing to a safe listed location. After you make any changes republish the flow and try running it again.

      > **Note**: To fix output connection errors for flows that output to a file or network share, download the flow to Tableau Prep Builder, then republish the flow to your server. Flows that output to a published data source or database can be edited directly on the web.

- **Errors in the flow:** If there are errors in one or more steps in the flow, you will see an error message. You can edit the flow directly on the web and republish it. You can also download the flow to Tableau Prep Builder, resolve the errors, republish the flow to the server and then run the flow again.

- **Suspended flow tasks:** When a scheduled flow task fails to run after a configured number of attempts, the flow task is suspended. By default, a flow task is suspended after 5 consecutive flow tasks failures.

  A flow can have multiple scheduled tasks assigned to it, but only the failed tasks are suspended. All other flow tasks will continue to run unless they have errors. To resolve a suspended task, review and resolve the errors then run the flow on-demand or let the flow run automatically based on the assigned schedule.

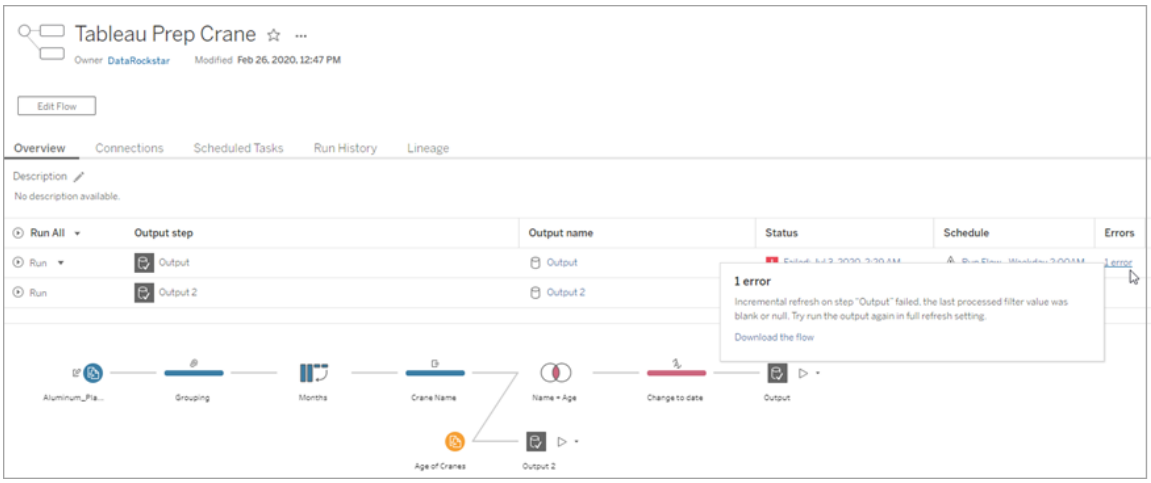
  > **Note:** Server administrators can configure the number of attempts before a flow run is suspended using the tsm configuration set option. For more details, see Step 5: Optional Server Configurations.

You can view errors on the following pages:

## Flow Overview page

On this page you can see the status of the most recent flow run and any errors. Hover on the error text to review the error details. If a scheduled task is suspended, a warning icon shows next to the schedule. Hover on the icon to view the status.

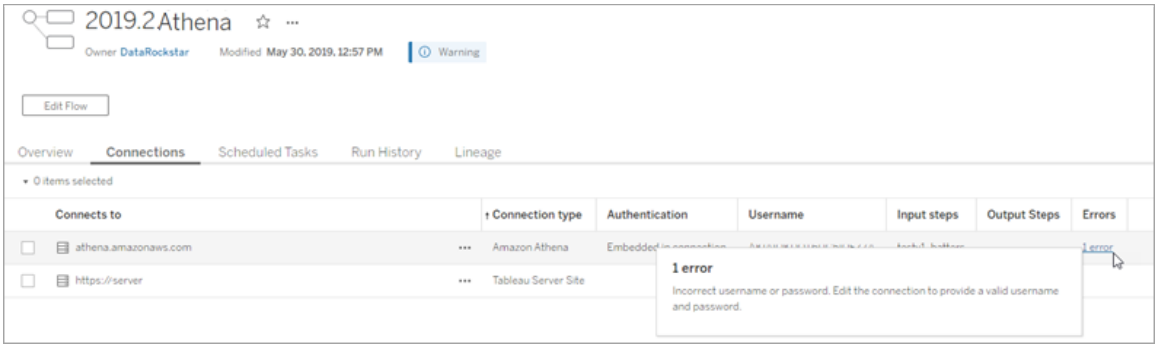
After you resolve the error that caused the flow to fail or the task to be suspended, you can run the flow manually or let the flow run based on the assigned schedule. For suspended flow tasks, click the **Go to Scheduled Task** link on the tooltip for the suspended task to navigate to the **Scheduled Tasks** page and click the **Resume Scheduled Tasks** button to resume the suspended tasks.



## Connections page

The **Connections** page shows the most recent status and any related connectivity errors. To correct input errors, click the **More actions** ••• menu for an input connection to edit the connection and change the server name, port, user name and password.

To fix output connection errors, edit the flow directly or download the flow in Tableau Prep Builder, correct the file path, then republish the flow to continue running it.



## Scheduled Tasks page

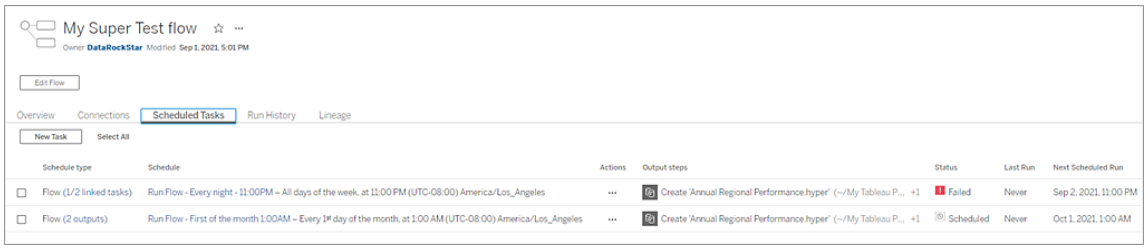
**Note**: The Data Management is required to see this tab.

View the scheduled tasks assigned to a flow. If a scheduled task is suspended, you can see the status of that tasks here and you can manually resume the flow tasks from this page. Before resuming a suspended task, resolve any errors in the flow.

Error details are not shown on this page, but you can review them on the **Overview** or **Run History** pages. You can also click the links in the **Schedule type** column to view the details of what was scheduled and to edit the tasks.

A suspended scheduled task will automatically resume when the flow is republished, if you edit a connection for the flow or manually run the flow tasks. To manually resume a suspended tasks, on the **Scheduled Tasks** page, click **Resume Scheduled Tasks**. This resumes all suspended tasks for the flow.

To resume individual tasks, click the **More actions** ••• menu for a scheduled task and select **Resume**. You can also click **Run Now** to run all tasks for the flow immediately.



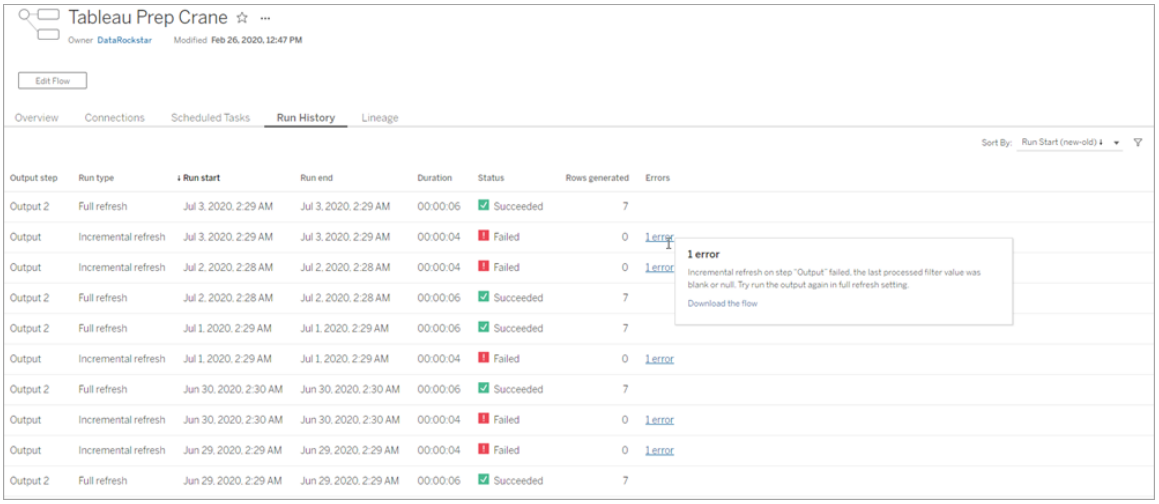
## Run History page

**Note**: The Data Management is required to see this tab.

The **Run History** page shows the details of all the flow runs that have either completed or are in progress for each output. View any error details by hovering over the errors in the **Errors** column. The duration column shows you the run time of the flow.

**Note**: Starting in version 2020.2.1, the **Run Type** field shows the refresh type for the output. In prior releases this field showed whether the output was run on a schedule or on-

demand. For more information about setting up output refresh types, see Refresh Flow Data Using Incremental Refresh.



## Alerts

When a flow fails, the alerts menu is populated with the error details with the option to re-run the flow, or download the flow to troubleshoot.

**Note**:Flow owners, Server or Site Administrators can see this menu.

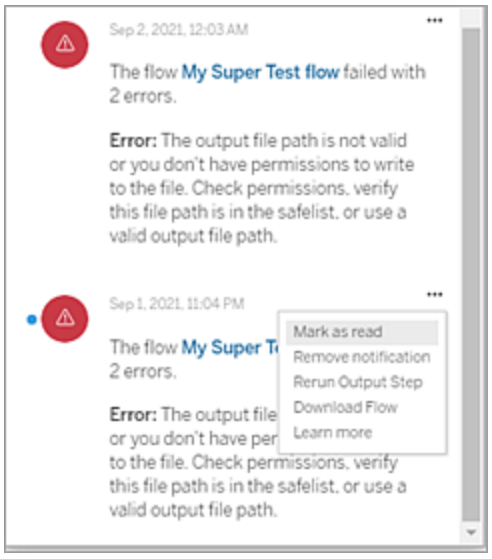


Tableau Prep Conductor process status

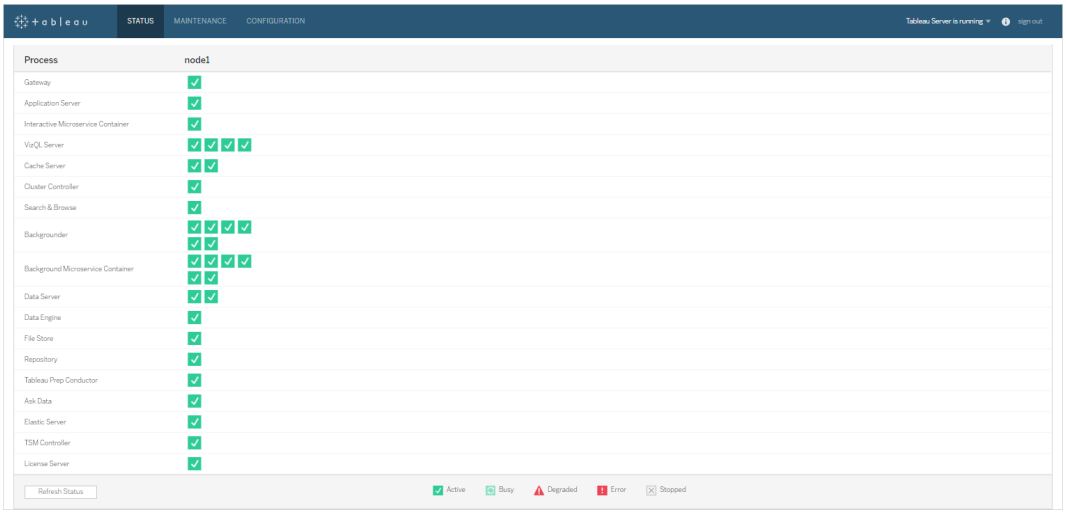
- The Tableau Services Manager (TSM) status page is accessible in TSM and can be viewed by TSM administrators. You must be able to log into TSM to see this page.
- The Tableau Server status page appears in the Tableau Server web UI and is accessible by Tableau Server administrators. If you hover your mouse pointer over the status indicator for a process, a tooltip shows the node name and the port the process is running on. The Tableau Server status page does not show TSM processes.



When Tableau Server is functioning properly, Tableau Prep Conductor will show as Active or Busy:

- **Active**—The process is functioning as intended.
- **Busy**—The process is completing some task.
- **Down**—The process is down. The implications of this differ depending on the process.
- **Status unavailable**—Tableau Server is unable to determine the status of the process.

Who can do this

- **Tableau Server Administrators**:
  - Setup email notifications at the server level
  - Set up email notifications for a site
  - View errors
  - Resume suspended tasks
  - View alerts
  - view process status
- **Tableau Site Administrators**:
  - Set up email notifications at the site level
  - View errors
  - Resume suspended tasks
  - View alerts
- **Flow owners, project leaders and any user who is granted permissions to view the flow**:
  - View errors
  - Resume suspended tasks
  - View alerts (Flow owners)

Administrative Views for Flows

Administrative views can be used to monitor the activities related to flows, performance history, and the disk space used. The **Status** page contains an embedded Tableau workbook

with various administrative views that can be used to monitor different types of server or site activity.

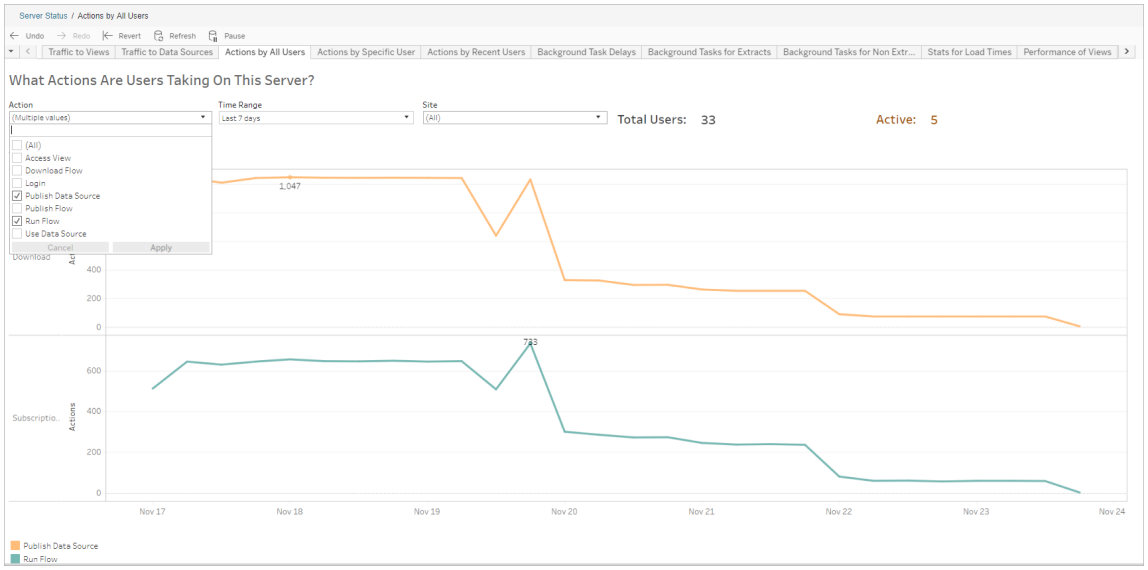
For **Tableau Server** installations, you must install PostgreSQL drivers before you can see Administrative views. For more information, see Database Drivers (Linux), Database Drivers (Windows). Server administrators can use these views to see activity both at the server level (aggregated for all sites) or for a specific site. Only server administrators can filter by site.

Who can do this?

Tableau Server administrators and Tableau Site administrators can both view and work with Administrative Views. Only Server administrators can filter by site.

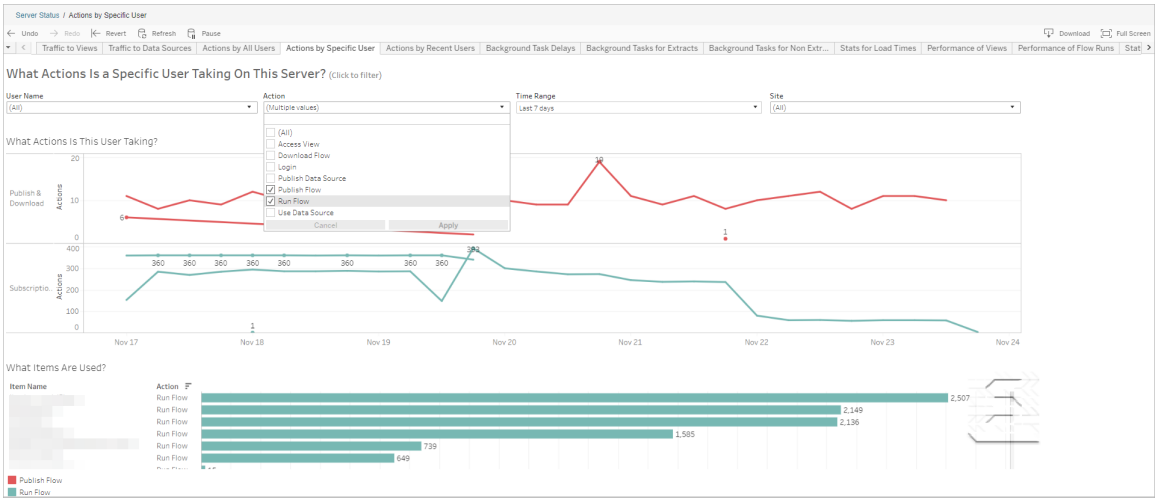
Action by all users

Use this view to gather insight into how flows are being used. This includes actions like publish, download, and flow runs. You can filter the view by actions, by site, and by time range. The Total Users count shows the number of users who have performed an action. This value is not affected by any filtering. The Active user count shows the number of users who have been active during the selected time period and performed one of the selected actions.



### Action by Specific User

Use this view to gather insights about how an individual user is working with flows. You can filter the view by user name, the type of action, time range, and by site.



### Action by Recent Users

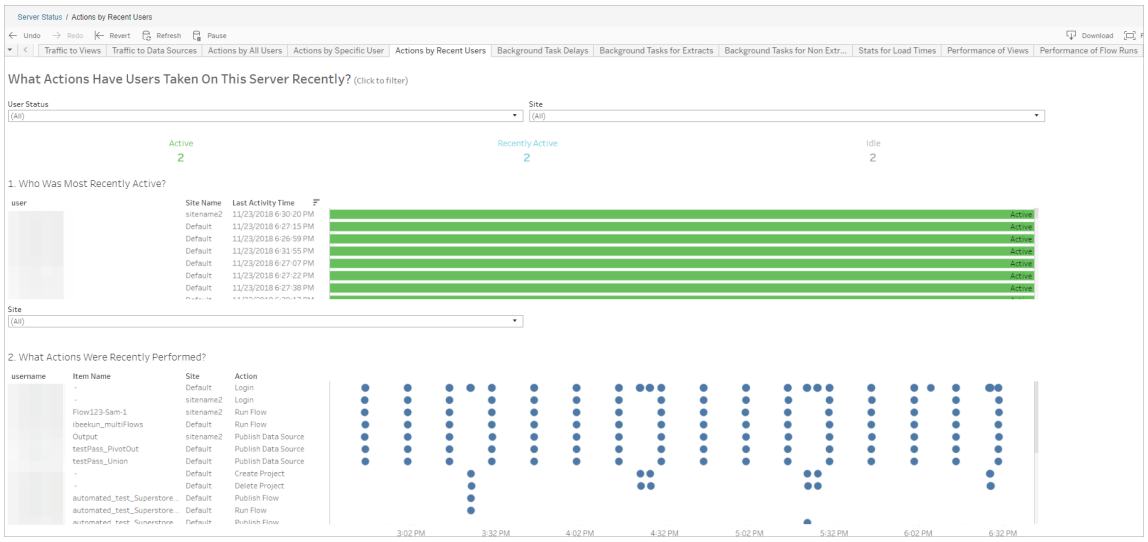
This view shows you which users have been active on Tableau Server over the past 24 hours.

This can be useful if you need to do some maintenance activity on the server and want to know which users and how many this will affect, and what they're doing.

The view shows **Active**, **Recently Active**, and **Idle** users that are currently signed in to Tableau Server.

For this view, an active user is one who took an action in the last 5 minutes, a recently active user is one who last took an action within 30 minutes, and an idle user is one who last took an action more than 30 minutes ago.

Select a user to see only the actions that user performed recently. Hover over an action to see details of the action.



## Backgrounder Task Delays

This view shows the delay for extract refresh tasks, subscription, and flow tasks—that is, the amount of time between when they are scheduled to run and when they actually run. You can use the view to help identify places you can improve server performance by distributing your task schedules and optimizing tasks.

Possible reasons for the delays and ways to reduce the delays include the following:

- Many tasks are scheduled for the same time.

  In the example view, tasks that show long delays are clustered at the same time every day, which creates spikes in the wait time. You can set the Timeline filter to a single day to view task delays by hour and identify the hours of the day when many tasks are scheduled at the same time. One solution is to distribute the tasks to off-peak hours to reduce load on the server.

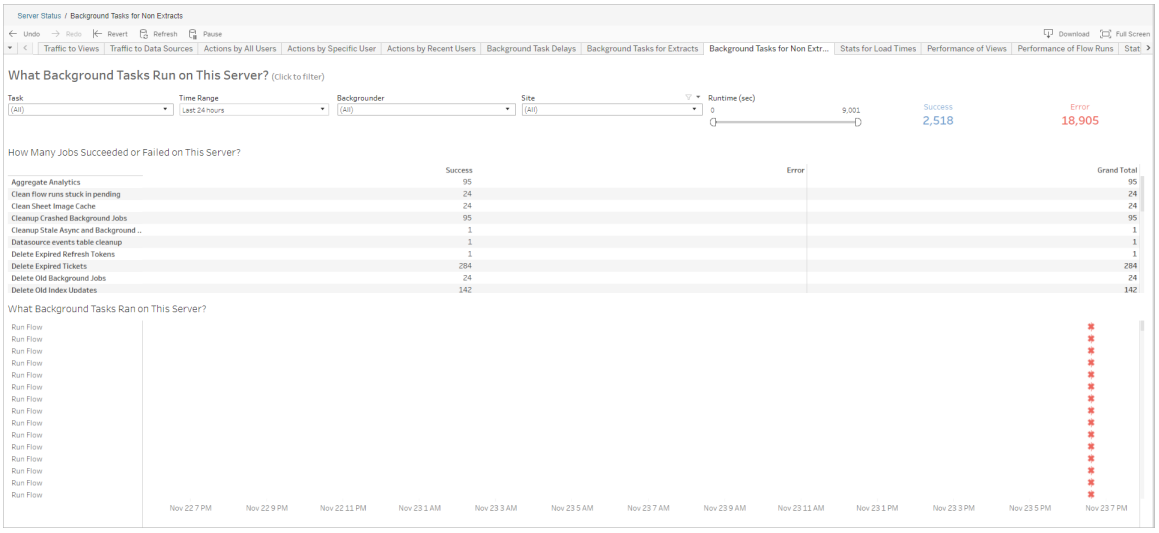
- Other server processes running at the same time are consuming server resources and slowing down performance.

  Monitor the CPU and memory usage of server processes to identify processes that consume the most resources, then adjust the configuration of processes on your server.

  For more information on monitoring processes, see Collect Data with Windows Performance Monitor.

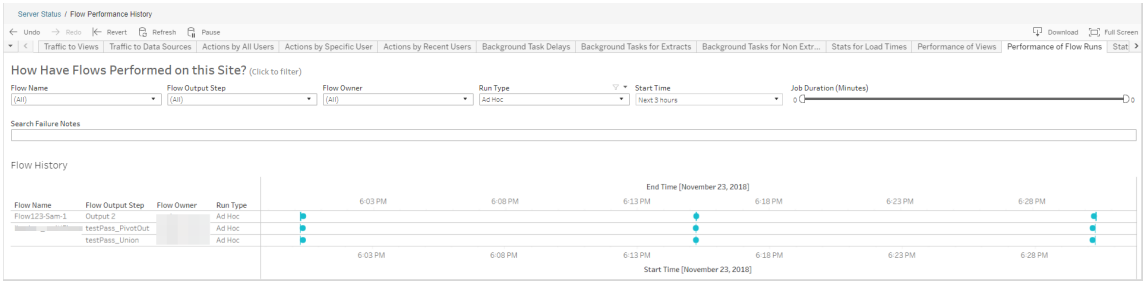
### Background Tasks for Non Extracts

Background Tasks are created to run flows (scheduled and ad hoc). You can use this view to see how many flow tasks succeeded or failed on this site. For details on a task, hover over its icon.



Performance of Flow Runs

Use this view to see the performance history for all the flows on a site. You can filter by Flow Name, Output Step Name, Flow Owner, Run Type (Scheduled or Ad Hoc), and the time the flow runs were started.



Questions you can answer using this view include:

- **What flow tasks are currently scheduled?** – To do this, use the Start Time filter and select the time frame you want to look at. For example, to see flow tasks that are scheduled in the next 3 hours, select **Hours** -> **Next** -> and enter **3**.
- **What is the duration of flow tasks?** - To answer this, click on a mark in the view to see details, including the task duration.
- **How many flows were run ad hoc, and how many were scheduled runs?** - To answer this, use the **Run Type** filter and select **Ad hoc** or **Scheduled**.

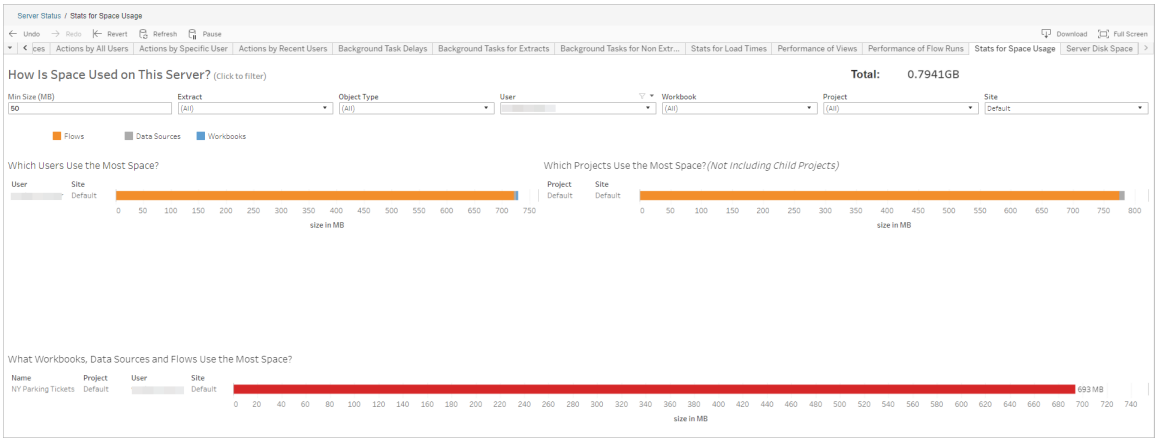
This view can also show you the following information:

- Flows with the highest run frequency have the most marks.
- To see flows that are currently running at the same time, hover over a mark that shows "**In Progress**" or "**Pending and select** "**Keep Only**" to filter all flow runs that are currently running.
- To see flows that are running at the same time during a specific time range, select a

range for the **Start Time** filter. For example, select "**Next three hours**" to see which flows will be running in the next three hours.

### Stats for Space Usage

Use this view to identify which flow outputs are taking up the most disk space on the server. Disk space usage is displayed by user, project, and by the size of flow output and is rounded down to the nearest number.



Use the Min Size filter to control which flow outputs are displayed, based on the amount of space they take up. Use the object type filter for flows.

- **What Users Use the Most Space** – This section shows the users who own flows (when filtered for flows) that are taking up the most space. Click a user name to filter the next two graphs for that user.
- **What Projects Use the Most Space** – This section shows the projects with flows (when filtered for flows) that are using the most space.
- **What Workbooks, Data Source and Flows Use the Most Space** – This section shows the flows (when filtered for flows) that take up the most space.

Who can do this

- **Tableau Server Administrators**:
  - Setup email notifications at the server level
  - Set up email notifications for a site
  - View errors
  - Resume suspended tasks
  - View alerts
  - view process status
- **Tableau Site Administrators**:
  - Set up email notifications at the site level
  - View errors
  - Resume suspended tasks
  - View alerts
- **Flow owners, project leaders and any user who is granted permissions to view the flow**:
  - View errors
  - Resume suspended tasks
  - View alerts (Flow owners)

## Developer Resources - REST APIs

Use Tableau Server REST APIs to automate and seamlessly integrate Tableau into your existing workflows. Tableau Server REST API gives you programmatic access to work with your content, users, sites, and now flows. Manage provisioning, permissions, and publishing on Tableau Server or Tableau Cloud via HTTP. The REST API gives you access to the functionality behind the data sources, projects, workbooks, site users, sites, and flows. You can use this access to create custom applications or to script interactions with server resources.

Tableau REST API supports the following flow functionality:

New flow endpoints have been added to support publishing flows, scheduling flows, running flows on demand, managing permissions, downloading flows and such. For a full list of all the new REST API endpoints for flows, see Flow Methods.

In addition, existing endpoints have been updated to support flow functionality such as Creating New Schedules for Flows, Creating new sites, updating existing sites, and managing default permissions.

**Note**: The Data Management license is required when using REST API to run flows.

## About Tableau Catalog

As of October 14, 2025, Data Cloud has been rebranded to Data 360. During this transition, you may see references to Data Cloud in our application and documentation. While the name is new, the functionality and content remains unchanged.

Data is increasing in volume, formats, and importance leading to more complex environments. With the rapid pace that data changes, it can be hard to keep track of that data and how it's being used in such complex environments. At the same time, more users need to access more of that data in more places, and it’s difficult for users to find the right data. Ultimately, this causes a lack of trust in the data because people question whether they’re using the right source or if the source is up to date.

Tableau Catalog integrates features like lineage, impact analysis, data dictionary, data quality warnings, and search into your Tableau applications, helping solve these problems differently from a stand-alone catalog. It focuses on both IT and the end user so that everyone using Tableau Server or Tableau Cloud has more trust in and visibility into the data, while also enabling more discoverability. Tableau Catalog builds a catalog out of the Tableau content being used by your organization, enabling comprehensive functionality like the following:

- **Impact analysis and lineage**.
  - You can see the workbooks and other Tableau content that depend on particular columns or fields from tables or data sources you manage. When you need to make changes to your data, you can notify the impacted Tableau authors using email.
  - As a workbook author, you can use lineage to trace the fields that your workbook depends on.

    - As a user, when you use a Tableau visualization, you can see where the data came from that was used to create the view.
- **Curation and trust**. As a data steward, you can add helpful metadata, like descriptions and certification, so that users find the right data. You can set data quality warnings, view data details on the Data Details pane, certify assets, and remove assets from the catalog.
- **Data discovery**. In Tableau Desktop or Tableau web authoring, you can use Tableau Catalog to search for databases, tables, data sources, and virtual connections to analyze in Tableau and connect to them from the search results.

Starting in 2019.3, Tableau Catalog is available as part of Data Management for Tableau Server and Tableau Cloud. When the product key is active and enabled, the catalog features described above are integrated into the product you're using, so you can work with the data where you find it.

## How Tableau Catalog works

Tableau Catalog discovers and indexes all the content on your site—workbooks, data sources, sheets, virtual connections, and flows—to gather metadata about the content. From the metadata, external assets (databases, tables, and other objects) are identified. Knowing the relationships between the content and the external assets enables Tableau to display the lineage of the content and external assets. Tableau Catalog also enables users to connect to external assets using Tableau Server or Tableau Cloud.

Users on your site can publish or delete content, can attach data quality warnings or certifications, or do anything else that changes the content or its metadata on the site, and Tableau Catalog will update its information accordingly.

For information about how you can use Tableau Catalog to support data governance in your organization, see Governance in Tableau in the Tableau Blueprint Help.

## Key Tableau Catalog terms

- Metadata - Information about the data.
- Tableau content - Content created in Tableau such as workbooks, data sources, virtual connections, and flows.

- External assets - Databases (including data files) and tables (including table-like objects) used by Tableau content, published to Tableau Server or Tableau Cloud.

## License Tableau Catalog

Tableau Catalog is licensed through Data Management. For information about how Data Management licensing works, see License Data Management.

## Enable Tableau Catalog

After Tableau Server or Tableau Cloud is licensed with Data Management capabilities, you can enable Tableau Catalog by doing one of the following tasks:

- **For Tableau Cloud**, no action is necessary. Tableau Catalog is on by default, configured to use derived permissions, and ready to use. For more information about derived permissions, see the Permissions on metadata topic.
- **For Tableau Server**, the Server admin must first enable the Tableau Metadata API using the `tsm maintenance metadata-services` command. For more information, see Enable Tableau Catalog.

  After the Metadata API is enabled, Tableau Catalog is on by default, configured to use derived permissions, and ready to use. For more information about derived permissions, see the Permissions on metadata topic.

## Features and functionality

To learn more about the features you can use with Tableau Catalog, see the following Help articles:

Data discovery

- In the **Connect** pane on Tableau Desktop, under **Search for Data** select **Tableau Server** to connect to data using Tableau Server or Tableau Cloud. When Tableau Catalog is enabled, in addition to searching for published data sources to connect to, you can now search for and connect to the specific databases, tables, and objects used by published data sources and workbooks on your Tableau Server or your Tableau Cloud site.

- Search is expanded to include results based on columns, databases, tables, and other objects when Tableau Catalog is enabled.
- If you author in the web, in addition to published data sources, you can also connect to databases and tables.
- If you use Tableau Prep on the web, you can create new flows based on external assets, such as databases and tables.
- If you connect to Salesforce Data Cloud, you'll see support for native Data Cloud objects built into Tableau Catalog. Data Lake Objects (DLOs), Data Model Objects (DMOs), and calculated insights appear distinct in search, connect, and lineage pages, which makes discovering, connecting to, and reusing them simpler.

Curation and trust

- Certify your data assets to help users find trusted and recommended data.
- Set data quality warnings to alert users to data quality issues, such as stale or deprecated data.
- Add sensitivity labels to warn users about data that needs to be handled with care.
- Add custom labels to classify data in ways that suit the needs of your organization
- Manage data labels to extend the label names and categories available to users.
- Categorize items on Tableau Server and Tableau Cloud using tags to help users filter external assets.
- Better understand published visualizations by using the Data Details tab to see information about the data used.
- Add descriptions to databases, tables, and columns to help users find the data they're looking for.

Lineage and impact analysis

- Use lineage to trace the source of your data and to analyze the impact of changes to your data and identify which users might be impacted.
- Email owners of a workbook, data source, or flow about data-related updates. Do the same with database, table, or object contacts.

Developer resources

You can use metadata methods in the Tableau REST API to programmatically update certain metadata. For more information about the metadata methods, see Metadata Methods in the Tableau Server REST API.

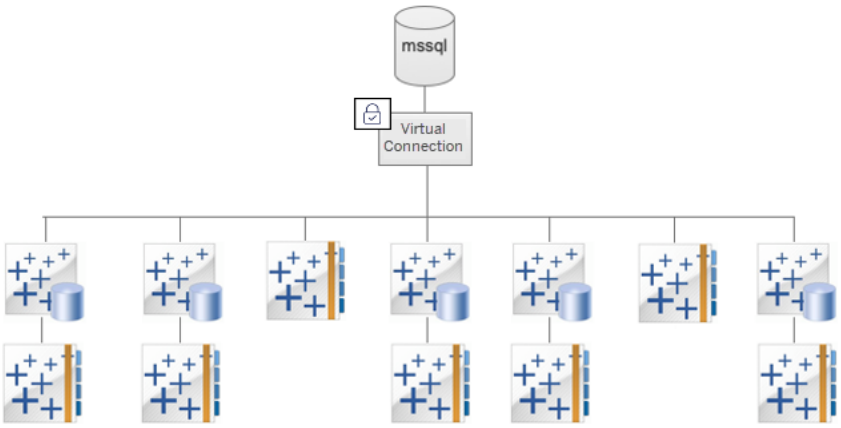
In addition to the REST API, you can use the Tableau Metadata API to programmatically query metadata from the content published to Tableau Server or Tableau Cloud. The Metadata API is fast and flexible and is best when you are looking to find out specific information about the relationship between metadata and its structures. Explore and test queries against the Metadata API using an interactive in-browser tool called GraphiQL.

**Note:** Data Management is not required to use the Metadata API or GraphiQL.

## About Virtual Connections and Data Policies

Virtual connections are a Tableau content type, along with data sources, workbooks, and flows, to help you see and understand your data. Virtual connections provide a central access point to data. Another key feature introduced with virtual connections is data policies, which support row-level security at the connection level, rather than the workbook or data source level. Row-level security data policies are applied to any workbook, data source, or flow that uses the virtual connection.

A virtual connection can access multiple tables across several databases. Virtual connections let you manage extracting the data and the security in one place, at the connection level.



For information about row-level security options, see an Overview of Row-Level Security Options in Tableau.

Not every virtual connection has an associated data policy. You can also use a virtual connection simply as a central place to manage connection credentials.

## Key terms

- Virtual connection. A sharable resource that provides a central access point to data.
- Connection. The server name, database, and credentials you use to access data. A virtual connection has one or more connections. Each connection accesses one database or file.
- Virtual connection table. A table in a virtual connection.
- Data policy. A policy that's applied to one or more tables in a virtual connection to filter data for users. For example, use a data policy to apply row-level security to tables in a virtual connection.
- Policy table. A fact or data table in a data policy that is filtered.
- Policy column. A column that's used to filter the data in the policy tables. A policy column can be in a policy table or in an entitlement table.
- Entitlement table. A table that includes both a policy column you can use to filter policy tables and another column you can relate (map) to a column in a policy table.
- Policy condition. An expression or calculation that is evaluated for every row at query time. If the policy condition is TRUE, then the row is shown in the query.

## License virtual connections and data policies

Virtual connections and data policies are licensed through Data Management. For information about how Data Management licensing works, see License Data Management.

## Enable virtual connections and data policies

Virtual connections and data policies are automatically enabled on Tableau Server and Tableau Cloud with Data Management.

## Permissions

Permissions for virtual connections work much like the permissions for other Tableau content. After you publish a virtual connection, anyone can view the connection. However, only the connection creator and administrators can access data using the connection, until the connection creator explicitly grants more permissions.

When you create a virtual connection, you must set the permissions for the Connect capability to enable other users to connect to data using the virtual connection. The Connect capability allows you to share a virtual connection and allows users to query it. With connect permissions, a user can view the tables in a virtual connection and create content using the tables. For more information, see Set permissions on a virtual connection.

Permissions vs. data policies

Permissions define what a person can or can't do with a piece of content in Tableau. Permissions are made up of capabilities—the ability to do things like view content, web edit, download data sources, or delete content. Permission rules define which capabilities are allowed or denied for a user or group on a piece of content. The interplay between license level, site role, and potentially multiple permission rules factor into the final determination of what a person can or can’t do—their effective permissions. See Permissions for details.

Data policies filter the data in a virtual connection, making sure that people see only the data they're supposed to see. A data policy is applied and filters the data when it's viewed in the Tableau content (for example, a workbook or flow). The policy condition in a data policy is a calculation or expression that defines access to the data. User functions are often used to limit access to users or groups. Access can be based on the user name, the group a user belongs to, or a region value. See Create a Data Policy for Row-Level Security for details.

Both permissions and data policies govern access. Simply put, permissions determine which *content* you can see, access, use, or create; data policies determine which *data* you can see.

How permissions and data policies work together

Tableau permissions are applied to Tableau content first. People can only do the things they have the capabilities to do with Tableau content—data policies don't override Tableau permissions. After permissions are evaluated, the data policy is applied to determine which data in the virtual connection the person can see based on the policy condition.

The following example describes the effects of permissions and data policies on a virtual connection that contains salary data:

- The virtual connection is in the HR project, which is restricted to Tableau users in the HR group. Anyone outside the HR group can't see content in the HR project, which means they can't browse to, connect to, or view the virtual connection.
- The virtual connection has Connect permissions granted only to members of the HR Business Partners group. All others in the HR group can see that the virtual connection exists, but they can’t view the data it contains. When they view a workbook that uses that virtual connection, they can't see any data.
- The virtual connection also contains a data policy that filters the salary data based on the individual user, so HR Business Partners can see only rows that pertain to employees in their business unit. When they view a workbook that uses that virtual connection, they see data only for their business unit.

## Features and functionality

For the manager of data, virtual connections provide:

- **Securely managed service accounts.** If you use a ‘service account’ model, now instead of having to share that service account information with any user who wants to access that data, you can give the service account credentials to the few analysts who are empowered to create virtual connections.
- **Agile physical database management.** You must make database changes (for example, a field is added or table name is changed) only one time in the virtual connection, rather than in every piece of content where the data is used.
- **Reduced data proliferation.** By centrally managing extract refresh schedules, refreshes are scheduled once, ensuring that anyone who accesses the data from that virtual connection is seeing fresh data.
- **Centralized row-level security.** You can create data policies that apply row-level security to both Tableau extracts and live queries at the connection level. The data policies are applied to any workbook, data source, or flow that uses the virtual connection.

**Note:** Data policies are valid for flow input data, but not for flow output data. Users with access to flow output data will see all of the data, and not only a subset of it that pertains only to them.

As the user of data, you benefit from virtual connections knowing that you have:

- **Appropriate access** to only the data you should see, because row-level security is already applied to the data.
- **Flexibility** to use data that's been curated and secured. The virtual connection stores and shares the connection information. All you have to do is create a data source with a data model specific to your needs.
- **Trust** that data is fresh because the extract refresh schedule has already been set.
- The ability to **share** content freely, assured that you won't put security at risk because data policies are always enforced.

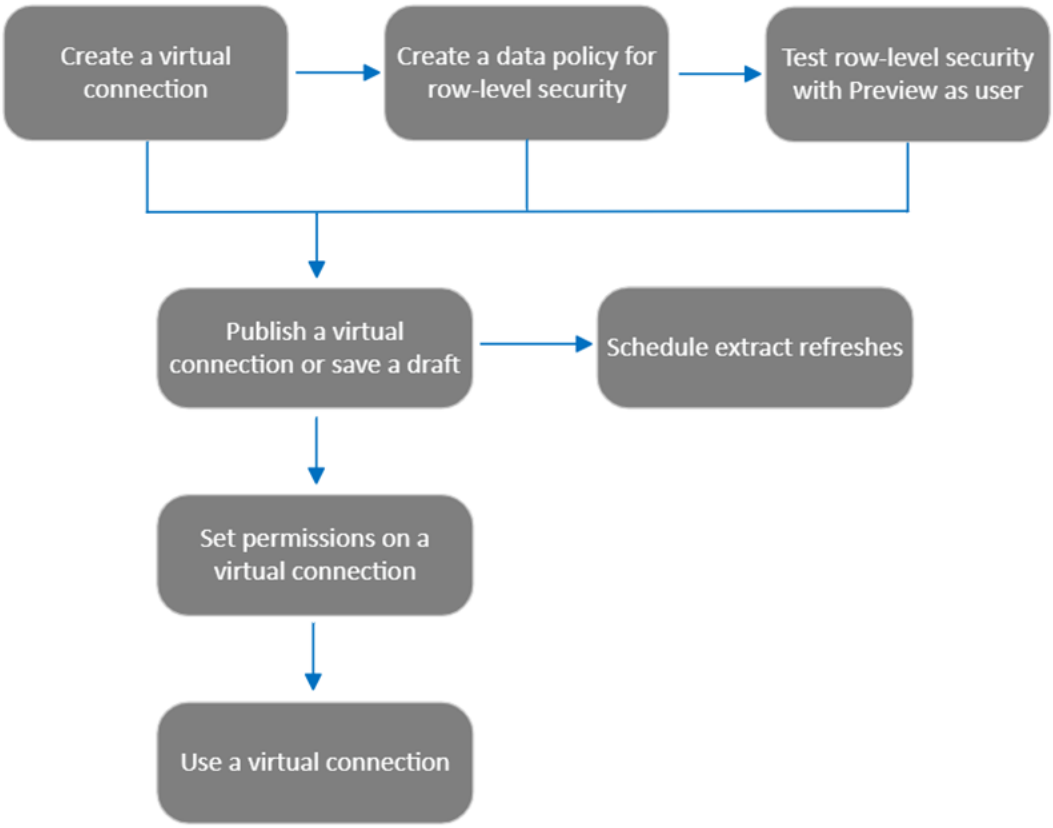
## Virtual connection editor workflow

The virtual connection editor enables you to create:

- Virtual connections, which are a Tableau content type that provides a sharable central access point to data.
- Data policies that support row-level security at the connection level.

After you create a virtual connection and its associated data policies, you can publish it and set the permissions to share with other users. You can also schedule extract refreshes so that all content that uses the virtual connection is accessing fresh data.

The following diagram shows the workflow to create a virtual connection. At any time during the process, you can publish or save a draft of your connection, but the connection must be published before you can schedule extract refreshes or use (or edit) a virtual connection. You must also set permissions before others can use the connection.



Click a step in the process to go to that help topic.

## Next step

The first step is to Create a Virtual Connection.

## Create a Virtual Connection

A virtual connection is a Tableau content type that provides a sharable central access point to data, and supports row-level security at the connection level. Creating a virtual connection is a multi-step process. This topic covers connecting to the data you want to share and working in the Tables tab of the virtual connection editor.

Connect to data

To create a virtual connection in Tableau Cloud or Tableau Server:

1. From the Home or Explore page, click **New** > **Virtual Connection**.
2. In the Connect to Data dialog box, select the connector for your data. For a list of supported connectors for virtual connections, see Creators: Connect to Data in the Tableau Desktop and Web Authoring help.
3. Enter the information you're prompted for. The credentials you enter are saved in the virtual connection, so connection users don't have to enter credentials to connect to the data.
4. Click **Sign In** if prompted. To add another connection, click and select a connector, enter credentials, and sign in.

A virtual connection can have multiple connections. Each connection accesses one database or file.

> **Note:** For Tableau Cloud, virtual connections that connect to private network data use Tableau Bridge to keep data fresh. For information about configuring Tableau Bridge, see Configure and Manage the Bridge Client Pool. For information about supported connections, see Connectivity with Bridge.

Add another connection

As needed, add another connection to a virtual connection and connect to more than one database by clicking next to **Connections**. You can add a connection to a different server or database, or to the same server or database.

With multiple connections, you can:

- Use a table from any connection or database as an entitlement table in a data policy that secures tables from other connections and databases.
- Add or replace tables in a virtual connection with tables from a different database. For example, say you migrate data from one database to another. In the virtual connection editor, you can add a connection to the second database and replace the existing tables from the first database with tables from the second one.
- Add multiple connections to the same server or database. This can be helpful when you need to for example access data from the same database but with different credentials.

- Share a group of tables that are related or meant to be used together, no matter where they're physically located. For example, from multiple databases you can group tables related to employee information.

When you open a virtual connection to edit it, if prompted you must authenticate connections in sequence. If any connections fail to authenticate, you can't edit the virtual connection.

Select tables to include in the connection

If necessary, select a database to view the tables in it.

1. On the left, under **Tables**, select the tables and click or drag them to the Tables tab on the right. You can include tables from different connections. Include an entitlement table, if you're using one.
2. (Optional) Click **New Custom SQL** to create a custom table schema.

**Note:** Virtual connections don't support tables with a spatial data type.

Select live or extract mode for tables

You can set individual tables—whether they're from multiple connections or not—to either live or extract mode in the same virtual connection.

- **Live**- Tables are queried directly from the database. (Live is the default.)
- **Extracts**- Tables are extracted and saved to Tableau.

As an example, you can set some tables to extract mode so that they're not impacted by report generation or heavy customer traffic.

Under Tables, select the table or tables you want to change the mode for and select **Actions**, and **Change to Live** or **Change to Extract**. Alternatively, select the Actions Menu (...) in the table's row and select **Live** or **Extract**.

Incremental Extracts

Starting in Tableau Cloud June 2024 and Tableau Server 2024.2, you can configure table extracts for incremental refresh.

When configuring an incremental extract, you specify a key column that is used to identify new rows. When the incremental extract is refreshed, only the rows where the key column has increased will be added to the extract. Fewer rows processed means a faster extract refresh job and less load on the database.

For example, suppose we have an extract for the **Batters** table, and the data in the extract is:

| Year | Team |
|---|---|
| 1978 | Lions |
| 1979 | Tigers |

The **Batters** table is configured for incremental extract refresh, and the key column is **Year**.

The live table is updated with a new row for **1980**:

| Year | Team |
|---|---|
| 1978 | Lions |
| 1979 | Tigers |
| 1980 | Bears |

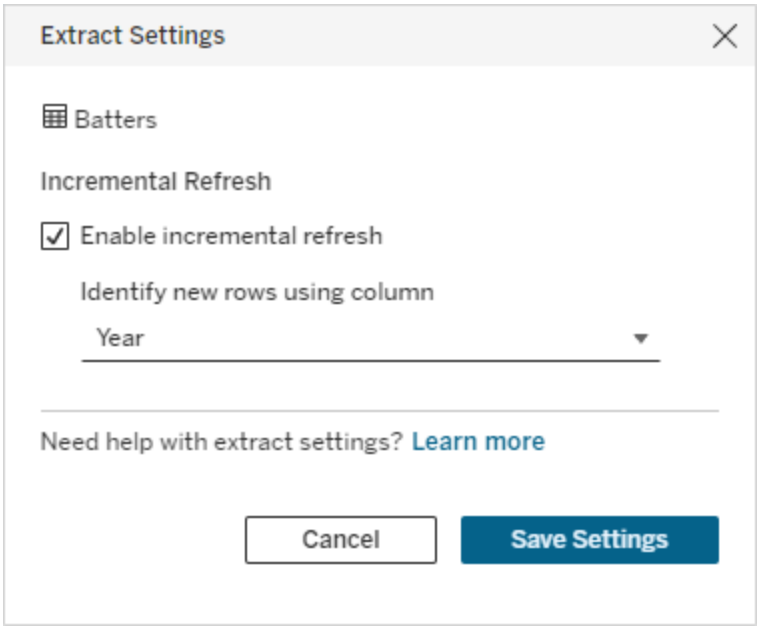
When the **Batters** table's extract is refreshed incrementally, only rows that exceed the greatest value in the extract's key column are added. In this case, that means that the **1980** row is added to the extract. Instead of refreshing the entire extract file, only 1 row is processed and appended.

You can still do a full refresh on an extract configured for incremental refresh if you want to refresh the entire extract.

To configure incremental refresh for a table extract:

1. Change the table from **Live** to **Extract.**
2. Select the Actions Menu (...) in the table's row and select **Extract Settings...**.
3. Check **Enable incremental refresh**.

4. Select an incrementing column to use when determining which rows to add.
5. Select **Save Settings**.



Convert to Custom SQL

Starting in Tableau Cloud June 2024 and Tableau Server 2024.2, you can approximate the SQL used to connect to a table and use that as a starting point for your own custom SQL. Custom SQL allows you to filter or make other query changes that can modify the result set. Creating custom SQL this way instead of using **New Custom SQL** in the data pane is less impactful to existing virtual connections. Downstream assets see the table as the same table instead of a new one.

To convert a table to custom SQL:

1. Select the Actions menu (...) in the row for the table.
2. Select **Convert to Custom SQL**.
3. In the **Edit Custom SQL** dialog, edit the SQL as needed.
4. Select **Generate Table**.

Note: The SQL that first appears in the dialog should be considered a starting point, and may not work without modification. The virtual connection editor lacks nuanced

> information about the specific SQL syntax used in the connection. If you encounter errors when selecting the Generate Table button, try removing or changing single quotes, double quotes, back quotes, and square brackets to make the SQL compliant with the database you're using.

To edit the custom SQL:

1. Select the Actions menu (...) in the row for the table.
2. Select **Edit Custom SQL**.
3. In the **Edit Custom SQL** dialog, edit the SQL.
4. Select **Generate Table**.

To return the table to its default state, without custom SQL:

1. Select the Actions menu (...) in the row for the table.
2. Select **Replace**.
3. In the replace table dialog, select the original table name.
4. Select **OK**.

Extract table data

After a table or tables are changed from live to extract but haven’t been extracted yet, click **Create Pending Extracts** (or **Run Pending Extracts** in Tableau Server 2023.3 and earlier) to run the pending extracts. After all pending extracts are run, click **Refresh All Extracts** (or **Run All Extracts** in Tableau Server 2023.3 and earlier) to extract all table data at that time.

Alternatively, in Tableau Cloud June 2024 or Tableau Server 2024.2 and later, select the Actions Menu (...) in the table's row and select **Refresh Extract...**. If incremental refresh is not configured for the table, you can only select **Refresh (Full)**. If incremental refresh is configured, you can choose either **Refresh (Full)** to refresh the extract completely, or **Refresh (Incremental)** to incrementally refresh the extract.

You must run any pending extracts before you publish the virtual connection. You can't edit the connection while extracts are generated.

Schedule extract refreshes of the tables in your virtual connection on the virtual connection page after you publish the connection. See Schedule Extract Refreshes for a Virtual Connection.

Set the table visibility state

Use the Visibility toggle on the Tables tab to show or hide tables and their data from users.

Users can see table data. You can create a data policy to govern which data users can see. (Visible is the default.)

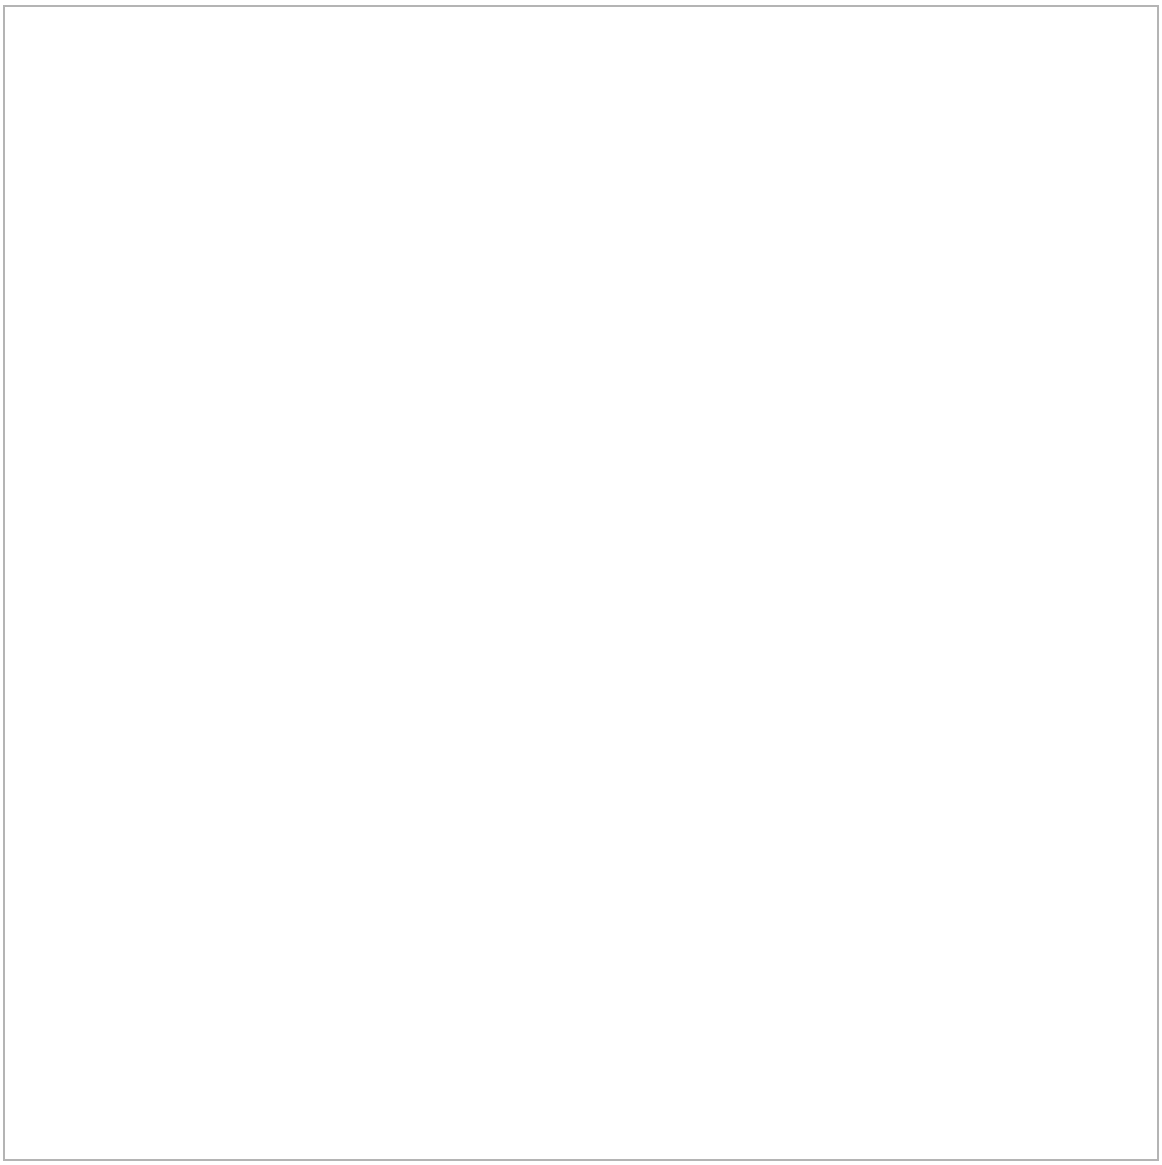
Users can't see table data. You can use hidden tables in a data policy and as an entitlement table.

See table details

Click a table at the top of the Tables tab to see its details. You can make simple edits in the Table Details section, such as change a table name, hide or rename a column, or change a data type.

Switch the table information you see using these icons:

- A list of columns in the table and each column's data type.
- Sample data for each column and linked keys, if available. Linked keys show which columns link to other tables. They're visible only when databases have primary and foreign key information.
- The range of values in a histogram for each column selected.



Refresh data from the database

Click the refresh icon in the toolbar to get the latest data from the database for all the connections in a virtual connection, including:

- The lists of databases, tables, and columns. Both the tables included in a virtual connection and not included are refreshed.
- Table and histogram data.

For tables in live mode, refreshing retrieves the latest list of databases, tables, and columns and the most recent table and histogram data. For tables in extract mode, refreshing retrieves the updated list of tables and columns. But to see the most recent table and histogram data, you must start a new extract. For example, when there's a new column in a database table and you click the refresh icon, the new column appears in the editor but its data does not. To see the most current data, you must start a new extract.

Refreshing data invalidates any currently cached data. Closing and reopening the editor, switching tables from extract to live mode, and changing a connection credential like user-name or password also refreshes data.

Who can do this

To create a virtual connection, you must

- have credentials to the database that the virtual connection connects to, and
- be a server or site administrator, or a Creator.

Next steps

After tables have been added and configured on the Tables tab, you can choose to Create a Data Policy for Row-Level Security or Publish a Virtual Connection and Set Permissions.

See also

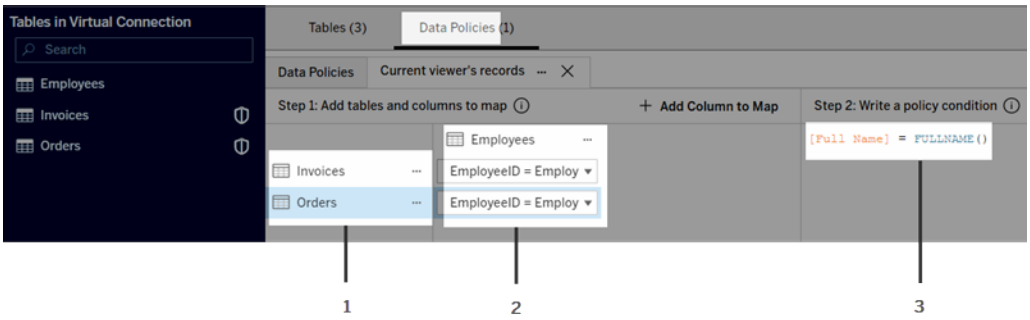
Use a .properties file to customize a JDBC connection — If you're customizing a JDBC-based connection, you can also make customizations in a .properties file

## Create a Data Policy for Row-Level Security

Use a data policy to apply row-level security to one or more tables in a virtual connection. A data policy filters the data, ensuring that users see only the data they're supposed to see. Data policies apply to both live and extract connections.

About data policies

A data policy has three main components:



1. The tables it applies to, called policy tables. These are the tables that are filtered.
2. The mapped columns that define the relationships between tables (for example, between entitlement and fact tables) and between table columns and policy columns. A policy column is the column used to filter data.
3. The policy condition, which is an expression or calculation that is evaluated for every row at query time. If the policy condition is TRUE, then the row is shown in the query.

When you create a data policy, you need a column you can use to filter the data. This column is called a policy column. Data is filtered by the policy condition, usually using a user function, such as USERNAME() or FULLNAME().

If your policy table includes a column that you can filter on, then use that column as your policy column.

When a policy table doesn't include such a column, use an entitlement table with a column you can use to filter the data. An entitlement table is a table that includes both a policy column you can use to filter policy tables and another column you can relate (map) to a column in a policy table (as shown in the data policy example image above).

Filter with a policy column from a policy table

The most common way to filter data is to use a column in the table that has the data that you want to filter on. Use that column as a policy column and then map the appropriate table columns to the policy column.

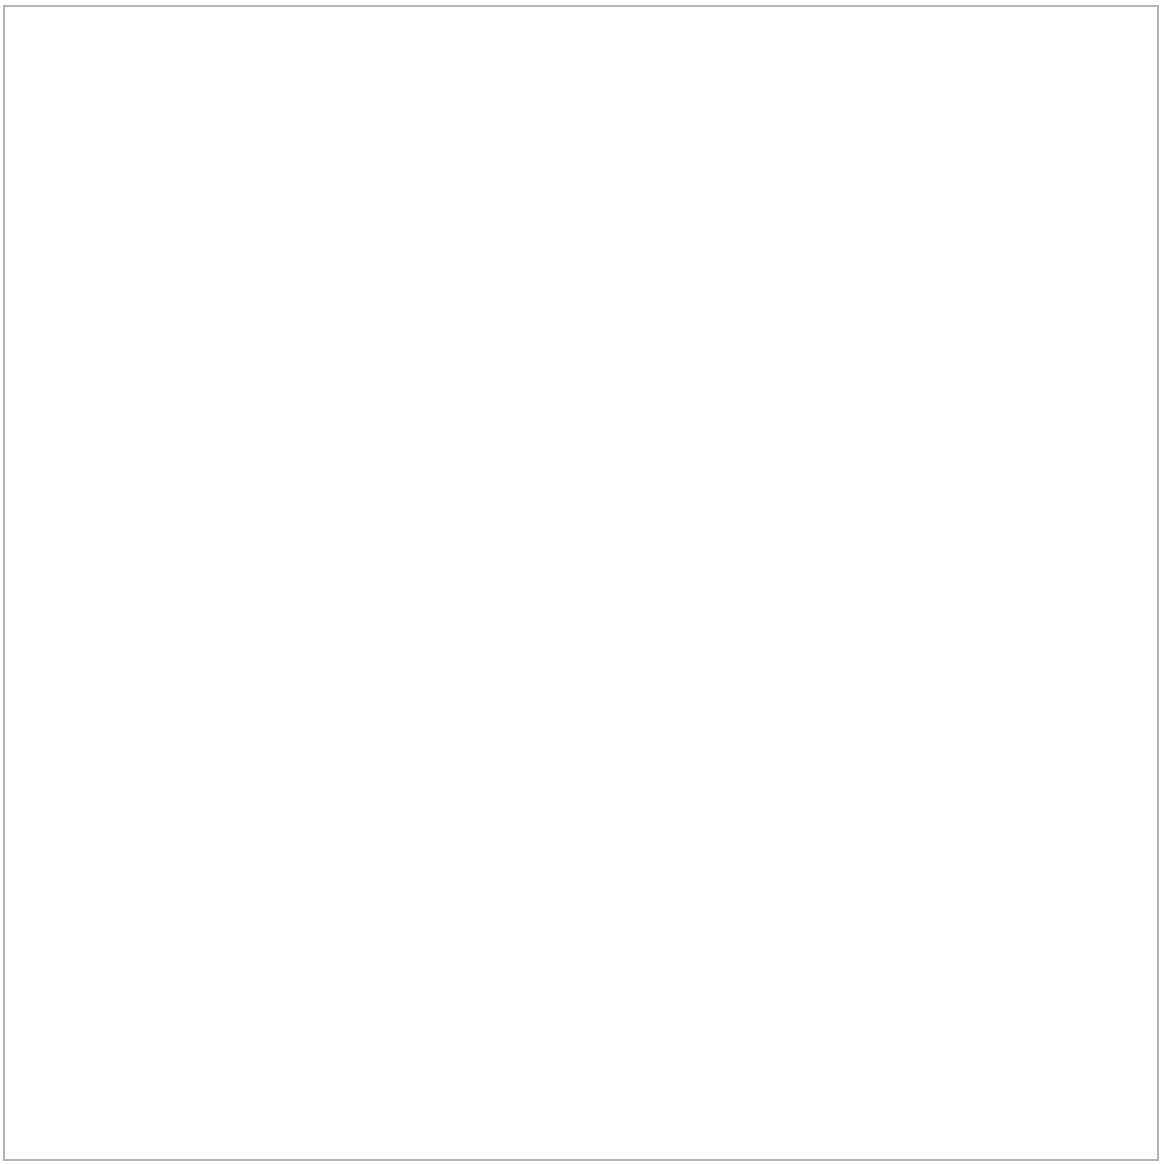
To use a policy column to filter your data, first, add tables to the policy from the left pane. To add a table, do one of the following:

- Double-click the table name.
- Click the drop-down arrow near the table name and select **Manage table with policy**.
- Or, drag the table to the right and drop it on **Add as Policy Table**.

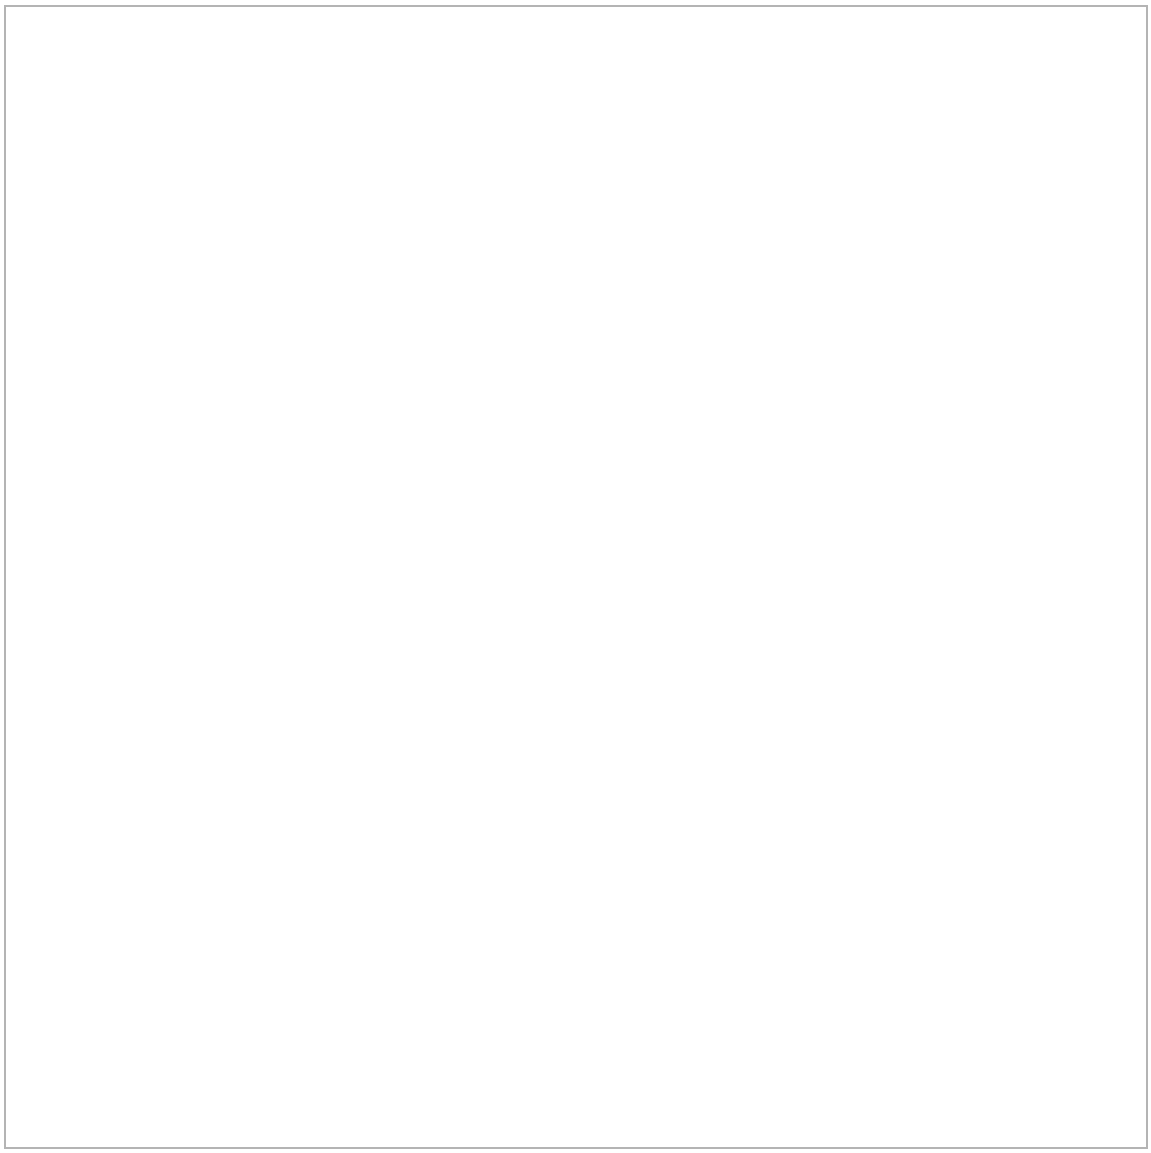
After a table is added to a policy, a shield icon appears to the right of the table name in the left pane indicating that it's a policy table.

Next, map columns to create a relationship between the column name in the table and the policy column name. Use the policy column name in the data policy condition to control row-level data access for users:

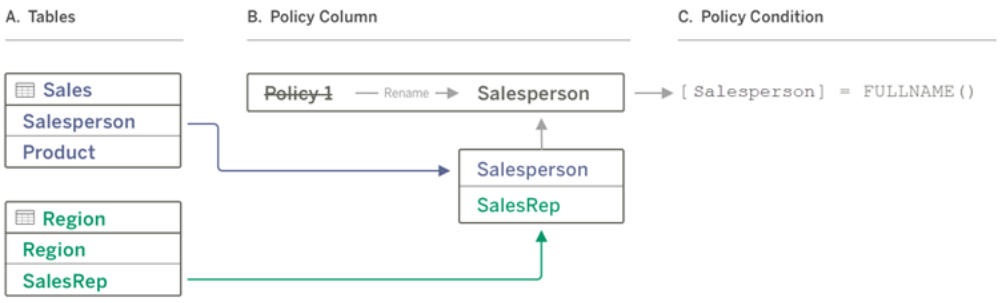
1. Click **+Add Column to Map** to add one or more columns you'll use to filter data.
2. Name the policy column. You'll use this name in the policy condition.
3. For each table the policy applies to, use the drop-down menu to select the table column that maps to the policy column.
4. Repeat this process for as many policy columns as you want to use in the policy condition.



**Tip:** Instead of using the +Add Column to Map button, you can start typing the calculation in the policy condition area and use auto-complete to choose the column name, which will then populate the policy column information under Step 1.



An example using a policy column from a policy table



A. The Sales table has a [Salesperson] column, and the Region table has a [SalesRep] column. The Salesperson and SalesRep data matches the full name of Tableau users on your site.
B. You want to filter the Sales and Region data by Salesperson, so you name the policy column "Salesperson" and then map the Salesperson column from Sales and the SalesRep column from Region to the Salesperson policy column.
C. Then write the policy condition to filter both tables. Use the [Salesperson] policy column and the FULLNAME() user function so that each user can see only their own data.

Filter with policy column from an entitlement table

Entitlement tables are used when your policy table doesn't contain a column you can filter on. You can use the entitlement table to map a column in the data table to a column in the entitlement table. Note the following:

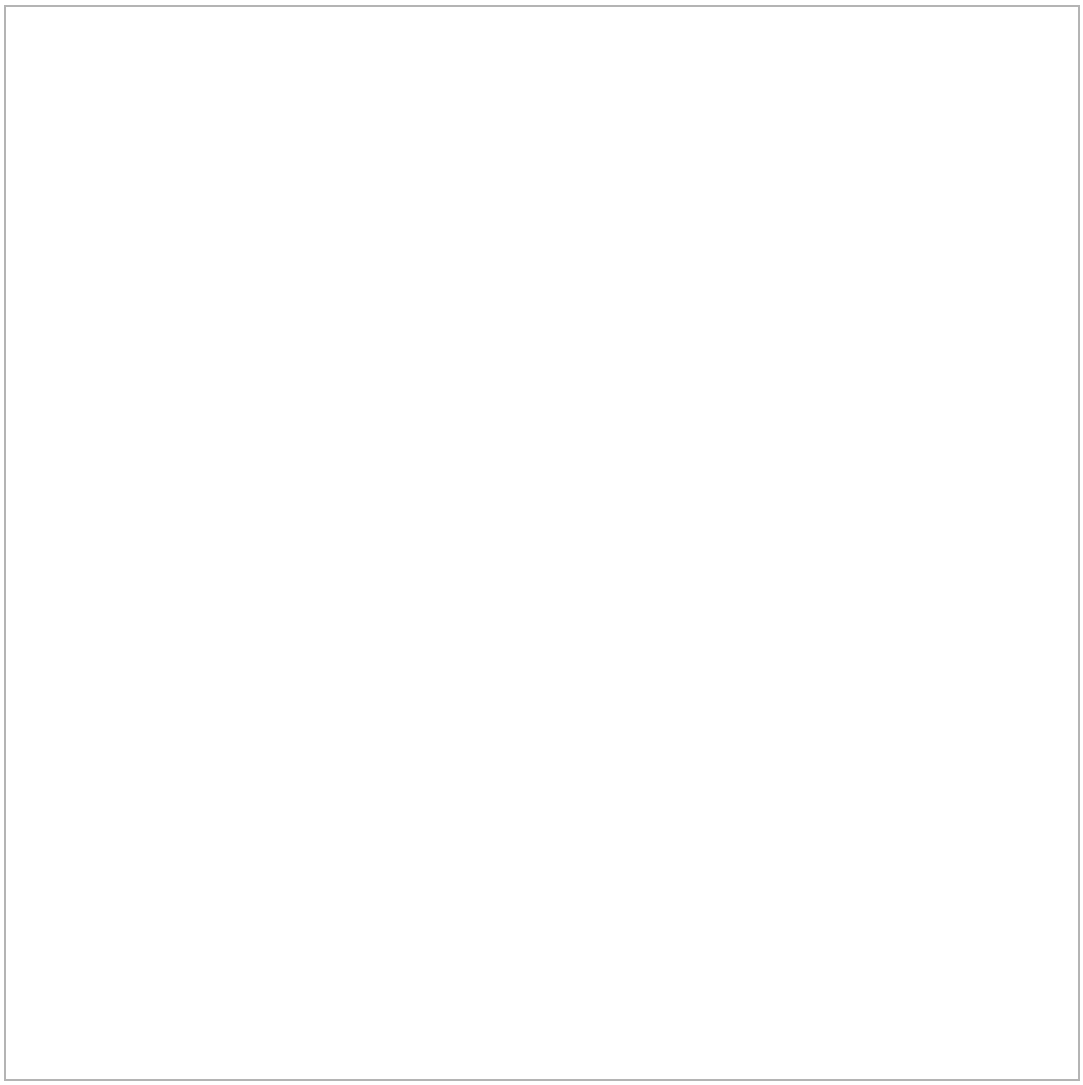
- Be sure to include the entitlement table as a table in the virtual connection. You can use a table from any connection or database as a central entitlement table that secures tables across many other databases. In some cases, an entitlement table that's in the same database as the tables you're securing can be a potential security risk because of the potential for exposing employee data. And having an entitlement table in a different database can make it easier to control permissions, for example, to grant someone access to a database.
- If you don't want virtual connection users to see the entitlement table, you can toggle the setting in the Visibility column on the Tables tab to hide it. Once hidden, the entitlement table is still available for policy filtering but can't be used in vizzes or workbook data sources.

**Note**: Connecting directly to a flow output (.hyper file) is not supported for the entitlement table. The flow output must write directly to the database.

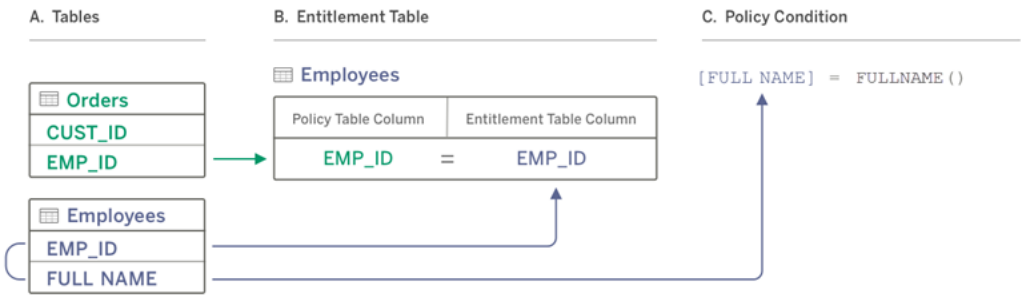
To use an entitlement table to filter your data:

1. Add the data tables that you want the data policy to apply to. Do one of the following:
   - Double-click the table name.
   - Click the drop-down arrow near the table name and select **Manage table with policy**.
   - Or, drag the table to the right and drop it on **Add as Policy Table**.
2. After a table is added to a policy, a shield icon appears to the right of the table name in the left pane indicating that it's a policy table.
3. Select the entitlement table, then either:
   - Click the drop-down arrow and select **Use as entitlement table**.
   - Or, drag the table to the right and drop it on **Add as Entitlement Table**.
4. For each table that the policy applies to, click the drop-down menu and select the

column to map the policy table to the entitlement table.



An example using a policy column from an entitlement table



A. The data you want to filter has an EMP_ID column, but not an employee name column. However, you have a second table that includes columns for both EMP_ID and the employee's FULL NAME. And, the values in the employee FULL NAME column match the full name of Tableau users on your site.
B. You can add Employees table to the policy as an entitlement table, and then map the policy table column name EMP_ID to the entitlement column name EMP_ID for each table.
C. Then use the FULLNAME() function in your policy condition to match the Tableau Server user's full name with the entitlement table's [FULL NAME] column (which is the policy column) so that each user can see only their own data.

Write a policy condition

The last step in creating a data policy is to write a policy condition, which is a calculation or expression used to define row-level access. Policy conditions are often used to limit access to users or groups through user functions.

A policy condition:

- Is required in a data policy.
- Must evaluate to true or false.
- Shows rows when the policy condition is true.

When you close a policy tab, it doesn't discard your work.

### Policy condition examples

Shows only rows where the Region column value is North:

```
[Region] = "North"
```

Enables a signed-in user to see the rows where the user's name matches the value in EmployeeName:

```
FULLNAME() = [EmployeeName]
```

Enables members of the Managers group to see all rows, while users can see only the rows where their username matches the value in the employee_name column:

```
ISMEMBEROF('Managers') OR USERNAME() = [employee_name]
```

### Supported Tableau functions in policy conditions

Policy conditions support a subset of Tableau functions:

- Logical (except null-related)
- String
- User
- Date
- Number: MIN, MID, MAX

To see which specific functions are supported, in the virtual connection editor, on the Data Policies tab, see the **Reference** panel on the right.

> **Note**: If the virtual connection has a data policy that contains user functions (for example, `USERNAME()`) and you connect to it from a workbook or data source and create an extract there, the extract will contain only the rows that match the virtual connection data policy at the time the extract is created. To take advantage of a virtual connection with user functions in the data policy, use a live connection from the workbook or data source to the virtual connection instead of an extract.

Who can do this

To create a data policy, you must

- have credentials to the database that the virtual connection connects to, and
- be a server or site administrator, or a Creator.

Next steps

After you create a data policy, the next step is to verify that it works as you expect it to. See Test Row-Level Security with Preview as User. Or, if you're ready to share the virtual connection and its data policies with others, see Publish a Virtual Connection and Set Permissions.

Resources

For detailed information about calculations, see Understanding Calculations in Tableau in the Tableau Desktop and Web Authoring help.

For information about user functions, see User Functions in the Tableau Desktop and Web Authoring help.

For information about other row-level security options in Tableau, see Overview of Row-Level Security Options in Tableau in the Tableau Server help.

## Test Row-Level Security with Preview as User

Use **Preview as user** to test your data policy. You can see the data as the user sees it and ensure that row-level security is working as expected. This helps when the data policy keeps you from seeing the rows in the table (for example, if only salespeople can see rows, and you're not a salesperson).

To preview the data when the data policy is applied:

1. Select a table.
2. In the Table Details section, select the **With policy applied** check box.
3. Click **Preview as user**, select a **Group** (optional) and a **User**.
4. Verify that the policy shows the correct data for that user in the table details.
5. Repeat for other users as needed.

**Tip:** In Table Details, click to show the range of values for a column, including which values show and which are filtered out by the data policy. Select one or two columns that are good indicators that the policy is correctly filtering the data.

Who can do this

To test a virtual connection, you must

- have credentials to the database that the virtual connection connects to, and
- be a server or site administrator, or a Creator.

Next step

After you test your data policy, when you're ready to share the virtual connection with others, see Publish a Virtual Connection and Set Permissions.

## Publish a Virtual Connection and Set Permissions

When you work in the virtual connection editor, your changes are automatically saved as a draft while you work. To share a new virtual connection with other users, you need to publish it.

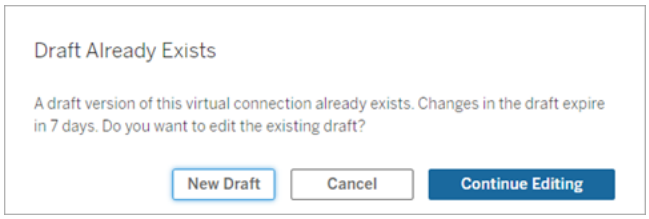
Save a draft

You can manually save a draft of the connection by clicking the save icon in the toolbar or by selecting **File** > **Save Draft** from the menu.

When editing a published virtual connection, the connection stays available to users in its current published state. You can save your updates as a draft while you work on the connection in the editor. To share the updates to the virtual connection with other users, you need to publish it.

Draft in progress

If you close the editor while updating a published virtual connection, the next time you open the connection in the editor within seven days, you have the option of continuing to make edits to the existing draft, starting a new draft, or opening the connection in its current published state by clicking **Cancel**.



To return to a draft version of an unpublished virtual connection, you need to manually save the URL of the draft **before** you close the editor. You can use the URL to open the draft in the editor the next time you want to work on the connection within seven days. For example:

```
https://yourserver.test.com/published-connection-edit-
or/?draft=d1789edc-5d9f-40ae-988d-9fc879f37a98
```

Publish the connection

To publish a new connection:

1. Click the **Publish** button in the upper right corner of the editor or select **File** > **Publish** from the menu.
2. In the Publish dialog box:
    a. Type a name in the **Name** field.
    b. Select a project to save the connection to.
3. Click **Publish**.

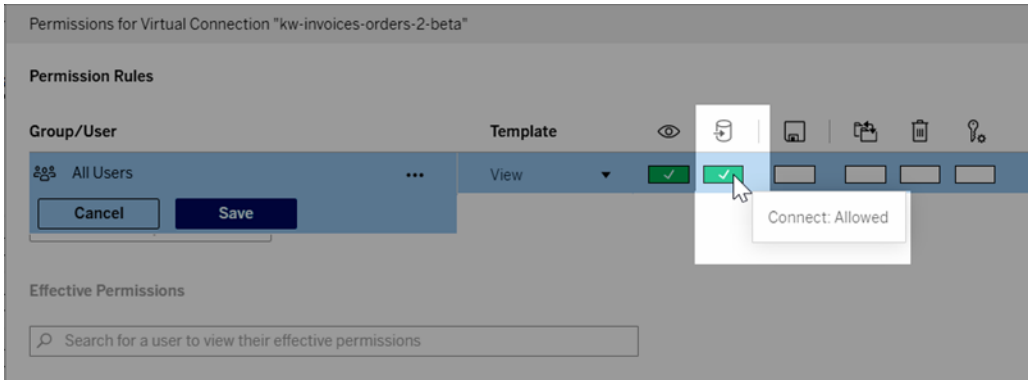
To publish an updated connection, click the **Publish** button in the upper right corner of the editor or select **File** > **Publish** from the menu.

Set permissions on a virtual connection

After you publish a virtual connection, you need to set the permissions so that others can use it. By default, all users can **View** the connection, in other words, see it listed under Virtual Connections in Tableau, but unless you set the **Connect** capability to Allowed, only you and administrators can use the virtual connection. For more information on the Connect capability, see Permissions.

To set permissions:

1. Navigate to the virtual connection.
2. Open the Actions menu (...) and click **Permissions**.
3. Check the box under the Connect icon so that connect is allowed for all users.



**Tip:** You can add additional rules if you want to grant the permission only to certain users or groups.

4. Click **Save**.

For more information about permissions on Tableau content, see Permissions. For information on embedding passwords when you publish Tableau content such as a data source or workbook that uses a virtual connection, see Virtual connections in the Tableau Server help.

Who can do this

To publish a virtual connection or set permissions, you must

- have credentials to the database that the virtual connection connects to, and
- be a server or site administrator, or a Creator.

Next step

After you publish a virtual connection and set its permissions, you can Use a Virtual Connection .

## Schedule Extract Refreshes for a Virtual Connection

One of the benefits of virtual connections is that you can reuse the same extract multiple times, reducing data proliferation and removing redundant extract refresh jobs. To ensure that extract

data is fresh for any content that uses a virtual connection, you can create an extract refresh schedule for the tables in your connection after you publish the connection.

You can also schedule extract refreshes of data sources and workbooks that use virtual connections. See Schedule Refreshes on Tableau Cloud and Refresh Data on a Schedule (Tableau Server).

Extract tables

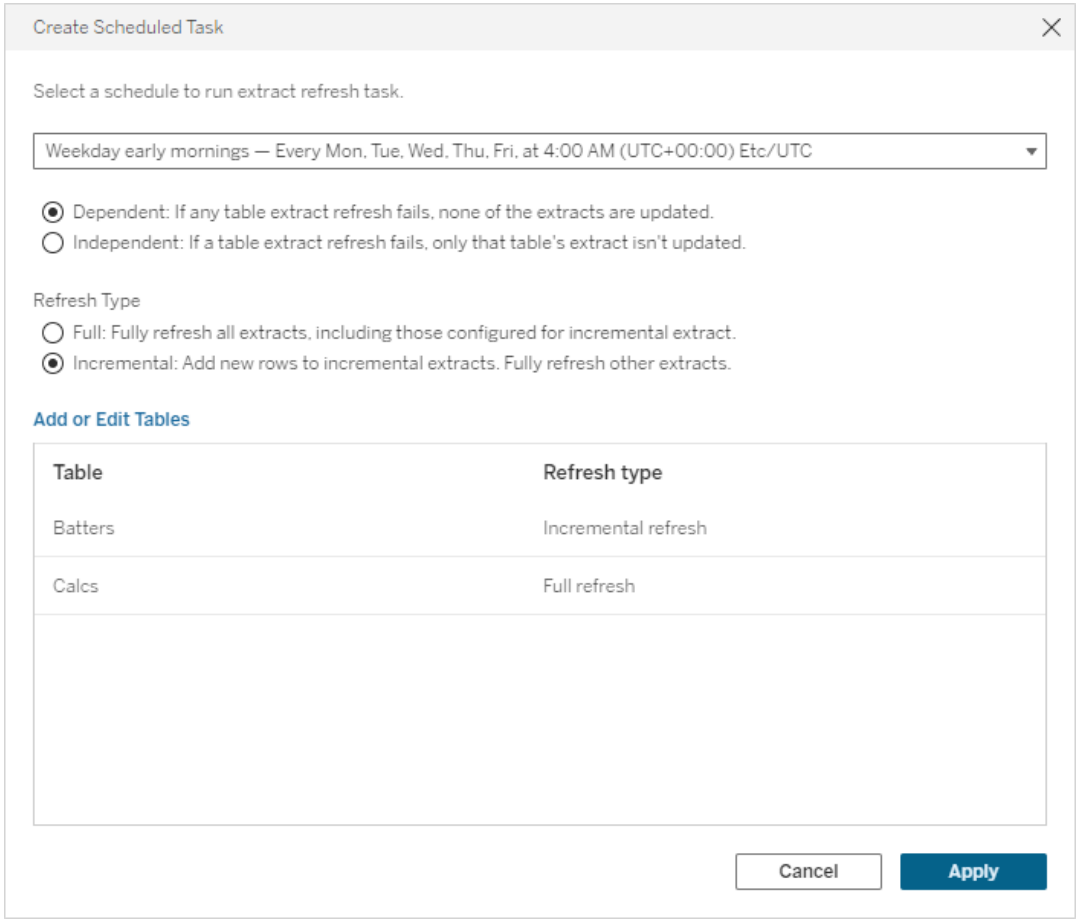
See Extract table data.

Schedule extract refreshes on Tableau Server

1. Navigate to the virtual connection page. (From the **Home** or **Explore** page, click **Virtual Connections** from the dropdown menu, then select your virtual connection.)
2. At the top of the page, a heading should say **Data is Extract**. If it says **Data is Live**, refresh your browser.
3. Select the **Scheduled Tasks** tab and click **+New Task**.
4. The **Create Scheduled Task** dialog box opens. The **Create Scheduled Task** dialog box looks different in Tableau Server and Tableau Cloud. If you're using Tableau Cloud, see Schedule Extract Refreshes for a Virtual Connection in the Tableau Cloud Product Help.
5. Select a schedule from the dropdown menu.
6. For cases when multiple tables use extracts, select **Dependent** or **Independent**. (In Tableau Server 2023.3 and earlier, these options were "Keep tables in sync" and "Refresh tables independently", but the underlying meaning is the same.)
    - **Dependent** means that none of the extracts will be updated if one or more tables' extract refresh jobs fails.
    - **Independent** means that the success or failure of a table's extract job doesn't affect whether or not other tables' extracts are updated.
7. Select **Refresh Type**. You can configure the type of extract in the virtual connection editor. For more information, see the Incremental Extracts section of the Create a Virtual Connection page. (In Tableau Server 2023.3 and earlier, virtual connections don't support incremental extracts, so you won't see these options.)
    - **Full** means that full extract refresh jobs will be run on all extracts in the virtual connection, regardless of whether they are configured for full extract refresh or incremental extract refresh.

- **Incremental** means that incremental extract refresh jobs will be run on all incremental extracts in the virtual connection. For all other extracts in the virtual connection, full extract refresh jobs will be run.

8. Select **Add or Edit Tables** and select the tables you want to refresh.
9. Select **OK**.
10. Select **Apply**.



Time limit for extract refreshes

To ensure that long running refresh tasks don't take up all system resources and don't prevent refreshes of other extracts on your site, extract refreshes for a virtual connection are subject to a two-hour time limit. For more information about the timeout limit for refresh tasks and suggestions for resolving these errors, see Time limit for extract refreshes. Note: Starting with Tableau Cloud June 2024 and Tableau Server 2024.2, virtual connections support incremental

refresh for table extracts. Prior to that release, virtual connections only supported full refreshes.

Who can do this

To publish a virtual connection or set permissions, you must

- have credentials to the database that the virtual connection connects to, and
- be a server or site administrator, or a Creator.

Next step

After you schedule extract refreshes for a virtual connection, you can Use a Virtual Connection

## Use a Virtual Connection

After a virtual connection is published and permissions are set, it's available to users to connect to data in the same ways that users access all data in Tableau. When you must edit a virtual connection or the data policy in the connection—for example, when the underlying schema changes—simply open the connection in the virtual connection editor, make your changes, and either save or publish the updates. You can also replace an existing data source in a workbook with a virtual connection.

Connect to a virtual connection

For web authoring in Tableau Cloud or Tableau Server:

1. On the Home or Explore page, click **New**.
2. Select the type of content you want to create: workbook, flow, or published data source.
3. In Connect to Data > On This Site > Content Type dropdown menu, select **Virtual Connections**.
4. Select the name of the connection and click **Connect**.

For Tableau Desktop and Tableau Prep:

1. On the Connect pane, under Search for Data, click **Tableau Server**.
2. Enter the server name and click **Connect**, or click **Tableau Cloud**.

3. Enter the information prompted for.
4. On the Search for Data dialog box, from the Content Type dropdown menu, select **Virtual Connections**.
5. Select the name of the connection and click **Connect**.

> **Note:** There's no need to enter credentials when you connect using a virtual connection. The credentials to access the data are embedded in the connection.

Edit a virtual connection or data policy

When editing a published virtual connection, the connection stays available to users in its current published state. For more information, see Publish a Virtual Connection and Set Permissions.

To edit a connection, navigate to it from the Explore page. Note that even though database credentials are embedded in the connection, only those with the database credentials can make any changes to a virtual connection.

1. From the dropdown menu, select **All Virtual Connections**, then select the connection you want to edit.
2. Click **Edit Virtual Connection**.
3. Enter the information prompted for to connect. To edit a connection, you must enter the credentials required to access the data.
4. Click **Sign In**.
5. In the virtual connection editor, make your changes and then either save a draft or publish the connection.

Respond to underlying schema changes

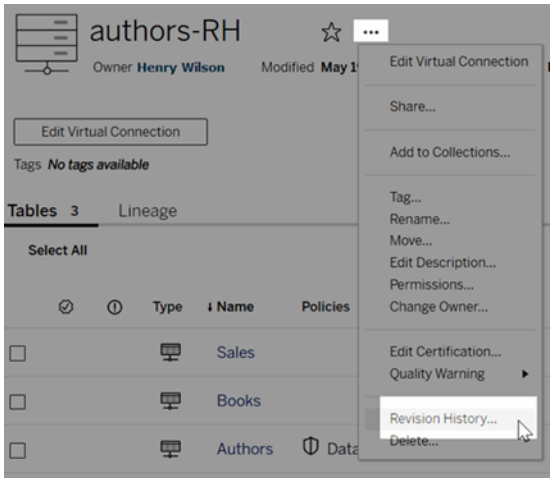
When the underlying schema in a virtual connection changes—for example, a table is added or deleted, or a column is added or renamed—you must edit the virtual connection to reflect the schema changes and then republish the connection. (If the connection has extracts, remember to refresh the extracts.) This way, you can add or edit the tables, columns, and policies in the connection before new data is exposed to everyone.

Work with virtual connection revision history

When you publish a virtual connection, a version is saved in the revision history for Tableau Cloud or Tableau Server. You can revert to a previous version at any time.

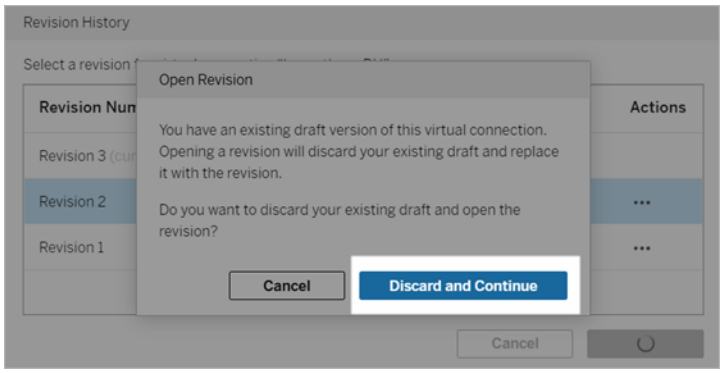
To access revision history, you must have a **Creator** site role and the **View** and **Overwrite** permissions.

To see the virtual connection revision history, click the actions menu (. . .) for the virtual connection, then click **Revision History**.

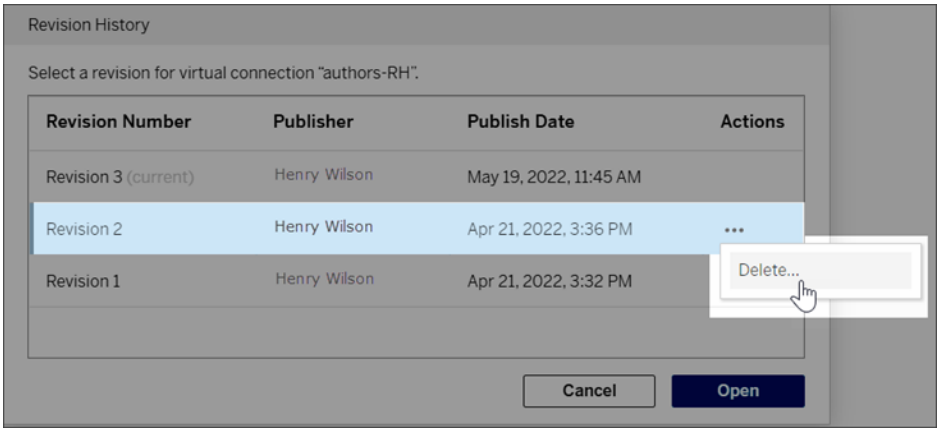


Restore or delete a virtual connection revision

To restore a virtual connection revision, select a revision, and then click **Open**. You are then prompted to discard the existing version of the connection. When you click **Discard and Continue**, the revision you selected becomes the current version of the connection.



To delete a revision, from the revision's actions menu (. . .), click **Delete**.



Replace an existing data source in a workbook with a virtual connection

For web authoring in Tableau Cloud or Tableau Server:

1. Download the workbook. For more information, see Download Views and Workbooks in Tableau Desktop Help.
2. In Tableau Desktop, open the workbook and replace its existing data source with a virtual connection. For more information, see Replace Data Sources in Tableau Desktop Help.
3. In Tableau Desktop, upload the workbook to your Tableau Cloud or Tableau Server site. For more information, see Upload Workbooks to a Tableau Site in Tableau Desktop Help.
4. In Tableau Cloud or Tableau Server, click **Publish** to save your changes to the server.

For Tableau Desktop:

1. Open the workbook and replace its existing data source with a virtual connection. For more information, see Replace Data Sources in Tableau Desktop Help.
2. Republish the workbook. For more information, see Simple Steps to Publish a Workbook in Tableau Desktop Help.

Who can do this

To use a virtual connection, you must be a Server Administrator, Site Administrator Creator, or Creator.

To edit a virtual connection or data policy, you must

- have credentials to the database that the virtual connection connects to, and
- be a server or site administrator, or a Creator.

To migrate existing content to use a virtual connection, you must

- be a server or site administrator, or
- be a Creator who is also the data source owner.
